Background-aim. Quality of life reflects the multidimensional impact of a clinical condition and its treatment on patients' daily lives. It is markedly impaired in heart failure and adversely affects prognosis. Short Form -36 (SF-36) is a generic quality of life measure containing eight dimensions. We aimed to investigate SF-36 psychosocial variables (vitality, social function, emotional role and mental health) in patients with heart failure and reduced ejection fraction (left ventricular ejection fraction<40%) (HFREF).
Methods. Clinical, echocardiographic and laboratory parameters were determined in 87 patients with HFREF (age: 64.81±12.05, 90% male, Ischemic: 84%) visiting our outpatient clinic. Furthermore, assessment of functional activity, quality of life and screening for depressive symptoms was performed using the Duke index, the Kansas City Cardiomyopathy Questionnaire (KCCQ), the Minnesota Living With Heart Failure Questionnaire (MLHFQ), the Beck Depression Inventory (BDI), and the Zung self-rating depression scale (SDS). Statistical analysis was performed using SPSS 19.
Results. Median vitality was 35.00(20.00, 50.00), median social function was 56.00(56.00, 67.00), median emotional role was 0.0(0.0,33.00) and median mental health was 52.00(36.00, 64.00). Vitality correlated positively with Na (r=0.236, p=0.049) and correlated negatively with NYHA (r= -0.270, p=0.025). Emotional role is positively associated with Hgb (r= 0.264, p=0.032) and Na (r= 0.322, p=0.007), whereas it is negatively associated with RV diameter (r= -0.287, p=0.046). Mental health correlated positively with age (r= 0.234, p=0.038), LVmass (r= 0.292, p=0.024) and Na (r=0.294, p=0.014). Vitality, social function and emotional role correlated positively with Duke index (r= 0.386, p<0.001), (r= 0.235, p=0.030), (r= 0.370, p<0.001) respectively. Vitality, emotional role and mental health showed a positive association with KCCQ overall summary (r= 0.513, p<0.001), (r= 0.298, p=0.006) (r= 0.305, p=0.005) respectively and a negative association with total score MLHFQ (r= -0.578, p<0.001), (r= -0.422, p<0.001), (r= -0.467, p<0.001) respectively. Vitality, emotional role and mental health correlated negatively with Self-rated raw score Zung (r= -0.527, p<0.001) (r= -0.321, p=0.004) (r= -0.544, p<0.001) respectively. Social function did not correlate with Self-rated raw score Zung (p=0.845).
Conclusion. Clinical, echocardiographic and laboratory parameters are significantly associated with SF-36 psychosocial variables. SF-36 psychosocial variables correlate positively with Duke index and KCCQ and negatively with MLHFQ and Self-rated raw score Zung.

P1056
Heart failure patients with previous anterior myocardial infarction have a lower cerebral blood flow

Y Yuksel Cavusoglu[1]; E Babayigit[1]; M Dural[1]; KU Mert[1]; B Gorenek[1]; T Ulus[1]
[1]*Eskisehir Osmangazi University, Eskisehir, Turkey*

Purpose: Heart and brain interaction is a well-known entity in heart failure (HF) and a reduced ejection fraction (EF) is an independent risk factor for stroke. HF patients with a history of myocardial infarction (MI) has more prone to have thromboembolic stroke. However, less is known about cerebral blood flow in HF patients with reduced EF, particularly who have a previous MI. We aimed to evaluate the transcranial Doppler (TCD) flow rates in HF patients with reduced EF who have previous anterior MI as compared with the patients who have non-anterior MI or healthy population.
Methods: We retrospectively evaluated 94 patients who underwent to TCD monitoring. 10 patients with an EF >40% and 12 patients with suboptimal signals of middle cerebral artery flow in TCD examination were excluded from the study. Of those with EF ≤ 40% (n=46), 24 HF patients (52.2%) had previous anterior MI and 22 patients (47.8%) had non-anterior MI (previous inferior, posterior, lateral or non ST elevation MI). A control group has been made of 26 healthy subjects who underwent TCD. Minimum, maximum and mean flow velocities of the both right middle cerebral artery (RMCA) and left middle cerebral artery (LMCA) determined by TCD were analyzed.
Results: The average maximum, mean and minimum velocities of RMCA were 87.8, 56.41 and 36.53 cm/s respectively in control group and 68.69, 44.41 and 30.29 cm/s, respectively, in HF patients with previous anterior MI (p<0.001, 0.001 and 0.017,

respectively). The average maximum, mean and minimum velocities of LMCA were 88.73, 57.15 and 36.34 cm/s, respectively, in control group and 69.75, 44.58 and 31.08 cm/s, respectively, in HF patients with previous anterior MI (p =0.001, 0.002 and 0.081 respectively). In HF patients with non-anterior MI; the average maximum, mean and minimum velocities of RMCA were 84.1, 52.94 and 37.0 cm/s respectively (p=0.027, 0.078 and 0.031 as compared to HF patients with anterior MI) and the average maximum, mean and minimum velocities of LMCA were 80.93, 50.84 and 34.81 cm/s, (p=0.09, 0.156 and 0.19 as compared to HF patients with anterior MI).
Conclusions: The results of this study showed that HF patients with previous anterior MI are more likely to have lower cerebral flow velocities as compared to those with previous non-anterior MI or healthy controls, suggesting more close heart and brain interaction in this group of patients.

P1057
Iron deficiency predictors in patients with CHF and rLVEF

VG Vera Gorbachova[1]; AV Lyashenko[1]; TI Gavrilenko[1]; LS Mhitaryan[1]; LG Voronkov[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, Heart failure, Kiev, Ukraine*

The aim is to study iron deficiency (ID) predictors in patients with chronic heart failure (CHF) and reduced left ventricular ejection fraction (rLVEF).
Methods. 134 stable compensated patients (pts) with CHF (113 men, 21 women), 18-75 years old, NYHA class II-IV, LVEF<40% were examined. Beside routine clinical and laboratory examination, iron panel test, 6 min walk test (6MWT), standardized endurance leg extensor test were performed. Quality of life was assessed by the Minnesota living with heart failure questionnaire (MLHFQ). Statistical data handling was made using logistic regression.
Results. ID was found in 83 (62%) of 134 patients with CHF and rLVEF. ID patients were comparable with those without ID by age, gender, heart rate, LVEF, as well as with the proportion of patients taking ACEi, beta-blockers and mineralocorticoid receptors antagonists. There was no statistically significant association between hemodynamic and major echocardiographic indices and the risk of ID in our patients (SBP, HR, left atrium, LVEF, LV MMi, EDVi). The presence of anemia (OR 3.64, p=0.004), III-IV NYHA functional class (OR 2.98, p=0.004) and the worse quality of life (OR 1.02, p=0.01) were found to be ID predictors. In patients with NYHA class II (OR 0.34, p=0.004) there was a lower risk of developing ID. The better thigh quadriceps endurance (OR 0.98, p=0.04), the lower risk of developing ID. Probability of ID decreases with higher levels of hemoglobin (OR 0.95, p=<0.001), MCV (OR 0.82, p<0.001), MCH (OR 0.8, p=0.01) and GFR (OR 0.98, p=0.04). At the same time, higher levels of citrulline (OR 1.01, p=0.02) and NTproBNP (OR 1.002, p=0.01) are reliably associated with increased risk of ID occurrence. According to the results of multivariable regression model, independent ID predictors were found to be decreased erythrocyte's MCV (OR 0.83, p=0.002) and elevated NTproBNP level (OR 1.002, p=0.01).
Conclusions. ID was found in 62% patients with CHF and rLVEF and was dependent on concomitant anemia. Risk of ID is higher in patients with NYHA class III-IV, in patients with poorer quality of life, with elevated citrulline and NTproBNP levels. Hemoglobin, MCV, MCH, GFR and better thigh quadriceps endurance were directly associated with the presence of ID. Independent predictors of ID were MCV and NTproBNP levels.

P1058
Comorbidities and financial difficulties of hospitalized heart failure patients amidst the Greek economic crisis

G Michas[1]; K Grigoriou[1]; T Thomopoulos[1]; G Blazakis[1]; P Stougiannos[1]; A Trikas[1]
[1]*Elpis General Hospital, Cardiology, Athens, Greece*

Funding Acknowledgements: Hellenic Society of Cardiology

Background/Introduction: Heart failure (HF) is a global pandemic affecting more than 26 million patients. As the world population ages, and survival from cardiovascular disease improves, the overall burden of HF is expected to increase over time. Patients with HF often have multiple comorbidities that complicate management and may adversely affect outcomes.
Purpose: The purpose of the study was to record the characteristics and comorbidities of hospitalized patients with HF. Data on medical insurance and ability of HF patients to afford their medications were also collected.
Methods: The study sample consisted of 152 HF patients who were hospitalized in the Cardiology Department of a tertiary hospital in Greece within a period of one year. Inclusion criteria were diagnosis of HF, age ≥18 years, and sufficient understanding of the Greek language. We collected data regarding socio-demographic and clinical characteristics of the HF patients and measured a multitude of laboratory and diagnostic parameters. We estimated the prevalence of depression by using the Patient Health Questionnaire-9 (PHQ-9). Sleep quality of the patients was measured using the Pittsburgh Sleep Quality Index (PSQI).
Results: Of the 152 HF patients, 94 (61.8%) were males and 58 (38.2%) females with an average age of 70.9±13.7 years. When the ejection fraction (EF) was considered, the proportion of patients with reduced, mid-range, and preserved EF were 54.6%, 20.4%, and 25.0%, respectively. 78.3% of the patients had arterial hypertension, 48.0% coronary artery disease, 46.1% dyslipidemia, and 46.1% atrial fibrillation. Diabetes mellitus was present in 38.2% of patients, while anemia and chronic kidney disease were particularly common in 32.9% and 31.6% of the patients, respectively. The majority (67.8%) of patients were overweight and obese. Poor sleep quality (global PSQI score ≥5) was recorded in 82.9% of HF patients. 67.8% of the patients reported the presence of depressive symptoms (PHQ-9 score ≥5), whereas the prevalence of major depressive symptomatology was 34.2% (PHQ-9 score ≥10). Lastly, although just 6.6% of the patients had no medical insurance, 36.8% of the total participants reported that they face financial difficulties to afford their medications.
Conclusion(s): The medical community must take measures to identify, evaluate and manage comorbidities in HF patients. Our attention should not only be focused on cardiovascular comorbidities. HF patients often suffer from anemia, chronic kidney disease, are obese, depressed, and have disturbed sleeping patterns. The Greek financial crisis might have exerted a negative effect on the patients' non-adherence to medical treatment, in the background of financial problems. As the austerity period is far from ending, the Greek HF community must strive to create the necessary structures were HF patients could be securely followed-up and treated.

P1059
Chronic kidney disease in patients with acute decompensated heart failure: prevalence and prognostic value

S Svetlana Avdoshina[1]; M Efremovtseva[1]; Z Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Objective: chronic kidney disease (CKD) is a frequent comorbidity in patients with heart failure (HF) which was shown to cause negative influence on prognosis in this population.
The purpose: to evaluate the incidence and prognostic value of CKD in patients with acute decompensated heart failure (ADHF).
Methods: 278 patients with ADHF were examined^ mean age was 69.7±10.2 years (M±SD), 55% were male, 47.8% current smokers, 30.6% alcohol abusers. Comorbidities: 90.3% had arterial hypertension, previous myocardial infarction 47.1%, atrial fibrillation 46%, stable angina 43.5%, anemia 40.6%, chronic obstructive pulmonary disease 34.9%, and diabetes mellitus (DM) 33.1%; 70% had anamnesis of symptomatic heart failure with frequent hospitalizations during the last year.
CKD and acute kidney injury (AKI) were diagnosed according to KDIGO 2012 Guidelines, glomerular filtration ratr (GFR) was calculated using CKD-EPI equation.
Results: Incidence of CKD in ADHF was 45% (n=125), and in 57.5% of patients CKD was diagnosed only at admission. Patients with ADHF with vs without CKD were older (70.8±10 vs 68.7±10.2, p<0.05), had higher rate of symptomatic HF with frequent hospitalizations during the last year (80% vs 61.2%, p<0.05), stable angina (80% vs 44.4%, p<0.01), DM (45.6% vs 22.9%, p<0.001), obesity (62.4% vs 50.3%, p<0.05), and anemia (56.8% vs 27.5%, p<0.001).
There were more pronounced signs of renal dysfunction in patients with CKD on admission to the hospital: serum creatinine 157±89 vs 98±31 μmol/l (p <0.001), GFRCKD-EPI 50±89 vs 66±18 ml/min/1.73 m2 (p <0.001), urea 12.6±8.3 vs 9.7±6.1 mmol/l (p <0.001). They also had lower levels of hemoglobin (11.9±1.9 vs 13.2±2.3 g/l, p <0.001), serum cholesterol (4.4±1.3 vs 5.2±1.2 mmol/l, p <0.001), and sodium (141.6±3.3 vs 143.2±3 mmol/l, p <0.01).
Left ventricular hypertrophy (detected with ultrasound) was more common in ADHF patients with vs without CKD (69.6 vs 43.1%, p <0.001) and was more pronounced (left ventricular mass index 194.9±77.4 vs. 166.2±82.3 g/m2, p <0.001).
Presence of CKD in patients with ADHF was associated with higher frequency of rehospitalizations due to decompensation of HF within 6 months after discharge (52% vs 30.7%, p<0.001). No associations of existing CKD with AKI development (46.4 and 41.2%, p >0.05) or in-hospital mortality (6.4 and 8.5%, p >0.05) were detected.
Conclusions: CKD is common (45%) but underdiagnosed comorbidity in patients with ADHF and is associated with more frequent episodes of HF decompensation. We did not reveal any negative effect of CKD on the incidence of AKI development and in-hospital mortality.

P1060
Iron deficiency prevalence in decompensated heart failure in elderly patients a prospective survey in an emergency hospital

D Bartos[1]; C Cristina Tirziu[2]; F Gherasie[2]
[1]*University of Medicine and Pharmacy Carol Davila , Bucharest, Romania*;
[2]*Emergency Hospital Bucharest, Bucharest, Romania*

Introduction: In patients with heart failure (HF), iron deficiency (ID) correlates with decreased exercise capacity and poor health-related quality of life, and predicts

worse outcomes. However, it is still underdiagnosed and by that, untreated. Since symptoms related to ID are not specific, only assessment of biological iron parameters allows its diagnosis. Both absolute (depleted iron stores) and functional (where iron is unavailable for dedicated tissues) ID can be easily evaluated in patients with HF using standard laboratory tests . ID prevalence in HF varies according to the clinical characteristics of the studied cohort and the applied definition of ID (it ranges from 33 to 74%, with higher rates in anaemics versus non-anaemics and decompensated versus stable HF). Even if presence of ID is well known in patients with HF with reduced ejection fraction (REfHF) and treatment recommendations are included in clinical guidelines, it is not the same situation in patient with HF and preserved ejection fraction (PEfHF).

Method: We prospectively enrolled 91 patients with decompensated chronic HF hospitalised in The our Emergency Hospital during a period of 6 month. Iron parameters were prospectively assessed during the 72 h after hospital admission. Anaemia was defined as Hb<13g/dl in men and <12g/dl in women. Iron deficiency in HF was defined according to the 2012 European Society of Cardiology Guidelines and patients were classified either as PEfHR or REfHF. We did not included patient with chronic Kidney disease with eGFR< 40 ml/min/1.73mp, nor patients with other condition possible to be associated with anemia (cancer, chronic inflammatory disease, different haematological conditions).

Results: The mean age of patients at inclusion was 78, sex distribution was 53% female and 47% male and all patients was NYHA III or IV at inclusion. Of 91 patients, 24,29% had REfHF and 75,71% had PEfHF . Prevalence of ID was higher in PEfHF than REfHF (38% vs 27,9%, p=0.107). Also prevalence of anaemia and ID was higher in PEfHF than REfHF (30% versus 22.5%, p=0.1996). Absolute ID was also higher in PEfHF than RefHF (24% versus 12,5%, p<0.02). We did not find any correlation between antiplatelet or anticoagulant treatment and the prevalence of ID.

Conclusion: ID and anaemia are highly prevalent among elderly patients with PEfHF. In our survey ID prevalence in patients with PEfHF (associated or not with anemia) was higher than in patient with REfHF (the overall ID difference did not reach statistic significance but the absolute ID did). Importantly, in particular absolute ID was common even in the absence of anaemia in both groups. Treatment of ID improves morbidity in patients with REfH. Taking into account that there are not at this time any strong treatment recommendation for patients with PEfHF we consider it could be useful to evaluate the impact of iron therapy in this particular group of patients.

P1062

Malnutrition risk in heart failure with reduced ejection fraction patients - single centerpilot study

J Migaj[1]; H Krysztofiak[1]; M Magdalena Dudek[1]; E Straburzynska-Migaj[1]; M Kaluzna-Oleksy[1]
[1]*Poznan University of Medical Sciences, 1st Cardiology Department, Poznan, Poland*

Background: Malnutrition results from loss of appetite, poor diet, digestive problems or chewing and swallowing difficulties. It is frequent in patients with intercurrent chronic illnesses such as e.g. heart failure. Mostly, the first warning symptom of malnutrition is a weight loss without using special diets, probably caused by malabsorption. Due to that, the treatment of heart failure patients wouldn't be as effective as it could be. Because of that, it is vital to find some biomarkers of malnutrition in order to identify malnourished patients earlier and change their therapy faster.

Purpose: To assess nutritional status of heart failure with reduced ejection fraction (HFrEF) patients and check the correlation between nutritional status and clinical, echocardiographic and biochemical parameters in those population.

Methods: This study included 100 consecutive patients hospitalized due to HFrEF in Ist Cardiology Department, Poznan University of Medical Sciences. The assessment of nutritional status was taken at admission based on polish version MNA form (Mini Nutritional Assessment). The clinical condition was evaluated according to NYHA class and the occurrence of HF decompensation. Furthermore, we analyzed chosen echocardiographic and biochemical parameters (especially: lipid panel, fasting glucose, thyroid function).

Results: Among all patients 40% had a normal nutritional status (group 1), 52% were at risk of malnutrition (group 2) and 7% were malnourished (group 3). In patients with coexisting diabetes mellitus malnutrition appeared more often (43% of patients in group 3 and only 15% in group 1). In group of malnourished patients we observed significantly lower fasting glucose level (group 1 – 6,09±1,0mmol/L, group 3 – 5,56±2,2mmol/L; p=0,0396) as well as LDL-C (p=0,0385) and total cholesterol levels (p=0,0396), however there is also higher bilirubin level (group 1 - 21±13umol/L, group 3 - 62±42umol/L; p=0,0284). There were no significant changes in thyroid hormones status as well as in natriuretic peptides level between analyzed groups. Furthermore, malnourished patients are more frequently hospitalized due to decompensated HF (p=0,0016).

Conclusions: Malnutrition in HFrEF patients is associated with abnormal lipids profile (decreased LDL-C and total cholesterol levels) and glucose level (low fasting glucose). It also affects higher risk of exacerbation of HF. Diabetes mellitus seems to be associated with a higher risk of malnutrition in patients with heart failure. More research is needed to confirm our findings.

P1063

The incidence of chronic heart failure in patients with type 2 diabetes mellitus

NB Yeshniyazov[1]; VV Medovchshikov[1]; EA Tereshchenko[1]; ER Khasanova[1]; ZD Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Department of internal diseases, Moscow, Russian Federation*

Introduction: Chronic heart failure (CHF) in patients with type 2 diabetes mellitus (T2DM) is one of the most common cardiovascular complications. However, currently there are few data on the incidence of CHF in T2DM, as well as hypo- and overdiagnosis of CHF.

Purpose: To assess the incidence of CHF in patients with T2DM.

Methods: The registry included patients ≥40 years with confirmed T2DM (HbA1c levels, glycemic profile) admitted to the city hospital from 01/08/2018 to 01/11/2018 (n=477). The first step was to assess the presence of a diagnosis of CHF in the patient's history. The second step was to assess the diagnosis of CHF according to the 2016 HF Guidelines (ESC) and compare results. All patients had results of NT-proBNP and echocardiography which were evaluated within 1-3 days after admission. NT-proBNP levels ≥125 pg/ml was considered as abnormal, echocardiography parameters were assessed according to the 2016 HF Guidelines (ESC). Statistical analysis was performed with STATISTICA 10.0 software package.

Results: In the whole group mean age was 69.7±11.4, 60.3% women. Among concomitant diseases met: hypertension 93.6 %, coronary heart disease 64.5%, atrial fibrillation 33.3%, previous myocardial infarction 32.9%, previous stroke 20.1%. The median NT-proBNP was 730 [110; 1877] pg/ml, mean ejection fraction (EF) was 49.6±11.2%. After general analysis patients were divided into 2 groups: group 1 (G1) – patients with a diagnosis of CHF at admission (78%, n=372) and group 2 (G2) – without CHF at admission (22%, n=105). In the G1 the median NT-proBNP was 820 [150; 2167] pg/ml, mean EF was 48.8±11.4%, in the G2 – 100 [50; 1160] pg/ml and 55.6±7% respectively. In G1 the diagnosis of CHF was confirmed in 291 patients (78%), with median NT-proBNP 1270 [532; 2638] pg/ml, mean EF 47±11.5%. In G1 the diagnosis CHF was excluded in 81 (22%). In G2 the diagnosis of CHF was first established in 51 patients (49%), the median NT-proBNP 1160 [550; 1800] pg/ml, mean EF 55.3±7.9%. The absence of CHF was confirmed in 54 (51%).

The distribution of patients by EF in confirmed CHF was the following: 52.1%, 39.4%, 8.5% with preserved, mid-range and reduced EF in G1, in G2 – 61.5%, 38.5%, 0% respectively.

Conclusions: The incidence of CHF was 71.7% in patients with T2DM admitted to the city hospital within 3 months. Among all patients, the presence of CHF was overestimated in 17% (n=81) and underestimated in 10.7% (n=51). It should be noted that the diagnosis of HF with reduced EF was correctly established prior to the hospitalization. Our results show that the diagnosis of CHF should be made after receiving all data (including NT-proBNP, echo) which will help to avoid underestimation or overestimation cases of CHF.

P1064

Comparison of serum selenium and thyroid hormones in patients with acute myocardial infarction, chronic heart failure and healthy volunteers.

MM Fraczek-Jucha[1]; M Kabat[2]; B Szlosarczyk[2]; J Nessler[2]; A Gackowski[2]
[1]*Jagiellonian University Medical College, Dep. of Emergency Medical Care, Dep. of Coronary Disease and Heart Failure, John Paul II Hospital, Krakow, Poland*;

Funding Acknowledgements: Jagiellonian University Medical College statutory funds; no K/ZDS/005640.

Background/Introduction: Selenium (Se) is incorporated in many selenoproteins i.e.: glutathione peroxidase (GPX) and iodothyronine deiodinases. Oxidative stress is increased in acute coronary syndromes (ACS) and heart failure (HF). In case of Se deficiency both GPX activity and thyroid hormones conversion may be decreased and have negative influence on cardiovascular system.

Purpose: We sought to evaluate Se levels in Polish patients with myocardial infarction (MI), heart failure (HF) and healthy volunteers in relation to thyroid hormones levels.

Methods: The study group: We studied 143 persons: 54 consecutive patients with acute MI (group MI), 59 consecutive patients with decompensated HFrEF, (group HF) and 30 healthy volunteers (group C).

Exclusion criteria: thyroid dysfunction, severe systemic disease, treatment with amiodarone, steroids or propranolol.

Laboratory tests: TSH, fT3, fT4, Se levels were analysed.

Table 1.Comparison of MI, HF and C group

Characteristics	Group MI n= 54	Group HF n= 59	Group C n= 30	p-value
Age, years	61.00 (53.75; 67.25)	65.00 (59.00; 74.00)	61.50 (57.50; 68.75)	0.0837
Male sex, n (%)	47 (87.04%)	48 (81.36%)	25 (83.33%)	0.7104
Smoking, n (%)	33 (61.11%)	21 (35.59%)	8 (27.59%)	0.0035 a,b
BMI, kg/m^2	26.18 (24.76; 30.79)	28.41 (25.50; 32.28)	30.11 (27.36; 34.76)	0.0127 b
Selenium, µg/l	65.91 (55.15; 76.10)	59.74 (47.73; 70.66)	93.18 (84.20; 99.10)	<0.0001 b,c
Selenium deficiency,n (%)	38 (70.37%)	44 (74.58%)	3 (10.00%)	<0.0001 b,c
TSH, µIU/ml	2.23 (1.20; 3.11)	1.60 (1.16; 2.03)	1.08 (0.68; 1.80)	0.0002 b,c
fT3, pmol/l	4.21(±0.69)	4.16(±0.94)	4.99(±0.66)	<0.0001 b,c
fT4, pmol/l	15.96(±2.27)	17.95(±2.98)	15.31(±1.91)	<0.0001 a,c
fT3/fT4 ratio	0.27(±0.04)	0.24(±0.06)	0.33(±0.05)	<0.0001a,b,c

Table legend: a - p<0.05 between group MI and HF, b - p<0.05 between group MI and C, c- p<0.05 between group HF and C.

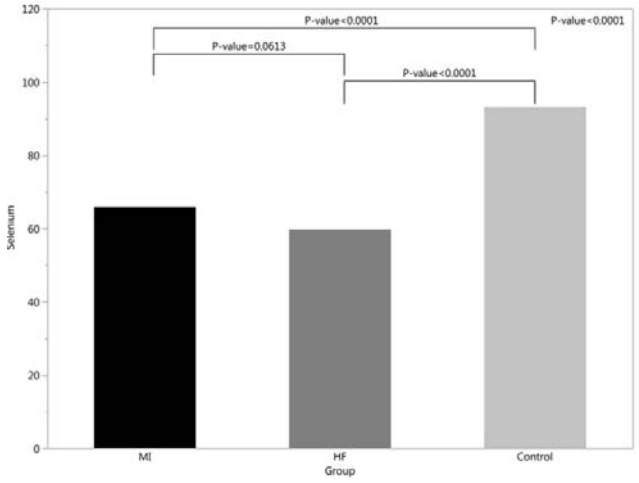

Figure 1. Serum selenium levels.

Results: Se levels were lowered in both MI and HF patients in comparison to healthy controls (Table 1, Figure 1). Patients with MI and HF presented higher levels of TSH and lower levels of fT3 and fT3/fT4 ratio in comparison to controls (Table 1).
There was a moderate correlation between Se and: fT3 (r=0.390, p<0.0001) and fT3/fT4 ratio (r=0.4294, p<0.0001).
Conclusions: Se deficiency is frequent, unrecognized finding in both patients with acute MI and chronic HF in comparison to healthy volunteers. Further studies are needed to investigate if Se deficiency may play a negative role in patients with MI, and HF.

P1065

Anger, anxiety, depression and quality of life in patients with right heart failure associated with COPD, according to their functional capacity

K L Rosales-Castillo[1]; C Pineda-Sanchez[1]; V Pelaez-Hernandez[1]; L V Pachicano-Romero[1]; A Orea-Tejeda[1]; G L Luna-Rodriguez[1]; L A Martinez- Bautista[1]; C Zepeda-Dominguez[1]; A A Ibarra-Fernandez[1]; D Gonzalez-Islas[1]; R N Sanchez-Santillan[1]; L Hernandez-Urquieta[1]; A J Flores-Vargas[1]; K Balderas-Munoz[1]; A Jimenez-Valentin[1]
[1]*National Institute of Respiratory Disease, Mexico City, Mexico*

Introduction . COPD has several comorbidities, including heart failure (HF), decreasing the functional capacity of patients due to their common symptomatology. This condition can be related to psychological comorbidities such as anger, anxiety and depression, emotions that negatively affect the quality of life and the prognosis of the patients.
Purpose. To investigate the levels of anger, anxiety, depression and quality of life in patients with HF related to COPD, depending on the level of functional capacity.
Method. A descriptive cross-sectional study was carried out that included 75 patients, who were classified according to the level of functional capacity by NYHA in I (N = 10), II (N = 33), III (N = 29) and IV (N = 3). We used the Hospital Anxiety and Depression Scale (HADS), the State-Trait Anger Expression Inventory (STAXI-2) and the SF-12 to assess health-related quality of life. An analysis of variance was performed, using SPSS v25.
Results. The sociodemographic characteristics by group were I: 55.4 ± 16.06 years, 55.6% women; II: 66.21 ± 11.77 years, 54.5% men; III: 69.26 ± 13.01 years, 64.5% women; IV: 83.00 ± 5.29 years, 75% women. There were statistically significant differences between the groups (I / II / III / IV) in the means of depression [F (3,74) =, p <0.05] (4.60 ± 3.62 / 4.48 ± 3.30 / 8: 34 ± 3.93 / 7.00 ± 3.00), internal anger-expression [F (3.74) =, p <0.05] (11.00 ± 4.92 / 11.85 ± 4.33 / 14.76 ± 4.08 / 14.33 ± 6.11) and quality of life [F (3.74) = , p <0.05] (71.59 ± 20.01 / 59.21 ± 23.37 / 38.79 ± 19.69 / 26.67).
Conclusion. Patients with lower functional capacity have greater depressive symptomatology, internalization of anger and lower quality of life, factors that in turn can affect their prognosis. Evaluating psychological aspects such as anger, anxiety and depression is fundamental for the treatment, since they can be factors related to future exacerbations and / or complications, worse prognosis and lower quality of life of the patient. Making the implementation of interdisciplinary teams necessary for the evaluation and treatment of patients.

P1066

The prevalence of chronic kidney disease and change in renal function during treatment optimization in patients with heart failure with reduced ejection fraction

K Krisztina Kosa[1]; B Muk[1]; D Vagany[1]; ZS Majoros[1]; M Szabo[1]; T Borsanyi[1]; M Dekany[1]; N Nyolczas[1]; RG Kiss[1]
[1]*Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary*

Introduction: Optimal neurohormonal therapy of chronic heart failure (CHF) is often complicated by the presence of chronic kidney disease (CKD), which is an important prognostic factor of CHF.
Purpose: We investigated the prevalence of different CKD stages and changes in renal function in the effect of treatment optimization (TO) in patients (pts) with heart failure with reduced ejection fraction (HFrEF) followed at our heart failure outpatient clinic (HFOC).
Methods: The prevalence of different CKD stages were assessed in 469 pts with HFrEF managed at our HFOC (male:77.19%, age:62.58±12.6 years, NYHA:3.12±0.78%, LVEF:26.88±6.51%, eGFR: 51.45±19.25ml/min/1.73m2). The change in eGFR before and after TO was also determined in the whole patient group and in pts with different CKD stages.
Results: In 29.63% of pts eGFR was above 60 ml/min/1.73m2 (CKD1-2), in 59.70% was 30-60 ml/min/1.73m2 (CKD3a-3b) and in 10.66% was under 30 ml/min/1.73m2 (CKD4-5) at baseline. After TO 19.40% of pts was at CKD1-2, 63.75% at CKD3a-3b and 16.84% at CKD4-5 stage. After TO significant eGFR decrease was detected in the whole population (51.45±19.25 → 46.03±17.09 ml/min/1.73m2; p<0.001), at baseline CKD1-2 (74.06±14.84 → 58.81±17.29 ml/min/1.73m2; p<0.001) and baseline CKD3a-3b (45-18±8-67 → 43-57±15-06 ml/min/1.73m2; p<0.001) pts compared to eGFR parameters before TO. Pts with CKD4-5 at baseline showed significant eGFR improvement (23.73±6,15 → 29.78±11,37 ml/min/1.73m2; p<0.005.) Neurohormonal antagonist usage did not show significant difference after TO in pts with CKD1-2 (BB: 89.01%, ACEi/ARB: 98.90%, MRA: 57.14%), CKD3a-3b (BB: 94.31%, ACEi/ARB: 97.99%, MRA: 66.22%) and CKD4-5 (BB: 93.67%, ACEi/ARB: 94.94%, MRA: 58.23%).
Conclusions: The prevalence of CKD in HFrEF population is very high. Based on our study results renal function worsening was detected after TO in mild and moderate CKD pts, however, renal function improvement was proved in the most severe CKD4-5 pts. Our data suggests that we should strive to achieve optimal neurohormonal antagonist therapy in CKD4-5 pts too, partly because, based on previous data, the severe CKD patient group is one of the pts who benefit most from this treatment and partly because, based on our study results it seems safe treatment option in this group of patients.

Acute Heart Failure

Prognostic significance of an early echocardiographic evaluation of right ventricular dimension and function in acute heart failure.

G Ruocco[1]; S Ghio[2]; R Nuti[1]; A Palazzuoli[1]
[1]*University of Siena, Siena, Italy*; [2]*Policlinic Foundation San Matteo IRCCS, Cardiology Division, Pavia, Italy*

Background: Sparse and contradictory data are available on the prognostic role of an early echocardiographic examination in patients with acute decompensated heart failure (ADHF). We planned a prospective study to elucidate which echocardiographic parameter is better related to prognosis in such patients.
Methods and Results: In a consecutive series of ADHF patients with either reduced (HFrEF) or preserved (HFpEF), a complete echocardiographic examination was performed within 12 hours from admission. End-point of the study was death or re-hospitalization at 6 months from hospital discharge.
Among the 381 patients enrolled, 209 had HFrEF and 172 had HFpEF. After 6 months from discharge, 73 died and 96 were re-hospitalized for cardiovascular causes. At multivariable analysis a large right ventricular diameter (RVEDD >40 mm, p=0.02), a reduced TAPSE (<18 mm, p=0.004) and inferior vena cava diameter >22 mm (p=0.02) were associated with 6-months events. Left ventricular ejection fraction (LVEF) and diastolic function analysis were not predictive of events. Pulmonary artery systolic pressure (PASP) >45 mmHg and TAPSE/PASP <0.425 were associated with prognosis at univariate but not at multivariable analysis. Conversely, the TAPSE/RVEDD ratio (dichotomized at its median value of 0.461) was a significant predictor of outcome at multivariable analysis (p<0.001).
Conclusions: in patients hospitalized for ADHF, early echocardiographic identification of right ventricular dilatation and dysfunction predict a poor outcome better than left ventricular systolic and diastolic dysfunction.

Funding Acknowledgements: HL130619-01A1

Background: Right heart catheterization (RHC) is an important diagnostic tool in patients (pts) with heart failure (HF). Intravenous (IV) pharmacological agents can be administered during RHC to assess the cardiac response. In our previous studies, we have shown that wearable chest patch based seismocardiogram (SCG) signals – the local body vibrations of the chest wall in response to cardiac ejection – can assess cardiopulmonary stress test parameters and can accurately quantify cardiac contractility changes [pre-ejection period (PEP)], which can be used to differentiate between compensated and decompensated patients with HF following a six-minute walk test.
Purpose: We compared RHC variables with features from simultaneously recorded SCG to evaluate the utility of the wearable sensor as an alternative to invasive measurements.
Methods: We enrolled 4 pts with HF with a mean age 52 ±11, 100% men, ejection fraction 0.26 ±0.21 and performed RHC at baseline and with infusion of IV vasodilator (nitroprusside or nitroglycerin). SCG and ECG signals were simultaneously recorded using our custom-built wearable chest patch (Fig. 1a). We segmented the RHC pressure signals and SCG signals into heartbeats and averaged the beats over 15 second windows for each intracardiac pressure, and extracted features (amplitude, frequency and time domain) from the SCG. We compared the changes in SCG features from baseline to those in response to the drug infusion and compared them with the changes in RHC pressures. We also combined the SCG features using dimension reduction techniques and calculated the distance between the two distributions (baseline and peak drug infusion), and compared them with the changes in RHC pressures.
Results: Cardiac contractility decreased (PEP increased) with vasodilator infusion, whereas pulmonary artery mean pressure (PAM) decreased (Fig. 1b). The distance between the two SCG distributions (corresponding to the two physiological states – baseline and peak drug infusion) showed good correlation (R2=0.87) with the changes in PAM (Fig. 1c).
Conclusions: Using simultaneous SCG and ECG we can track the changes in corresponding RHC pressures for patients with HF. This wearable device can potentially provide non-invasive monitoring of the hemodynamics related to medication changes in pts with HF.

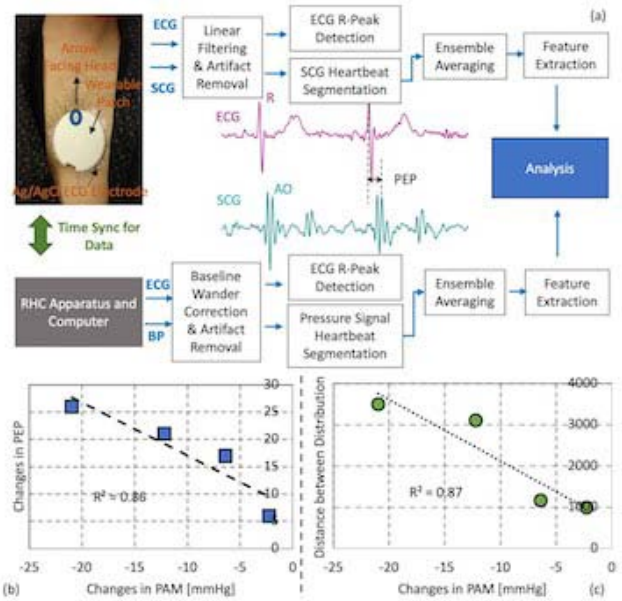

Figure 1: (a) Image showing the wearable patch for measuring ECG and SCG signals from the chest, corresponding wearable signals and data processing block diagram for wearable and RHC signals. (b) Changes in PEP from baseline to peak drug infusion is showing strong correlation with changes in PAM from RHC. (c) Distance between combined SCG features at baseline and peak drug infusion is showing strong correlation with changes in PAM.

Morphological characteristics of myocardial inflammation and long-term outcomes in patients with acute decompensation of ischemic chronic heart failure

EV Ekaterina Kruchinkina[1]; YV Rogovskaya[2]; ON Ogurkova[1]; TE Suslova[1]; AM Gusakova[1]; RE Batalov[1]; VV Ryabov[3]
[1]*Cardiology Research Institute Tomsk National Research Medical Center Russian Academy of Sciences, Tomsk, Russian Federation*; [2]*National Research Tomsk State University, Tomsk, Russian Federation*; [3]*Siberian State Medical University, Tomsk, Russian Federation*

Aim: To determine the morphological characteristics of myocardial inflammation and to assess the dynamics of serum biomarkers and long-term outcomes in patients with cute decompensation of ischemic chronic heart failure (ADHF).
Methods: This open-label, nonrandomized, single-center, prospective trial was registered at clinicaltrials.gov (#NCT02649517). This trial included 18 patients (78% men; age of 60.12±9.30 years; LVEF of 29.92±18.22%) with ADHF and ischemic systolic dysfunction. Inclusion criterion was ADHF not earlier than six months after optimal surgery (PCI or/and CABG) and with optimal drug treatment for ADHF. All patients underwent invasive angiography and endomyocardial biopsy with immunohistochemistry. Patients were divided into five groups according to the results of immunohistochemistry and immune fluorescence assay: group 1 (viral antigens +/myocardial inflammation+ and serum antibodies to cardiomyocytes), group 2 (viral antigens+/myocardial inflammation+), group 3 (viral antigens+/myocardial inflammation - and serum antibodies to cardiomyocytes), group 4 (viral antigens+/myocardial inflammation -), group 5 (myocardial inflammation-/ serum antibodies to cardiomyocytes). On admission and at one-year follow up, serum levels of IL-1β, IL-6, IL-10, hsCRP, TNF-α), troponin I, IFN-γ, BNP and NT-proBNP were measured using multiplex immunoassays. Serum anti-fibrillary, anti-sarcolemmal and anti-nuclear antibodies to cardiomyocytes were determined using indirect immunofluorescence (IMMCO Diagnostics).
Results: We identified morphological criteria for myocardial inflammation in 56% (n = 10) in group 1 and 2 in equal parts. We did not find morphological criteria for myocardial inflammation in 44% (n = 8) in group 3 - 22% (n = 4) and group 4 – 17% (n = 3). On admission, in group 1 increasing of troponin I and hsCRP was observed in 11% (n = 2), and 5.5% (n = 1) after one year. On admission, in group 2 increasing of troponin I was find - 11% (n = 2) and hsCRP - 5.5% (n = 1), and after a year only troponin I was increased in 5.5% (n = 1). On admission, in group 3 we observed an increase in troponin I, hsCRP - 5.5% (n = 1) and after a year only troponin I was increased in 11% (n = 2). There was no increasing troponin I, hsCRP in group 4 and group 5 on admission and after a year. The mortality rate in group 2 within one

year was 11% (ADHF-5.5%, sudden cardiac death-5.5%), and in group 3 – 5.5% of ADHF.
Conclusion: Patients with CHD and ADHF are a heterogeneous group. Half of patients had myocarditis. Viral and viral-autoimmune myocarditis were detected in equal parts. Among cases without myocarditis we detected virus-positive patients in 88%. Antibodies to cardiomyocytes were found in 57% of them. The only patient had antibodies to cardiomyocytes without myocarditis. The most common antigens to enterovirus and human herpesvirus type 6. The presented data can be find new criteria for the phenotyping of ADHF to medical treatment.

Heart failure patients with residual congestion and worsening renal function was associated with increased 1-year cardiovascular event

T Toshitaka Okabe[1]; T Yakushiji[1]; T Kido[1]; T Kimura[1]; J Saito[1]; S Simazu[1]; Y Oyama[1]; M Ono[1]; W Igawa[1]; S Ebara[1]; K Yamashita[1]; MH Yamamoto[1]; K Amemiya[1]; N Ismoura[1]; M Ochiai[1]
[1]Showa University Northern Yokohama Hospital, Division of cardiology and cardiac catheterization laboratories, Yokohama, Japan

Background: There are a few studies about the relationship between serum B-type natriuretic peptide (BNP) for the maker of residual congestion at discharge, the development of worsening renal function (WRF), and cardiovascular event in patients with heart failure (HF).
Purpose: Our purpose was to evaluate the association between serum BNP level at discharge or WRF during hospitalization for HF, and cardiovascular mortality in patients with HF.
Methods: We divided the patients with acute decompensated HF into four groups by the median value (284.3 pg/mL) of serum BNP level at discharge and by the occurrence of WRF. We evaluated the association between serum BNP/WRF and 1-year cardiovascular/all-cause mortality/HF readmission. The four groups were 1) less than the median BNP level and no occurrence of WRF (C-W-), 2) less than the median BNP level and occurrence of WRF (C-W+), 3) equal or greater than the median BNP level and no occurrence of WRF (C+W-), and 4) equal or greater than the median BNP level and occurrence of WRF (C+W+).
Results: Among 311 patients enrolled, WRF developed in 102 patients (32.8%). Patients in C-W- group was significantly younger than patients in the others (P=0.007). Systolic blood pressure was significantly different among the groups (P=0.02). The risk of cardiovascular death and HF admission was significantly different between the four groups (P =0.0001). In Cox proportional hazard models, patients in W+C+ had the highest risk of composite endpoint (Hazard ratio (HR), 5.12; 95% confident interval (95% CI), 2.01-14.38; P=0.0005). Patients with W+C- and those with W-C+ had a higher risk than patients with W-C- (HR, 3.70; 95% CI, 1.28-11.17; P=0.02; HR, 3.67; 95% CI, 1.47-10.14; P=0.005, respectively).
Conclusions: Heart failure patients with the development of WRF combined with elevated BNP at discharge had the highest risk of 1-year cardiovascular event of cardiovascular death and HF readmission.

P1071

Cardiac acoustic biomarkers reflect disease status and cardiac functions in patients with acute decompensate heart failure: the ACTOR-HF trial

J Shitara[1]; T Kasai[1]; S Yatsu[2]; A Kurita[1]; H Matsumoto[1]; M Hiki[1]; H Daida[1]
[1]Juntendo University, Circulation, Tokyo, Japan; [2]Juntendo University Shizuoka Hospital, Circulation Department, Izunokuni, Japan

Introduction: Biomarkers reflecting rapid changes in disease status and cardiac function are important for patient care of heart failure (HF), whereas only a few biomarkers are available and most of them have limitations for daily use. Cardiac acoustic biomarkers (CABs), which are acoustic and temporal metrics incorporating heart sounds and electrocardiographic signals, can be recorded noninvasively and easily, and can be assessed on daily basis using an ambulatory acoustic cardiography device on the chest. The aim of this study is to assess temporal changes of CABs and their association with disease status and cardiac functions in patients hospitalized for acute decompensated HF (ADHF).
Methods: We prospectively enrolled 60 patients hospitalized for ADHF. Echocardiographic parameters and CABs were evaluated at admission, pre-discharge and the first clinic visit following discharge. The following CABs were recorded by an ambulatory acoustic cardiography device for 5 minutes at rest: electromechanical activation time (EMAT, time-interval from Q wave onset to S1) and total electromechanical systolic interval (QoS2, time-interval from Q wave onset to S2), both of which are generally regarded as an indicator of left ventricular systolic performance; and S3 Intensity (peak-to-peak amplitude of S3).
Results: A total of 60 patients with ADHF enrolled from April, 2017, to December, 2018 in this trial. The mean age was 70±13 years, and 76.7% were men. One third of them have HFpEF (defined as ejection fraction > 50%). The mean hospitalization period was 20±11 days. The prolonged EMAT (i.e. EMAT≥120msec) was detected in 17 patients (28%) and the increased S3 Intensity (i.e. S3 Intensity≥2.0) was observed in 15 patients (25%) at admission. From admission to the pre-discharge and to the first clinic visit, S3 Intensity significantly decreasedP<0.001 and P<0.001, respectivelyand QoS2 significantly increasedP=0.002 and P<0.001, respectively-while EMAT was not changed. Correlations between changes in CABs and echocardiographic parameters revealed significant direct correlation between changes in QoS2 and changes in stroke volume index (r=0.383, P=0.004) (Figure) and between changes in S3 Intensity and changes in trans mitral flow E/A (r=0.571, P=0.001) (Figure).Conclusion: Temporal changes of CABs reflect alterations of disease status and cardiac functions in patients hospitalized for ADHF.

Admission copeptin activity closely associated with left ventricular filling pressure in patients with acute decompensated heart failure

O Oleg Narusov[1]; A Skvortsov[1]; V Protasov[1]; A Sychev[1]; D Protasova[2]; V Masenko[1]; S Tereshchenko[1]
[1]National Cardiology Research Center, Moscow, Russian Federation; [2]National Research Center for Preventive Medicine, Moscow, Russian Federation

Purpose: to evaluate association novel biomarkers activity with left ventricular filling pressure in patients (pts) with acute decompensated heart failure (ADHF).
Methods. In the prospective single-center trial were included 159 hospitalized pts with ADHF III-IV FC NYHA and LV systolic dysfunction due to coronary artery disease, arterial hypertension and dilated cardiomyopathy. Echocardiography and determination of the biomarkers concentrations (soluble ST2 (sST2), copeptin, galectin-3, hsTnT and NGAL) compared with NT-proBNP were performed at admission and discharge. Left ventricular filling pressure was assessed by E/E'.
Results. Admission biomarkers concentrations were 3615,5 (1578,0; 6289,3) pg/ml, 60,49 (41,9; 92,9) ng/ml, 40,61 (29,1; 48,9) pmol/l, 14,2± 3,8 ng/ml, 29,95 (21,8; 49,6) pg/ml and 62,35 (43,0; 87,5) ng/ml (NT-proBNP, soluble ST2, copeptin, galectin-3, hsTnT and NGAL, respectively). Mean E/E' was 22,29±8,02. E/E' correlated with the concentrations of NT-proBNP, copeptin, NGAL and sST2 (relatively r=0,708 (p<0,01), r=0,767 (p<0,01), r=0,365 (p<0,05), r=0,405 (p<0,05)). After treatment, the concentrations of all biomarkers, except NGAL, decreased significantly (Δ%= -37,56%, -29,9% , -25,9%, -12,97%, -10,61% (p<0,0001 for all) for NT-proBNP, sST2, copeptin, galectin-3, hsTnT, respectively). E/E' also decreased to 17,78±6,48 (p<0,0001). At the discharge, only concentrations of NT-proBNP and copeptin continued to correlate with E/E', but weaker than at the admission (respectively r=0,613 and r=0,578, p,0,01 for all). Further ROC analysis showed that the predictive value of the admission and discharge opeptin levels for shot, long- and medium-term prognosis is not inferior to that of NT-proBNP (discharge concentrations for shot, long- and medium-term prognosis respectively: AUC= 0,714 (95%CI 0.550, 0.877), p=0,021 vs AUC= 0,704 (95%CI 0.565, 0.843), p=0,01; AUC = 0.735(95% CI 0.640- 0.830), p <0.0001 vs 0.727(95% CI 0.639-0.816), p <0.0001; AUC=0,739 (95%CI 0,640;0,838), p<0,0001 vs 0,732 (95%CI 0,637-0,826), p<0.0001). Probably this is due to the revealed close association of copeptin concentration and filling pressure in pts with ADHF.
Conclusion. Among novel biomarkers admission copeptin activity most closely and better than NT-proBNP associated with left ventricular filling pressure in patients with ADHF.

Comparison of chromogranin A to proven biomarkers of natriuretic peptide, and ST2 as a prognostic marker in patients with acute heart failure

B Boeun Park[1]; SY Jang[1]; DH Yang[1]; YJ Park[1]; HN Kim[1]; JH Lee[1]; MH Bae[1]; HS Park[1]; YG Cho[1]; SC Chae[1]; NK Kim[1]
[1]*Kyungpook National University Hospital, Cardiology, Daegu, Korea (Republic of)*

Background: Chromogranin A (CgA) level have been reported to predict mortality in patients with heart failure. However not much information in available regarding predictive power, clinical availability to date. We compared predictive power of chromogranin A to previously proven biomarkers of natriuretic peptide, and ST2 in patients with acute heart failure.Method: Between Jun. 2017 and Jun. 2018, patients who had CgA test in acute stage of heart failure hospitalization were retrospectively enrolled. A total of 264 patients were enrolled and median follow-up duration was 166 days. Relationship between four biomarkers and prognosis (in-hospital mortality, composite outcome of all-cause mortality and hospitalization for heart failure) of the patients were investigated.
Results: In-hospital mortality of the study population was 7.3% (n=19). During the follow-up, composite event of mortality and hospitalization for heart failure was observed in 12.6% (n=33). In receiver-operating curve analysis to predict in-hospital mortality, area under curves (AUC) were 0.715, 0.740 and 0.778 for NT-proBNP, CgA, and ST2, respectively. Cutoff value for predicting in-hospital morality for CgA was 158 pmol/L. During the follow-up, patients with high CgA (>158pmol/L) was associated with worse outcome (52.3% vs. 19.9%, p<0.001). Level of CgA was related to NYHA class, age, history of hypertension and diabetes, serum levels of NT-proBNP and ST2.
Conclusion: CgA presented comparable prognostic power to that of proven biomarkers of NT-proBNP and ST2 in patients with acute heart failure. CgA showed additive prognostic implication on NT-proBNP level in patients with acute heart failure.

Blood urea nitrogen and biomarker trajectories in acute heart failure

O Barnett[1]; Y Horiuchi[2]; N Wettersten[2]; P Murray[3]; A Maisel[2]
[1]*Danylo Halytsky Lviv National Medical University, Lviv, Ukraine*; [2]*University of California San Diego, Division of Cardiovascular Medicine, San Diego, United States of America*; [3]*University College Dublin, Department of Nephrology, Dublin, Ireland*

Background: Blood urea nitrogen (BUN) is considered a biomarker of neurohormonal activation in heart failure (HF) and higher levels are associated with worse outcomes.
Purpose: To investigate whether BUN and/or BUN/creatinine (BUN/Cr) is associated with biomarkers of organ dysfunction or injury and predicts outcomes independent of these biomarkers in patients with acute HF (AHF).
Methods: The Acute Kidney Injury Neutrophil gelatinase-associated lipocalin (NGAL) Evaluation of Symptomatic heart fallure Study was a multicenter, prospective cohort study of AHF patients. We retrospectively analyzed 918 patients for the relationship between BUN and BUN/Cr to other biomarkers including brain natriuretic peptide (BNP), high sensitivity cardiac troponin I (hs-cTnI), urine and serum NGAL (uNGAL and sNGAL), and galectin 3. These biomarkers were measured at admission, 4-hours, day 1, 2, 3 and discharge. Clinical outcome was death at 1 year.
Results: Higher quartiles of BUN and BUN/Cr were significantly associated with higher biomarkers levels during hospitalization. The highest quartile of BUN and BUN/Cr were significantly associated with death at 1 year (Figure 1). However, in multivariate Cox analysis, a U-shaped relationship between BUN and BUN/Cr and death at 1 year was observed with the second quartile of BUN and the third quartile of BUN/Cr showed the lowest risk (Figure 2).
Conclusions: BUN and BUN/Cr were associated with biomarkers of organ dysfunction and injury in AHF. A U-shaped relationship was observed between BUN and BUN/Cr and death at 1 year.

Menage a trois - Laboratory markers of myocardial injury, systemic inflammation, and thrombosis in patients with acute heart failure syndromes: insights from the CATSTAT-HF study

JA Borovac[1]; D Glavas[2]; Z Susilovic Grabovac[2]; D Supe Domic[3]; T Ticinovic Kurir[4]; J Bozic[1]
[1]*University of Split School of Medicine, Department of Pathophysiology, Split, Croatia*; [2]*University Hospital of Split, Division of Cardiology, Department of Internal Medicine, Split, Croatia*; [3]*University Hospital Center Split, Department of Medical Laboratory Diagnostics, Split, Croatia*; [4]*University Hospital of Split, Division of Endocrinology, Department of Internal Medicine, Split, Croatia*

Funding Acknowledgements: Nothing to declare.

Background: Previous studies have shown that several pathophysiological mechanisms including myocardial injury and activation of thrombotic and inflammation pathways might impact on outcomes among patients with acute heart failure (AHF) syndromes.
Purpose: Primary goal of the study was to determine the prevalence of laboratory marker abnormalities with respect to myocardial injury, systemic inflammation, and thrombosis. Secondly, we aimed to examine the association of these laboratory indices with N-terminal prohormone of brain natriuretic peptide (NT-proBNP), New York Heart Association (NYHA) class, left-ventricular ejection fraction (LVEF), estimated glomerular filtration rate (eGFR) and glycated hemoglobin (HbA1c) values.
Methods: A total of eighty patients with documented AHF according to ESC 2016 HF criteria were consecutively enrolled in the study during 2018. All patients underwent a physical examination, transthoracic echocardiography and blood withdrawal for laboratory analyses. Laboratory markers of principal interest were high-sensitivity cardiac troponin I (hs-cTnI), C-reactive protein (CRP) and D-dimers. Abnormal cut-offs were set according to assay specifications as follows: hs-cTnI ≥15.6 ng/L for women and ≥34.2 ng/L for men, CRP ≥5.0 mg/L, and D-dimers ≥0.5 mg/L. Finally, NT-proBNP, NYHA class, LVEF, eGFR, and HbA1c values were obtained in all patients.
Results: Mean age of the cohort was 69.6±10 years, 47.5% were women and a vast majority (88.3%) were in NYHA III class or higher. Median NT-proBNP value was 3333 pg/mL (IQR 1219, 6990) with mean LVEF of 42%, mean eGFR of 57 mL/min/1.73 m2 , and mean HbA1c of 6.6%. Median values of examined

laboratory markers were 20.3 ng/L (IQR 11.1, 36.5), 10.5 mg/L (IQR 5.9, 23.3) and 1.1 mg/L (IQR 0.7, 2.2) for hs-cTnI, CRP and D-dimer, respectively. Abnormalities of these markers were common in the observed cohort with 73.7%, 69.8%, and 47.9% of patients having abnormal CRP, D-dimer and hs-cTnI levels, respectively (Figure 1). One fifth (20.8%) of the cohort did not have an abnormality in any of the aforementioned markers. A total number of laboratory abnormalities positively correlated with NYHA class (r=0.448, p=0.002). hs-cTnI values correlated positively with NYHA class (r=0.374, p=0.021), HbA1c (r=0.312, p=0.014) and negatively with LVEF (r=-0.344, p=0.041). CRP correlated negatively with estimated glomerular filtration rate (r=-0.345, p=0.002) and positively with HbA1c (r=0.316, p=0.010). D-dimer values positively correlated to CRP (r=0.495, p=0.016) and NT-proBNP (r=0.330, p<0.05).

Conclusions: Abnormalities of laboratory markers that reflect myocardial injury, systemic inflammation and thrombosis are highly prevalent among patients with AHF syndromes. These markers generally appear to be associated with worse cardiovascular, renal and glycemic parameters.

P1076

Uptake of heart failure guidelines in the management of acute heart failure admissions with a focus on NT-proBNP: a UK tertiary centre experience.

A Babu[1]; Y Yanish Purmah[2]; P Desai[1]
[1]University Hospital Birmingham, Cardiology, Birmingham, United Kingdom of Great Britain & Northern Ireland; *[2]University of Birmingham, Cardiology, Birmingham, United Kingdom of Great Britain & Northern Ireland*

Introduction Brain natriuretic peptides (BNP) are peptides released mainly from the cardiac ventricles and have diuretic, natriuretic as well as hypotensive effects. NT-proBNP, derived from proBNP, and is increased in heart failure (HF) patients. In the acute phase, NT-proBNP measurement can improve the diagnostic accuracy of HF in patients presenting with dyspnoea. Furthermore, NT-proBNP levels also correlate with prognosis in acute HF admissions. The use of NT-proBNP has also been shown to be cost effective with reduction in hospitalisations. UK NICE guidelines from 2018 as well as ESC guidelines on HF have recommended that all patients admitted with suspected HF should have NT-proBNP measured.

Purpose We investigated the proportion of patients presenting with acute HF to our hospital who had an NT-proBNP measured on admission. Our target was that 100% of patients should have this measured.

Methods A standardised pro-forma for data collection was used to collect data about our acute heart failure admissions from 4th January 2018 until 27th November 2018. Basic demographics, NT-proBNP levels, echo data and discharge diagnoses were recorded. Our IT coding data was filtered to include patients who had "heart failure" as their primary discharge diagnosis.

Results 113 patients were found to have a primary diagnosis of HF on their discharge summary. The majority of patients were males (66%) with a mean age of 62 years old. Our cohort was an "all-comer" population and included patients with ischaemic heart disease (39%), hypertension (32%), diabetes (35%) and AF (32%). 23% of our patients had a diagnosis of CKD.

35 patients (31%) did not have an NT proBNP level measured despite "heart failure" being the primary discharge diagnosis. 7 patients without NT-proBNP measurement did not have a prior diagnosis of HF before admission.

It is therefore possible that there is a lack of knowledge about the up to date guidelines on the management of HF and also, more specifically, about lack of knowledge about prognostic value of NT-proBNP in patients already known to have HF.As a result of this study, we will implement teaching programmes on updates about HF management for our non-cardiologist colleagues. Our HF specialist nurses will also play a vital role in education on the wards. We will also be collaborating with our IT department to design an alert which prompts the clinician about the guidelines about NT-proBNP measurement as well as alerting our HF team directly if there are patients with very high NT-proBNP levels in the hospital.

Conclusion There is suboptimal adherence to national and international HF guidelines, with one third of our acute HF patients not having their NT-proBNP measured on admission. This issue has major clinical and cost-effectiveness implications for our patients and we will be implementing enhanced education measures and IT collaborations to improve adherence to the HF guidelines in our hospital.

P1077

Pregnancy-associated plasma proteins in patients with Infarction acute phase STEMI

G Guzeliya Kayumova[1]; V Razin[1]
[1]Ulyanovsk State University, Ulyanovsk, Russian Federation

Introduction . Worldwide deaths from cardio - vascular disease ranks first among all causes of overall mortality. To improve risk stratification and diagnosis of acute coronary syndrome are open and actively exploring new protein growth factors and damage associated with pregnancy plasma protein-A.

The purpose of the comparative analysis of PAPP-A levels in the blood plasma of patients with acute coronary syndrome.

Material and methods: In the study 71 patients were enrolled with acute coronary pathology, the average age was 57 ± 8.5 years of age. In the blood plasma of patients was measured PAPP-A. Blood sampling was carried out at the time of patient's admission to the verification of the final diagnosis. The concentration of PAPP-A was measured by immunofluorescence. The control group consisted of 20 healthy individuals. The comparison group consisted of 40 patients with hypertension and coronary heart disease with stable forms of angina. The statistical processing of the material held by a "Statistics 8.0" package.

Results: PAPP-A in 37 patients with Infarction acute phase STEMI were the highest 27,64 ± 11,60 and close to the cases of mortality 27,7 ± 7,1. In 34 patients with Infarction acute non phase STEMI PAPP-A concentrations were slightly lower segment 11,02 ± 7,18, but fairly significantly (p <0.05) higher than that of patients with a diagnosis of unstable angina, 8.22 ± 3.16. All patients with myocardial infarction at admission were decorated complications of acute period. 38 patients had a higher risk for Killip 2,5-4. 9 patients had a higher risk of fatality on a scale of Grace in hospital = 40-50%. Absolute mortality from heart attack was 9 cases, which fully complies with Grace in hospital. Analysis of PAPP-A was statistically significant (p <0.05) due to weak negative outlook mortality on a scale of Grace in 6 months p = 0,001, r = -0,25.

Conclusion: PAPP-A levels are significantly higher in patients with acute coronary artery disease compared to healthy people and patients with arterial hypertension and coronary heart disease (stable form). In patients with Infarction acute phase STEMI PAPP-A is greater than the value in unstable angina in 3,4 times, and in patients with Infarction acute phase STEMI in 2,5 times. In case of death PAPP-A is 3.3 times higher than that in unstable angina. PAPP-A - factor protein damage, and can be used as the analyzer is unstable atherosclerotic plaques in acute coronary events.

P1078

Soluble CD163 is associated with LV ejection fraction in patients with STEMI

R Radek Pudil[1]; L Zahalkova[1]; C Andrys[2]; J Krejsek[2]; J Stasek[1]; V Palicka[3]
[1]Charles University Faculty of Medicine and University Hospital Hradec Kralove, Prague Hradec Kralove, Czechia; *[2]University Hospital Hradec Kralove, Immmunology and Allergology, Hradec Kralove, Czechia*; *[3]University Hospital Hradec Kralove, Institute of Clinical Biochemistry and Diagnostics, Hradec Kralove, Czechia*

On behalf of: Research group of the Charles University Q40/03
Funding Acknowledgements: PROGRES Q40/03

Background: CD163 molecule belongs to important parts of the scavenger system, which helps to eliminate hemoglobin-haptoglobin complex and has a potential to suppress reactive oxygen radicals production in patients with acute coronary syndromes. The increase of sCD163 was also observed in patients with heart failure. Purpose: The aim of the study was to analyze clinical significance of increased sCD163 in left ventricular functional changes in patients with acute myocardial infarction (STEMI).

Methods: In the group of 29 patients (64.5±7.5 years, 4 females) with acute STEMI, we assessed concentrations of plasma sCD163 (at the time of admission, 24h and 96h later) and analyzed its association with left ventricular systolic function (LVEF).

Results: The plasma sCD163 level was increasing during the time of observation when compared to normal levels [0h: 1770.5 μg/L (IQR: 1451-2096.2 μg/L) vs.

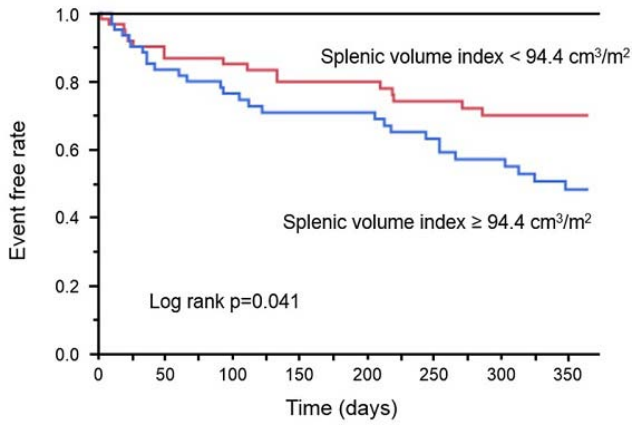
1178 μg/L (1078-1265 μg/L), p<0.001; 24h: 2063 μg/L (1589-2453 μg/L) vs. 1178 μg/L (1078-1265 μg/L), p<0.001; 96h: 2116 μg/L (1924-2458 μg/L) vs. 1178 μg/L (1078-1265 μg/L), p<0.001]. In patients with LVEF ≤40%, plasma sCD163 concentration was significantly increased when compared to pts with LVEF >40% [0h: 1996 μg/L (1756-2145 μg/L), vs. 1456 μg/L (1280.5-2006.5 μg/L), p 0.022; 24h: 2435 μg/L (2145-2753 μg/L) vs. 1689 μg/L (1421.5-2131 μg/L), p 0.003; 96h: 2458 μg/L (2036-2783 μg/L) vs. 2032 μg/L (1761.5-2143.5 μg/L), p 0.004]. Concentration of sCD163 was negatively associated with left ventricular ejection fraction (24h: r -0.39, 95% CI: -0.57- -0.03, p 0.04).
Conclusion: Plasma sCD163 concentration is increased in patients with acute myocardial infarction (STEMI) and is associated with left ventricle ejection fraction and could serve as a potential tool for risk stratification of these patients.

P1079

Splenic volume index using computed tomography is associated with heart failure readmission in patients with acute decompensated heart failure

D Maeda[1]; K Sakane[1]; Y Kanzaki[1]; T Okuno[1]; S Nakayama[1]; R Horai[1]; K Tsuda[1]; K Akamatsu[1]; T Fujisaka[1]; T Ito[1]; K Sohmiya[1]; M Hoshiga[1]
[1]Osaka Medical College, Takatsuki, Japan

Background: The spleen is the organ which related to inflammation, and the splenic size is affected by hemodynamic congestion and sympathetic stimulation. However, the association between the splenic size and prognosis in patients with heart failure has been unknown.
Methods: Between January 2015 and March 2017, we analyzed 125 acute decompensated heart failure patients who performed computed tomography on admission day. Splenic size was measured by three-dimensional computed tomography. Patients were divided into two groups according to median of splenic volume index (SpVi: splenic volume / body surface area), and compared their baseline characteristics and the rate of heart failure readmission at one year.
Results: The median of SpVi was 94.4 cm3/m2 (IQR: 65.3 to 139.4 cm3/m2). There was no difference in age between two groups. Patients with large SpVi had significantly enlarged left atrium and left ventricle. In multiple regression analysis, posterior wall thickness and left ventricular end-diastolic diameter had significant positive correlations with SpVi. Kaplan-Meier analysis revealed large SpVi group had lower event free rate (log rank p = 0.041) than small SpVi group. After adjusting for age, sex, systolic blood pressure, creatinine, hemoglobin and log B-type natriuretic peptide, SpVi was independently related to heart failure readmission (Hazard ratio 2.64 [95% CI: 1.34 to 5.35], p = 0.005).
Conclusions: Increased splenic volume is independently associated with heart failure readmission in patients with acute decompensated heart failure.



Kaplan-Meier curve of heart failure r

P1080

It is the real deal: right ventricular dysfunction is a common finding across different ejection fraction phenotypes in acutely decompensated heart failure patients

JA Borovac[1]; D Glavas[2]; Z Susilovic Grabovac[2]; J Bozic[1]
[1]University of Split School of Medicine, Department of Pathophysiology, Split, Croatia; [2]University Hospital of Split, Division of Cardiology, Department of Internal Medicine, Split, Croatia

Funding Acknowledgements: Nothing to declare.

Background: Dysfunction of the right ventricle (RV) can often be underestimated during the work-up of a congested patient with acutely decompensated heart failure (ADHF).
Purpose: To determine the prevalence of RV dysfunction in ADHF patients and to characterize parameters of RV dysfunction when stratified by sex and the left ventricular ejection fraction (LVEF).
Methods: Twenty-six patients with LVEF <50% and 26 with LVEF ≥50%, that fulfilled ESC 2016 HF criteria for ADHF were consecutively enrolled in the study. Parameters of RV function including tricuspid annular plane systolic excursion (TAPSE), tricuspid lateral annular systolic velocity (S'), fractional area change (FAC), RV 2D free wall strain (FWS) and pulmonary artery systolic pressure (PASP) were measured by transthoracic echocardiography with abnormal cut-offs defined by ASE/EACVI criteria.
Results: Mean age of patients was 69.6 ± 10.6 years with equal sex distribution. Reduced FWS was the most common (71.9%) RV abnormality among ADHF cohort while decreased S' was least frequently (49%) encountered (Figure 1). Women had significantly higher RV FAC and RV 2D FW strain values than men (35.9 ± 9.1 vs. 29.1 ± 9.8 % and -19.2 ± 6.2 vs. -14.7 ± 4.9 %, respectively). Distribution of reduced TAPSE and RV S' was significantly higher among patients with LVEF <50% compared to those with LVEF ≥50% (p=0.031 and p=0.023, respectively; Mann-Whitney U test) (Table 1).
Conclusions: RV dysfunction is a common finding among ADHF patients and seems to affect men more than women. Prevalence of RV dysfunction is substantial in both LVEF phenotypes, although those with LVEF <50% are generally more affected and dominantly present with reduced RV FW strain while elevated pulmonary pressures seem to predominate among patients with preserved LVEF.

Table 1. RV dysfunction and LVEF

VARIABLE	LVEF <50%	LVEF ≥50%
TAPSE, mm	15.5 ± 5.6	18.8 ± 4.8
TAPSE <17 mm, %	67.5%	33.3%
RV S', cm/s	9.6 ± 3.1	11.8 ± 3.3
RV S' <9.5 cm/s, %	58.8%	29.4%
RV FAC, %	31.6 ± 10.6	35.2 ± 7.9
RV FAC <35%, %	63.6%	50.0%
RV 2D FW strain, %	-16.0 ± 5.5	-19.7 ± 6.7
RV 2D FW strain <20%, %	76.0%	57.1%
PASP, mmHg	37.8 ± 13.3	45.7 ± 23.5
PASP >35 mmHg, %	54.5%	62.5%

Concomitant pericardial effusion predicts adverse outcomes in patients with acute myocarditis

J Y Jae Yeong Cho[1]; KH Kim[1]; HY Kim[1]; H Park[1]; HJ Yoon[1]; YJ Hong[1]; HW Park[1]; JH Kim[1]; Y Ahn[1]; MH Jeong[1]; JG Cho[1]; JC Park[1]
[1]Chonnam National University Hospital, Cardiology, Gwangju, Korea (Republic of)

Background: Acute myocarditis is still one of the most serious cardiovascular diseases with difficulty in both diagnosis and treatment. The disease is often accompanied by pericardial effusion because this category of the disease usually presents in the form of myopericarditis. However, there is lack of data that explain the prognostic implication of pericardial effusion in acute myocarditis. The aim of this study was to investigate the impact of pericardial effusion on adverse clinical outcomes in patients with acute myocarditis.
Methods: A total of 116 patients (39.5±20.1 years, 76 males) with acute myocarditis consecutively admitted to a tertiary hospital between 2011 and 2016. All patients were diagnosed with acute myocarditis by clinical symptom and signs, abnormal findings in cardiac imaging such as echocardiography or magnetic resonance image, and elevated cardiac troponin-i. They were divided into two groups according to the presence of pericardial effusion; the pericardial effusion (PE) group (n=56, 43.4±18.3 years, 29 males) vs. the non-pericardial effusion group (non-PE) group (n=54, 36.6±21.1 years, 43 males). Baseline characteristics, echocardiographic findings, laboratory findings, and clinical outcomes were compared between the two groups. The primary endpoint was in-hospital death or ECMO therapy.
Results: PE was noted in 56 out of 110 patients (50.9%) with acute myocarditis. Patients with PE tended to be older (43.4±18.3 vs. 36.6±21.1 years, p=0.071) and was more likely to be female (48.2% vs. 20.4%, p=0.002). Hypotension (systolic blood pressure < 90mmHg) was more frequent in PE group (25.0% vs. 5.6%, p=0.005). NYHA functional class was higher in PE group (1.9±1.5 vs. 1.2±1.4, p=0.021). High serum lactate level was noted in PE group (4.2±4.1 vs. 1.8±1.3, p=0.008).
Multivariate analysis using binary logistic regression showed that cardiac troponin > 10 ng/ml (OR 9.02, 95%CI 2.10-38.74, p=0.003) and the presence of pericardial effusion (OR 17.9, 95%CI 2.10-152.58, p=0.008) were the only independent predictors for the primary endpoint.
Conclusion: In patients with acute myocarditis, the presence of pericardial effusion indicates more adverse disease course. Early intensive immunosuppressive therapy or preparing for mechanical circulatory support would be warranted.

P1083

The effect of prehospital diuretic administration on clinical outcomes in patients with acute heart failure.

E Goncalvesova[1]; M Dankova[1]; P Lesny[1]; M Luknar[1]
[1]The National Institute of Cardiovascular Diseases, Department of Cardiology, Bratislava, Slovakia

On behalf of: SLOVASeZ II, III Investigators

Background: Most patients with AHF present with congestion. Early decongestion with diuretic agents could improve their clinical outcomes.
Aim: The aim was to analyse the impact of prehospital diuretic administration on clinical outcomes in patients with acute heart failure (AHF)
Methods: SLOVASeZ II, III registries enrolled 1239 consecutive patients hospitalised due to AHF. Patients were divided into two groups: with prehospital intravenous diuretic administration (D+, n=602) and without (D-, n= 607) diuretic agents within 24 hours before hospitalisation. The primary outcomes were: length of hospital stay and in-hospital death.
Results: A total of 1239 patients were divided into two groups (with and without prehospital diuretic administration). The average age was 71±11,8 years with gender distribution 634/605 (men/women). HFrEF/HFmrEF/HFpEF was in 417/190/349 patients. In 304 (24,5%) patients there was newly diagnosed AHF, the sudden worsening of AHF in 289 (23,3%) and progressive worsening of AHF in 646 (52,1%) patients. The baseline characteristics were similar between groups. The length of hospital stay did not differ between groups (the average for D+ 9,4 vs. 9,1 days for D-, p=0,83). The rate of in-hospital death did not differ between the groups (8,8 vs. 6,4%, p=0,11).
Conclusions: The prehospital intravenous diuretic administration within 24 hours before admission was not associated with clinical outcomes in a large prospective cohort of patients with AHF.

P1084

Characteristics and outcomes of diabetic patients with reduced left ventricular ejection fraction post acute myocardial infarction.

L Giudicatti[1]; J Spiro[1]; K Lam[2]
[1]Royal Perth Hospital, Cardiology, Perth, Australia; *[2]Fiona Stanley Hospital, Cardiology, Perth, Australia*

Introduction: Diabetes is associated with higher morbidity and mortality in patients with heart failure and coronary artery disease. Recent studies have shown a reduction in cardiovascular endpoints including all-cause mortality and myocardial infarction in patients treated with sodium-glucose transporter 2 (SGLT-2) inhibitors. Data regarding the effect of SGLT-2 inhibitors in type 2 diabetics with ischaemic cardiomyopathy is limited. Our aim was to assess the clinical features, outcomes, and treatment strategy of diabetic and non-diabetic patients at our institution with left ejection fraction (LVEF) ≤40% following myocardial infarction (MI). Particular focus was directed to use of SGLT-2 inhibitors .
Methods: Retrospective study of consecutive patients undergoing inpatient coronary angiography at a tertiary hospital over a 9-month period (01/01/17 - 30/09/2017). 1,635 patients were identified. 92 patients satisfied inclusion criteria; 60% STEMI, 40% NSTEMI. 85% had new diagnosis of heart failure. 34/92 (37.0%) were diabetic, 8/34 (23.5%) newly diagnosed. Mean HbA1c in the diabetics was 8.32. 38.2% of the diabetics were eligible for SGLT-2 inhibitor initiation.
Results: There was no significant difference between diabetics and non-diabetics with respect to sex, age, peak troponin, length of admission, history of ischaemic heart disease, prior left ventricular dysfunction and heart failure therapies on admission or discharge. Diabetics had higher rates of hypertension (75% vs 34%, p<0.001), higher triglyceride levels (1.94mmol/L vs 1.46mmol/L, p=0.025) and were more likely to be on lipid lowering therapy at admission (62% vs 25%, p=0.006) but not at discharge than non-diabetics. There was an increase in use of SGLT-2 inhibitors from 2.9% diabetics on admission to 20.1% on discharge. One-year survival post-discharge was higher in diabetics (100%) vs non-diabetics (90.6%), (p=0.045).
Conclusion: This analysis offers hypothesis-generating data supporting the potential protective effect of SGLT-2 inhibitors on survival in diabetics with left ventricular dysfunction post-MI. Ongoing efforts should be directed at identifying diabetic patients eligible for SGLT-2 inhibitors in high-risk cohorts.

P1085

The EuroDEM- study: does arrival mode affect ED management and outcome of acute heart failure patient?

P Harjola[1]; P-L Martin[2]; T Tarvasmaki[3]; V-P Harjola[1]; S Laribi[2]
[1]Helsinki University Central Hospital, Department of emergency medicine and services , Helsinki, Finland; *[2]Tours University, School of Medicine and Tours University Hospital, Department of emergency medicine , Tours, France*; *[3]Helsinki University Central Hospital, Cardiology, Heart and Lung center, Helsinki, Finland*

Funding Acknowledgements: Helsinki University Hospital, Department of emergency medicine and services

Background: Acute heart failure (AHF) is often encountered in emergency departments (ED). From 11% to 53% of AHF patients arrive to the ED by ambulance.
Purpose: The aim of our study was to show potential effects of arrival mode on the ED management and short-term prognosis of AHF patients.
Methods: The EuroDEM study was a European multinational multicentre study. Data on patients presenting with shortness of breath were collected from 66 EDs. Patients with discharge diagnosis of AHF were categorized into two groups based on their arrival mode to the ED: those arriving by ambulance (emergency medical services (EMS) patients) and those self-presenting (non-EMS patients). ED management and prognosis were compared between the two groups.
Results: The study included 507 AHF patients. The majority (60.9%) arrived at the ED by ambulance. EMS patients tended to be older (mean age 80 years vs. 75 years) and more often females (56% vs. 42%) compared to non-EMS patients. On admission to the ED, EMS patients had higher heart rate (90/min vs 85/min, p=0.019) and respiratory rate (24/min vs 21/min, p=0.026). Diuretics were administrated to 67% of all AHF patients, nitrate-infusion to 12 % and intravenous morphine to 8%. Seventy-nine percentage received supplementary oxygen, and 9.5% non-invasive ventilation (NIV). No significant difference was seen in the ED management between the patient groups apart from the use of supplementary oxygen (EMS 85% vs non-EMS 69%, p< 0.0001) and NIV (EMS 13% vs non-EMS 4%, p=0.0017). Thirty-two percentage of non-EMS patients and 16 % of EMS patients were discharged home from ED (p<0.0001). The mean length of hospital stay was 7 days in both groups. In-hospital mortality was 5.0 % for non-EMS and 10.9 % for EMS patients (p= 0.06).
Conclusion: Majority of AHF patients arrive to the ED by ambulance. The arrival mode does not seem to affect the ED management apart from the use of ventilatorysupport. Non-EMS patients are more often discharged home from the ED, whereas the in-hospital mortality is higher among EMS patients.

P1086

Multicenter randomized clinical trial of the efficacy and safety of intravenous Quercetin in patients with acute decompensated heart failure

S Sergey Kozhukhov[1]; A Parkhomenko[1]
[1]*NSC "Institute of Cardiology", Kiev, Ukraine*

Objectives: To evaluate the efficacy and safety of early treatment with intravenous high water-soluble Quercetin (Q) in acute decompensated heart failure (ADHF) patients with reduced left ventricular ejection fraction (EF).
Design and Methods: In open-label multicenter (8 centers involved) clinical trial (II phase) 91 patients admitted for ADHF were randomized either to Q1 scheme (n=28) or to Q2 scheme (n=34) or to control group (n=29). Inclusion criteria: chronic HF of ischemic etiology > 1 year, EF ≤ 40%, sinus rhythm. Intravenous Q was used during 5 days with Q1 800 mg and Q2 450 mg total dose. All patients received recommended standard HF therapy. Primary surrogate endpoint: EF increase ≥ 5%, EDV decrease ≥ 5% and decrease ≥ 6 points by HF severity scoring system compared the baseline values and those on day 10. HF severity score included: dyspnea, arrhythmia, orthopnoe, jugular-venous distension, crackles, gallop rhythm, hepatomegaly, edema, systolic blood pressure, respiratory and heart rate. The results of the difference in EF, EDV and HF severity score between baseline and 10th day were translated into points (high efficacy - 3 points, moderate - 2 points, poor -1 point, no effect - 0 points) and summarized in each group. Secondary endpoint was evaluated by cardiovascular death and re-hospitalization for HF within 180 days. All adverse events were used to assess the safety of Q.
Results: The study groups did not differ in terms of demographic characteristics and main clinical data. EF increase ≥ 5% was observed: Q1 group – in 67.9%, Q2 – in 79.4% and in 55.6% patients of the control group. EDV decreased ≥ 5%: Q1 – in 69.2%, Q2 – in 58.8% and in 51.8% of controls respectively. HF severity score (decrease ≥ 6 points) was significantly higher in Q1 and Q2 in compare to control group (82.1, 82.4 and 62.1%, both p<0.05 respectively). The primary endpoint was 2.14 point in Q1, 2.12 - in Q2 and 1.62 - in the control group (both p<0.05). There was no significant difference in secondary endpoint between groups: 17.2% in Q1, 14.3 in Q2 and 24.1% in the control group respectively. Treatment by Q was safe without any serious adverse events.
Conclusion: Our results show that intravenous Q contributes to the improvement of left ventricle contraction and remodeling, and reduces clinical severity of HF in ADHF patients. According to our data, Q2 regime with the low dose of the study drug is preferred. Study results give the background for further larger phase 3 trials of Q use in ADHF patients.

P1087

Optimal intravenous anesthesia in patients with acutely decompensated heart failure undergoing transcatheter aortic valve implantation

J E Pino[1]; F Ramos Tuarez[1]; P Torres[1]; K Chen[1]; M Kabach[1]; A Alrifai[1]; L Lovitz[1]; R Cubeddu[2]; M Rothemberg[2]; R Chait[1]; M Nores[2]
[1]*University of Miami/ JFK Medical Center, Cardiovascular Disease, Atlantis, United States of America*; [2]*JFK Medical Center, Atlantis, United States of America*

Background Patients with severe aortic stenosis (AS) and concomitant acutely decompensated heart failure (ADHF) undergoing transcatheter aortic valve implantation (TAVI) represent a specially challenging population. Optimal anesthetic therapy in this population is unknown.
Purpose To evaluate the optimal anesthetic therapy selection and relevant clinical outcomes in patients with severe AS and ADHF undergoing TAVI
Methods This is a retrospective cohort study of patients that underwent TAVI in our institution between 04/2012 and 12/2016. Optimal use of anesthetics was defined as ≤3 anesthetic agents (not including ketamine). End-points included: 30-day mortality, heart failure readmission, acute kidney injury (AKI), and length of stay (LOS).
Results: Out of 570 patients that underwent TAVI in our institution, 92(16%) had ADHF (see Table 1 for baseline characteristics). The average amount of anesthetics administered was 3.3 and, 50/92 (56%) of patients with ADHF had optimal anesthesia use. The 30-day mortality was 2(4%) for patients with optimal anesthetic use vs. 3/42(7.5%) for the non-optimal group (p=0.65).
A regression model demonstrated that LOS increased 1.1days for every anesthetic agent used (p=0.047). For the optimal group, heart failure associated readmission was 2/50 (4%) vs. 10/42 (25%) for the non-optimal group (p=0.004). Post TAVI AKI was similar in both groups (p=0.36).
Conclusion: This study suggests that optimal anesthesia use in patients with ADHF undergoing TAVI decreases LOS and heart failure readmission at 30-days with no impact in post-TAVI AKI and 30-day mortality.

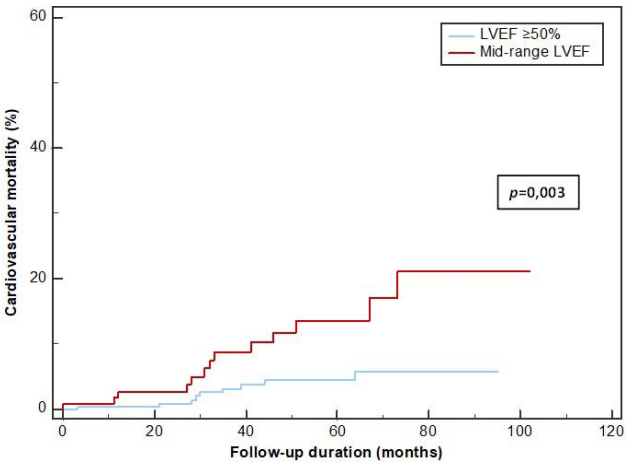
Angiotensin-converting enzyme inhibitors in acute coronary syndrome with mid-range ejection fraction

F M Fernando Manuel Fonseca Goncalves[1]; JP Guimaraes[1]; SC Borges[1]; JJ Monteiro[1]; PS Mateus[1]; JI Moreira[1]
[1]*Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal*

Introduction: Classically included in the group of patients with 'preserved' left ventricular systolic function (LVEF), heart failure (HF) with mid-range ejection fraction (40-49%) is a group of patients with more recent individualization, whom approach and treatment in the context of ischemic heart disease are not yet fully established. The aim of this study was to evaluate the impact of angiotensin-converting enzyme inhibitors (ACEI) on acute coronary syndrome (ACS) with mid-range LVEF (MREF) and its comparison with patients with LVEF ≥50%.
Methods: This was a retrospective study of patients with nonfatal ACS, periodically included in our center registry between October/2010 and November/2017, who were evaluated for LVEF during the index event. Patients were subdivided into 2 groups - group 1 with MREF and group 2 with LVEF ≥50%. The primary endpoints evaluated were cardiovascular mortality (CV) and MACE (myocardial infarction, coronary revascularization and CV death), at a median follow-up of 42 months (IQR 27-59).
Results: A total of 394 patients were identified, 28,9% belonging to group 1 and 71,1% to group 2. The prescription of ACEI at discharge was 90,4% in group 1 and 90% in group 2.
Cardiovascular mortality was significantly higher in group 1 (11,4% vs. 3,6%, p<0,05). In addition, there was a trend for more MACE in this group (17,5% vs. 11,4%, p=0,104).
In a multivariate analysis adjusted for age and ACS type, the use of ACEI in group 1 was associated with lower CV death (HR 0,2, 95% CI 0,1-0,8). There was also less MACE, but this difference did not reach statistical significance (HR 0,5, 95%



ACEI CV Mortality Kaplan Meier Curves

CI 0,2-1,5). In group 2, no significant differences were found either for CV death (HR 0,9, 95% CI 0,2-4,5) or for MACE (HR 0,8, 95% CI 0,3-2,1), despite a tendency for fewer events.
Conclusions: In ACS, MREF appears to be associated with worse prognosis when compared with LVEF ≥50%. The prescription of ACEI was associated with a decrease in cardiovascular events in the MREF group, which did not occur significantly in the LVEF ≥50% group.

P1089
Haemodynamic effects of heart rate lowering in patients admitted for acute heart failure: to save energy by improving effectiveness

J Jessica Rossi[1]; S Mazzetti[1]; R Abete[1]; D Margonato[1]; M Chioffi[1]; C Vecchio[2]; C Cavalotti[3]; G Malerba[4]; A Ciro'[5]; P Delfino[1]; A Mortara[1]
[1]Polyclinic of Monza, Cardiovascular department, Monza, Italy; [2]Saronno General Hospital , Cardiologia, Saronno, Italy; [3]Niguarda Ca' Granda Hospital, Cardiologia, Milan, Italy; [4]Di Circolo Hospital, Cardiologia, Varese, Italy; [5]San Gerardo Hospital, Cardiologia, Monza, Italy

Background: Heart rate (HR) is a parameter with prognostic value for patients presenting with heart failure (HF) and sinus rhythm in both acute and chronic setting. In patients admitted for acute decompensation, HR could be a compensatory mechanism but also contribute to worsening HF, and indication to drugs which improve HR control is unclear. We analyzed the hemodynamic effect of early administration of ivabradine combined with usual care, 48-72hrs after hospital admission for HF in patients with sinus rhythm and HR >75 bpm.
Methods and results: Non-invasive hemodynamic parameter (stroke volume, SV, cardiac output, CO, Systemic Vascular Resistance, SVI) were obtained by the Niccomo Device (Medis, Germany) through a bioimpedence technique. Measurements with this device have been shown to be accurate, highly reproducible and sensitivity to normal hemodynamic changes. In this ongoing study, the first 16 acute HF patients enrolled had the following clinical characteristics: mean age 69±16, 31% females, ischemic aetiology 31%, hypertensive 25%, idiopathic 44%, LVEF 39±20%, BNP 1348±1198 pg/mL. Despite clinical stabilization of the patient, after 48-72 hrs from admission, HR was persistently elevated (79,5± 8,5 bpm) and Ivabradine 5 mg bid was started on-top of standard care (beta blockers 62,5 %, diuretics 81,25%, ACE i 62,5%, ARB 12,5%, MRA 56,25%). Measurement were made at the baseline (48-72hrs from admission), after 24-48-72 hrs from starting Ivabradine and at the time of discharge. Treatment with ivabradine was well tolerated in all patients. HR was progressively reduced from 79,5 ± 8,4bpm to 64,2 ±10,1 bpm at hospital discharge, p<0.01. We observed a significant hemodynamic improvement by HR control with an increase of stroke volume (baseline 74,4±9,4 ml vs 85,49±16,4 ml at discharge, p 0,017), and only a minimal reduction of cardiac output (baseline 6,6 ±0,7 L/min vs 5,32 ±1 L/min at discharge, P=ns). All other measures of heart work were also significantly affected by reducing HR.
In conclusion: The strategy of the early administration of ivabradine, during a decompensated episode of HF to control HR on top of usual care including beta-blockers, is feasible and safe. The effect of lowering HR may save energy without affecting cardiac output as confirmed by the significant increase of stroke.

P1090
Predictors of response to levosimendan in patients with decompensated heart failure

P Lesny[1]; M Dankova[1]; M Luknar[1]; V Simovicova[1]; A Dlesk[1]; E Goncalvesova[1]
[1]National Cardiovascular Institute, Bratislava, Slovakia

Background: Levosimendan is an inodilator with potential efficacy and safety benefit over catecholaminergic inotropes used in decompensated heart failure (DHF) patients (pts). We sought to determine predictors of response to levosimendan infusion in pts admitted for decompensated advanced heart failure.
Patients and methods: From January 2015 to December 2018, levosimendan was administered in 101 pts (90 men) hospitalised with DHF at a single centre. Mean age was 51.5 ± 10.1 years, main diagnosis was dilated cardiomyopathy in 48 % pts, coronary artery disease in 33 % of pts. Mean baseline systolic blood pressure was 103.8 ± 12.8 mm Hg, heart rate 78.7 ± 15.8 beats per minute, median NT-proBNP was 6571 ng/L. Patients discharged without subsequent additional intravenous inotropic therapy were defined as responders (R). Other pts (intravenous inotropes added and/or ventricular assist device implanted and/or heart transplant and/or death during hospitalisation), were non-responders (NR). Twenty one simply available clinical and laboratory parameters were included in multivariate logistic regresion analysis to determine independent predictors of reponse to levosimendan.
Results: There were 75% R and 25% NR. The hospital mortality rate was 4 %. During the hospitalisation 13 % and 2 % of pts, respectively, underwent ventricular assist device implantation or heart transplant. Significant differences were observed between R and NR patients in baseline bilirubin and beta-blocker use (28 ± 18 vs 47 ± 29 umol/L, p=0.003; 63 vs 30 %, p=0.001, respectively). Beta-blocker use was identified as the only independent predictor of response to levosimendan.
Conclusions: Three quarters of patients responded to levosimendan. Patients who tolerate beta-blocker benefit most from levosimendan therapy. Responders had lower baseline bilirubin.

P1091
Levosimendan for primary graft failure treatment after orthotopic heart transplantation

M Zaleska-Kociecka[1]; J Dutton[1]; M Morosin[2]; R Fernandez Garda[1]; D Garcia Saez[3]; A Simon[3]; B Zych[3]; S Kaul[1]; TC Aw[4]; N Lees[5]; A Hurtado Doce[1]
[1]Harefield Hospital, Intensive Therapy Unit, London, United Kingdom of Great Britain & Northern Ireland; [2]Royal Brompton Hospital, Adult Intensive Care Unit , London, United Kingdom of Great Britain & Northern Ireland; [3]Harefield Hospital, Transplantation and Mechanical Circulatory Support, London, United Kingdom of Great Britain & Northern Ireland; [4]Royal Brompton Hospital, Anaesthesia, London, United Kingdom of Great Britain & Northern Ireland; [5]Harefield Hospital, Anaesthetics and Intensive Therapy Unit, London, United Kingdom of Great Britain & Northern Ireland

Introduction: Primary graft failure (PGF) is a life-threatening complication, and a leading cause of early mortality after orthotopic heart transplantation (OHT). PGF is defined as severely impaired systolic function accompanied by hypotension, low cardiac output, and high filling pressures occurring in the first 72 hours in the absence of hyperacute rejection and cardiac tamponade. The treatment strategies include supportive care, inotropes (catecholamines, phosphodiesterase inhibitors) and mechanical circulatory support (MCS). It is known that most inotropic agents can be associated with an increase in morbidity and mortality. Levosimendan (LS) increases cardiac contractility without increasing myocardial oxygen consumption or causing pro-arrhythmogenic effects. There is limited data of its use in after OHT.
Purpose: The aim of the study is to evaluate the role of LS in patients with PGF requiring MCS after OHT.
Method: We retrospectively analysed 153 consecutive OHT patients in our hospital from 2013 to 2018. We assessed the incidence of PGF requiring ECMO and evaluated subgroups based on LS treatment as shown in (Fig1).
Results: There were 40 (26.5%) cases of PGF requiring ECMO support, of whom 12 patients received LS (LS group) and 28 did not (non-LS group). The mean age at the time of OHT was similar in both groups (44 vs 44.1; p=0.985. Apart from a higher incidence of female sex in the LS group (67% vs 25% in the non-LS group; p=0.012) there were no significant differences in baseline characteristics. Fewer patients in the LS group had ECMO implanted before leaving theatre (4/12 vs 20/28 in the non-LS group; p=0.024), however over 90% of patients in each group received ECMO within the first 24 hours after OHT. Median time to the onset of LS infusion was 120 hours, (Q1-Q3: 60-230hours) from ITU admission. Successful weaning from ECMO was comparable between the groups (8/12 vs 23/28 cases in the non-LS group; p=0.283), however the duration of MCS in the LS group was significantly longer with median time of 8.18 days (Q1-Q3: 5.9-11.4) as opposed to to 4.7 days (Q1-Q3:2.7-6.1) in the non-LS group (p=0.005). Although thirty-day mortality was not statistically different between the groups (6/12 vs 6/28 in the non-LS group; p=0.071), 90-day mortality was significantly higher in the LS group (10/12 vs 11/28 in the non-LS group; p=0.011).

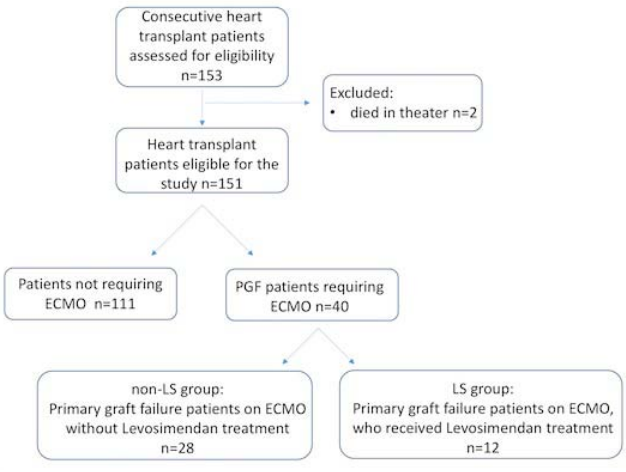


Fig 1. Study flow chart

Conclusions: Previously reported outcomes of LS use in the PGF post-OHT vary. We have retrospectively described our experience which shows no apparent benefits of the drug. The reasons for this may be related to 1) more severe circulatory failure compared to previously reported cases (all our patients required MCS) 2) later time to initiate MCS in the LS group 4) more severe circulatory failure in the LS group as the patients needed longer time on MCS 3) relatively late LS use in the course of circulatory failure. Further insight into the impact of LS on inotropic support and time of MCS weaning is pending.

P1092

Lack of prognostic effect of N-terminal pro-brain natriuretic peptide levels in acute heart failure and functional severe tricuspid regurgitation

M Soler Costa[1]; G Minana[1]; M Amiguet[1]; J Gonzalez[1]; V Pernias[1]; E Santas[1]; E Valero[1]; R De La Espriella[1]; J Nunez[1]
[1]*University Hospital Clinic of Valencia, CARDIOLOGY, Valencia, Spain*

Background: In patients with acute heart failure (AHF), plasma levels of N-terminal pro-brain natriuretic peptide (NT-proBNP) have generally shown to be associated with higher risk of adverse clinical outcomes. However, its prognostic value in patients with predominant facts of right ventricular failure remains unclear. Functional tricuspid regurgitation (TR) has emerged as a powerful prognosticator and a potential therapeutic target in heart failure setting.
Purpose: In this work, we aimed to evaluate the association between NT-proBNP and long-term mortality across TR status in an unselected cohort of patients admitted with AHF.
Methods: We prospectively included a cohort of 2961 patients admitted with the diagnosis of AHF. TR severity was assessed during hospitalization using a multiparametric integrative approach, and classified as none, mild, moderate, and severe. We used multivariable Cox regression analysis to identify the association between severe TR grade and long-term all-cause mortality.
Results: At a mean follow-up of 3.35±3.20 years, 1821 (61.5%) patients died. The mean (SD) age was 73.9±11.1 years, 49% were women, 51.8% displayed left ventricular ejection fraction>50%, and the median (IQR) of NT-proBNP was 4823 pg/ml (2086-9183). The proportion of patients with severe TR was 10.1%. In the whole sample, NT-proBNP (per increase in 2000 pg/ml) was independent and significantly associated with higher risk of mortality (HR=1.06, 95% CI: 10.5-1.08, p<0.001). However, a differential prognostic effect was found across severe TR status (p-value for interaction=0.008). In those with no severe TR, NT-proBNP remained significantly associated with higher risk (HR=1.07, 95% CI:1.05-1.08, p<0.001). On the contrary, when severe TR was present, NT-proBNP was not longer associated with mortality (HR=1.02, CI 95%:0.98-1.05, p=0.284).
Conclusion: In patients with AHF and severe TR, NT-proBNP did not show to be related with the risk of mortality.

P1094

In-hospital results of application of extracorporeal membrane oxygenation in cardiosurgery

N Natallia Piatrovich[1]; L Shestakova[1]; R Yarosh[1]; M Bushkevich[1]; D Krachak[1]; V Krachak[1]; A Achinovich[1]; Y Ostrovsky[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Department of extracorporeal blood circulation, Minsk, Belarus*

Background: Extracorporeal membrane oxygenation (ECMO) is the only method that temporarily replaces the pumping function of the heart and / or pulmonary gas exchange function in the acute period of the disease. ECMO is resorted to in the case of postcardiotomy syndrome of small cardiac output, refractory cardiogenic shock, cardiac graft dysfunction, decompensation of chronic heart failure (as a bridge to heart and / or lung transplantation) or acute respiratory failure. Despite of certain risks the frequency of application increases annually. The main tasks of the doctor: 1) a thorough and timely assessment of the general status of the patient, indications and contraindications to ECMO; 2) round-the-clock system monitoring of the patient's condition, physiological and mechanical circuit of ECMO; 3) prevention of development and / or treatment of possible complications.
Purpose: To analyze in-hospital results of using ECMO in cardiac surgery patients.
Methods: A retrospective single-center review of 112 patients aged 56,2 ± 13,5 years (80,4% of men, 19,6% of women) who were treated with ECMO in 2010-2018. Connection options: veno-venous (n = 6), veno-arterial (n = 106, 15,1% - central access, 84,9% - peripheral). Indications: postcardiotomy syndrome of small cardiac output (58%), cardiac graft dysfunction (17%) and isolated respiratory failure (5,4%). This method was also used in case of refractory cardiogenic shock (19,6%) in patients with decompensated chronic heart failure, acute myocardial infarction and life-threatening heart rhythm disorders. Used invasive methods of LV unloading to prevent or treat pulmonary edema, maintain and improve the residual pumping function of LV during veno-arterial ECMO: intraaortic balloon pump (n = 43), atrioseptostomy (n = 7), active drainage of LV / LP (n = 13), single drainage of pulmonary artery. Renal replacement therapy was performed in 32 cases (28,6%). The system of selective antegrade distal perfusion of the lower extremities was used to prevent ischemia in 37 patients.
Results: The mean time of mechanical support was 184,1 ± 124,05 h (3 hours-25 days). Stabilization of systemic hemodynamics, normalization of pulmonary gas exchange and successful weaning from ECMO in 57,5%. Stay in ICU was 16,4 ± 10,4 days, in hospital – 41,9 ± 18 days. Hospital survival rate – 49,1%. The main causes of deaths: progressive heart failure with the development of irreversible multi-organ changes, infectious complications and sepsis, strokes and bleedings.
Conclusions: Extracorporeal membrane oxygenation is an effective method of maintaining the hemodynamic and / or respiratory status of patients with acutely developed and potentially reversible respiratory, cardiac or cardiorespiratory failure, resistant to standard therapy. ECMO increases the hospital survival rate of initially severe patients and for certain groups is the only possible method of treatment.

Acute Heart Failure - Epidemiology, Prognosis, Outcome

Obesity Paradox in Acute Heart Failure from Single Center Observational Study

S Shinya Ito[1]; K Yamaji[1]; S Mori[1]; M Yano[1]; T Morinaga[1]; M Fukunaga[1]; A Isotani[1]; M Hyodo[1]; K Ando[1]
[1]*Kokura Memorial Hospital , Cardiology, Kitakyushu, Japan*

Background: The study sought to investigate the impact of baseline body mass index (BMI) on adverse clinical outcomes in patients presented with acute heart failure requiring hospitalization.
Methods: We retrospectively reviewed 641 consecutive patients who presented with acutely decompensated heart failure requiring hospitalization in 2015. BMI was assessed at the time of hospital admission in 631 patients (98.4%). The patients were divided into 3 groups according to BMI: <18.5 (low BMI group, N=83, 13.2%), ≥18.5 and <25.0 (normal BMI group, N=374, 59.4%), ≥25 (high BMI group, N=173, 27.5%). The primary endpoint was a composite of all-cause mortality and recurrent heart failure requiring hospitalization.
Results: The median follow-up period was 2.0 years. The cumulative incidence of primary endpoint was markedly higher in patients in the low BMI group (57.8%) than in those in the normal BMI group (49.5%) and high BMI group (45.7%, logrank P=0.0097, 0.0026, respectively). In the multivariable analysis, the excess adjusted risk of low BMI relative to normal BMI and low BMI to high BMI was significant in terms of primary endpoint (adjusted HR: 1.57, 95%CI: 1.13-2.15, P=0.009, adjusted HR: 1.52, 95%CI: 1.03-2.23, P=0.04).
Conclusion: Patients with low BMI had markedly higher risk for all-cause mortality and recurrent heart failure requiring hospitalization than those with normal or high BMI after the index heart failure hospitalization.

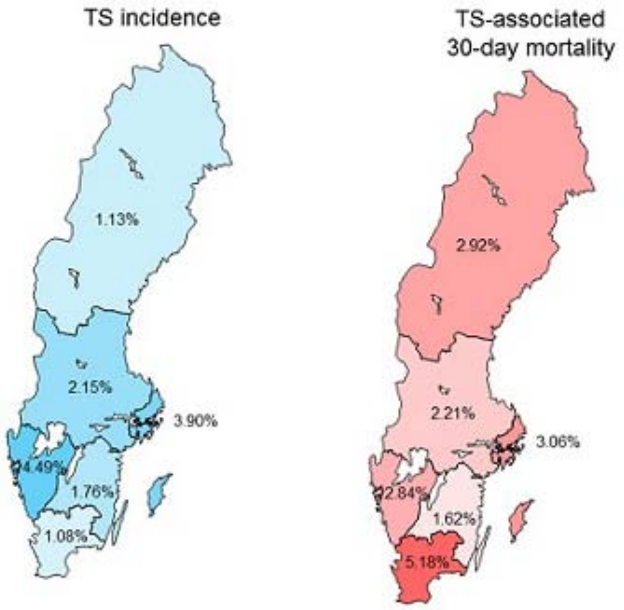
P1096

Regional differences in the incidence and prognosis of the takotsubo syndrome

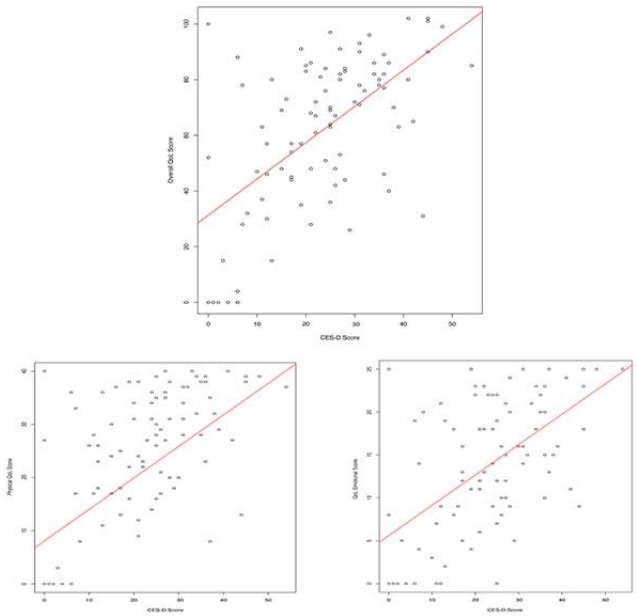
B Bjorn Redfors[1]; S Jha[1]; S Thorleifsson[1]; O Angeras[1]; G Sarno[2]; A Ravn-Fischer[1]; O Frobert[3]; T Jernberg[4]; P Tornvall[5]; A Lyon[6]; S James[2]; D Erlinge[7]; E Omerovic[1]
[1]*Sahlgrenska Academy, Univ. of Gothenburg, Dept of Molecular & Clinical Medicine/Cardiology, Gothenburg, Sweden*; [2]*Uppsala University Hospital, Uppsala, Sweden*; [3]*Orebro University Hospital, Orebro, Sweden*; [4]*Danderyd University Hospital, Stockholm, Sweden*; [5]*South Hospital Stockholm, Stockholm, Sweden*; [6]*Royal Brompton Hospital, London, United Kingdom of Great Britain & Northern Ireland*; [7]*Skane University Hospital, Lund, Sweden*

Background: Takotsubo syndrome (TS) is an acute cardiac syndrome with a clinical presentation that is very similar to acute myocardial infarction (AMI). Similar to AMI, TS carries a considerable risk of severe complications and death.
Purpose: Whereas regional differences exist in the care and outcome for patients with AMI, it is unknown whether regional differences exist in the care and outcome of patients with TS.
Methods: Using the nationwide Swedish Angiography and Angioplasty Registry (SCAAR) we identified 2,898 patients with TS in Sweden between January 2009 and February 2018. We compared the six health care regions in Sweden in regards to both the incidence of TS among patients with suspected acute coronary syndrome, and the prognosis for patients with TS.
Results: The reported incidence of TS was highest in the Western health care region (Västra Götaland) whereas unadjusted and adjusted mortality for patients with TS was highest in the Southern health care region (Figure). With the Western health care region as the reference region, the adjusted 5-year mortality risk increased

from North to South (hazard ratio [HR] 0.62, 95% confidence interval [CI] 0.31 – 1.23 for the Northern versus Western region; and HR 1.30, 95% CI 0.88 – 1.90 for the Southern versus Western region, ptrend=0.031).
Conclusions: The incidence and prognosis of TS differed between different health care regions within Sweden. The extent to which these observed differences relate to socioeconomic factors, rural-urban differences, climate and other geographical factors, and regional health care policies remains to be established.



correlated with the presence of depressive symptoms, both in the physical (r=0.56, p<0.01), emotional (r=0.56, p<0.01) and overall score (r=0.59, p<0.01) (fig 1).
Conclusion: The prevalence of impaired QoL is high in HF patients. Even when the toll of the disease on the physical components is similar in women and men, in the emotional construct women with HF diagnosis exhibited worse QoL than their male counterparts. As we expected, impaired QoL is associated with a higher prevalence of depressive symptoms in this population.



Depressive symptoms and QOL

Gender-related differences in quality of life and depressive symptoms in chilean heart failure patients

F Felipe Diaz[1]; H Verdejo[2]; O Vera[3]; J Martinez[2]; PI Ivanovic[4]
[1]Columbia University Medical Center, New York, United States of America; *[2]Pontifical Catholic University of Chile, Santiago, Chile*; *[3]La Florida Hospital, Santiago, Chile*; *[4]Universidad Andres Bello, Santiago, Chile*

Funding Acknowledgements: FONDECYT 1150359 (HV) - Regular UNAB DI-38 -18/"CBC"

Introduction: Heart Failure (HF) is one of the leading causes of morbidity and rehospitalization in older people. HF deteriorates the quality of life (QoL) and increases the rates of depression in elderly subjects, but gender-related differences are often unacknowledged.
Aim: To evaluate gender differences in QoL and prevalence of depressive symptoms in patients hospitalized with the diagnosis of decompensated heart failure.
Methods: Cross-sectional study. We included patients admitted due to ADHF in a Chilean University Hospital between 2015-2017. QoL was evaluated by the Minnesota Living With Heart Failure Questionnaire. We analyzed the physical construct (questions 2,3,5,6,7,12, and 13) and the emotional construct (questions 17-21). The prevalence of depressive symptoms was evaluated using the CES-D scale, with a cut-off of 16 points or more suggesting clinical depression. Differences between QoL and depression in HF patients were analyzed through Chi-square and Student´s T scores as corresponding. Correlation between variables was evaluated by Pearson´s correlation. Mortality data were obtained from the Chilean National Registry database. All statistical analyses were carried out in R v.3.5.1.
Results: We included 92 individuals, 48.4% female, mean age 71.2±14.6. In both genders the prevalence of depressive symptoms was high (68. 1% male vs. 77,2% female p=0.45), and the QoL was poor (MLWHF mean score 68.5±14.5). Even when the patients with poorer QoL were often women, it did not reach statistical significance (38.6% female vs. 23.4% male p= 0,17). There were no differences in the prevalence of poor QoL according to age (71.7 vs. 69.6, p= 0,53), educational level (28.1% less than eight years. 29.6% more than eight years), or health insurance (19.4% private insurance vs. 34.5% public insurance p=0.21). We did not observe differences between gender and QoL both in total score or in the physical component; however, women reported impaired QoL in the emotional components when compared with men (score 15.9 vs. 12.2, p=0.02). A worse QoL was strongly

P1098
Early urinary sodium as an early marker of diuretic resistance

M Marta Cobo Marcos[1]; IZR Isabel Zegri Reiriz[1]; PRP Paloma Remior Perez[1]; SGG Sergio Garcia Gomez[1]; DGR Daniel Garcia Rodriguez[1]; ARC Alejandra Restrepo Cordoba[1]; APH Antonio Portoles Hernandez[1]; FDR Fernando Dominguez Rodriguez[1]; AH Aitor Hernandez[1]; ALS Angela Lopez Sainz[1]; PGP Pablo Garcia Pavia[1]
[1]University Hospital Puerta de Hierro Majadahonda, Department of Cardiology, Madrid, Spain

Background and purpose: Impaired natriuresis has been associated to worse long-term outcomes in heart failure (HF) patients.
The value of urine sodium as an early prognostic marker during acute decompensated HF (ADHF) admission is unknown.
The aim of this study was to evaluate if urinary sodium early after admittance can predict worsening HF (WHF) during HF admission.
Methods: Charts of all consecutive patients admitted with decompensated HF at our center from January to December 2018 were retrospectively reviewed.
Patients were eligible if they were admitted with an ADHF diagnosis and needed intravenous diuretic for congestion relief. The dose of diuretic administered was at the discretion of the clinician, based on the patient's situation at the time of admission.Worsening HF was defined as clinically persistent congestive signs associated with poor diuretic efficacy measured by weight, after 48 hours of diuretic treatment.According to a prespecified protocol, patients with WHF were upgraded to continuous furosemide perfusion and a thiazide was added.Blood tests and a spot urinary sample were collected in the first 6 hours after diuretic administration.
Results: Among 89 patients [60% males, median age 77 (IQR= 68-83), 17% with HFrEF] who were evaluated in this study, 28 (31,4%) patients fulfilled the definition of WHF. Patients who developed WHF were more likely to have lower urinary sodium at admittance (73.1 vs 92.7 mEq; p=0.014) than patients without WHF. Urinary sodium was better predictor than fractional excretion of sodium or urinary Na/K.
In the cohort, 66 % of patients with early urinary sodium < 50 mEq developed WHF vs 26% of patients with urinary sodium ≥ 50 mEq [HR=2.53 (1.46;4.4), p=0.03).

Conclusions: Low urinary sodium early during ADHF admission is a good predictor of WHF occurrence. This measure could be a marker to identify patients who would benefit from more intensive diuretic strategies.

P1099

Diuretic dose and worsening renal failure in acute heart failure. DOSE-AHF in real life

IZR Isabel Zegri Reiriz[1]; APH Antonio Portoles Hernandez[1]; ARC Alejandra Restrepo Cordoba[1]; XCM Xabier Cia Mendioroz[1]; JBH Jorge Baena Herrera[1]; SLJ Sara Lozano Jimenez[1]; FDR Fernando Dominguez Rodriguez[1]; PGP Pablo Garcia-Pavia[1]; M Marta Cobo Marcos[1]
[1]*University Hospital Puerta de Hierro Majadahonda, Department of Cardiology, Madrid, Spain*

Background and aim: Diuretics are the main treatment in acute heart failure (AHF). Evidence about optimal dose is scarce. On the other hand, worsening renal function (WRF) is common in AHF patients. The aim of this study is to evaluate if high diuretic doses are effective and safe in ADHF.
Methods: Consecutive patients with AHF from 2013 to 2018 were retrospectively reviewed.According to DOSE-HF protocol they were divided in two groups depending on initial diuretic dose in the first 48 hours: low dose (LD) (<2.5 patient basal dose) vs high dose (HD) (≥ 2.5 patient basal dose).
Results: Among 202 patients evaluated, 38 (18.8%) patients received high diuretic dose. WRF developed in 12% of patients and was independent of administered diuretic dose (table). HD group presented a trend in greater weight loss at discharge and in lower hospitalization rate at 90 days (table).
Conclusions: In a real life HF sample, HD in AHF tended to produce greater congestion relief and a decrease in HF hospitalizations. WRF was independent to the diuretic dose administered.

Diuretic dose the first 48 hours	High dose (19%)	Low dose (81%)	p value

Is diabetes a predictor of worse outcome in decompensated heart failure?

E Fairman[1]; F Delfino[1]; V Mauro[1]; A Charask[1]; Y Castillo Costa[1]; A Raffaeli[1]; F Saltos[1]; V Rodriguez Rohwain[1]; L Caceres[1]; A Barsotti[1]; F Bottini[1]; L Rojo[1]; C Barrero[1]
[1]*Clinica Bazterrica Clinica Santa Isabel, buenos aires, Argentina*

There is general agreement that diabetes (DBT) worsens outcome of chronic heart failure. Nevertheless its significance in decompensated heart failure (DHF) pts is not uniformly accepted.
Purpose: To compare clinical characteristics and inhospital and one-year outcomes between diabetic and non diabetic pts admitted for DHF.
Methods: Retrospective analysis of a database of 1004 consecutive pts with DHF admitted to 2 CCUs between 2010 and 2017 and followed up for one year. The diagnosis of DHF was made by clinical evaluation of the attending physician and BNP or NTproBNP levels. DBT was defined according to previous clinical history. One-year follow up was obtained by clinical visits or by phone. Reduced ejection fraction was defined when <0.45.
Results: Baseline characteristics are shown in table. There were no significant differences between diabetics and non diabetics in inhospital mortality (6.1% vs 6.3% p:NS) and in one-year mortality (34.3% vs 40.2% p:NS). Stratified by age, DBT did not influence mortality. Also in an unconditional logistic regression analysis DBT was not an independent predictor of inhospital and one-year mortality.
Conclusions. Diabetic patients were younger, predominantly men, showed a higher prevalence of reduced ejection fraction and of coronary etiology. In our population of elderly patients with DHF diabetes did no predict a worse outcome wether inhospital or at one-year.
Advanced age and acute decompensation play a major role in outcome thus neutralizing the relative impact of DBT

Baseline Characteristics

The relationship between transient and persistent worsening renal function and 1-year cardiovascular event in patients with acute decompensated heart failure

T Kimura[1]; T Toshitaka Okabe[1]; T Kido[1]; S Shimazu[1]; J Saito[1]; Y Oyama[1]; W Igawa[1]; M Ono[1]; S Ebara[1]; K Yamashita[1]; MH Yamamoto[1]; K Amemiya[1]; T Yakushiji[1]; N Isomura[1]; M Ochiai[1]
[1]*Showa University Northern Yokohama Hospital, Division of cardiology and cardiac catheterization laboratories, Yokohama, Japan*

Background: Worsening renal function (WRF) is major complication in patients with heart failure (HF). There are few studies to investigate the difference between transient and persistent WRF in prognosis.
Purpose: Our purpose was to investigate the association between transient and persistent WRF and mid-term prognosis in HF patients.
Methods: We studied 404 patients with acute HF who admitted to our hospital. WRF was defined as a relative increase in serum creatinine of at least 25% or an absolute increase in serum creatinine ≥0.3 mg/dL from the baseline. We evaluated the association between transient and persistent WRF and 1-year composite endpoint of cardiovascular mortality and HF readmission in HF patients.
Results: WRF was occurred in 106 patients (26.2%). Patients with transient WRF had a higher systolic blood pressure than those with persistent WRF and without WRF (152.49±40.08 mmHg vs. 144.64±38.04 mmHg vs. 138.54±30.10 mmHg, P =0.01). Patients with persistent WRF had the highest serum creatinine (1.66±1.04 mg/dL, 1.31±0.73 mg/dL in patents with transient WRF, 1.04 0.53 mg/dL in patients without WRF; P<0.0001) and had the highest serum BNP (1251.4±1206.2 pg/mL, 755.9±457.8 pg/mL, 858±830.2 pg/mL, P=0.02, respectively). In Cox proportional hazard models, persistent WRF was only associated with increased risk of composite endpoint (hazard ratio, 3.9; 95% confident interval, 1.92 to 7.65; P <0.0001). However, transient WRF was not associated with increased risk of composite endpoint (P=0.34).

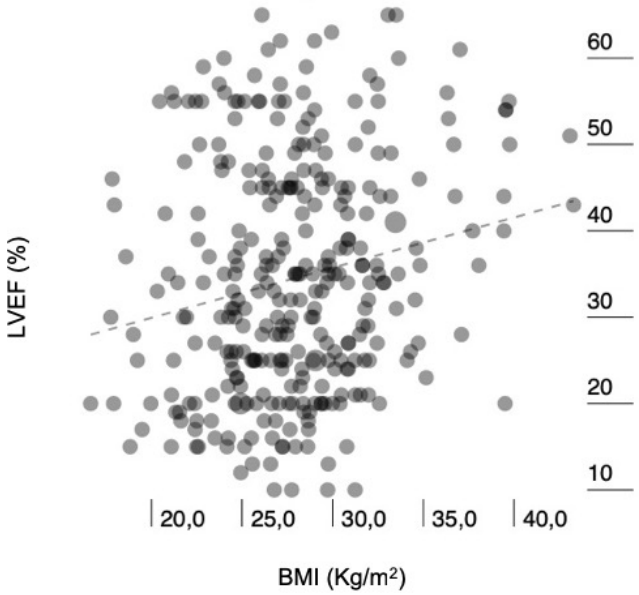
Conclusion: Whereas transient WRF was not associated with increased risk of cardiovascular death and HF readmission, persistent WRF was associated with increased risk of cardiovascular death and HF readmission in patients with HF.

P1102

The obesity paradox in practice: cardiovascular versus non-cardiovascular mortality in heart failure

D Daniel Seabra[1]; A Neto[1]; I Oliveira[1]; A Andrade[1]; J Azevedo[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Cardiology Department, Penafiel, Portugal*

Introduction: Obesity (body mass index (BMI) ≥30kg/m2) significantly increases the risk for the development of new-onset heart failure (HF). Nevertheless, in patients (pts) with already-established chronic HF, obesity is paradoxically associated with higher survival rates compared with normal-weight pts – the 'obesity paradox'.
Purpose: Assess the relation between BMI and cardiovascular and non-cardiovascular mortality rates in pts with chronic HF and reduced ejection fraction (HFrEF).
Methods: Unicentric, retrospective analysis of pts followed in a HF Clinic (HFC) since 3/2011. Included pts with reduced ejection fraction (EF) (<50%) and previous diagnosis for at least 6 months. Pts were divided into 3 groups: BMI <25 kg/m2(G1), BMI ≥25 and <30 kg/m2(G2) and BMI ≥30 kg/m2(G3). Pts without confirmed biometric data were excluded. Clinical, demographic, analytical, electrical, echocardiographic characteristics and major cardiac events - HF hospitalization (HFhosp) and mortality (from cardiovascular cause (CVm) and non-cardiovascular cause (nCVm)) – were appraised.
Results: Included 331 pts with mean age of 60.6 ± 13.2 years, mean BMI (mBMI) of 27.8± 4.5kg/m2 and male predominance (77%). G1 consisting in 90 pts with mBMI 22.6 kg/m2, G2 with 150 pts (mBMI 27.6kg/m2) and G3 with 91 pts (mBMI 33.3kg/m2). Age and BMI were inversely correlated (p=0.023), without gender differences between groups. G3 had more hypertension (p=0.04) and diabetes (p=0.05), but lower smoking (p=0.01) and renal chronic disease (p=0.034); there were no significant differences in atrial fibrillation prevalence, alcohol consumption or underlying HF etiology. During follow-up (FU), after optimized medical therapy (OMT), left ventricle ejection fraction (LVEF) was positively correlated with mBMI (p<0.001). There was a reduced BNP value in G2 and G3, although not statistically significant. Regarding clinical events G1 had higher mortality rate, especially when compared to pts with mBMI ≥25kg/m2(G2 and G3; 38% vs 18%, p<0.001). G1 had higher nCVm (p<0.001). There were no differences in CVm neither HFhosp among groups.
Conclusion: In this cohort, BMI <25kg/m2was associated with higher mortality, particularly due to non-cardiovascular causes but no differences were seen between groups regarding in cardiovascular mortality or HF hospitalization.

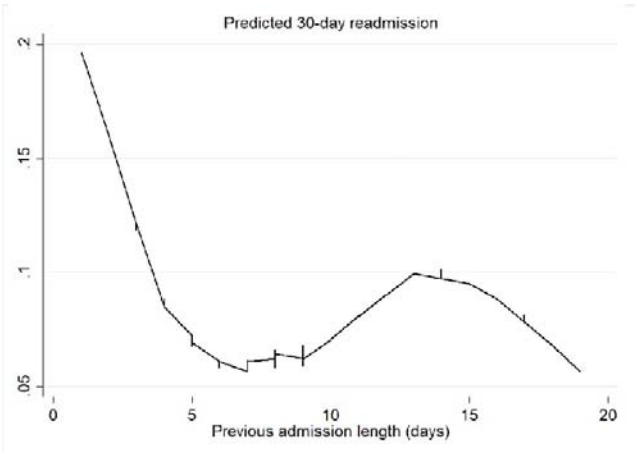


P1103

Acute decompensated heart failure in the emergency department: lower 30-day readmission rates in 1000 patients

P Patricia Alves[1]; V Marinho[1]; JP Almeida[1]; R Baptista[1]; I Fonseca[1]; L Goncalves[1]
[1]*University Hospitals of Coimbra, Cardiology, Coimbra, Portugal*

Background: Acute decompensated heart failure (ADHF) is the first cause of hospitalization among elderly patients. We aimed to characterize the characteristics and outcomes of a large contemporaneous cohort of ADHF patients admitted to our emergency department (ED).
Methods: We conducted a retrospective, observational study of all 1057 patients admitted to our ED with a discharge diagnosis of ADHF from November 2016 to December 2017. Baseline clinical data and outcomes (in-hospital, 30-day and follow-up (median period of 5 [IQR 3-11] months) all-cause mortality and readmissions) were determined.
Results: Mean age was 78±10 years and 53% were male; of the 1057 patients, half (53%) were hospitalized. The median admission length was 9 [IQR 5-15] days and in-hospital mortality was 12.7%. Median BNP values were 739 [IQR 381-1486] pg/mL and mean creatinine 1.43±0.8 mg/dL. After discharge, all-cause readmission at 30 days was 8% and related to previous admission length. 30-day readmission was higher with previous admission length less than 5 days, lower with 5-10 days and again higher with length above 10 days (Figure 1). All-cause mortality at 30 days was 15%, with age [HR 1.4 (95%CI 1.1-1.9), p=0.04] and creatinine [HR 2.3 (95%CI 1.3-5.3), p=0.04] as positive predictors. Follow-up (median 5 month) readmission rate for previously hospitalized patients was 30% and its only predictor was left ventricular ejection fraction (LVEF) [HR 0.93 (95%CI 0.91–0.96), p=0.05]. Follow-up all-cause mortality was 28% and was predicted by age [HR 1.4 (95%CI 1.2-1.7), p<0.01] and creatinine [HR 1.5 (95%CI 1.1 – 1.9), p<0.01]. Of the 47% patients that were directly discharged from the ED, 14% were readmitted at 30 days. Predictors for 30-day readmission were BNP [OR 1.5 (95%CI 1.1-1.8), p=0.02] and C-reactive protein (CRP) [HR 1.9 (95%CI 1.2-1.8), p=0.01]. In this group, 30-day mortality was 4.6% and only predicted by creatinine [HR 2.5 (95%CI 1.1-4.8), p=0.04]. Follow-up all-cause readmission was 32% and predicted by LVEF [HR 0.91 (95%CI 0.90–0.93), p<0.01]; all-cause mortality was 15% and was predicted by CRP [HR 1.15 (95%CI 1.0–1.3), p<0.01] and BNP [HR 1.3 (95%CI 1.1–1.5), p<0.01]. Comparing the characteristics of admitted vs discharged ADHF patients, patients with a prior hospitalization had a lower 30-day readmission rate (8% vs 14%, p=0.01), same overall readmission rate (30% vs 32%), but a higher 30-day mortality (13% vs 5%, p<0.01) and overall mortality (28% vs 15%, p<0.01).
CONCLUSIONS: Half of patients admitted to the ED were hospitalized. Of these, only 8% are readmitted within 30 days. In-hospital mortality is high. Among discharged patients directly from the ED, 1 in 7 were readmitted at 30-days.



P1104

Diuretic efficacy as a prognostic marker in patients admitted for heart failure

IZR Isabel Zegri Reiriz[1]; APH Antonio Portoles Hernandez[1]; ARC Alejandra Restrepo Cordoba[1]; XCM Xabier Cia Mendioroz[1]; JBH Jorge Baena Herrera[1]; FDR Fernando Dominguez Rodriguez[1]; SLZ Sara Lozano Jimenez[1]; PGP Pablo Garcia Pavia[1]; M Cobo Marcos[1]
[1]*University Hospital Puerta de Hierro Majadahonda, Department of Cardiology, Madrid, Spain*

Background and purpose: Diuretic metrics objectively quantify the diuretic response in heart failure (HF) patients. Although diuretic efficacy (DE) parameters by weight and fluid output have been proposed, it is unknown if one parameter is superior to the other.
We sought to determine which DE parameters are associated to adverse events during the follow-up in patients admitted with HF.

Methods and results: Charts of all consecutive patients admitted with decompensated HF at our center from 2013 to 2018 were retrospectively reviewed.
DE measurements by weight and fluid output at 48, 72 and 96 hours after admission were collected retrospectively for 103 patients (71 % males, median age 73.4 (IQR= 66-82), 37% with HFrEF).
We analyzed their association with adverse events at 90 and 365 days after discharge.
Only DE by weight (adjusted weight loss per unit of furosemide) at 48 hours was found to be a predictor of events at 90 days. Patients with a poor diuretic response [defined as DE by weight at 48 hours below the median (-0.21 kg/40 mg furosemide)] had a greater risk of rehospitalization due to HF [HR 3.27 (0.95;11.1), p=0.041].
Conclusions: Poor DE by weight at 48 hours after admittance is associated with HF rehospitalization at 90 days. This finding could lead to the early identification of patients resistant to diuretic treatments in whom intensification of treatment could prevent HF rehospitalizations.

Demographics, management, and in-hospital outcomes of patients with hospitalized acute heart failure syndromes in the contemporary real clinical practice

H Hidenori Yaku[1]; T Kato[1]; T Morimoto[2]; Y Inuzuka[3]; Y Tamaki[4]; N Ozasa[1]; E Yamamoto[1]; T Kimura[1]
[1]Kyoto University Graduate School of Medicine, Department of Cardiovascular Medicine, Kyoto, Japan; *[2]Hyogo College of Medicine, Clinical Epidemiology, Nishinomiya, Japan*; *[3]Shiga Medical Center for Adults, Department of Cardiovascular Medicine, Moriyama, Japan*; *[4]Tenri Hospital, Department of Cardiovascular Medicine, Tenri, Japan*

On behalf of: KCHF investigators

Background: There is a scarcity of reports on the clinical characteristics and management practice in the contemporary all-comer patients with acute decompensated heart failure (ADHF).
Purpose: This study aimed to evaluate the clinical characteristics of and practice for the treatment of contemporary all-comer patients with ADHF in Japan.
Methods and Results: The Kyoto Congestive Heart Failure (KCHF) registry is a prospective observational cohort study enrolling 4056 consecutive patients who had hospital admission due to ADHF without any exclusion criteria between October 2014 and March 2016 in the 19 participating hospitals in Japan. Baseline characteristics, clinical presentations, management, and in-hospital outcomes were compared among heart failure (HF) with reduced left ventricular ejection fraction (LVEF) (HFrEF: LVEF<40%), HF with mid-range LVEF (HFmrEF: 40%≤ LVEF <50%), and HF with preserved LVEF (HFpEF: LVEF ≥50%). Among 4041 patients with documented LVEF, 1744 (43%) had HFpEF, 746 (19%) HFmrEF, and 1551 (38%) HFrEF. The median age was 80 (IQR, 72–86) years in the entire population, and was higher with increasing LVEF (p<0.001). The in-hospital mortality rate was higher in the HFrEF population than in the HFmrEF and HFpEF populations (9.2%, 4.8%, and 5.1%, P<0.001).
Conclusions: This registry elucidated the clinical features and clinically relevant in-hospital outcomes in contemporary consecutive patients with ADHF in the real-world clinical practice in Japan, demonstrating changes in the characteristics of patients with ADHF. When classified by LVEF, significant differences in characteristics and in-hospital outcomes existed among patients with HFrEF, HFmrEF, and HFpEF.

P1106

Incidence and prognosis of the takotsubo syndrome compared to acute myocardial infarction

B Bjorn Redfors[1]; S Jha[1]; S Thorleifsson[1]; O Angeras[1]; C Dworeck[1]; A Ravn-Fischer[1]; P Petursson[1]; G Sarno[2]; A Lyon[3]; O Frobert[4]; S James[2]; D Erlinge[5]; E Omerovic[1]
[1]Sahlgrenska Academy, Univ. of Gothenburg, Dept of Molecular & Clinical Medicine/Cardiology, Gothenburg, Sweden; *[2]Uppsala University Hospital, Uppsala, Sweden*; *[3]Royal Brompton Hospital, London, United Kingdom of Great Britain & Northern Ireland*; *[4]Orebro University Hospital, Orebro, Sweden*; *[5]Skane University Hospital, Lund, Sweden*

Background: Takotsubo syndrome (TS) is a potentially life-threatening acute cardiac syndrome with a clinical presentation very similar to myocardial infarction (MI) and for which the natural history, management and outcome remain incompletely understood.
Purpose: The aims of this study were to assess the relative short- and long-term mortality risk of TS , ST-elevation MI (STEMI) and non STEMI (NSTEMI) and to identify predictors of in-hospital complications and poor prognosis in patients with TS.
Methods: Using the nationwide Swedish Angiography and Angioplasty Registry (SCAAR) we identified almost all (n=117,720) patients who underwent coronary angiography due to TS (N=2,898 [2.5%]), STEMI (N=48,493 [41.2%]) or NSTEMI (N=66,329 [56.3%]) in Sweden between January 2009 and February 2018.
Results: Patients with TS were more often women as compared with patients with STEMI or NSTEMI. TS was associated with unadjusted and adjusted 30-day mortality risks lower than STEMI (adjusted hazard ratio [adjHR] 0.60, 95% confidence interval [CI]0.48-0.76, p<0.001), but higher than NSTEMI (adjHR 2.70, 95% CI 2.14-3.41, p<0.001). Compared to STEMI, TS was associated with similar risk of acute heart failure (adjHR 1.26, 95% CI 0.91–1.76, p=0.16) but lower risk of cardiogenic shock (adjHR 0.55, 95% CI 0.34–0.89, p=0.02). The relative 30-day mortality risk for TS versus STEMI and NSTEMI was higher for smokers than non-smokers (adjusted pinteractionSTEMI=0.01 and pinteractionNSTEMI=0.01).
Conclusion: Thirty-day mortality in TS was higher than in NSTEMI but lower than STEMI, despite a similar risk of acute heart failure in TS and STEMI. Among patients with TS, smoking was an independent predictor of mortality.

P1107

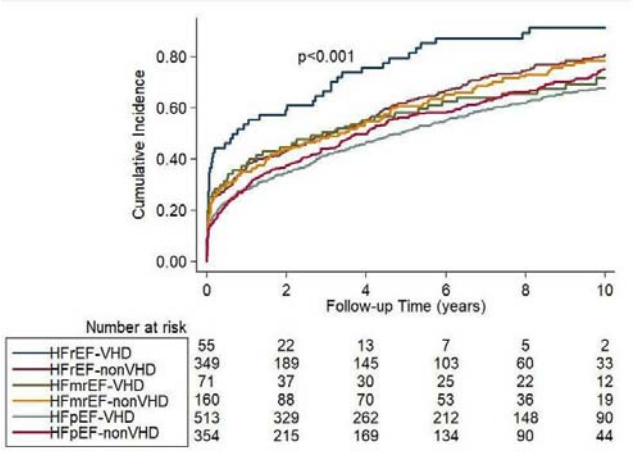
Immediate and Long-term survival outcomes of Patients Admitted with Decompensated Heart Failure with underlying Valvular Heart Disease

S Sivadasanpillai Harikrishnan[1]; P Jeemon[1]; G Sanjay[1]
[1]Sree Chitra Tirunal Institute for Medical Sciences & Technology (SCTIMST), Cardiology, Trivandrum, India

On behalf of: Chitra Heart Failure Study

Introduction: Valvular heart disease (VHD), especially rheumatic heart disease(RHD) is a common cause of heart failure in India . The data on long-term outcomes of these patients is scarce.
Objective: Was to collect data regarding clinical characteristics, in-hospital of patients with VHD in a tertiary care center admitted over a period of 10 years (2001-2010) and assess the long-term follow-up.
METHODS: Patients aged 18 years and above with valvular heart disease were selected from the hospital database of patients admitted in our centre with acute decompensated heart failure(ADHF) during the study period. Patients who had concurrent ischemic heart disease were excluded. Demographic data, risk factors, comorbidities, in-hospital outcomes and long-term survival were captured. The patients were grouped on the basis of left ventricular ejection fraction into Heart failure with preserved ejection fraction (HFpEF; EF > 50%), HF with mid-range EF (HFmrEF; EF 40-49%) and HF with reduced EF (HFrEF; EF <40%). Subjects who were admitted with HF due to other causes were included as a comparator for survival analysis (non-VHD)
Results: Of the 1502 patients who were admitted with ADHF during this period, 639 had VHD(42.5%). Of patients with VHD,51.5% were females. Majority of the VHD patients had RHD (515 patients, 80.6%). Mean age of the population was 44.9 years (SD = 12.8 years). Patients with RHD were significantly younger than others (RHD =43.3 years SD 12.5 years, non-RHD 51.5 years; SD 12.3 years, p<0.001). More than four-fifths had HF with preserved ejection fraction (HFpEF = 80.3%). Atrial fibrillation or flutter was present in 59.2% of patients. Anemia (Hb<10 g/dL), renal dysfunction during hospitalisation and active infective endocarditis were present in 6.1%, 29.6% and 6.7 % of patients respectively.
The median duration of hospitalization was 6 days (interquartile range 3-10) and during hospitalization, 113 patients (17.7%) died. The total time at risk was 3370 person-years (p-y) and 461 patients died during the study period with a median survival time of 4 years. The survival of patients with VHD and others (non-VHD) grouped on the basis of EF is provided in figure 1. Patients with VHD with reduced

ejection fraction (valvular cardiomyopathy) had the worse prognosis among the groups. (p<0.001)



VHD and HF Types based on EF - Survival

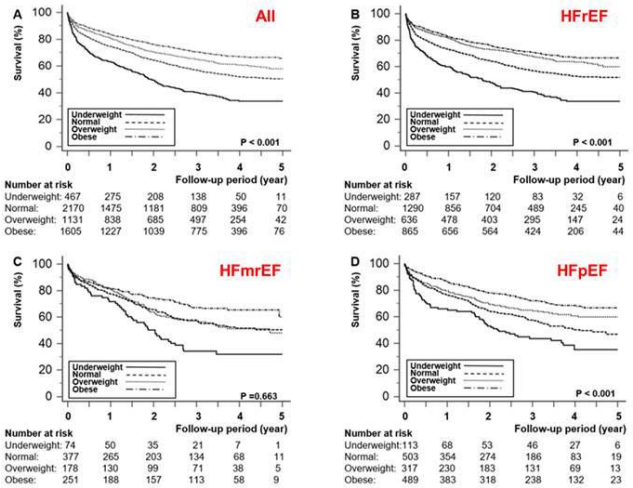
Body mass index and long-term survivals in admitted patients with acute heart failure according to their heart failure phenotype

J-H Ju-Hee Lee[1]; D-H Bae[1]; M Kim[1]; KK Hwang[1]; M-C Cho[1]
[1]*Chungbuk National University Hospital, Cardiology, Cheongju, Korea (Republic of)*

On behalf of: KorAHF investigators
Funding Acknowledgements: This work was supported by Research of Korea Centers for Disease Control and Prevention.

Backgrounds: Obesity is a major risk factor for incident heart failure (HF). Paradoxically, a high body mass index (BMI) appears to be beneficial even in patients with HF (obesity paradox). We investigated the presence of debatable 'obesity paradox' in admitted patients with acute HF according to HF phenotype.
Methods: We evaluated the admitted patients hospitalized for acute HF in 10 regionally-representative tertiary university hospitals who registered in the Korean Acute Heart Failure (KorAHF) Registry from March 2011 to February 2014. The primary outcome was 5-year total mortality according to BMI categories by WHO criteria for Asian.
Results: Among the 5,625 patients who were registered at KorAHF Registry, we excluded 209 patients without information about left ventricular ejection fraction (LVEF) and 42 without BMI. A total of 5374 (53.3% males, mean age: 68±14years) were analyzed. The mean BMI was 23.3±3.9Kg/m2. The patients were categorized to underweight (BMI<18.5Kg/m2, 467 patients, 8.7%), normal (18.5≤BMI<23Kg/m2, 2171 patients, 40.3%), overweight (23≤BMI<25Kg/m2, 1131 patients, 21.0%) and obese (BMI≥25Kg/m2, 1605 patients, 29.8%). In patients with higher BMI, younger people, men, hypertension and diabetes were more frequent. Mean follow up duration was 855±591days. In the follow-up duration, 38.2% died. Obese patients had the best survival whereas underweight patients had the worst survival. After multivariate analysis, obese patients were associated with the best and underweight patients with the worst survival regardless of HF type.
Conclusions: Obesity was associated with favorable long-term survival in admitted patients with acute HF regardless of their HF phenotype.



Survival curves according to BMI.

P1109

Incidence and outcome of takotsubo syndrome compared to acute myocardial infarction, in men versus women

B Bjorn Redfors[1]; S Jha[1]; S Tholeifsson[1]; T Jernberg[2]; O Angeras[1]; O Frobert[3]; P Petursson[1]; P Tornvall[4]; G Sarno[5]; A Ravn-Fischer[1]; A Lyon[6]; S James[5]; D Erlinge[7]; E Omerovic[1]
[1]*Sahlgrenska Academy, Univ. of Gothenburg, Dept of Molecular & Clinical Medicine/Cardiology, Gothenburg, Sweden*; [2]*Danderyd University Hospital, Stockholm, Sweden*; [3]*Orebro University Hospital, Orebro, Sweden*; [4]*South Hospital Stockholm, Stockholm, Sweden*; [5]*Uppsala University Hospital, Uppsala, Sweden*; [6]*Royal Brompton Hospital, London, United Kingdom of Great Britain & Northern Ireland*; [7]*Skane University Hospital, Lund, Sweden*

Background: Takotsubo syndrome (TS) is an acute cardiac syndrome with a clinical presentation very similar to acute myocardial infarction (AMI). One striking feature that distinguishes TS from AMI is that approximately 90% of TS patients are women. However, even though women are more often affected by TS, men that develop TS have been reported to have worse outcomes than women with TS. We sought to compare men and women with TS, and contrast the observed sex differences in TS and AMI.
Methods: Using the nationwide Swedish Angiography and Angioplasty Registry (SCAAR) we identified almost all (n=117,720) patients who underwent coronary angiography due to TS (N=2,898 [2.5%]), STEMI (N=48,493 [41.2%]) or NSTEMI (N=66,329 [56.3%]) in Sweden between January 2009 and February 2018. We compared the association between sex and adverse clinical outcomes for patients with TS versus AMI.
Results: Patients with TS were more often women (73.0%) as compared with patients with STEMI (27.3%) or NSTEMI (30.0%), p<0.0001. A statistical interaction was present between TS and sex such that men with TS had an unadjusted risk of dying within 30 days that was similar to that of men with STEMI, whereas women with TS had a better unadjusted 30-day prognosis than did women with STEMI (Table). However, after multivariable adjustment, the statistical interaction with regards to mortality risk between sex and TS versus AMI did not persist (Table).
Conclusion: As compared to sex-related differences in prognosis after AMI, men with TS have disproportionally worse prognosis than women with TS. Some of the TS-specific sex-related risk may be related to other cardiovascular risk factors and comorbidities.

	Hazard Ratio (95% Confidence Interval)		
All-cause death	Women	Men	$P_{interaction}$
30 Day Prognosis			
Unadjusted			
TS vs. STEMI	0.27 (0.21 - 0.36)	0.62 (0.43 - 0.90)	0.0004

P1110

Hazardous effects of widespread inotrope use in acute heart failure patients

HJ Hyun-Jai Cho[1]; JH Kang[1]; HY Lee[1]; BH Oh[1]
[1]*Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea (Republic of)*

On behalf of: Korean Acute Heart Failure (KorAHF) registry

Background: The majority of acute heart failure (HF) patients are treated with diuretics to optimize volume status and vasodilators for symptom resolution and congestion relief. Inotropes can be administered in patients with hypotension or signs and symptoms of peripheral hypo-perfusion. Current guidelines recommend

that inotropes should not be used in patients with normal systolic blood pressure. However, inotropes are widely applied in the real world.
Purpose: We aimed to evaluate the effect of inotropes in acute HF patients from a nationwide Korean Acute Heart Failure (KorAHF) registry.
Methods and Results: A total of 5625 patients were analyzed. Those with isolated right HF (154 patients, 2.7%) were excluded, leaving 1703 (31.1%) patients who received inotropes during admission and 3768 (68.6%) patients who did not receive inotropes. The majority of inotrope users was normal SBP (≥90 mmHg, 1478 patients, 86% of users) at the initial point. The primary outcomes were in-hospital adverse events and post-discharge 1-month mortality. Inotrope users had a higher event rate than non-users (in-hospital adverse events: 13.3% vs 1.4%, p<0.001; 1-month mortality: 5.5% vs 2.5%, p<0.001), while inotrope use was an independent predictor for clinical outcomes (in-hospital adverse events: ORadjusted 5.459, 95% CI 3.622–8.227, p<0.001; 1-month mortality: HRadjusted 1.839, 95% CI 1.227–2.757, p=0.003). Subgroup analysis showed that inotrope use was an independent predictor for detrimental outcomes in patients with normal initial SBP (in-hospital adverse events: ORadjusted 5.931, 95% CI 3.864–9.104, p<0.001; 1-month mortality: HRadjusted 3.584, 95% CI 1.280–10.037, p=0.015). For patients with a low initial SBP, inotrope use was not a risk factor for adverse outcomes (in-hospital adverse clinical outcome: ORadjusted 0.575, 95% CI 0.013–25.167, p=0.730; post-discharge 1-month mortality: HRadjusted 1.714, 95% CI 0.372–7.893, p=0.489). Because of the distinct baseline characteristics among inotrope users and non-users, we performed two different methods to compensate for the differences; the propensity score matching (PSM) method and the IPW Cox proportional hazards regression model. The matched populations showed consistent results.
Conclusion: Inotropes are still widely used, even in acute HF patients presenting with a normal blood pressure. We have demonstrated the hazardous effects of inotrope use in acute HF patients. The infusion of inotropes is strongly associated with in-hospital adverse outcomes and 1-month follow-up mortalities. Clinicians should be cautious with the usage of inotropes in acute heart failure patients, especially in those with a normal blood pressure.

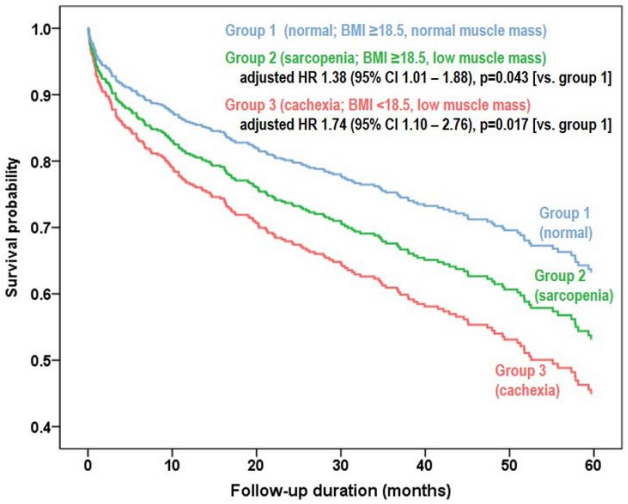
Clinical usefulness of cystatin C in patients with acute heart failure: implications for sarcopenia and cachexia

I In-Chang Hwang[1]; GY Cho[1]; YE Yoon[1]; JJ Park[1]; JB Park[2]; JH Park[3]
[1]Seoul National University Bundang Hospital, Seongnam, Korea (Republic of); *[2]Seoul National University Hospital, Seoul, Korea (Republic of)*; *[3]Chungnam National University Hospital, Daejeon, Korea (Republic of)*

Background: Sarcopenia and cachexia are frequent in patients with chronic heart failure (HF), and contribute to excess mortality. Cystatin C can be utilized to estimate muscle mass and to assess the presence of sarcopenia or cachexia. However, the clinical usefulness of cystatin C is not fully investigated in patients with acute HF.
Purpose: We aimed to investigate whether the estimates of muscle mass using cystatin C can provide additional prognostic information in patients who admitted for acute HF.
Methods: We retrospectively identified 586 patients with acute HF in whom the muscle mass was estimated using body weight, serum creatinine, and serum cystatin C measured during index hospitalization. Study population was categorized into three groups: patients with BMI ≥18.5 kg/m^2 and muscle mass ≥45.0kg in men or ≥30.9kg in women (group 1 [normal]; n=264), patients with BMI ≥18.5kg/m^2 but reduced muscle mass (group 2 [sarcopenia], n=263), and those with BMI <18.5kg/m^2 (group 3 [cachexia]; n=52). The risk of all-cause mortality was compared between these 3 groups.
Results: During a median 34 months of follow-up (interquartile range, 16–54), 213 patients (37%) died. There was no J-curve phenomenon between BMI, cystatin C, and estimated muscle mass with the risk of mortality. The annualized mortality rates were 10.4% in group 1 (normal), 14.7% in group 2 (sarcopenia), and 20.3% in group 3 (cachexia). Compared with group 1 patients, the risk of mortality was significantly higher in group 3 patients (adjusted HR 1.74; 95% CI 1.10–2.76; p=0.017) as well as in group 2 patients (adjusted HR 1.38; 95% CI 1.01–1.88; p=0.043), even after adjusting for clinical risk factors and echocardiographic parameters.
Conclusions: Cystatin C is a useful biomarker for estimation of muscle mass and for assessment of sarcopenia or cachexia, which provide independent prognostic value in patients with acute HF.



Survival curve

P1112

Prognostic value of bioimpedance vector analysis-assessed cachexia in patients with decompensated heart failure

A Klimenko[1]; A Rakisheva[2]; S Villevalde[3]; Z Kobalava[1]
[1]RUDN University, Moscow, Russian Federation; *[2]Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*; *[3]Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation*

Objective: Decompensated heart failure (DHF) is one of the leading causes of hospitalization worldwide. Cachexia is a serious complication in chronic heart failure patients. Bioimpedance vector analysis (BIVA) is a non-invasive, accurate technique, which could be helpful in identification of cachexia and muscle wasting in patients with DHF. The aim of the study was to determine cachexia in DHF patients by BIVA and to evaluate the association with heart failure rehospitalization rate during 6 months.
Methods: in 183 patients admitted with DHF (125 male, 68.9±9.4 years (M±SD), BMI 30.5±6.9 kg/m2, 86.9% arterial hypertension, 55.7% ischemic heart disease, 53% myocardial infarction, 51.4% atrial fibrillation, 36.1% diabetes mellitus, known chronic kidney disease (CKD) 39.9%, ejection fraction (EF) 44.3±14.9%) BIVA was performed. BIVA results were expressed using resistance (R/h) and reactance (Xc/h). Cachexia by BIVA was defined in patients, who dropped outside right lower quadrant of reference curve of 95% R/Xc graph. Mann-Whitney and Spearman tests were performed. P <0.05 was considered statistically significant.
Results: cachexia by BIVA was identified in 31% DHF patients. DHF patients with BIVA detected cachexia compared with DHF patients without cachexia were older (73.7±8.4 vs 67.2±8.6 years, p<0.05) and mostly female (86% vs 62%, p<0.01), had higher resistance R/h (285.5±49.9 vs 211.3±44.3 Om/m, p<0.05) and reactance Xc/h (22.8±4.6 vs 18.2± 6.5 Om/m, p<0.05), lower fat-free mass (57.1±8.3 vs 68.2±12.5 kg, p<0.001), lower musculoskeletal mass (27.3±5.5 vs 36.0±8.4 kg, p<0.001). There were no differences in prevalence of main comorbidities between groups, but there was tendency to higher rate of preexisting CKD (63% vs 53%, p>0.05), chronic obstructive pulmonary disease (29% vs 23%, p>0.05) and higher proportion of patients with reduced EF (43% vs 37%, p>0.05) in DHF with BIVA detected cachexia patients. Patients without cachexia demonstrated higher volume overload compared with cachexia DHF patients (total body water 49.9±9.1 vs

41.8±6.1 kg, p<0.01; extracellular body water 21.9±3.5 vs 16.6±2.5 kg, p<0.01) and had more marked clinically presentation of systemic congestion (bilateral crackles (82 vs 71%, p<0.05), Rg-hydrothorax (63 vs 36%, p<0.001), orthopnea (86 vs 50%, p<0.01), oedema (100 vs 86%, p<0.05)). Patients without cachexia compared with BIVA detected cachexia patients demonstrated better outcomes: lower readmission rate due to heart failure decompensation during 6 months (35% vs 57%, p<0.05).
Conclusions: In 31% of patients hospitalized with DHF cachexia by BIVA was detected. Patients with BIVA detected cachexia had worse prognosis compared with patients without cachexia. Evaluating cachexia by BIVA added useful information to standard clinical parameters and could help to determine the patient population with higher risk of rehospitalization rate and apply adequate preventive strategy.

P1113
Healthcare Expenditure of Patients with Heart Failure in a Developing Country

A Ajit Singh[1]; T Devasia[2]; Y Rao[3]; H Kareem[2]; G Paramasivam[2]; S Chauhan[4]; PN Shetty[2]; MS Rao[2]; D Uppunda[2]
[1]*Kasturba Medical College and Hospital, Manipal Academy of Higher Education, Manipal, India*; [2]*Kasturba Medical College and Hospital, Cardiology, Manipal, India*; [3]*Saint James School of Medicine, Pharmacology and Ethics, Anguilla, Anguilla*; [4]*Melaka Manipal Medical College, Pharmacology, Manipal, India*

On behalf of: Manipal Heart Failure Registry [MHFR]

Objectives: Analysis of healthcare expenditure of patients with heart failure for 12 months from the time of index admission.
Methods: Manipal Heart Failure Registry (MHFR), established in 2015 in a tertiary care hospital in Southern India, is a prospective observational cohort of patients diagnosed with heart failure.
From this registry, we analysed the total expense incurred during index hospitalization from in-patient bills which included the consultation charges, expenses for ICU/ward stay, investigations, interventional procedures and medications. Similarly, the expenses incurred for medications, scheduled or unscheduled hospital visits and re-hospitalization(s) during the 12 months follow up period were calculated.
Results: A total of 610 patients with mean age of 65.0 ± 13.6 years were included among which 59.8% were males and 38.9% had ischemic heart failure. Average duration of index hospitalization was 5.3 days with an average expenditure of INR 59492 (€710). This included the charges for hospitalization and consumables [INR 9210.9 (€110)], investigations [INR 6465.0 (€65)], medicines, devices and procedural charges [INR 38940.1 (€461)], consultation/professional charges [INR 2158.2 (€26)] and expenditure incurred by caregivers [INR 2717.8 (€40)]. Follow up data were available for 98.1% of the patients. Re-hospitalization rate was 10.8% and 34.1% patients had unscheduled visits to the hospital due to worsening symptoms. Average expenses during the 12 months follow-up period was INR 22680 (€268) which included re-hospitalizations, scheduled/unscheduled visits, and medications. Patients who were non-compliant to medicines or were re-hospitalized during the follow-up period spent considerably more than those who were not [INR 32876 (€387) vs INR 20899 (€247), p= 0.042; INR 35255 (€416) vs INR 20213 (€237), p= 0.002, respectively].
Conclusions: Healthcare expenditure of patients with heart failure in India is much lower than their western counterparts. Hospitalizations and interventional procedures account for bulk of the expenses incurred. Drug non-compliance is an important and easily avoidable cause for increased healthcare expenditure.

P1114
Are predictor factors of mortality different depending on the etiology of acute heart failure?

I Ines Almeida[1]; H Santos[1]; H Miranda[1]; L Santos[1]; J Chin[1]; C Sousa[1]; S Almeida[1]; J Tavares[1]
[1]*Hospital N.S. Rosario, Barreiro, Portugal*

Introduction: Acute heart failure (AHF) is a life-threatening medical condition requiring urgent treatment and associated with high morbimortality.
Objective: Evaluation of predictor factors (PF) of in-hospital (IH), 6-months (6m) and 1-year (1y) mortality (M) concerning the etiology of AHF that motivate P hospitalization.
Material and methods: Single center retrospective analysis of P data admitted with AHF between 2001-2017. P were divided in 2 groups concerning the etiology of cardiomyopathy: ischemic (G1, n=214) versus non-ischemic (G2, n=251). Data was collected regarding clinical, laboratorial and echocardiographic parameters in both groups to determine PF of stablished endpoints.
Results: 465 P were reviewed, age 67.9±12.2 years, 69.9% males. 64% had hypertension, 39.4% diabetes and 34.4% dyslipidaemia. 57.3% had a de novo diagnosis. In G2P the most prevalent etiologies were idiopathic dilated (53%) and valvular (35.5%). There were no differences between groups regarding age, gender, laboratorial tests (BNP, haemoglobin (Hb), creatinine (Cr), urea (U)) and ejection fraction. Total IH M was 6.7%, 51.6% in G2. At univariate analysis in G1P, PF of IH M were inotropic use (odds ratio (OR) 12.522, p 0.001, confidence interval (CI) 2.75-57.10), profile at admission (OR 4.842, p 0.004, CI 1.65-14.17), U (OR 1.014, p 0.005, CI 1.00-1.02), age (OR 1.090, p 0.007, CI 1.02-1.16), systolic blood pressure (SBP) (OR 0.977, p 0.009, CI 0.96-0.99) and Hb (OR 0.722, p 0.025, CI 0.54-0.96). At multivariate analysis, independent PF of IH M were inotropic (p <0.001), profile (p 0.001), U (p 0.002), SBP (p 0.007) and Hb (p 0.022). These also were independent FP of 6m and 1y M except Hb (p 0.970 and 0.168). In G2, PF of IH M were inotropic use (OR 8.722, p 0.001, CI 2.41-31.51), profile at admission (OR 12.853, p <0.001, CI 3.54-46.67), SBP (OR 0.973, p 0.012, CI 0.95-0.95), U (OR 1.011, p 0.012, CI 1.00-1.02) and Cr (OR 1.019, p 0.045, CI 1.01-1.04). At multivariate analysis, independent PF of IH M were inotropic (p <0.001), profile (p <0.001), Cr (p 0.001), SBP (p 0.009) and U (p 0.002). The only independent PF of 6m M was U (p 0.011) and1y M Cr (p <0.001) and profile (p 0.008).
Conclusion: In our center using real life data, the hemodynamic profile and use of inotropes were important factors of prognosis regardless of the etiology of HF. These results are in accordance with larger studies.

P1115
Predictor factors of rehospitalization and mortality in acute heart failure

I Ines Almeida[1]; H Santos[1]; H Miranda[1]; L Santos[1]; J Chin[1]; C Sousa[1]; S Almeida[1]; J Tavares[1]
[1]*Hospital N.S. Rosario, Barreiro, Portugal*

Introduction: Acute heart failure (AHF) is a life-threatening condition requiring immediate diagnosis and initiation of treatment. The first months after an AHF episode are characterised by high readmission and mortality rates.
Objective: Evaluation of predictor factors (PF) of in-hospital (IH) mortality (M), and 6-months (6m) and 1-year (1y) rehospitalization (RH) and M in patients admitted with AHF.
Material and methods: Single center retrospective analysis of P data admitted with AHF between 2001-2017. Data was collected regarding clinical, laboratorial and echocardiographic parameters to determine PF of stablished endpoints.
Results: 465 P were reviewed, age 67.9±12.2 years, 69.9% males. 64% had hypertension, 39.4% diabetes and 34.4% dyslipidaemia. 57.3% had a de novo diagnosis. Total IH M was 6.7%. At univariate analysis, PF of IH M were inotropic use (odds ratio (OR) 10.258, p <0.001, confidence interval (CI) 3.859-27.265), clinical profile at admission (OR 7.274, p <0.001, CI 3.314-15.967), systolic blood pressure (SBP) (OR 0.975, p <0.001, CI 0.962-0.989), urea (OR 1.102, p <0.001, CI 1.006-1.019), age (OR 1.067, p 0.001, CI 1.026-1.110), brain natriuretic peptide (BNP) dosage (OR 1, p 0.002, CI 1.003-1.009), haemoglobin (OR 0.810, p 0.029, CI 0.671-0.978) and creatinine level (OR 1.019, p 0.047, CI 1.002-1.038). At multivariate analysis, independent PF of IH M were profile at admission (p<0.001), creatinine (p<0.001), BNP (p<0.001), inotropic (p 0.002) and urea (p0 0.021). Concerning to 6m M, at univariate analysis, the PF were urea (OR 1.010, p 0.001, CI 1.004-1.016) and age (OR 1.036, p 0.008, CI 1.010-1.069). At multivariate analysis, they both showed to be independent PF of 6m M (urea p <0.001 and age p 0.007). Concerning to 1y M, the only PF was urea (OR 1.009, p 0.039, CI 1.002-10.18). This was also the only PF of 6m RH (OR 1.008, p 0.006, CI 1.002-1.013). The only PF for 1y RH was ejection fraction (OR 0.971, p 0.018, CI 0.947-0.995).
Conclusion: In this study, and accordingly with larger studies, hemodynamic and analytical profile at admission were important factors of prognosis.

Coronary Artery Disease

P1116
Long-term biological variation of high-sensitivity cardiac troponin t using minimal important differences and reference change values in stable outpatients with cardiovascular disease

T Tobias Taeger[1]; E Giannitsis[1]; K Greve[1]; H Froehlich[1]; M Mueller-Hennessen[1]; M Vafaie[1]; HA Katus[1]; L Frankenstein[1]; M Biener[1]
[1]*University Hospital of Heidelberg, Department of Cardiology, Heidelberg, Germany*

Objective: To evaluate the long term biological variation of high-sensitivity cardiac troponin T (hs-cTnT) in stable outpatients with cardiovascular disease (CVD) .
Methods: After applying 8 exclusion criteria to 965 patients, hs-cTnT was measured at index visit and at a 12-month interval in 169 stable outpatients presenting for routine follow-up visits for any CVD. Stability was defined as absence of any endpoint within the follow-up period. Reference change values (RCVs) and minimal important differences (MIDs) were determined to assess biological variation of hs-cTnT.
Results: MID and RCV for the 12 months interval in patients were 3.8 ng/L or 44.2%, respectively. MID and transformed MID values were lower than the corresponding RCV with a value of 5.1 ng/L for the transformed RCV and 28.1% for the transformed

MID. Similar patterns were shown in different subgroups as sex, age, and renal function. We observed a baseline hs-cTnT value dependent change of MID and RCV with increasing values for MID and decreasing values for RCV which converge to stable values between a baseline hs-cTNT value of 11 to 25 ng/l.
Conclusions: Biological variation of hs-cTnT over 12 months in stable outpatients depends on the concentration at index visit, and is consistent among important prespecified subgroups. MID shows a low biovariability over 12 months.

	RCVabs (ng/ml hs-cTnT)	MID (ng/ml hs-cTnT)	RCV (%)	MIDrel (%)
Total	5.1	3.8	44.2%	28.1%
< 14	3.8	2.3	37.0%	26.4%
>= 14	5.5	3.3	28.7%	15.9%
male	5.6	3.9	44.2%	27.3%
female	3.8	3.2	45.0%	30.1%
eGFR >= 60ml/min	4.3	3.4	41.6%	27.9%
eGFR < 60ml/min	7.5	4.4	47.0%	27.7%
age >= 70	6.3	4.1	45.0%	28.5%
age < 70	4.2	3.4	43.1%	27.3%

MID and RCV values and as transformed values including the different subgroups

The impact of coronary sinus reducer on left ventricular function in patients with refractory angina; new horizons in ischemic cardiomyopathy?

G Georgios Tzanis[1]; A Palmisano[1]; G Gallone[1]; F Ponticelli[1]; L Baldetti[1]; A Esposito[1]; A Colombo[1]; F Giannini[1]
[1]*San Raffaele Hospital of Milan (IRCCS), Milan, Italy*

Funding Acknowledgements: Georgios Tzanis acknowledges funding received from the European Society of Cardiology in form of an ESC Training Grant

Background: Coronary sinus (CS) Reducer System is a balloon-expandable, stainless steel mesh, implanted percutaneously in the CS to create a controlled narrowing of the lumen and establish pressure gradient across it. CS Reducer implantation has been shown to improve angina and quality of life in patients with coronary artery disease having angina refractory to medical therapy and not amenable to any further revascularization.
Purpose: To evaluate the impact of CS Reducer implantation upon left ventricular (LV) function as assessed by cardiac magnetic resonance (CMR) in patients with refractory angina and coronary artery disease not amenable to further revascularization.
Methods: Prior to device implantation and at 4-months, all patients underwent clinical assessment with evaluation of: CCS class, six-minute walk test (6-MWT) and resting ventricular volumes and function, measured using CMR.
Results: Nineteen patients (18 males/1 female, 66±10 years), underwent successful Reducer implantation. Sixteen patients improved by ≥ 1 CCS class. Eight patients experienced 1 CCS class reduction, 7 patients 2 CCS class reduction, 1 patient 3 CCS class reduction and 3 patients did not experience any benefit in angina class. The 6MWT was also improved 4 months after Reducer implantation (from 319±77 meters to 418±107 meters, p=0.002).
Four months after Reducer implantation, we noticed a significant improvement in LV ejection fraction (LVEF) (61 [IQR 47-71] to 66 [IQR 57-72] %; p=0.009), a reduction in LV end-diastolic volume (LVEDV)/Body surface area (BSA) (65.7 [IQR 57.4-89.6] to 64.7 [IQR 53.7-74.1] ml/m2; p=0.036, respectively) and a reduction in LV end-systolic volume (LVESV)/BSA (28.7 [IQR 18.6-38.8] to 20.0 [IQR 15.0-31.4] ml/m2; p=0.007, respectively). Patients with reduced EF (EF<50%, n=6) presented a greater increase of EF at follow up compared to patients with preserved EF (11.3 [IQR 6.5-54.5] vs 3.8 [IQR 0.6-9.1] %; p=0.029). The observed decrease in LVESV/BSA was greater in patients with reduced EF (23.6 [IQR 11.6-33.8] vs 4.2 [IQR -2.0-8.4] ml; p=0.005).
Conclusions: CS Reducer implantation improved angina symptoms, functional capacity and left ventricular function in patients with refractory angina. The improvement was pronounced in the subgroup of patients with reduced ejection fraction. The hypothesis generating results indicate a new approach to be tested in ischemic cardiomyopathy.

P1118
Interventricular septal dysfunction due to myocardial infraction can result in right ventricular failure in long term follow up

CS Chan Seok Park[1]; AM Gwon[1]; GH Kim[1]; JS Cho[1]; HJ Youn[1]
[1]*Catholic University Medical College, Seoul, Korea (Republic of)*

Background: Diastolic functional parameters and interventricular septal thickness are related to right ventricular dysfunction after anterior myocardial infarction. This finding suggest that interventricular septal function can affect right ventricular function in myocardial infarction patients. We measured right ventricular free wall strain using dedicated software whether the ischemic insult on interventricular septum can affect the long-term right ventricular function, which is important parameter for the development of heart failure.
Methods: The patients diagnosed as acute myocardial infarction due to left anterior descending artery disease who underwent successful revascularization were enrolled. Echocardiographic exams were performed 2 times, within 72 hours and 1 year after the revascularization. Strain values of interventricular septum and right ventricular free wall were derived from the Dicom images. The analysis was performed using the dedicated software for the measurement of right ventricular strain.
Results: Total 53 patients were enrolled. The values of global left ventricular strain were increased after the follow up. There were no changes in global longitudinal strain of the right ventricle. But longitudinal stain values acquired from right ventricular free walls were decreased even the improved left ventricular strain values.
Conclusion: Interventricular septal dysfunction due to ischemic injury resulted from anterior myocardial infarction can affect long term right ventricular dysfunction. This finding suggests the interventricular dependence between cardiac chambers and can provide the development of heart failure in myocardial infarction patient after the successful revascularization.

Left and right ventricular strain			
	Initial (n=53)	Follow up (n=53)	P value
Left ventricle			
Global longitudinal strain (%)	-13.25±4.50	-16.25±4.21	<0.001
Longitudinal strain, septum (%)	-11.26±5.74	-14.88±5.18	<0.001
Right ventricle			
Global longitudinal strain (%)	-19.90±4.60	-20.08±5.07	0.839
Longitudinal strain, septum (%)	-15.20±4.52	-16.04±5.27	0.367
Longitudinal strain, free wall (%)	-20.58±5.27	-18.82±5.70	0.049

New biomarkers of cardiovascular endpoints and heart failure progression analysis after myocardial infarction

N Naufal Zagidullin[1]; AF Hamitova[1]; IA Lackman[2]; ZF Maksimenko[2]; DF Gareeva[1]; EL Tulbaev[1]
[1]*Bashkir State Medical University, Chair of Internal Diseases, Ufa, Russian Federation*; [2]*Ufa State Aircraft Technical University, Ufa, Russian Federation*

Background: Myocardial infarction (MI) is one of the main factors in chronic heart failure (HF) onset or progression. Creatine phosphate kinase (CPK), troponins (Tr) and NTproBNP seems to have prediction potential in HF and primary cardiovascular endpoints prediction in the remote period, and recently the new and more sensitive biomarkers such as soluble ST2 and Pentraxin-3 (Ptx-3) are intensively investigated. For Ptx-3 the normal range is not yet defined.
Objective: was to study predictive power of ST2, Ptx-3 and NTproBNP biomarkers on cardiovascular endpoints in 12 months after MI and systolic left ventricular ejection fraction (LVEF) failure progression and cut-off point for mortality for ST2.
Materials: NTproBNP, Ptx-3 and ST2 were estimated 3 days after MI (both STEMI and nonSTEMI) in 180 patients. In 12 months (369.2±11.9) the primary endpoints (MI, stroke, death, and hospitalization) were analyzed. Patients were divided into 1st groups with serum ST2 below normal threshold (n=108, 60.0±2.3 years, ST2=27.9±8.9 ng/ml) and 2nd – with ST2 above the threshold (n=72, 63.9±1.9, ST2=97.7±21.9 ng/ml). The survival binary logistic regression and RandomForest educational models was constructed based on patient investigation parameters during hospitalization and primary endpoints in 1 year to estimate impact of biomarkers. Additionally, in 58 patients (36 from the 1st and 22 from the 2nd groups) the LVEF was investigated by means of echocardiography to find biomarkers of systolic function decline progression.
Results: In 1-year the mortality ratio (6.9% vs 4.6%), strokes (4.2 vs. 1.9) and hospitalizations (11.1 vs 4.6) were higher in the 2nd group but of MI – in the 1st (12.5 vs 16.7). NTproBNP was significantly higher in the 1st group (883.1±76.4,

vs 1820.8±144.1 pg/ml, p<0.012), Ptx-3 differed in less extent between the group compared to ST2 (144.5±25.1 vs. 203.1±32.7 ng/ml, p<0.041). By binary regression analysis high ST2 increased probability of stroke on 1.4% but decreased of MI on 1.3% (p<0.05). High NTproBNP (marginal impact on mortality + 1.52 %, p<0.01) and Ptx-3 (marginal impact +1.18%, p<0.05) both were risk factors of mortal endpoints. Random Forest education analysis increased predictive power of biomarkers in 2-3 times: mortality was predicted mostly by age, MI in the past and NTproBNP (last on 5.64 %) and Ptx-3 (on 3.48) and MI and stroke – ST2 (3.15 and 2.95 respectively). PTX-3 > 43.9 ng / ml was shown to be mortality risk factor with sensitivity 70.0% and specificity 52.9%. In 1-year in the groups with high and low ST2 the biomarker failed to predict the LVEF decline (p=0.4).

Conclusions: NTproBNP, ST2 and Ptx-3 biomarkers showed predictive power in cardiovascular endpoints in 1-year FU analysis after MI but failed to predict systolic left ventricular function decline.

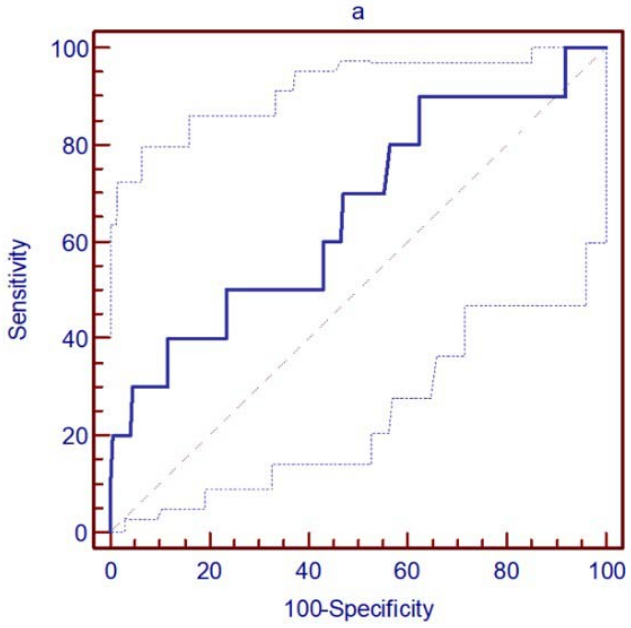

Fig. 1. Cut-off value on Ptx-3 in 1-year

P1120

Selective beta blockers are beneficial for chronic obstructive pulmonary disease patients with acute myocardial infarction: a nationwide study of 186,326 patients

WH Wen-Hwa Wang[1]; CC Cheng[1]; GY Mar[1]; KC Wei[1]; WC Huang[1]; CP Liu[1]
[1]Kaohsiung Veterans General Hospital, cardiovascular , Kaohsiung, Taiwan, Province of China

β-blockers are important for acute myocardial infarction (AMI) patients due to their better outcomes, both short-time and long-term. Nevertheless, β-blockers are under-prescribed in chronic obstructive pulmonary disease (COPD) patients with AMI for fear of the bronchospasm. The aim of this study was to investigate the association between the usage of selective β-blockers and the risk of mortality in COPD patients after first AMI via a nationwide, population-based cohort study. In this retrospective study, 186,326 AMI patients have been identified between January 2000 to December 2012 from National Health Insurance Research Database. Among those patients, 23,116 had COPD and only 7,609 patients (32.92%) were prescribed β-blockers, while 15,507 were not. We stratified those patients into cardio-selective and non-selective β-blockers groups. Multivariate Cox proportional hazards models were used to estimate adjusted hazard ratios (HR) with 95% confidence intervals (95% CI). Those who had taken cardio-selective β-blocker showed a reduced risk of mortality (HR: 0.93; 95% CI: 0.89-0.98; p<.01). Hence the study concludes that cardio-selective β-blockers improve overall survival among COPD patients after first AMI.

P1121

Identifying acute coronary syndrome in patients presenting to the emergency department with chest pain. Development of the CHEST PAIN-ALERT algorithm

I Igor Mrdovic[1]; L Savic[1]; N Zlatic[1]; V Zobenica[1]; D Jelic[1]
[1]Clinical Center of Serbia, Beograd, Serbia

Background: Coronary artery disease is the most common precipitating cause of heart failure (HF) worldwide. Early identification of acute coronary syndrome (ACS) in patients presenting to the emergency department (ED) with chest pain (CP) can result in timely treatment, which can prevent left ventricular remodeling and reduce the occurrence of HF.

Purpose: This investigator-initiated, single-center, observational, prospective cohort study aimed at developing the best possible clinical algorithm to identify the presence of ACS in patients presenting to the ED with CP.

Methods: 224 all-comer patients enrolled prospectively in the CHEST PAIN-ALERT trial were grouped into derivation and validation sets in a ratio of 1:1. Data concerning 1. patient demography, 2. risk factors, 3, current therapy, 4, ECG at presentation and 5. pain characteristics were collected. Patients with CP that had stopped before presentation were excluded, as well as the non-cooperative patients, patients who participated in another trial, or have other medical condition which in the investigator's opinion may interfere with the patient's optimal participation in the study. The primary end point was confirmation of the diagnosis of ACS. ACS was defined as the presence of unstable angina, acute myocardial infarction (AMI) or sudden coronary death. The decision on the presence of ACS was made using highly sensitive cardiac troponin, echocardiographic recording and coronary angiography, as well as data from a 15-day follow-up, in accordance with the actual ESC guidelines and the universal definition of acute myocardial infarction. Telephone interviews included data about performed diagnostic procedures (stress test, echocardiography, ECG-holter monitoring, angiography), medical therapy for ACS, revascularization (percutaneous, surgical), and adverse events (recurrence of ischemia, heart failure, stroke, bleeding, hospitalization).

Results: The diagnosis of ACS was confirmed in 51/224 (22.8%) patients. The CHEST PAIN-ALERT algorithm's AUC (figure 1), sensitivity, specificity, positive and negative predictive value were: 0.945, 95.0%, 85.5%, 0.613 and 0.986, respectively. Positive and negative likelihood ratios were: 6.55 and 17.1, respectively. One of 112 patients (0.89%) was false negative and 12/112 patients (10.7%) were false positive. Conclusions: CHEST PAIN-ALERT algorithm showed an excellent predictive value to identify the presence or absence of ACS among CP patients presented to the ED. Early identification of ACS is a cornerstone for timely treatment, which might reduce the incidence of subsequent HF in these patients.

Clinical characteristics, management and in-hospital mortality of patients with non-st-segment elevation vs. st-segment elevation myocardial infarction in kosovo

F Zhubi Bakija[1]; Z Rexhaj[1]; A Ferati[1]; E Zhubi[1]; E Koci[1]; R Leka[1]; E Haliti[1]; A Poniku[1]; A Ahmeti[1]; A Batalli[1]; SH Elezi[1]; F Shatri[1]; H Selmani[1]; G Bajraktari[1]
[1]*University Clinical Centre of Kosovo (UCC), Cardiology, Pristina, Kosovo Republic of*

Background: Myocardial infarction (MI) is a major cause of mortality for all regions of the world. Based on the presenting electrocardiogram, acute MI is categorized generally as non-ST-segment elevation MI (NSTEMI) and ST-segment elevation MI (STEMI). The clinical presentation, treatment and outcome of patients differ between these two types of MI.
Aim: The objective of this study was to assess clinical characteristics, management and its impact on in-hospital mortality in patients with MI.
Methods: This retrospective study included all patients hospitalized for ACS from January 1st, 2014 to December 31st, 2018, at the Clinic of Cardiology of the University Clinical Center of Kosova, in Prishtina, Kosovo. All clinical, biochemical, ECG, echocardiograms and the results of the invasive diagnostic and interventional results were registered, both in NSTEMI and STEMI patients.
Results: Among 4667 admitted patients with ACS (mean age 63 ± 12 years, 30% female), according to the final discharged diagnosis, 2982 (64%) patients were identified with STEMI, 1546 (33%) with NSTEMI, and 113 (3%) unstable angina. NSTEMI patients were older than STEMI patients (p=0.025), with more female presented (p=0.002), were less smokers (p=0.012), and more hypertensive (p<0.001), compared to STEMI patients. The primary percutaneous intervention (PPCI) was performed equally in NSTEMI and STEMI patients (33.4% vs. 34.4%, p=0.343), whereas NSTEMI patients were less likely to be transferred to 24 hours PPCI center (15% vs. 29%, p < 0.001) compared to STEMI patients.
In-hospital mortality in the whole group of patients that were not transferred to the 24 hours PPCI center did not differ between NSTEMI and STEMI patients (8.3% vs. 9.2%, p = 0.388). The mortality was higher in patients that did not underwent reperfusion by PPCI both in NSTEMI (10.1% vs. 2.1%, p<0.001) and STEMI (10.8% vs. 4.7%, p<0.001), compared to those that underwent PPCI. The mortality rate of patients with MI did not differ between NSTEMI and STEMI patients that were treated medically (14% vs. 11.4%, p = 0.107) or by PPCI (3.0% vs. 4.7%, p=0.299).
Conclusion: During last five years majority of patients with acute MI were not treated with PPCI in Kosovo, in whom the mortality rate remain very high. NSTEMI patients are less likely to be transferred to a 24 hours PPCI center than STEMI patients, despite the same in-hospital mortality rate of these two groups of patients. These findings highlight the need for the implementation of the strategy of early and urgent invasive treatment of NSTEMI patients in Kosovo.

P1123

Manifestations of frailty in elderly patients with acute coronary syndrome

N Nino Soseliya[1]; O Lukina[1]; N Bagmanova[1]; L Babaeva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation*

Background. Detecting frailty in elderly patients with acute coronary syndrome (ACS) is important to predict the occurrence of adverse outcomes, but because of its complexity, frailty screening is not commonly performed. The quality of life of older people is determined not only by the presence of chronic diseases, but also geriatric syndromes. The most common geriatric syndromes are sensory deficits (decreased vision and hearing), cognitive impairment and depression, incontinence urine, falls, decreased mobility and malnutrition. The aim of the study was to assess patient distribution depending on positive responses to screening questions.
Methods: In 130 patients ≥75 years (83±5 years, arterial hypertension (AH) 92%, previous myocardial infarction (MI) 32%, atrial fibrillation 32%, diabetes 27%, chronic heart failure (HF) 77%, acute heart failure (ACF) (Killip I - 60%, II- 29,2%, III - 10%,IV- 0,8%), admitted with MI (75%) or unstable angina (25%), frailty (national validated questionnaire), nutritional status (Mini Nutrition Assessment), cognitive function (Mini Mental State Examination) were assessed. National validated questionnaire includes 7 questions. Frailty was diagnosed with ≥3 points, pre-frail 1-2 points and non-frail – 0 points.
Results: Mean score on a national validated questionnaire was 2,9±1,4 points. Only 8.5% of patients responded negatively to all questionnaire questions. None of the patients had 7 points. 6,2, 19,2, 32,3, 23,8, 6,9 and 3,1% patients had 1, 2, 3, 4, 5 and 6 points. Most often patients noted decreased vision and hearing (56.9%). 48,5 and 48,5% of patients had reduction of mood and the episodes of urinary incontinence. 44,6% patients gave positive answers about memory impairment, understanding, orientation, or ability to plan. 37,7% patients had injuries associated with a fall during the last year, 34,6% - weight loss. 20% patients had difficulties in walking.
Patients with weight loss had more pronounced score on MNA score (22,3±2,7 vs 23,7±2,8 points, p<0,01). Patients with positive answers about memory impairment, understanding, orientation, or ability to plan had more cognitive dysfunction (25,8±4,9 vs 28,3±4,1 points, p<0,01).
8,5 % of the patients were non-frail, 25,4 % pre-frail and 66,1 % frail. Patients with frailty were more likely women (72 vs 59%; p<0,05), had higher incidence of AH (94 vs 86%; p<0,01), MI in this hospitalization (86 vs 55%; p<0,05), GFR <60 ml/min/1,73 m2 (71 vs 48%; p<0,05).
Conclusion: Frailty occured in 66,1% of elderly patients with ACS, was associated with increased prevalence of cardiovascular diseases. Most often, patients had decreased vision and hearing, reduction mood and the presence of episodes of urinary incontinence.

P1124

SCAD (Spontaneous coronary artery dissection) UK data an observation study of PSCAD vs. Non PSCAD

N Nalin Natarajan[1]; DA Adlam[1]
[1]*Glenfield Hospital, Leicester, United Kingdom of Great Britain & Northern Ireland*

Funding Acknowledgements: The British Heart Foundation, The NIHR rare disease translational collaboration, The Leicester NIHR Biomedical Research Unit and BeatSCAD

Spontaneous coronary artery dissection (SCAD) is a devastating condition, which affects predominantly young females. It has been associated with Pregnancy and post partum. It is a non-inflammatory, non-atherosclerotic cause of acute myocardial infarction. It can result in significant morbidities such as ventricular arrhythmias, sudden cardiac death and left ventricular systolic dysfunction (LVSD).
The purpose of this study was to compare PSCAD vs. non-PSCAD cohorts to see if there were any substantial differences. UK (United Kingdom) data for SCAD was reviewed from 01/01/2007 to 01/10/2017. Pregnancy and post partum associated SCADs were analysed. Post Partum was defined to be up to 1 year after pregnancy. 24 PSCAD were identified which were randomly matched by age in a 2:1 Ratio. In total 72 SCAD's were selected. 2 patients were withdrawn after the angiograms were reviewed (24 PSCAD and 46 non PSCAD). Data was reviewed using the national registry and SCAD experts reviewed angiograms for all patients.
Mean age for the entire cohort was 35.35. In the PSCAD cohort 62.50% presented as a STEMI (ST elevation Myocardial infarction) with 45.83% having ECG changes in the anterior leads. Compared to non-PSCAD cohort 58.70% presented as a STEMI with 41.30% having ECG changes in the anterior leads. In the PSCAD cohort 33.33% affected the LMS (Left main stem), 20.83% affected the RCA (Right coronary artery), 70.83% affected the LAD (left anterior descending), 29.17% affected LCX (left circumflex artery) and 41.67% affected more than one vessel affected. In 29.17% of cases percutaneous coronary intervention (PCI) was undertaken and 8.33% cases required a coronary artery bypass graft (CABG). In the non-PSCAD group 10.86% affected the LMS, 10.86% affected the RCA, 76.09% affected the LAD, 13.04 % affected LCX and 4.35% affected more than one vessel. 28.26% underwent PCI with 10.87% cases requiring CABG.
Heart failure was reviewed in both cohorts with Echocardiogram or Magnetic resonance imaging (MRI) reviewed at least 3 months after the event. In the PSCAD group 50 % had normal LVSF (Left ventricular systolic function), 20.83% with mild LVSD, 16.67 with moderate LVSD, 4.17 % with severe LVSD and in 8.33% data was not available. In non-PSCAD group 54.35% had normal LVSF, 19.57% had mild LVSD, 10.87% had moderate, 0 % had severe LVSD and in 15.22% data was not available.
In both sub groups the commonest vessel affected was the LAD. However, the PSCAD group had a higher number of LMS and multi vessel cases of SCAD's. This highlights that this cohort has a more severe form of SCAD. From a heart failure perspective in both subgroups at least half the patients regained normal LV function.

P1125

Effect of intravenous ferric carboxymaltose on left ventricular systolic function after acute myocardial infarction

F Barilla[1]; L Luca Monzo[1]; I Cardillo[1]; I Ferrari[1]; F Biccire[1]; C Torromeo[1]; G Pannarale[1]; V Paravati[1]; C Gaudio[1]
[1]*Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrological, Anesthesiological, and Geriatric Sciences, Rome, Italy*

Introduction: Treatment with intravenous ferric carboxymaltose (FCM) showed to improve symptoms, functional capacity, and quality of life in patients with heart failure and iron deficiency. No data are currently available in the setting of acute coronary syndromes. The aim of our study was to investigate the role of iron supplementation on left ventricular (LV) function and shape in acute myocardial infarction (AMI).Material and methods: A total of 11 consecutive patients (age 64 ±

12 years) hospitalized for ST elevation myocardial infarction (STEMI) in the anterior wall underwent physical examination, echocardiography and blood samplings with the assessment of high sensitivity troponin (hsTr), ferritin, transferrin and transferrin saturation (TSAT) within 24h from admission. Echocardiographic examination, ferritin and transferrin saturation (TSAT) were re-assessed after 3 months from FCM administration. The determination of the initial iron need was calculated based on body weight and haemoglobin levels. A single dose of intravenous FCM (500 mg) was administered in patients with a TSAT ≤20% as an undiluted slow bolus injection within 24h from hospital admission and irrespective of anaemia status. If needed, a second dose was administered one week later.
Results: All patients showed a ferritin concentration <100 ugr/ml. Five patients had a TSAT ≤20% (group A) and 6 patients a TSAT >20% (group B). The two groups were similar in terms of door-to-balloon time, LV systolic function and volumes at baseline. After three months of follow-up all patients treated with FCM showed a TSAT >20% and a haemoglobin value >13 gr/dl. Patients in group A showed a significant increase in left ventricle ejection fraction (from 38.6 ± 1.3% to 46.8 ± 3.5%; p=0.0015) a and a slight non-significant trend in reduction of left ventricular end-diastolic volume (from 84.6 ± 26.2 ml to 79.1 ± 16.5 ml, p=0.42) from baseline. Opposite, no significant modifications in LV systolic function and remodeling parameters were showed in group B.
Conclusions: The administration of FCM in patients with STEMI in the anterior wall and iron deficiency was correlated to an improvement in LV systolic function compared to patients with normal TSAT. Potential beneficial effect of FCM administration in patients with AMI should be further examined.

Valvular Heart Disease

Prevalence, clinical features and outcomes of different phenotypes of acute kidney injury in infective endocarditis

N Povalyaev[1]; A Pisaryuk[2]; M Sorokina[3]; A Balatskiy[1]; E Kotova[2]; Y Karaulova[4]; M Efremovtseva[2]; A Milto[4]; S Ratchina[2]; A Safarova[4]; Z Kobalava[2]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation; *[2]Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*; *[3]Dmitry Rogachev National Research Center of Pediatric Hematology, Oncology and Immunology., Moscow, Russian Federation*; *[4]City Clinical Hospital named after V.V. Vinogradov, Moscow, Russian Federation*

Background: Renal lesions in infective endocarditis (IE) clinically may appear like subclinical manifestation as well as fulminant kidney failure. However, one third of IE patients has serum creatinine elevation concordant with acute kidney injury (AKI) criteria. Clinical phenotypes of AKI in patients with IE was never studied.
Materials/methods: 209 patients with verified IE (DUKE 2009, 2015), hospitalized and treated from January 2010 to June 2018, were included in the study. Kidney function was assessed using CKD-EPI formula. AKI and chronic kidney disease (CKD) were diagnosed according to current guidelines (KDIGO 2012, 2017). Serum creatinine decrease on ≥26,5 mcmol/L in 48 hours after the hospitalization was counted as early-onset AKI. Patients with serum creatinine elevation on ≥26,5 mcmol/L in 48 hours during the hospitalization were diagnosed with late-onset AKI
Results: AKI was diagnosed in 138(66%) patients. In 70 patients (50,7%) AKI was affected by underlying CKD.
Patients with AKI with underlying CKD comparing to patients with AKI de novo had higher occurrence of dyspnea (79% vs 62%, p<0.05), had lower LV EF (52±9 vs 57±7, p<0.01) and higher perioperative risk based on EuroSCORE II (38(17-64) vs 10(3-28), p<0.001). Patients with AKI de novo had less significant symptoms of heart failure (p<0.001). Glycopeptides were more frequently used in patients with AKI and underlying CKD. In-hospital mortality was higher in patients with AKI with underlying CKD as compared to the patients with AKI de novo (52,9% vs 35,7%, p<0,05). RRT was held in 1 (1,5%) patient with AKI de novo and in 2 (2,9%) patients with AKI and CKD. Patients with late-onset AKI were older (median age 61,5±17,3 vs 51,0±18,9 p<0,01), had higher Charlson index (median points 6,7±4,1 vs 5,1±4,0 p<0,01) and higher perioperative risk based on EuroSCORE II (median score [IQR] 27,8[9,23-50,9] vs 13,0 [3,4-39,4] p<0,05) Patients with late-onset AKI had significantly lower incidence of cough (p<0.05) and septic shock at admission (p<0.05). Patients with late-onset AKI more frequently received oxacillin, and aminopenicillins, and patients with early-onset AKI more frequently received cephalosporines and lipopeptides.
Conclusions: AKI occurrence on the background of the CKD is associated with glycopeptide therapy and higher in-hospital mortality rate. Patients with late-onset AKI were older, had more comorbidities and higher perioperative complications risk. We have not found any significant data on relationships of the IE causative agent and early onset of AKI, which disagrees with the literature data.

P1127
Prognostic significance of biomarkers in infective endocarditis

M Abellas Sequeiros[1]; JL Moya Mur[1]; E Navas[2]; MP Martin Davila[2]; S Del Prado[1]; A Lorente Ros[1]; JM Vieitez Florez[1]; J Rodriguez-Roda Stuart[3]; C Fernandez-Golfin[1]; JL Zamorano Gomez[1]
[1]University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain; *[2]University Hospital Ramon y Cajal de Madrid, Infectious diseases, Madrid, Spain*; *[3]University Hospital Ramon y Cajal de Madrid, Cardiac Surgery, Madrid, Spain*

Introduction: Infective endocarditis (IE) is still a fatefull disease with a high rate of morbidity and mortality. The use of prognostic biomarkers let us focus on those patients with worse prognosis. Does heart failure biomarkers may help identify critically ill patients?
Methods: Patients presented at the Endocarditis team were prospectively assessed. Aetiology, baseline characteristics and outcomes (need of intensive care and in-hospital mortality) were collected. Brain natriuretic peptide (BNP) and troponine I (Tn I) levels at income were recorded. T test was conducted.
Results: 113 patients were studied between 2014 and 2018. Mean age was 68 years old; 70 (68%) patients were men and 21% had ischaemic aetiology. 34% had atrial fibrillation and 21% were diabetic. Aortic infective endocarditis represented 42% of the total; 37% were mitral endocarditis. Prosthetic valve endocarditis was 33%; cardiac device-related infective endocarditis was 18%. The most frequent microorganism underlying was Staphylococcus aureus (33%).Patients with higher levels of BNP had a higher need of intensive care (p=0,018), as those with higher Tn I concentration (p= 0,032). BNP was also related to more mortality (p= 0,052). However, this result was not applicable for Tn I (p=0,269). Acute phase reactants were also associated with need of intensive care: C-reactive protein (p= 0,024) and procalcitonin (p=0,008). Procalcitonin, but not C-reactive protein, associated higher in-hospital mortality (p=0,002).
Conclusions: Heart failure biomarkers have prognostic impact on patient affected by IE, predicting the necessity of intensive care. BNP has a tendency to predict also in-hospital mortality. Acute phase reactants predict both outcomes (need of intensive care and in-hospital mortality). The precise identification of heavily ill patients is crucial to try to overtake a discouraging ending, and biomarkers may play an important roll for it.

P1128
Transcatheter aortic valve replacement in patients with aortic stenosis and mitral regurgitation

M Munoz-Garcia[1]; E Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; F Carrasco-Chinchilla[1]; AJ Dominguez-Franco[1]; L Morcillo-Hidalgo[1]; JM Garcia-Pinilla[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]
[1]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

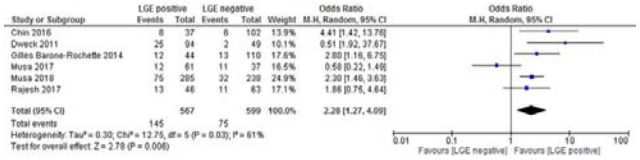
Background: Many patients undergoing transcatheter aortic valve replacement (TAVR) for aortic stenosis also have significant mitral regurgitation (MR). We sought to understand the association of concomitant MR with TAVR clinical outcomes, as well changes in MR after TAVR.
Methods: Patients who underwent TAVR at our center,between april 2008 to December 2017, were studied, with longer term clinical outcomes
Results: Of 667patients, 92 (13.8%) had moderate MR, and 47 (2.1%) had severe MR. At 3.2±2.2 years, mortality was 39.4%, 46.1%, 39.1%, 57.6% and 50% and heart failure (HF) rehospitalization was 7%, 7.9%, 17.6%, 21.9% and 46.2% (p < 0.001) in the no, mild, moderate, moderate-severe and severe MR patients, respectively. After procedure, 64 patients (9.9%) had moderate MR and 24 patients (3.7%) had severe MR. At follow-up, the mortality was 35.9%, 46.5%, 48.4%, 52.9% and 85.7%, p <0.001 and HF rehospitalizations 9.1%, 5.5%, 23.4%, 35.3% and 40 % in the no, mild, moderate, moderate-severe and severe MR patients, respectively. MR improved early after TAVI grade in 88 patients (13.2%). Baseline MR is not associated with mortality (HR= 0.883 [95 CI 0.708-1.102], p= 0.114), but MR post-TAVI was associagted with increase risk of mortality (HR= 1.539 [95 CI 1.187-1.996], p= 0.001. In 7 patients with persistent MR received percutaneous mitral repair with MitraClip.
Conclusions: In our series, Moderate or severe MR after TAVI is associated with increased mortality or HF rehospitalization, this increased risk may be atrributable to the minority of patients whose MR does not improve and could benefit from percutaneous mitral procedures (Mitraclip).

P1129

The prognostic role of late gadolinium enhancement in patients with aortic stenosis: a systematic review and meta-analysis

C Christos Papanastasiou[1]; D Kokkinidis[2]; P Kampaktsis[3]; I Bikakis[4]; D Cunha[5]; E Oikonomou[6]; J Greenwood[7]; M Garcia[8]; T Karamitsos[1]
[1]Ahepa University Hospital, 1st Cardiology Department, Thessaloniki, Greece; *[2]Albert Einstein College of Medicine, Department of Medicine, New York, United States of America*; *[3]Weill Cornell Medical College, Department of Medicine, New York, United States of America*; *[4]401 Army General Hospital of Athens, Athens, Greece*; *[5]University of Iowa, Department of Radiology, Iowa City, United States of America*; *[6]University of Athens Medical School, Athens, Greece*; *[7]University of Leeds, Leeds Institute for Cardiovascular and Metabolic Medicine, Leeds, United Kingdom of Great Britain & Northern Ireland*; *[8]Albert Einstein College of Medicine, Division of Cardiology, New York, United States of America*

Background: Myocardial fibrosis is a common feature of many cardiac diseases. Cardiac magnetic resonance (CMR) has the ability to non-invasively detect regional fibrosis, using the LGE technique. Several studies have explored whether LGE is associated with adverse outcome in patients with AS.
Purpose: The aim of this systematic review was to explore the prognostic value of late gadolinium enhancement (LGE) in patients with aortic stenosis (AS).
Methods: Electronic databases were searched to identify studies investigating the ability of LGE to predict all-cause mortality in patients with AS. A random effects model meta-analysis was conducted. Heterogeneity was assessed with I2.
Results: Six studies comprising 1,250 patients met our inclusion criteria. LGE was present in 45.3% of patients. In the pooled analysis, LGE was found to be a strong univariate predictor of all-cause mortality (pooled unadjusted OR: 2.28, 95% CI: 1.27 to 4.09, I2=61%). Four of the included studies reported adjusted HR for mortality. LGE was independently associated with mortality, even after adjusting for baseline characteristics (pooled adjusted HR: 2.50, 95% CI: 1.64 to 3.83, I2=0%).
Conclusion: Fibrosis on LGE-CMR is a powerful predictor of all-cause mortality in patients with AS and may serve as a novel marker for risk stratification. Future studies should explore whether LGE-CMR can also be used to optimize timing of AS-related interventions.



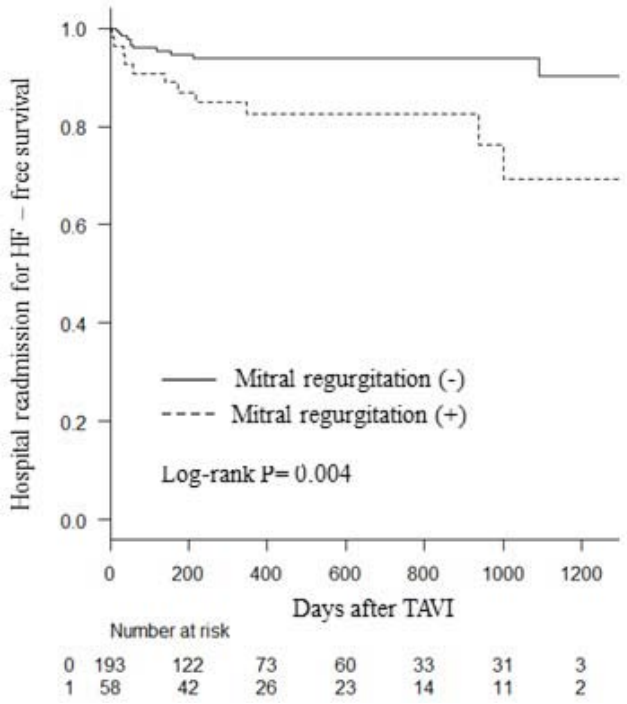
Meta-analysis results

P1130

Impact of significant mitral regurgitation for predicting hospital readmission for heart failure after transcatheter aortic valve implantation

Y Tamura[1]; Y Konami[1]; H Suzuyama[1]; K Kodama[1]; H Yasuda[1]; E Taguchi[1]; Y Horibata[1]; T Sakamoto[1]
[1]Saiseikai Kumamoto Hospital, Cardiovascular medicine and surgery, Kumamoto, Japan

Introduction: Transcatheter aortic valve implantation (TAVI) has been performed for the patients with symptomatic, severe aortic valve stenosis (AS) deemed inoperable or at high risk for surgery. Although mitral regurgitation (MR) frequently coexists in patients with AS, there are conflicting reports regarding MR on outcomes after TAVI.
Purpose: We studied the impact of pre-existing MR for predicting hospital readmission for heart failure (HF) in patients after TAVI.
Methods: We retrospectively enrolled patients with AS underwent TAVI from December 2013 through June 2018. Significant MR was defined as grade 2 or higher MR on preoperative echocardiography. We used Cox regression analysis to estimate the hazard ratio for MR on hospital readmission for HF.
Results: We analyzed 251 consecutive patients (mean age 84.8 ± 5.0 years; male 29.9%). Of these, 55 patients (22.8%) had significant MR on preoperative echocardiography. Moreover, 19 patients (7.9%) experienced hospital readmission for HF after TAVI (the median follow up period 367 days). The significant MR group had higher hospital readmission compared to the non-significant MR group (16.4% vs. 5.4%, P<0.05). In the Cox proportional hazards model, significant MR was significantly associated with hospital readmission for HF (Figure. adjusted hazard ratio, 2.56; CI: 1.08^3/$_4$6.04; P = 0.032).
Conclusion: These results demonstrate that significant MR can be significantly associated with hospital readmission for HF in patients after TAVI.



Hospital readmission for heart failure

P1131

Pulmonary hypertension is a poor long-term prognostic factor in patients with primary mitral regurgitation, not in patients with secondary mitral regurgitation

JH Lee[1]; JH Jae-Hyeong Park[2]; HJ Kwon[2]; BS Seo[2]; JK Oh[2]; IW Seong[2]
[1]Chungbuk National University Hospital, Cardiology, Cheongju, Korea (Republic of); *[2]Chungnam National University Hospital, Daejeon, Korea (Republic of)*

Background: In patients with primary mitral regurgitation (MR), the prevalence of pulmonary hypertension (PH) is about 20% and its presence is a poor prognostic factor. However, it is still unknown the prognostic significance in patients with secondary MR. We studied long-term survival in patients with MR and evaluated the prognostic significance of PH according to the type of MR.
Materials and methods: We included all consecutive MR patients with more than moderate degree. We determined MR severity with analysis of stored echocardiographic images and the presence of PH was defined as TR Vmax more than 3.0m/sec. The clinical outcome was assessed with the review of their medical records.
Results: We analyzed total of 605 patients (301 males, 67±15 years old) with significant MR patients. Of them, 354 patients (58.5%) had primary MR and 351 (58.0%) had PH. They were followed for 30±51 months for checking major adverse cardiocerbrovascular events (MACCE). During this period, total of 222 patients (36.7%) had more than 1 episode of MACCE; 229 admissions for HF, 31 strokes, 26 mitral valve surgery, and 91 deaths. On the survival analysis, the presence of PH was a significant prognostic factor of total survival (HR=2.498, 95% CI=1.364-4.573, P=0.003) and MACCE (HR=2.666, 95% CI=1.783-3.986, P<0.001) after adjustment of age, gender and LVEF. PH was a poor prognostic factor of total survival (HR=7.175, 95% CI=2.175-23.674, P=0.001) and MACCE (HR=5.828, 95% CI=2.957-11.488, P<0.001) in patients with primary MR. However, PH was not a prognostic factor total survival (HR=1.012, 95% CI=0.497-2.061, P=0.974) and MACCE (HR=1.399, 95% CI=0.852-2.296, P=0.185) in patients with secondary MR.
Conclusion: The presence of PH was a poor prognostic factor in patients with primary MR, not in patients with secondary MR.

P1132

Central nervous system complications in patients with infectious endocarditis: population characterization and predictors of embolization

A Briosa[1]; S Alegria[1]; AR Pereira[1]; D Sebaiti[1]; A Marques[1]; AC Gomes[1]; I Cruz[1]; R Miranda[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Lisbon, Portugal*

Introduction: Infectious endocarditis (IE) is a one of the major causes of morbidity and mortality in patients (pts) with valvular heart disease. Among the morbidity causes, cerebral embolism represents an important burden of disability.
Aim: To characterize patients with infectious endocarditis and neurological complications and to determine predictors of central nervous system (CNS) embolization
Methods: We analysed a population of pts with suspected/confirmed infectious endocarditis, according to Duke criteria, in the last 12 years (2006-2017). The clinical and imaging data were collected as well as complication rates and mortality data.
Results: We included 174 pts, 36,8% had evidence of systemic embolization. The most frequent embolization site was CNS (n=34, 19,5%). Pts with CNS embolization were predominantly male (73,5%), with a mean age of 62±11 years old. 58,8% had hypertension (HTN), 41,2% diabetes (DM), 17,6% chronic kidney disease (CKD). 8.8% were iv drug users ,11,8% had active cancer and 5,9% were HIV positive. None had right-sided valves involvment.The most common microbiologic agents were staphylococcus and streptococcus (both corresponding to 29,4%). 20,6% of pts had no agent isolation. 79,4% had ischemic stroke (haemorragic transformation in 20,6%), 14,7% had haemorragic stroke, 14,7% mycotic aneurism, and 2,9% had myelitis/meningitis. 35,3% had recurrence of stroke (including both ischemic and haemorragic). In-hospital mortality was 35,3%.
Comparing to global population, there were no differences between both groups in what concerns sex (n=0,663), HTN (n=0,964), CKD (p=0,734), IV drug (p=0,463) and HIV (p=0,407). There were no differences between ages or affected valve (mitral vs aortic).
CNS embolization group were more likely to have diabetes (41,2% vs 12,5% p=0,009), prosthetic valve endocarditis (35,3% vs 6,3% p=0,004) and global complications (82,4% vs 44,8% p= 0,002), especially heart failure (HF) (44,1% vs 13,8% p=0,009). They were more associated with invasive procedures in the last 3 months (teeth procedures included) (35,7% vs 11,1% p= 0,032). In addition, they had longer hospitalizations (53 vs 38 days, p= 0,021).
On the other hand, they less frequently had anemia (41,2% vs 71% p=0,016) and fever (58,8% vs 83,9% p=0,027) at presentation. No differences were found in what concerns echocardigraphic changes or survival between the two groups.
In multivariate logistic regression, the only independent risk factors were the absence of anemia (OR: 0,066 95%CI 0,009-0,467 p=0,006) and prosthetic valve EI (OR: 22 95% CI 1,3-374 p=0,032).
Conclusions: For the population studied, CNS embolization was a common complication (especially isquemic stroke) associated to longer hospitalizations. Multiple regression showed that the absence of anemia and the prosthetic valve EI were the only independent predictors of this important morbidity cause.

P1133

Type 2 diabetes is a strong predictor of mortality in patients with prosthetic valve endocarditis with or without heart failure

MM Monica Mariana Baluta[1]; E Panaitescu[2]
[1]*Carol Davila University of Medicine-St Pantelimon Clinical Emergency Hospital-Cardiology Department, bucharest, Romania*; [2]*University of Medicine and Pharmacy Carol Davila, Complementary sciences Dpt., Medical Informatics and Biostatistics, Bucharest, Romania*

Background. Prosthetic valve endocarditis (PVE) has a high mortality rate. The impact of type 2 diabetes mellitus (T2DM) on PVE in-hospital mortality and complications had different reports in the literature.
Purpose. To determine whether T2DM influenced prognosis in patients hospitalized for PVE with or without prior heart failure (HF) in non-reference centers.
Method. We analyzed retrospectively 56 patients with definite or possible PVE (modified Duke criteria) admitted in two non-reference centers over a 5 years period contemporary with The International Collaboration on Endocarditis-Prospective Cohort Study. They were divided in early (E-n=29) and late (L-n=27) PVE and presented with or without prior HF symptoms. The initial intention to treat was medical, with a full course of antibiotics established by an infectious disease physician. The influence of T2DM on patients outcome was analyzed.
Results.
About half (48%) of studied patients had type 2 diabetes at baseline (44% in EPVE and 52% in LPVE). Our findings reveal that they were older, predominantly men, compared to those non-diabetic. Among diabetes patients 84,6% had heart failure symptoms in EPVE and 57% in LPVE. The most common organism detected by blood cultures: 14,8% Coagulase-negative staphylococci; 11,1% S. aureus; 7,4 % Enterococcus, with a strong relation with the initial source of infection (p<0.0001) for all detected etiologies. Due to antibiotic pretreatment 52% of T2DM patients had negative cultures in our study. In the Infectious disease department the in-hospital mortality was strongly related to the presence of T2DM (OR=9.33, RR=2.30, p=0.047) irrespective of etiology (p=0.581). In the ID department T2DM in-hospital mortality was 41,7% vs 2% in all patients. The overall mortality, with antibiotic treatment and early surgery was 20,8% in T2DM vs 7,6 % in all studied patients. Transfer rate due to complication was 63% (DM) vs 27 % in all patients. Transfer rate in patients with diabetes was higher in late PVE (61,4%) vs early PVE (36,4%). Valvular replacement mortality was 36,4%, quite similar between early and late PVE and it was affected by heart failure presence. Analysis was performed after exclusion of patients lost to follow up.
Conclusion: Type 2 diabetes represents a strong independent predictor for mortality in early and late PVE patients with initial medical intention to treat. Heart failure syndrome, when associated to diabetes has an adverse perioperative outcome in those that need early valve surgery.

P1134

Outcomes, survival analysis and the role of kidney damage in modeling the risk of adverse outcome in patients with infective endocarditis

A Alexandra Pisaryuk[1]; N Povalyaev[2]; M Sorokina[2]; A Balatskiy[2]; E Kotova[3]; YU Karaulova[3]; M Efremovtseva[3]; A Milto[3]; S Ratchina[3]; A Safarova[3]; P Kahktsyan[4]; ZH Kobalava[3]
[1]*City Clinical Hospital No 64, cardiology department, Moscow, Russian Federation*; [2]*M.V. Lomonosov Moscow State University, Moscow, Russian Federation*; [3]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*; [4]*Bakoulev Center for Cardiovascular Surgery RAMS, Moscow, Russian Federation*

Background: Patients with infective endocarditis (IE) and renal lesions have worse outcomes even after performing a surgery. Kidney function worsening onset independently associated with increase in post-operative complications rate and in-hospital mortality.
Materials/methods: 209 patients with verified IE (DUKE 2009, 2015), hospitalized and treated from January 2010 to June 2018, were included in the study. Kidney function was assessed using CKD-EPI formula. AKI was diagnosed according to current guidelines (KDIGO 2012). Surgery was performed on 34 patients, all patients had indications for operative treatment. Cox's proportional hazards model are described.
Results: The study investigated complications and outcomes of IE, and it has been established that patients with impaired renal function are more likely to have embolic events (p=0,033), onset/worsening of heart failure symptoms (p<0,001), persisting fever (>7 days despite antimicrobial therapy) (p<0,001), persisting infection (i.e. positive blood culture despite antimicrobial therapy) (p<0,005), septic shock (p<0,003), major bleedings (p<0,028). These patients also had higher in-hospital mortality (p<0,001) (tab. 1). Survival analysis established that cumulative survival was higher in patients who underwent surgery relative to ones who were treated conservatively (fig. 1). Predictors of worse prognosis are septic shock (HR 2,8 95% confidence interval (CI) 1,6-5,0; p<0,001), AKI (HR 2,2; 95% CI 1-4,9; p<0,043), persisting fever (HR 1,9; 95% CI 1,1-3,3; p<0,023) and heart rate at admission >110 per minute (HR 1,1; 95% CI 1,0-1,1; p<0,023).
Conclusions: Current study revealed strong role of kidney lesions in development of complications, in-hospital mortality and worse survival in patients with infective endocarditis.

Concomitant cardiomyopathies and their association with heart failure in subjects with bicuspid aortic valve

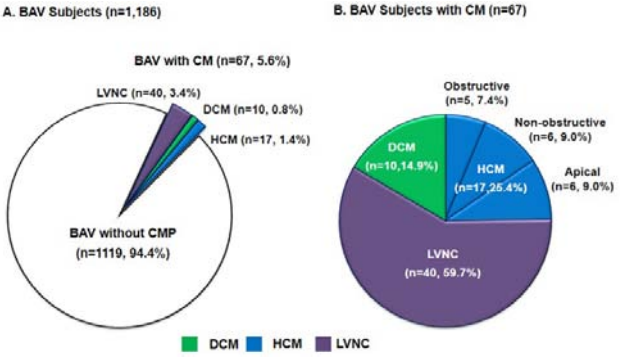
CY Chi Young Shim[1]; H Jeong[2]; D Kim[3]; SY Lee[4]; GR Hong[1]; JW Ha[1]
[1]Yonsei Cardiovascular Center, Yonsei University Medical Center, Seoul, Korea (Republic of); *[2]Hospital Myongji, Division of Cardiology, Goyang, Korea (Republic of)*; *[3]Samsung Medical Center, Seoul, Korea (Republic of)*; *[4]Sejong General Hospital, Bucheon-Shi, Korea (Republic of)*

Background: In this study, the prevalence, characteristics, and clinical significance of concomitant specific cardiomyopathies were investigated in subjects with bicuspid aortic valve (BAV).

Methods: We retrospectively evaluated 1,186 adults with BAV (850 males, mean age 56 ± 14 years). Left ventricular non-compaction, hypertrophic cardiomyopathy, and idiopathic dilated cardiomyopathy were diagnosed when patients fulfilled current clinical and echocardiographic criteria. Clinical and echocardiographic characteristics including comorbidities, heart failure presentation, BAV morphology, function, and aorta phenotypes in BAV subjects with or without specific cardiomyopathies were compared.

Results: Overall, 67 subjects (5.6 %) had concomitant cardiomyopathies: 40 (3.4%) patients with left ventricular non-compaction, 17 (1.4%) with hypertrophic cardiomyopathy, and 10 (0.8%) with dilated cardiomyopathy. BAV subjects with hypertrophic cardiomyopathy had a higher prevalence of diabetes mellitus, heart failure with preserved ejection fraction, and tended to have type 0 phenotype, while BAV subjects with dilated cardiomyopathy showed a higher prevalence of chronic kidney disease and heart failure with reduced ejection fraction. BAV subjects with left ventricular non-compaction were significantly younger, predominantly male, and had greater BAV dysfunction and a higher prevalence of normal aorta shape. In multiple regression analysis, presence of cardiomyopathy was independently associated with heart failure (odds ratio 2.866, 95% confidential interval 1.652–4.974, $p < 0.001$) even after controlling confounding factors.

Conclusion: Concomitant cardiomyopathies were observed in 5.6% of subjects with BAV. A few clinical and echocardiographic characteristics including comorbidities, heart failure presentation, BAV morphology, function, and presence of aortopathy were found. The presence of cardiomyopathy was independently associated with heart failure.



BAV cardiomyopathy

Validation of heart failure risk scales in patients with genetically proven idiopathic restrictive cardiomyopathy.

A Anna Kostareva[1]; V Bart[1]; A Polyakova[1]; A Gudkova[1]; M Sitnikova[1]
[1]Almazov Federal Centre of Heart, Blood and Endocrinology, St. Petersburg, Russian Federation

Funding Acknowledgements: Russian foundation of Fundamental Science 19-015-00313, SPbSU grant 11934817

Background: Several scales exist for assessing prognosis and risk of adverse events in patients with heart failure (HF). Identification of high-risk patients with HF with a high probability of reaching endpoints over the next year may serve as an indication for the active inclusion of the patient on the waiting list for heart transplantation. The difficulty of applying these scales for patients with idiopathic restrictive cardiomyopathy (RCM) is that most of the existing scales are developed and validated for a group of patients with HF-rEF, while the group of RCM is mainly represented by patients with HF-pEF. The most well-known survival scales for HF patients are Seattle risk scale (SHFM), HFSS scale, MAGGIC scale, MECKI scale, 3C-HF and MUSIC scale. The aim of the study was to estimate the potential validity (sensitivity and specificity) for several SHFM, MAGGIC, MUSIC and 3C-HF scales in a group of patients with idiopathic restrictive cardiomyopathy.Material and Methods: the study group included 35 patients with genetically proven RCM. Death and heart transplantation were considered as endpoints. ROC - analysis was performed using STATISTICA program, comparison between various risk scales was performed using Friedman test.

Results: the study included 35 patients with genetically proven RCM with a mean follow up 2,4 years [1 – 26], being 2,2 years [1 – 18] for patients presented in childhood and 5,6 years [1 – 26] for patients presented in adulthood. Transplantationfree5-yearsurvivalwas66,5%, 10-years survival was – 52,5%; 27% reached primary endpoints within three years after disease presentation. HF risk scales (SHFM, MAGGIC, MUSIC and 3C-HF) were tested only on patients SHFM, MAGGIC, MUSIC and 3C-HF) demonstrated high sensitivity and specificity with AUC=0,920, 0,947, 0,954 and 1.0 correspondingly (Figure 1). Risk scales including atrial fibrillation and atrial dimension parameters as factor (MUSIC and 3C-HF) demonstrated superior AUC compared to others scales (SHFM, MAGGIC).

Conclusion: we demonstrated that heart failure risk scales such as SHFM, MAGGIC, MUSIC and 3C-HF can be successfully applied in a cohort of patients with idiopathic RCM with superior specificity and sensitivity of scalesincluding parameters such as atrial fibrillation and atrial dimension (MUSIC and 3C-HF).

P1137

Prevalence and prognostic impact of non-ischemic late gadolinium enhancement in patients undergoing stress perfusion cardiac magnetic resonance.

C Grigoratos[1]; I Gueli[2]; C T Arendt[3]; D Leithner[3]; A Meloni[4]; C Nugara[5]; A Barison[4]; G Todiere[4]; V O Puntmann[3]; G Novo[5]; A Pepe[4]; E Nagel[3]; M Emdin[1]; G D Aquaro[4]
[1]Sant'Anna School of Advanced Studies, Pisa, Italy; *[2]Cisanello Hospital, Cardiac Thoracic and Vascular Department, Pisa, Italy*; *[3]JW Goethe University, Frankfurt am Main, Germany*; *[4]Gabriele Monasterio Foundation, Pisa, Italy*; *[5]University of Palermo, Palermo, Italy*

Funding Acknowledgements: C.G. received a research grant from the ConAlbe Onlus for the realization of this study.

Background: Stress perfusion cardiac magnetic resonance (stress-CMR) provides information on myocardial ischemia and fibrosis using Late Gadolinium

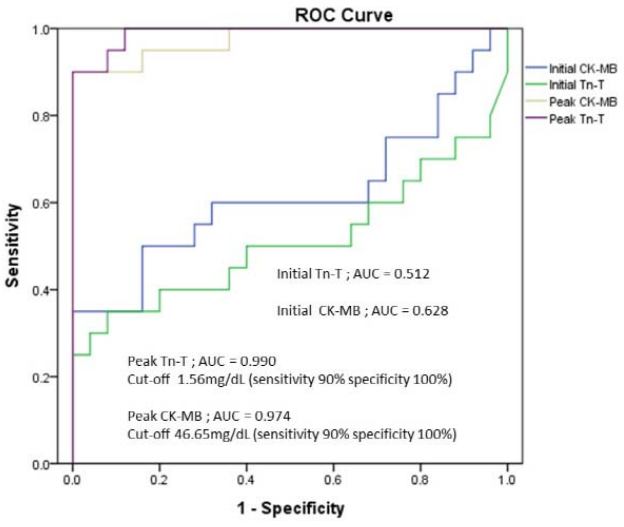
Enhancement (LGE). Usually an ischemic pattern of LGE (I-LGE) is expected and most frequent. However, non-ischemic LGE (NI-LGE) can be occasionally found suggesting alternative diagnosis. The prevalence and prognostic significance of NI-LGE in patients undergoing stress-CMR is yet to be defined.
Methods and results: Stress-CMR with either dipyridamole or adenosine was performed in 483 patients (355 males, 73%) and follow-up was completed in 269 (median time: 1850 days; interquartile range: 1225-2705 days). Composite endpoint included cardiac death, ventricular tachycardia, myocardial infarction, stroke, hospitalization for cardiac cause and coronary revascularization performed beyond 90 days from stress-CMR scans.
Two hundred and sixty-one patients (54%) had negative LGE (no-LGE), 165 patients (34%) I-LGE and 57 patients (12%) NI-LGE. Stress induced perfusion defects (ISCH) were found in 74 patients with no-LGE, 83 patients with I-LGE and 19 with NI-LGE. Fifty-six events occurred in the no-LGE group, 54 in I-LGE and 6 in the NI-LGE group. On Kaplan Meier curves patients with LGE had worst prognosis than patients without LGE, regardless of the presence of ISCH and type of LGE seen, either ischemic ($p < 0.0001$) or non-ischemic ($p < 0.005$). The additional presence of ISCH was associated with worse prognosis in patients with NI-LGE ($p < 0.05$).
Conclusion: Non-ischemic LGE can be detected in 12% of patients during stress-CMR providing a diagnosis of non-ischemic cardiac disease, which may be missed by alternative diagnostic tests. Patients with NI-LGE have worse prognosis than those with no-LGE. The additional presence of ischemia yields a worse prognosis in patients with NI-LGE.

P1138

Differential diagnosis of stress induced cardiomyopathy from anterior myocardial infarction with changing pattern of cardiac enzyme

SK Sung Kee Ryu[1]; YS Byun[2]; H Chung[3]; CW Goh[4]; JY Park[1]; SH Park[1]; JW Choi[1]
[1]Eulji University College of Medicine Eulji Hospital, Seoul, Korea (Republic of); [2]Inje University, Division of cardiology, Seoul, Korea (Republic of); [3]Kyung Hee Medical Center, Division of Cardiology, Seoul, Korea (Republic of); [4]Hallym University, Division of Cardiology, Chuncheon, Korea (Republic of)

In echocardiographic study stress induced cardiomyopathy (SCMP) has similar pattern of wall motion abnormality with anterior myocardial infarction. For definite differentiation coronary angiography is needed but always available due to poor general condition of SCMP patients especially in intensive care unit. The changing pattern of cardiac enzyme can be the clue for differential diagnosis of SCMP from anterior MI.
Method: We checked initial and follow-up peak CK-MB and troponin-T(Tn-T) level in acute anterior MI and SCMP from January of 2017 to December of 2018.
Result : 27 SCMP and 30 anterior AMI patients were enrolled. Mean age was 69.3 ± 14.1 years and female was 38.6%. Age was older, female proportion was higher, and LVEF was lower in SCMP group. (75.4±10.8 vs. 63.9±14.6 years, 66.7%vs.13.3% $p<0.01$, 41.3±8.4 vs. 46.9±9.7% $p<0.05$) Initial CK-MB was higher in MI group (23.3±43.5 vs. 5.9±5.1ng/ml $p<0.05$), but initial Tn-T was not significantly different. (0.9±1.8 vs. 0.2±0.3 ng/ml p=NS), But Peak Tn-T and CK-MB and their changes from initial level were significantly higher in AMI than SCMP group. (6.8±3.2 vs. 0.4±0.4ng/ml, 197.6±99.9 vs. 9.7±10.7ng/ml, 5.1±3.4 vs. 0.2±0.4, 174.3±102.7 vs. 3.8±8.2, $p<0.001$).



ROC curves for diagnosis of anterior AMI

Conclusion: Follow-up changes of cardiac enzyme can be a good tool for differential diagnosis of SCMP from anterior acute MI. We may rule out SCMP from AMI with peak Tn-T > 1.56 or CK-MB > 46.65ng/ml.

P1139

Characteristics of patients with advanced heart failure managed in a cardiomyopathy expert center

R-D Robert-Daniel Adam[1]; S Militaru[2]; A Ionescu[3]; M Chivulescu[4]; BA Popescu[1]; C Ginghina[1]; R Jurcut[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; [2]Cliniques Saint-Luc UCL, Cardiology, Brussels, Belgium; [3]Nouvel Hopital Civil, Cardiology, Strasbourg, France; [4]Oslo University Hospital, Rikshospitalet, Cardiology, Oslo, Norway

Background: Cardiomyopathies are a heterogenous group of intrinsic myocardial diseases most frequently genetic, whos evolution can lead to sudden cardiac death or heart failure (HF). Advanced HF (AHF) occurs when patients experience persistent severe symptoms that interfere with daily life despite maximum evidence-based medical therapy, as defined by severe persistent symptoms (NYHA class III-IV), severe cardiac dysfunction or high levels of BNP, pulmonary or systemic congestion requiring high-dose IV diuretics, episodes of low cardiac output requiring inotropes or malignant arrhytmias.
Purpose: to describe the particularities of the patients with genetic cardiomyopathies and AHF from the Expert Center for rare genetic cardiovascular diseases.
Methods: We evaluated cardiovascular parameters in all consecutive pts diagnosed with AHF in our center considering HFA-ESC criteria for defining AHF. All pts had a cardiomyopathy (dilated, DCM; hypertrophic, HCM; restrictive, RCM; arrhythmogenic, AC; specific diseases). Analyzed data on file included clinical, biologic (cardiac and renal markers), ECG, ECG holter and echocardiographic (conventional measurements and myocardial Doppler velocities and Speckle tracking based deformation study).
Results: The database included 22 pts consecutively diagnosed with AHF due to the evolution of a cardiomyopathy, with an average age of 46.2±13.9 years, 16 men (72.7%). The main diagnostics were: DCM (11, 50%), cardiac amyloidosis (5, 22.7%), HCM (2, 9.1%), RCM (2, 9.1%), Fabry disease (1, 4.5%) and AC (1, 4.5%). All patients were in NYHA class III (14, 63.6%) and IV (8, 36.4%), with INTERMACS between stages 1 and 6. Permanent pacemakers were present in 11 pts (50%), and ICDs in 7 pts (31.8%). Lab work-up showed very high levels of BNP (1608.6±1037.1pg/ml) or NTproBNP (10038.4±6008.3pg/ml), positive Troponin I (0.076±0.05ng/ml) and GFR below 60 mL/min in 11 pts (50%) at baseline. Atrial fibrillation was present in 10 pts (45.5%). Holter ECG study showed nonsustained VT in 9 pts (40.1%). Cardiac ultrasonography findings included: HpEF in 5 pts (22.7%) and HFrEF in 17 pts (77.3%), with LVEF ranges from 14% to 60%, abnormal LV longitudinal function (mean septal S' wave 3.8±1.1 cm/s), all pts had diastolic dysfunction (E/E' 23.1±10, LAVi 65.1±25.8 mL/m2). Mitral regurgitation was present in all 22 pts (severe in 8, 36.4%) and 18 pts (81.8%) presented indirect criteria for pulmonary hypertension. All pts received diuretics as part of their treatment, 20 (90.9%) needed diuretics associations, 18 (81.2%) required IV diuretics during their evolution and 3 of them (13.6%) inotropic agents.
Conclusions: Although they are not the most frequent causes of HF, genetic cardiomyopathies can lead to AHF that represents the end stage in the evolution of the disease in absence of a pathogenic treatment, leading to persistent symptoms and decreased quality of life, increasing the number of hospitalizations and their costs.

Funding Acknowledgements: Supported by Ministry of Health of Czech Republic Grant No 16-30537A

Introduction: In patients with newly diagnosed left ventricle (LV) dysfunction of non-ischemic etiology there is a considerable chance of recovery of LV function. It is known that the presence of myocarditis increases the chance of improving the left ventricle ejection fraction (LVEF) in comparison with patients without evidence of myocardial inflammation.
Purpose: To evaluate the differences in LVEF changes between inflammatory cardiomyopathy (ICM) and non-inflammatory dilated cardiomyopathy (DCM) groups in different time periods during the first year after the diagnosis was established.
Patient and methods: DCM group: 126 patients, 79% men and 21% women, mean age 48.6 ± 10.4 years, symptoms duration to diagnosis 2.9 ± 2.6 months. ICM group:

86 patients, 77% men and 23% women (p = 0.74 for the difference between groups), mean age 44.5 ± 12.6 years (p = 0.02), symptoms duration 2.3 ± 2.2 months (p = 0.07).
Results: In the DCM group, the baseline LVEF was 23.9 ± 7.0%, in the ICM group 24.3 ± 7.2% (p = 0.77). In the 12-month follow-up, LVEF in DCM group improved to 31.3 ± 10.3% (p 0.001), in ICM group to 41.1 ± 12.1% (p 0.001), the difference between the groups was 7.4 ± 9.9% (DCM) vs 16.8 ± 13.4% (ICM; p 0.001). In the first 3 months, LVEF increased by 3.9 ± 8.1% (DCM) vs 11.4 ± 9.7% (ICM; p 0.001), between the 3rd and 6th month by 2.0 ± 5.6% (DCM) vs. 3.8 ± 7.3% (ICM; p = 0.08) and between 6th and 12th month by 1.5 ± 6.7% (DCM) vs. 1.6 ± 7.3% (ICM; p = 0.63).
Conclusion: Although the improvement of LVEF in the ICM group was more pronounced throughout the first year after diagnosis in comparison to DCM group, statistical significance of the difference between the two groups was achieved only within the first 3 months after the diagnosis was established.

P1141
Efficiency of plasma exchange in patients with immune mediated dilated cardiomyopathy and arrhythmias

V Victoria Kulikova[1]; AV Nedostup[1]; OV Blagova[1]; VA Zaidenov[2]; AG Kupriyanova[3]; IA Nechaev[1]; AA Ragimov[1]
[1]I.M. Sechenov First Moscow State Medical University, Department of Internal medicine, Moscow, Russian Federation; *[2]Institute of Transplantology and Artificial Organs, Moscow, Russian Federation*; *[3]Research Clinical Institute of pediatrics, Moscow, Russian Federation*

Purpose: to investigate the clinical efficiency of plasma exchange (PE) in patients with arrhythmias and inflammatory dilated cardiomyopathy (iDCM) due to immune-mediated myocarditis in comparison with group without PE.
Methods: There were 20 patients with arrhythmias resistant to antiarrhythmic drugs (AADs) (premature atrial contractions (PACs, n=3), premature ventricular contractions (PVCs, n=8) more than 3000 per day, and atrial fibrillation (AF, n=9)) and 14 iDCM patients in the treatment group (left ventricular end-diastolic diameter (LVEDD) 6.3±0.6 cm, left ventricular ejection fraction (LVEF) 33.5±8.1%, NYHA functional class 2 [1;3]). All the patients had two or more fold increase of at least two anti-heart antibodies (AHA) level. PE group patients were underwent a single volume therapeutic PE. We also evaluated 26 patients with arrhythmias (PACs n=4, PVCs n=12, AF n=10) and 19 iDCM patients (LVEDD 6.6±0.8 cm, LVEF 32.6±7.3%, NYHA functional class 3 [2;3]) who were followed without PE. Patients underwent endomyocardial biopsy n=17), cardiac CT n=38, MRI n=21, myocardial perfusion scan n=39, and coronary angiography n=20 to diagnose myocarditis. Cardiac echo, AHA level and 6-minute walk test distance in iDCM patients and AHA level and Holter monitoring in patients with arrhythmias were assessed at baseline and with two follow-up (FU) visits in about 6 and 12 month in all groups.
Results: AHA level decreased just after PE and during the FU in the PE group (p<0.05). The iDCM PE group patients had significant improvement in LVEF (41.4±8.2% and 46.3±12.7% during FUs (p<0.05) vs. 39.1±13.7% and 37.2±10.7% in control group). 50% iDCM study group patients and 32% control group patients with absolute LVEF improvement >10% were classified as responders. Responders in the PE group had initial higher systolic PAP (44±13.4 vs. 27.9±6.0, p<0.05). 65% PE group patients with arrhythmias and 58% patients controls were classified as responders as they achieved a decrease of PAVs, PVCs or AF frequency > 75% relative to baseline. The PE group responders had a higher level of AHA to cardiac nuclear antigens at baseline, p<0.05. 45% PE group patients with arrhythmias and 73% control group patients got methylprednisolone respectively, p>0.05. The mean dose was 8[4;16] and 16[10;24] mg per day, p>0.05. 43% iDCM PE group patients and 89% control group patients got methylprednisolone, p<0.05. The mean dose was 11.8±6.6 and 21±12.4 mg per day respectively, p<0.05.
Conclusions: PE improves AAD's effect, cardiac function and daily activities in patients with immune mediated arrhythmias and iDCM. There were 65% and 50% PE group responders in patients with arrhythmias and iDCM respectively. Initial higher systolic PAP was good outcome predictor in iDCM patients. The high AHA level to cardiac nuclear antigens at baseline was significantly associated with good outcome in patients with arrhythmias. PE helps to avoid using immunosuppressive drugs or reduce its doses

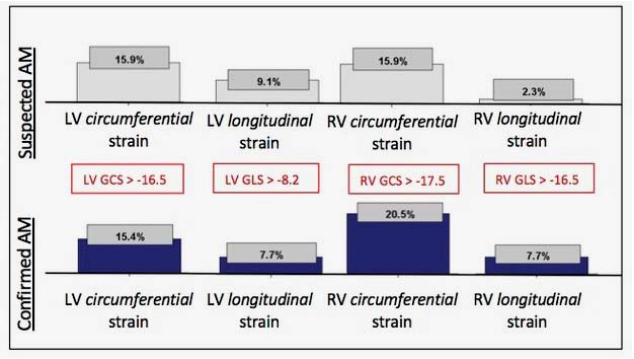
Strain analysis reveals subtle systolic dysfunction in "confirmed" and "suspected" myocarditis with normal LVEF: a cardiac magnetic resonance study

A Cannata'[1]; A Aldostefano Porcari[1]; M Merlo[1]; L Crosera[1]; D Stolfo[1]; M Cittar[1]; M Della Paolera[1]; G Barbati[2]; L Pagnan[3]; M Belgrano[3]; MA Cova[3]; P Gentile[1]; A Aleksova[1]; G Vitrella[1]; G Sinagra[1]
[1]University Hospital Riuniti, Trieste, Italy; *[2]University Hospital Riuniti, Biostatistics Unit, Department of Medical Sciences, Trieste, Italy*; *[3]University Hospital Riuniti, Department of Radiology, Trieste, Italy*

Background: Lake Louise Criteria (LLC) have a good accuracy for the diagnosis of acute myocarditis (AM) with normal left ventricular (LV) ejection fraction (EF). However, they are time dependent and some AM could be misdiagnosed, due to the limited accessibility of Cardiac Magnetic Resonance (CMR). Cardiac deformation imaging could be a novel tool in this setting of patients.
Purpose: Our aim was to assess a feature tracking (FT) imaging in patients with "suspected" and "confirmed" AM and normal LVEF without regional wall motion abnormalities.
Methods: Eighty-three patients with clinically suspected AM and normal LVEF were divided in two groups based on CMR-LLC: 39 positive LLC patients ("confirmed AM group") and 44 negative LLC patients ("suspected AM group"). An age and gender-matched control sample of 42 normal subjects underwent CMR as well. Cardiac strains of both ventricles were measured by FT analysis in all groups. Lower cut-off for normal values were defined by the 5th percentiles of control group strain values.
Results: Compared to controls, both "suspected" and "confirmed" AM patients showed significantly impaired LV global longitudinal strain [p=0,004; 7.7% and 9.1% in "confirmed" and "suspected" AM, respectively], LV global circumferential strain [p=0,04; 15.4% and 15.9%, respectively] and right ventricular global circumferential strain [p=0,013; 20.5% and 15.9%, respectively]. No significant differences in FT analysis between "confirmed" and "suspected" AM were found.
Conclusions: CMR-FT derived strain analysis can identify patients with "suspected" and "confirmed" AM with subtle ventricular dysfunction compared to healthy subjects and suggests the need for new diagnostic tools in AM.



P1143
Biomarkers of iron status (transferrin saturation, serum ferritin) in the course of acute myocarditis: relations with neurohormonal activation, cardiac dysfunction and clinical recovery

P Franczuk[1]; A Kosiorek[1]; M Tkaczyszyn[1]; M Drozd[1]; A Zapolska[1]; T Walczak[1]; K Kulej-Lyko[2]; N Sidorowicz[2]; A Soltowska[3]; W Banasiak[4]; J Jaroch[3]; P Ponikowski[2]; EA Jankowska[1]

Funding Acknowledgements: This research was financially supported by the National Science Centre (Poland) grant number 2014/13/B/NZ5/03146.

Introduction: Immune response is considered the major pathophysiological trigger leading to acute myocarditis (MCD). Optimal iron status is essential for the functioning of immune cells, cardiomyocytes and cardiofibroblasts. Therefore, there are premises to consider iron metabolism as a significant modulator of complex pathophysiology of MCD.
Purpose: We aimed to assess iron status in the course of MCD and relate it with clinical and laboratory measures.
Methods: We prospectively enrolled consecutive patients hospitalized for acute MCD in 2 tertiary referral cardiology centers during 2015-2018 and followed them up for 30 weeks. MCD was diagnosed based on the following criteria: 1) new onset symptoms suggestive of myocarditis (effort intolerance, dyspnea, palpitations or

chest pain), 2) elevated high sensitivity cardiac troponin I (hs-cTnI), 3) exclusion of obstructive coronary artery disease.

Results: Study group comprised 41 patients with confirmed MCD [age: 31 (26–34) years, men: 95%] and 15 healthy age- and gender-matched subjects [age: 30 (28–33) years, men: 87%]. All patients survived hospitalization and follow-up, no subject needed ventricular assist device.

Patients with MCD had lower LVEF (56±10% vs. 69±14%) and higher CRP [32 (14–8754) vs. 3 (3–3) mg/l], NT-proBNP [452 (240–877) vs. 33 (18–46) pg/ml], hs-cTnI [7.3 (3.3–12.8) vs. 0,01 (0.01–0.01) μg/l] than the control group (all p<0.001). Regarding iron status, MCD group presented higher serum ferritin [213 (121–386) vs. 135 (84–210) μg/l] and lower transferrin saturation (TSAT) [21±10 vs. 28±15%] (all p<0.05). In patients with MCD ferritin correlated with CRP (r=0.46, p<0.01), TSAT correlated neither with CRP nor with ferritin (all p>0.02).

Patients with MCD and NT-proBNP >1000 pg/ml had lower TSAT (16±8 vs. 23±9%; p<0.05) and LVEF (47±13 vs. 59±7%; p<0.001) than the remaining subjects. No difference in ferritin was observed (p>0.2). 46% of patients during acute phase of MCD had LVEF≤55% – these patients presented lower TSAT (17±8% vs. 24±10%) and higher NT-proBNP – [577 (436–1657) vs. 358 (167–499) pg/ml] (all p<0.05). After 30 weeks only in 13% patients LVEF≤55% persisted and related to lower baseline TSAT (9±1% vs. 21±9%) and higher CRP (147±113 vs. 52±40 mg/l) (all p<0.05). LVEF≤55% was not related to ferritin (both p>0.2).

After 6 weeks of follow-up patients with MCD already presented higher LVEF (61±8%; p<0.05) and haemoglobin [14.7 (14.0–15.7) g/dl], lower CRP [3 (3-3) mg/l], NT-proBNP [34 (25–67) pg/ml], hs-cTnI [0.01 (0.01–0.01)], ferritin [124 (78–168) μg/l] and higher TSAT (26±7%) (all p<0.01). There was no further change in these parameters within the next 24 weeks (all p>0.2).

Conclusions: In patients with acute MCD, iron status is deranged. In these patients serum ferritin is an indicator of inflammatory response, whereas TSAT relates to neurohormonal activation and cardiac dysfunction. Iron status normalizes within 6 weeks after acute phase of MCD.

Cardiovascular Surgery - Transplantation

P1145

Long-term survival after heart transplantation or implantation of mechanical circulatory support in patients with advanced heart failure due to giant cell myocarditis or cardiac sarcoidosis

E Emanuele Bobbio[1]; S Esmaily[1]; S Bartfay[2]; E Bollano[2]; P Dahlberg[2]; G Dellgren[3]; K Karason[2]

[1]Sahlgrenska Academy - University of Gothenburg, Goteborg, Sweden; *[2]Sahlgrenska University Hospital, Cardiology, Goteborg, Sweden*; *[3]Sahlgrenska University Hospital, Transplantation, Goteborg, Sweden*

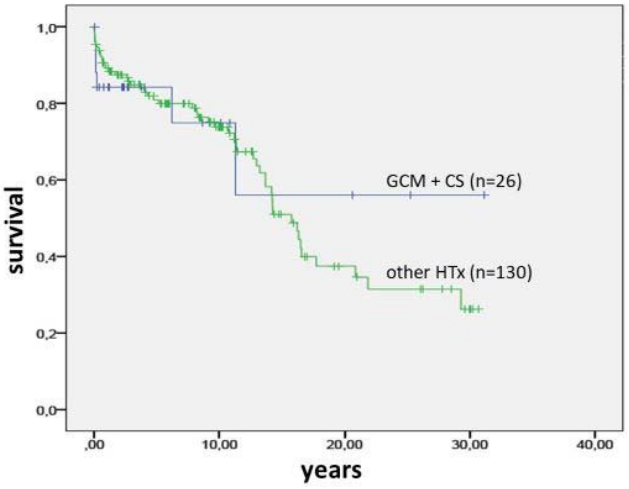
Background: Giant cell myocarditis (GCM) and cardiac sarcoidosis (CS) are rare inflammatory disorders that may cause cardiomyopathy. Both are generally progressive and often require advanced heart failure (HF) therapies. The long-term survival of patients with GCM or CS treated with heart transplantation (HTx) or mechanical circulatory support (MCS) is poorly investigated.

Purpose: To investigate outcome of patients with GCM or CS who undergo HTx or implantation of MCS.

Methods: Data from all patients who received HTx or MCS due to GCM or CS at our Institution between 1990s and 2018 was reviewed. Data was compared to 130 controls that were treated with HTx due to all other heart diseases, 5 for each patient included, matched by sex, age, and HTx duration.

Results: A total of 26 patients who underwent HTx or received MCS because of GCM or CS were included. Fifteen of them (58%) suffered from GCM and 11 from CS. Endomyocardial biopsy confirmed diagnosis in 10/15 (67%) patients with GCM and 4/11 (36%) patients with CS and the remaining were diagnosed by pathological investigation of the explanted heart. Altogether 8/15 (53%) of GCM patients and 2/11 (18%) of CS patients required implantation of durable MCS, but 2 patients with GCM died before HTx. Treatment-requiring cardiac allograft rejection was observed in 6/13 (46%) GCM patients and in 1/11 (9%) CS patients. Disease recurrence in the graft was identified in 2/13 (15%) patients with GCM as well as in 2/11 (18%) CS-patients. The mean survival time was numerically higher for patients with ICM (20.2 years, 95 % CI=12.2-28.2) than for the control group (16.9 years, 95 % CI=14.5-19.4), but the difference was not statistically significant (log-rank test (p=0.75) Breslow-test (p=0.68)).

Conclusion: Patients with GCM or CS with advanced HF who are treated with HTx or MCS have similar long-term survival as HTx recipients treated due to all other heart diseases.



Kaplan-Meier curve

Anti-thymocyte globulin induction therapy usage is not associated with short and long-term survival differences in heart transplant patients

S Jia[1]; D Nagpal[2]; L Goldraich[3]; RA Davey[3]; R Mckelvie[3]; S De[3]; SJ Smith[3]

[1]University of Western Ontario, Schulich School of Medicine and Dentistry, London, Canada; *[2]London Health Sciences Centre, Cardiac Surgery, London, Canada*; *[3]London Health Sciences Centre, Cardiology, London, Canada*

Purpose: The use of induction therapy for heart transplant remains in debate. Additionally, agent choice is a major consideration for centers and may influence survival outcomes. It is important to have evidence-based justification for the usage of induction therapy agents due to costs and risks.

Methods: A retrospective analysis of heart transplant patients who received anti-thymocyte globulin (ATG), anti-lymphocyte globulin (ALG), and muromonab-CD3 (OKT3) at a tertiary academic center was conducted. Patients who received cyclosporine (CyA) alone served as control. Baseline characteristics were collected for each group. Survival at 3 months, 1 year, and 10-year post transplant were compared.

Results: A total of 513 patients receiving induction therapy or CyA between April 1981 and September 2007 were included. Mean baseline characteristics of the three groups are detailed in Table 1. At 3-months post transplant ATG, ALG, OKT3, and CyA had survival rates of 78.7, 81.6, 85.1, and 61.9 percent, respectively. The survival 1-year post transplant for ATG, ALG, OKT3, and CyA were 74.5, 76.4, 81.1, and 61.9 percent, respectively. After 10-years post transplant 56.4, 53.6, 47.3, and 33.3 percent of ATG, ALG, OKT3, and CyA receiving patients survived, respectively. P>0.5 for all intervals.

Conclusions: Anti-thymocyte globulin is not significantly associated with short and long-term survival differences in heart transplant patients compared to no induction and off-market induction agents. Further controlled trials are needed to provide additional evidence for current use.

Table 1. Baseline characteristics of ind

Induction Agent	ALG	ATG	OKT3	CyA
N	250	94	148	21
Ischemic Time Minutes	200.6 (±85.8)	235.6 (±90.8)	213.0 (±83.7)	150.6 (±60.3)
Donor Age	27.8 (±11.5)	34.5 (±13.4)	32.3 (±12.2)	23.0 (±6.7)

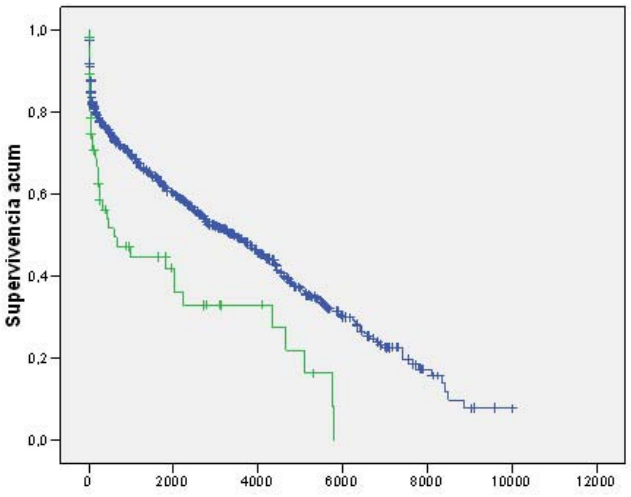
Does the age of the recipient influence the survival of the heart transplant?

RLV Lopez-Vilella[1]; ISL Sanchez-Lazaro[1]; ME Ezzitouny[1]; SLE Lozano Edo[1]; LMD Martinez Dolz[1]; LAB Almenar Bonet[1]
[1]*Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit. Cardiology Department, Valencia, Spain*

Objectives: There are many factors that are associated with mortality in heart transplantation HT). Although in earlier stages of HT the indications were limited to recipients less than 60 years of age, the continuous improvement of clinical results has encouraged the expansion of selection criteria, offering the option of HT to patients up to 70 years of age. There are no studies, based on extensive and multicentric data, that analyze the evolution and influence of the age of the recipient HT on survival. The objective of this study was to know the influence of the age of the recipient on the mortality of the heart transplant.
Methods: It is a retrospective study. All heart transplants performed in our center from 1993 to december 2018 were consecutively selected. Pediatric transplants, combined transplants and retransplantation were excluded. The data were extracted from the National Registry of Cardiac Transplantation.

Table 1

	Recipient <65	Recipient ≥65	p
Series overall survival (days)	3875±155	2077±353	<0.001
Survival at 30 days (n,%)	648 (88.3%)	44 (78.6%)	0.034
Survival at 6 months (n,%)	558 (76%)	34 (60.7%)	0.011
Survival at 12 months (n,%)	529 (72.1%)	26 (46.4%)	<0.001



Results: 802 patients were selected. The majority were males (661 patients, 83.5%), with an average age of 52 ± 11 years. 7.5% of the recipients were 65 years of age or older (60 patients). Long-term overall survival was lower in recipients older than 65 years (Figure 1). If survival data are analyzed in the short and medium term, we found that recipients aged 65 or older had a lower survival at 30 days, at 3 months and at 1 year after transplantation (Table 1). In addition, within the group of recipients aged ≥ 65 years, survival was lower in the subgroup of patients aged 69 years or older (2050 ± 409 days in recipients aged 65-66 years, 2145 ± 787 days in recipients 67 to 68 years and 924 ± 505 days in recipients 69 years of age or older, p. 0.8), although there was a small number of patients in this last subgroup.
Conclusions: HT recipients older than or equal to 65 years have a shorter survival in the short, medium and long term. Given the increasing number of elderly recipients in recent years, studies with a larger number of patients will be necessary to analyze the impact of these findings.

P1148

Usefulness of the biomarker CA125 in the diagnosis of acute cellular rejection in allogeneic heart transplantation

RLV Lopez-Vilella[1]; ISL Sanchez-Lazaro[1]; CA Aguado[2]; NMF Manchenyo Franch[3]; ME Ezzitouny[1]; SLE Lozano Edo[1]; BL Laiz[2]; LMD Martinez Dolz[1]; LAB Almenar Bonet[1]
[1]*Hospital Universitario y Politécnico La Fe, Heart Failure and Transplant Unit. Cardiology Department, Valencia, Spain*; [2]*Hospital Universitario y PolitÇcnico La Fe, Clinical Analysis Department, Valencia, Spain*; [3]*Hospital Universitario y PolitÇcnico La Fe, Pathological Anatomy Department, Valencia, Spain*

OBJECTIVES: CA 125 has emerged as a marker of congestion in acute heart failure (HF). The evolution of CA125 in patients with heart transplantation (HT) and if the presence of a rejection is associated with an increase in its values is unknown. The objectives of this study are to describe the evolution of CA125 during the first year after HT and to evaluate the association between CA125 levels and the appearance, during the first year after transplantation, of acute cellular rejection. METHODS: A retrospective study in which all patients undergoing HT were selected from 2017 to 2018. Combined transplants, retransplantation, pediatric and patients who died before performing the first endomiocardial biopsy were excluded. CA 125 was determined before transplantation, and in all the post-transplant reviews: In the first week after transplantation, and in months 1.5, 3, 4, 5, 6, 9 and 12. Endomyocardial biopsy was performed in all these reviews. Cellular rejection was classified using the 2004 ISHLT criteria. The total number of patients included was 23, with 103 reviews with. RESULTS: 78.3% were males. In 19 of the 23 patients there was at least one determination of CA125 prior to transplantation, and if there were several determinations, the one closest to the HT was selected. The mean value of CA125 pretransplant was 138.78 ± 199 U / mL. Figure 1 shows the evolution of CA125 after the transplant. One month after the transplant, the average value of CA125 had been reduced to almost a quarter. After 6 months it tends to remain stable. There were 54 biopsies without rejection (52.4%), 44 with 1R (42.7%) and 5 with 2 R (4.9%). There was a tendency towards slightly higher levels of CA125 in relation to those biopsies that showed some degree of cellular rejection other than 0 R (Table 1), however, this association did not reach statistical significance. If we compare the mean value of CA 125 in patients with grade 2R acute cellular rejection, it is higher than the mean of patients with 1R rejection or without rejection (20 vs 50 U/mL respectively, p 0.02).
Conclusions: The rapid reduction of CA 125 corroborates its usefulness as a marker of congestion. The most advanced degree of rejection has the highest values of CA125. However, the elevation is light and with few cases. More studies and will be needed, in order to find a value that suggests rejection and be able to consider it as a useful marker in the non-invasive diagnosis of rejection.

Table 1

	CA125 (mean±ED)	p
No rejection (0R)	21.12± 17.76U/mL	0.44
Rejection (1R, 2R)	25.53± 29.2 U/mL	0.44

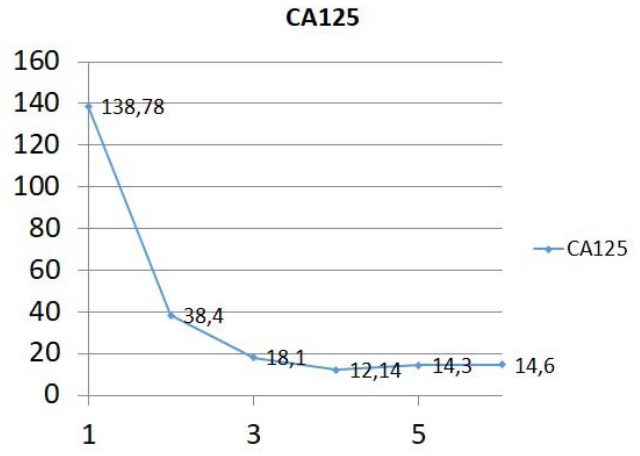


Figure 1

P1149

The impact of ischemic time and procurement distance on long-term survival following heart transplantation in a tertiary care center: 30 years of experience

S Jia[1]; D Nagpal[2]; L Goldraich[3]; P Pflugfelder[3]; RA Davey[3]; R Mckelvie[3]; S De[3]; X Cai[3]; SJ Smith[3]

[1]University of Western Ontario, Schulich School of Medicine and Dentistry, London, Canada; *[2]London Health Sciences Centre, Cardiac Surgery, London, Canada*; *[3]London Health Sciences Centre, Cardiology, London, Canada*

Purpose: Determining the boundaries of the catchment area for receiving donor hearts has important consequences in the balance between transplant ischemic times and increasing the supply of hearts. This is especially important in countries where there are large geographic distances, such as in Canada.
Methods: A retrospective analysis of all patients since the initiation of the heart transplant program at a tertiary academic center were included. Ischemic time and procurement distance were obtained from the surgical and medical records and survival data was collected for up to 10 years post transplant. Comparisons of mean ischemic time and procurement distance were made between short (3 months), medium (1 year), and long (10 years) term survivors and those that died.
Results: 513 patients between April 1981 and January 2009 were included. Patients that survived 3 months post transplant had a mean ischemic time of 211 minutes whilst those that did not had a mean ischemic time of 202 minutes. After 1-year post transplant, the mean ischemic time was 211 minutes for the survivors and 201 minutes for those that did not survive. And after 10-year post transplant, the mean ischemic time was 216 minutes for the survivors and 201 minutes for those that did not survive. P was greater than 0.05 for the difference in mean ischemic time for all survival intervals analyzed. Chi square analysis for the difference in survival at 3 months, 1 year, and 10 years for mean ischemic time categories of <2 hours, 2-4 hours, and >4 hours also did not show significance. Similarly, patients that survived 3 months post transplant had a mean procurement distance of 652 km whilst those that did not had a mean procurement distance of 586 km. After 1-year post transplant, the mean procurement distance was 643 km for the survivors and 631 km for those that did not survive. And after 10-year post transplant, the mean procurement distance was 667 km for the survivors and 621 km for those that did not survive. P was greater than 0.05 for the difference in mean procurement distance for all survival intervals analyzed. Chi square analysis for the difference in survival at 3 months, 1 year, and 10 years for mean procurement distance categories of <500 km, 500-1000 km, and >1000 km also did not show significance.
Conclusions: There were no significant difference in short, medium, and long-term survival outcomes with regards to ischemic time and transport distance. Further multi-centered and multi-geographical studies are needed to determine if there is a benefit to restricting donor catchment area to improve transport time.

[1]University Hospital of Guadalajara, Department of Cardiology, Guadalajara, Spain; *[2]University Hospital of Guadalajara, Cardiac Rehabilitation Unit, Guadalajara, Spain*; *[3]Hospital General de Ciudad Real, Nefrology, Ciudad Real, Spain*

Introduction: The physiopathological mechanisms of exercise in patients with coronary disease undergoing revascularization are not yet fully known. The aim of this study is to determine the abnormalities of the different parameters of the ergometry with the oxygen consumption in patients with multivessel coronary disease, without evidence of ischemia.
Methods: Cross-sectional study. A total of 220 patients were evaluated, an exercise ergometry with oxygen consumption (ECO) was evaluated after 1 to 2 months after suffering an acute coronary event, pacientes with ergometry positive for ischemia were excluded. Patients were divided into two groups: group 1 those with single coronary vessel disease and group 2 those with disease of 2 or more vessels.
Results: Mean age was 57.5 + 8.8 years, 14.5% (32 patients) were women, mean LVEF 56.4±9.6%, 51.8% had disease of 2 or more coronary vessels. Regarding the baseline characteristics, patients with coronary disease multiple had older ages (59.1Vs.55.9 years, p=0.007), higher percentage of hypertensive patients (64%Vs37.7%, p<0.001), and peripheral arteriopathy (14%Vs4.7%, p=0.02). The univariate analysis of the different ECO parameters is shown in Table 1. In the multivariate analysis, it was found that hypertensive individuals were independent predictors of multivessel disease (OR 2.11, CI 3.85-1.15, p=0.016), peripheral arterial disease (OR 3.85, CI 14.08-1.05, p = 0.042) and higher VE/VCO2 slope (OR 1.08, CI 1.014-1.143, p=0.016) .
Conclusions: there were no statistically significant differences at aerobic capacity and cardiac output determined during the exercise test with oxygen consumption among patients with multivessel and single vessel disease. On the other hand, patients with multivessel disease were worse at ventilatory parameters. Furthermore, at the multivariate logistic regression test the VE/VCO2 slope was demonstrated as an independent predictor of multivessel disease. In brief these results may be influenced by a depressed production of nitric oxide during exercise which blunts the pulmonary vasodilatation response to exercise, contributing to V/Q mismatch.

VARIABLES	Multivessel	P

Introduction: Cardiorespiratory Fitness (CRF) is associated with a high risk of cardiovascular disease and all-cause mortality. The reference range for CRF may differ among nations, with Asians under-represented.
Purpose: We sought to establish reference values of CRF for Asians.
Methods: We analyzed 2646 healthy Korean adults recently enrolled with estimated maximal oxygen uptake (VO2max) values during treadmill test. Patients with cardiovascular or renal disease, systemic infection, pregnant women and those with injuries unable to measure physical fitness were excluded. Age-specific mean VO2max values were compared with those from recent American, Norwegian, Danish cohorts and old Korean data.
Results: Age-specific reference values for healthy Korean adults were as shown (Table). A nomogram was drawn to predict exercise capacity for a given age and MET value (Figure). Compared to other countries, Asians showed less CRF reduction as aging than other Westerners. Compared to old Korean data from the 1980s, adjusted values were similar, except for those under 30 years old which decreased.
Conclusions: While there was no significant change in CRF over time in the same ethnic group, there was a clear inter-ethnic difference. CRF should be assessed according to ethnic or national standards, and it is necessary to establish a reference for each nation or ethnicity with periodic updates.

Cardiorespiratory fitness of Koreans

Men	Women						
Age	VO2max (ml/kg/min)	N	P-value fortrend*	Age	VO2max (ml/kg/min)	N	P-value fortrend*
19-29	42.3±(6.3)	209	< 0.01	19-29	34.3±(4.3)	110	< 0.01

[1]University Hospital of Guadalajara, Guadalajara, Spain; *[2]Hospital General de Ciudad Real, Nefrology, Ciudad Real, Spain*; *[3]University Hospital of Guadalajara, Cardiac Rehabilitation Unit, Guadalajara, Spain*

Introduction: Patients with chronic obstructive pulmonary disease (COPD) have a higher risk of cardiovascular morbidity and mortality, with ischemic heart disease being the main cause of death among these patients. This study has been developed with the intention of providing information on cardiac efficiency to exercise in this type of patients.

PARAMETERS	COPD	P	
YES	NOT		
METS	6,6+1,6	8,5+2,3	<0,001
VO2 peak (ml/kg/min)	16,2+5,1	21,1+5,9	<0,001

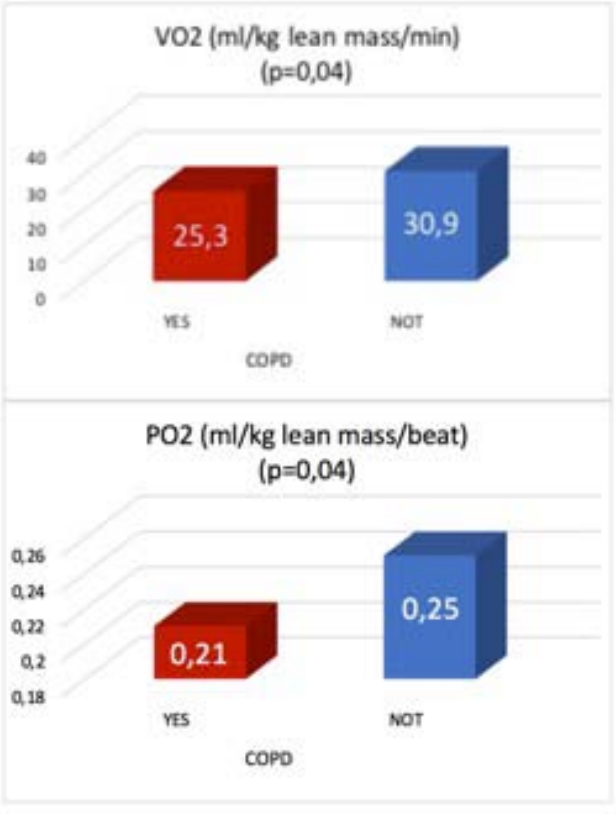
BR: respiratory reserve



Methods: Cross-sectional study. 162 patients subjected to ergometry with oxygen consumption, with a diagnosis of ischemic heart disease who underwent cardiac catheterization for an acute coronary syndrome, between 2 and 3 months prior to the test, excluding those with a positive result for ischemia myocardial. The diagnosis of COPD was established by spirometry at rest and cardiac efficiency and aerobic capacity using pulse oxygen (direct relationship with cardiac output) and peak oxygen consumption.
Results: A total of 162 patients were evaluated, the mean age was 57.8±8.8 years, 24 pct (14.8%) had moderate-severe COPD, 13% women, mean LVEF 55.6±10.2%. Patients were divided into 2 groups (moderate-severe COPD and without COPD/mild bronchopathy). Among the baseline characteristics of both groups, we found that the bronchopathies had a higher BMI (p=0.002), without finding differences in other CVRF and echocardiographic parameters. In the multivariate analysis, moderate-severe chronic bronchopathy was independently associated with a worse aerobic capacity (β: -0.31,95% CI -0.51,-0.11; p=0.003). The parameters of oxygen consumption in absolute value and adjusted per kg of lean mass are detailed in the table.
Conclusions: The COPD was associated independently with a worse aerobic capacity, with a lower cardiac response to exercise expressed in a lower pulse of oxygen, despite not showing significant differences in LVEF. In addition, the ventilatory parameters were altered with a worse relation of ventilation/perfusion.

Introduction: Cardiac rehabilitation (CR) is a secondary prevention method for the treatment of cardiovascular diseases and associated with a reduction in both cardiac morbidity and mortality. CR improves functional capacity and perceived quality of life whilst also supporting early return to work and the development of self-management skills. Bioelectrical impedance spectroscopy is applied to measure changes in body composition based on the frequency-dependent electrical properties of tissues. The objective of this study was to analyze the effects of CR on body composition of patients with ischemic heart disease as evaluated by bioelectrical impedance analysis.
Methods: CR programme was performed to the participants with an integrated multidisciplinary team consisting of cardiologist, experienced nurse and physiotherapist in the CR center of our hospital. Body composition was noninvasively assigned by the bioelectrical impedance analysis using the TANITA MC-980 segmental body composition analyser before and after the CR program. All data entered into a dataset and "before & after" comparison was made between dependent variables.
Results: This study enrolled 112 patients (mean age: 57.5±9.4; male:78) who participated in CR program after the diagnosis of ishemic heart disease between 2016 and 2019. The median duration of CR was 38 (30-49) sessions. Body mass index (30.7±4.7 vs. 29.7±4.1 kg/m2; p<0.001), body fat mass (25.3±8.7 vs. 23.4±7.8 kg; p<0.001), body fat percentage (30.2±7.6 vs. 28.9±7.3 %; p<0.001), visceral fat percentage (13.1±4.1 vs. 12.2±3.9 %;p<0.001), body fat free mass (56.6±8.9 vs. 56.1±8.8 kg; p=0.003), body muscle mass (54.1±8.1 vs. 53.3±8.7 kg; p=0.009), body fat to fat free mass ratio (0.45±0.17 vs. 0.43±0.18; p<0.001) and metabolic age (59.5±11.5 vs. 56.9±11.3 years; p<0.001) decreased significantly after CR. Whereas, body muscle to fat mass ratio (2.42±0.82 vs. 2.56±0.87; p=0.004), body muscle to visceral fat mass ratio [16.4 (13.2-25.3) vs. 19.1 (14.1-28.9); p<0.001] and body fat to visceral fat mass ratio [7.7 (6.2-10.1) vs. 8.3 (6.7-10.2); p<0.001] increased significantly after CR. Total body water (40.5±5.9 vs. 40.3±6.2 kg; p=0.454) and basal metabolic rate [1709 (1487-1837) vs. 1692 (1464-1824) kcal/day; p=0.374] did not significantly differ after CR .
Conclusion: This study revealed that CR had beneficial effects on body mass composition in patients with ischemic heart disease. Body composition evaluation by bioelectrical impedance spectroscopy may be used as an easy and fast technique for the assessment of patients referred to CR and should be routinely performed.

P1154

Impact of combined multimodal approach (recommended pharmacological treatment, cardiovascular rehabilitation and dietary compliance) in rehospitalization and morbidity rate of heart failure patients.

[1]General Hospital of Serres, CORONARY UNIT, Serres, Greece; *[2]Ahepa University Hospital, Thessaloniki, Greece*; *[3]Evangelismos General Hospital of Athens, Athens, Greece*; *[4]Amalia Fleming Hospital, Dept of Internal Medicine, Athens, Greece*; *[5]Onassis Cardiac Surgery Center, Athens, Greece*; *[6]Tzaneio General Hospital of Piraeus, Cardiology Department, Athens, Greece*; *[7]Ahepa University Hospital, 1st Propedeutic Dept of Internal Medicine, Thessaloniki, Greece*

Background: Heart Failure (HF) is a clinical syndrome accompanied by either, reduced or preserved ejection fraction or mixed features. The goals of treatment of HF patients are to improve their clinical status, functional capacity and quality of life, prevent hospital admission and reduce mortality and morbidity. There are few medical reports investigating the effect of combined optimal pharmacological treatment according guidelines (OFT), participating at cardiovascular rehabilitation program (CRP) and restricted HF dietary program (DP) compliance, in rehospitalization rate of HF patients, in order to reduce HF morbidity (MO) and mortality (Mo).
Purpose: In our study we investigate whether, the combination of OFT, CRP before discharge and compliance of recommended dietary guidelines results in reduction of HF patients' rehospitalization, MO and Mo.The period of our study was the 1 year after patients discharge.
Patients and Methods
30 patients with HF of various etiologies [15 male (M),15 female(F),average age 65years], treated only with OFT and another group of 30 patients (15 M,15 F, average age 65 years), treated with OFT,CRP during their last hospitalization due to decompensated HF, and restricted DP (maintain water balance, avoiding salt intake, daily weight measurement, adjustment of diuretic therapy).CRP included the mobilization of the patient (active bending movements and extension of the upper and lower limbs on a bed, familiarization with self-care and self-service activities, muscle pump activation exercises) and pulmonary physiotherapy (diaphragmatic breathing training, cough exercise, combined movements of upper limbs and respiration).
Results: We found statistically significant difference (p<0.05) between the two groups, in rehospitalization rate due to decompensated HF, in the period of the one year after their discharge from the hospital. The group of patients with only intervention the OFT, rehospitalizion due to decompensated HF was more frequently (50%) in comparison to multimodal approach group (OFT,CRP and DP).
Conclusion: The combination of OFT,CRP before the discharge of hospitalized patients due to decompensated HF and following of DP, provokes a beneficial effect to various physiological mechanisms (avoiding muscle mass reduction, increase of venous return, myocardial contractility promotion, afterload reduction, increase of preload, disturbance of autonomic nervous system function preventing arrhythmias, increased alveolar ventilation, reduction of subjective feeling of dyspnea-fatigue, increase of lung capacity and strengthening of respiratory muscles). Those mechanisms presents a positive hemodynamic response in cardiac function, concluding that the multimodal approach of HF patients after their discharge from the hospital leads to reduction of rehospitalization rate, of morbidity, increasing survival rate and so saving of financial resources in health care systems.

Usefulness of exercised based cardiac rehabilitation in heart failure patients with chronic total occlusions

I Ivana Burazor[1]; M Moraca[1]; A Kovacevic[1]; S Juricic[2]; A Djordjevic Dikic[2]; S Stojkovic[2]; P Seferovic[2]; B Beleslin[2]; Y Adler[3]; D Constatinos[4]; M Ostojic[5]
[1]Institute for treatment and rehabilitation, Belgrade, Serbia; *[2]University Clinical Center of Serbia, Belgrade, Serbia*; *[3]Chaim Sheba Medical Center, Tel Hashomer, Israel*; *[4]Academy of Athens Biomedical Research Foundation, Athens, Greece*; *[5]Institute for Cardiovascular Diseases Dedinje, Belgrade, Serbia*

Current data suggest that successful percutaneous coronary intervention for chronic total occlusions (CTO) is associated with improvement in patient symptoms, quality of life, left ventricular function, and survival. We aimed to investigate usefulness of exercised based cardiac rehabilitation in functional capacity improvement in heart failure patients with CTO after myocardial infarction (MI) and by pass surgery.
Patients and methods: Medical records from Cardiac rehabilitation Department, Institute for Rehabilitation were screened for patients with previous MI and CTO. Medical data of the identified cases was retrieved and reviewed. Patients were divided according to ejection fraction (EF) in to 3 groups: with reduced EF (<40), mild range EF (40 to 49) and preserved EF (>50).
Results: Out of 3225 patient screened patients, previous MI with CTO was diagnosed in 118 patients (92% were males, 33 to 84 years of age). PCI recanalization was successful in 14%. Risk factors were noted. Blood was sampled for lipid analysis. Target TC and LDL levels were reached in 100%. Previous medical treatment and ejection fraction were noted (20% with EF<40%,34% with EF from 40 to 49, and 46% with EF >50%). Exercise test was performed on admission and exercise based cardiac rehabilitation program was tailored individually. One to two treatment sessions per day were given by a physiotherapist seven days a week. No rhythm disorders or ST segment changes were detected by telemetry while crossing over Nyllin steps, cycling or free walking. Patients fulfilled cardiac rehabilitation program

without any complications. Exercised tests on discharged (21st day) have shown functional capacity improvement in all patients greater than 30%.
Conclusions: Patients with previous MI and CTO are not often referred to secondary prevention exercise based cardiac rehabilitation program. Our results showed that the programs are safe and useful in heart failure patients regardless EF. Further efforts are required to set up guidelines for long term management and cardiac rehabilitation might have important role.

P1156
Influence of the gender in response to phase ii of the cardiac rehabilitation program. evaluation of aerobic capacity and analytical parameters

N G Uribe Heredia[1]; J Balaguer Recena[1]; LG Piccone Saponara[2]; R Arroyo Espliguero[3]; M Viana Llamas[3]; H Alvaro Fernandez[1]; E Vallejo Sacristan[1]; ME Jimenez Martinez[3]; E Diaz Caraballo[3]; B Tarancon Zubimendi[3]; S Moreno Reviriego[3]; MA San Martin Gomez[3]; I Rodriguez Guinea[3]; C Solorzano Guillen[3]; J Benitez Peyrat[3]
[1]University Hospital of Guadalajara, Cardiac Rehabilitation Unit, Guadalajara, Spain; *[2]Hospital General de Ciudad Real, Nefrology, Ciudad Real, Spain*; *[3]University Hospital of Guadalajara, Department of Cardiology, Guadalajara, Spain*

Introduction: We know that there are differences in the oxygen consumption to exercise between men and women, being lower in women due to differences in anthropometric measurements, body fat percentage, hormonal influence on metabolism, in addition to other factors; but the objective of this study is to determine if the improvement or increase in oxygen consumption and the control of risk factors in women with heart disease undergoing a cardiac rehabilitation program (CR-P) is similar to that of males.
Methods: Prospective observational study. A total of 233 patients were included consecutively in a conventional CR-P between March 2015 to September 2018, performing daily continuous training for 8 weeks (phase II of CR-P), they underwent an ergometry with oxygen consumption before and after phase II. In addition, echocardiographic variables, blood analysis and cardiovascular risk factors (CVRF) were evaluated.
Results: 233 patients were analyzed, mean age was 57,5±9,1 years, 38 women (16,3%), mean LVEF 56,3±9,9%, ischemic heart disease 91%, 47,6% were in functional class II-III (NYHA) prior to CR-P, 49,8% HBP, 70,4% dyslipidemia, 21,5% diabetes, 65,7% smokers and 36,5% obese. Regarding the baseline characteristics such as age, BMI, CVRF and LVEF between men and women, there were no statistically significant differences, only difference in the percentage of active smokers was observed, being higher in men (71.3%Vs36.8%, p=<0.001). In the multivariate analysis, it was determined that being a woman is a predictor of a lower increase in recovery time to exercise (0,9±7,9Vs2,5±7,7) with an OR 1,06 (IC 95% 1,01-1,13; p=0,03) and a lower increase in oxygen consumption (0,8±2,2Vs2,3±3,2) at the end of CR-P with an OR 1,21 (IC 95% 1,04-1,21; p= 0,02).
Conclusions: In our study, the percentage of women participating in CR-P is markedly lower than men. We can also conclude that the fact of being a woman is a predictor factor for a lower increase in oxygen consumption and recovery time to exercise after phase II of CR-P, nor did it show a significant reduction in some prognostic analytical markers such as B-BNP and CRP, improvements that men did.

Table 1. Comparison according to gender

PARAMETERS	MEN	P	WOMEN	P		
PRE CR-P	POST CR-P	PRE CR-P	POST CR-P			
CRP (mg/L)	3,4±5,1	2,2±2,9	0,003	3,9±7,9	3,3±5,5	0,62
B-BNP (pg/mL)	83,9±139,6	67,06±121,2	0,01	79,8±64,5	73,7±64,8	0,46
Recovery time(beat/1er min)	16,0±8,3	18,6±9,0	<0,001	14,9±8,9	15,9±8,0	0,48

Cardiac rehabilitation in patients with systolic dysfunction, a wasted opportunity?

R Regina Dalmau[1]; A Castro[1]; S Espinosa[1]; L Martin Polo[1]; I Marco[1]; C Merino[1]; A Iniesta[1]; S Rosillo[1]; O Gonzalez[1]; L Pena[1]; A Velez[1]; H Arranz[1]; A Araujo[1]; E Lopez De Sa[1]; JL Lopez Sendon[1]
[1]University Hospital La Paz, Madrid, Spain

Background: despite being strongly recommended in guidelines, cardiac rehabilitation programs (CRP) are often an unmet need in heart failure patients. A low referral rate and the particular conditions of these patients may explain the gap. We compared the baseline characteristics of patients referred to a CRP according to their left ventricular ejection fraction (LVEF >35% or ≤35%). Methods: 921 patients referred to a CRP were analyzed. Before starting the CRP, an echocardiogram and a treadmill exercise test was performed. Patients were classified according to their LVEF (>35% or ≤35%), and their base-line characteristics were compared. Results: we analyzed 921 sequential patients, 749 (81,4%) had a LVEF >35%, and 172 (18,6%) a LVEF ≤35%. The majority of them (91%) had been referred after an ACS. Mean age was 56,9, women were less represented in the low LVEF group (10,5% vs 16,7%, p=0,04). CV risk factors were common in both groups, with a similar distribution. Patients with low LVEF were more likely to have co-morbidities such as COPD, renal impairment, atrial fibrillation, or moderate to severe valvulopathies. As expected, exercise capacity was lower in the low LVEF group (6,37±3.0 vs 8,04±2,4 METS, p <0,001). Patients with low LVEF were more likely to dropout the program (15,1% vs 10,1%, NS). Conclusion: A higher burden of comorbidities and a worse functional status can explain the poor referral and completion of CRP in patients with left ventricular systolic dysfunction, as they require a more individualized intervention.

Baseline characteristics comparison

	EF>35%	EF≤35%	p
Female sex	16,7%	10,5%	0,04
Mean age	56,9	56,8	NS

Cardiovascular Disease in Special Populations

P1158
Trastuzumab associated cardiotoxicity in breast cancer patients: a report after 4 years of follow up at a specialized centre

M E Tettamanti[1]; I Gimenez[1]; C Chacon[2]; J Nadal[3]; V Costanzo[3]; A Nervo[3]; F Losco[3]; R Chacon[3]; D A Santos[1]
[1]Alexander Fleming Institute, Cardio Oncology, Buenos Aires, Argentina; *[2]Alexander Fleming Institute, Radiotherapy, Buenos Aires, Argentina*; *[3]Alexander Fleming Institute, Oncology, Buenos Aires, Argentina*

Background: about 20% to 30% of breast cancer express HER2 receptor, a member of the epidermal growth factor family, and confers a poor prognosis. Treatment of HER2+ breast cancer (H2BC) includes adriamycin and trastuzumab (T), a monoclonal antibody that recognizes an extracellular domain of HER2. HER2 is also expressed in adult cardiomyocites and serves as a coreceptor for neuregulin, a pro survival factor released by cardiac endothelial cells. Then, by binding cardiac HER2, T can produce cardiotoxicity (CTX). Although T has been extensively used in our country, its impact with regard to CTX has never been reported.
Purpose: to report the CTX associated to adjuvant T use in H2BC patients (P) in a non selected cohort after having completed cancer treatment.
Methods: 231 (26%) out of 888 consecutive breast cancer P were H2BC and received adriamycin and T. Left ventricular ejection fraction (LVEF) was assessed at baseline and every 3 months. After treatment, P were classified according to the magnitude of LVEF drop from baseline in one of three groups: group 1 (up to 10 percentage points, LVEF≥55%), group 2 (≥16 percentage points or 10 to 15 percentage points from baseline and LVEF < 55%) and group 3 (a deeper drop with an LVEF ≤ up to 45%).
Results: P were followed up to 48 ± 12 months. 150 out of 231 H2BC P (65%) showed a ≥10 percentage points decrease of LVEF from baseline: 81 out of 231 P (35%) fall into group 1, 45 out of 231P (19%) into group 2 and 24 out of 231 P (10%) within group 3. The relative decrease of LVEF along treatment was 15%, 20% and

20% (p < 0, 04) for groups 1, 2 and 3. Furthermore, within each group, 27 P (33%), 19 P (42%) and 10 P (41%) of P finished treatment and remained with a <50% LVEF in the long term (p 0, 01), for groups 1, 2 and 3, respectively.
Conclusions: >60% of H2BC P treated with T in a non-selected cohort showed a significant drop in LVEF at the end of the follow up period, irrespectively of the applied definition of CTX, and 33 to 42% of them stayed with a <50% LVEF. These facts underscore the importance of continuous cardio – oncologic surveillance along treatment with T. The mechanisms by which T causes cardiomyopathy and by which neuregulin confers cardiac protection are not fully understood. Further insight is needed regarding these aspects so that we can effectively prevent cardiac damage in this subset of P.

Main oncologic features of H2BC patients

	H2BC patients (n=231)	Group 1 (n=85)	Group 2(n=45)	Group 3 (n=24)	p
Mean adriamycin cummulative dose (mg)	400,54 ±68	392,44±22	411±11	409,28±33	0,7
Mean Radiotherapy dose (Gy)	2,2± 0,12	2,1±0,1	2±0,9	2,2±0,2	0,55

Body mass index and resting heart rate in unselected prospectively enrolled cancer patients

S Sara Hadzibegovic[1]; L-C Lueck[1]; P Weinlaender[1]; A Lena[1]; J Eucker[1]; S Von Haehling[2]; U Landmesser[1]; SD Anker[1]; MS Anker[1]
[1]Charite University Hospital, Berlin, Germany; *[2]University Medical Center Gottingen (UMG), Gottingen, Germany*

Background: In cancer patients, an elevated resting heart rate (RHR) as well as low body mass index (BMI) and weight loss (cachexia) have independently been shown to be associated with increased mortality.
Purpose: We aimed to examine, whether there is an association between BMI and parameters from resting electrocardiogram (ECG) in a prospective cancer population.
Methods: 250 unselected cancer patients without significant cardiovascular disease at baseline were enrolled between 2005 and 2018 (age 60±12 yrs, 51% men, BMI 24.5±4.6kg/m2, presence of cachexia: 48%, and cancer stage I/II/III/IV 10/12/26/52%). The cancer diagnosis was histologically confirmed and included 73 patients with pancreatic (29%), 46 with colorectal, 46 with lung (both 18%), 22 (9%) with breast cancer and 63 with lymphoma (25%). A routine clinical investigation was performed in all patients including resting ECG, blood pressure assessment and blood chemistry.
Results: We divided the cancer patients into two groups with low (BMI <23, n=100, mean BMI 20.5±1.8kg/m2) and high BMI (≥23, n=150, mean BMI 27.2±3.8kg/m2). The low BMI group showed higher resting heart rate (80±14 vs 76±14 bpm, p=0.029), Left-Sokolow-Lyon-Index (2.1±0.7 vs 1.7±0.6mV, p=0.0001), and lower PR interval (147±21 vs 156±25ms, p=0.0020). QRS and QTc duration were not significantly different (both p>0.8). Blood pressure (BP) was lower in the low BMI group (systolic BP 121±19 vs 128±18mmHg, p=0.0067, diastolic BP 74±12 vs 77±9mmHg, p=0.052, and mean BP 90±13 vs 94±10mmHg, p=0.0070). Medication with beta-blocker or ACE-inhibitor was similar in both groups (both p>0.05). Hemoglobin (11.2±1.9 vs 11.8±1.9g/dL, p=0.02) and platelets (228±96 vs 278±160/nL, p=0.002) were lower in patients with low BMI, leukocytes were not significantly different (p>0.6). Patients with NYHA grade 3/4 (18% of patients) compared to NYHA grade 1/2 (82%) demonstrated higher resting heart rate (83±14 vs 77±14bpm, p=0.019), other ECG parameters with respect to NYHA grade were not significantly different.
Conclusion: Cancer patients with low BMI and dyspnea had higher resting heart rate and showed several ECG abnormalities.

Echocardiographic assessment in cancer patients

A Lena[1]; P Weinlaender[1]; L-C Lueck[1]; S Hadzibegovic[1]; U Keller[1]; S Von Haehling[2]; U Landmesser[1]; SD Anker[1]; U Wilkenshoff[1]; MS Anker[1]
[1]Charite University Hospital, Berlin, Germany; *[2]University Medical Center Gottingen (UMG), Gottingen, Germany*

Introduction: Various malignant cancer diseases and various anti-cancer therapies may cause relevant cardiac morphologic and functional alterations detectable by transthoracic echocardiography.
Purpose: To compare echocardiographic characteristics of cancer patients without known significant cardiovascular disease and healthy controls.
Methods: From November 2017 to December 2018, we prospectively included 100 unselected cancer patients without significant cardiovascular (CV) disease (age 62±15yrs, 55% female, body mass index (BMI) 25±5kg/m2) and 26 controls (age 56±9yrs, 61% female, BMI 25±3kg/m2). The cancer group had the following histologically proven malignancies: 41 solid cancers (20 breast, 8 colorectal, 6 non-small cell lung, 7 others) and 59 lymphoma. Cancer stage was I/II/III/IV in 8, 16, 23, and 53%, respectively. 37% of cancer patients were treatment naïve. We performed transthoracic echocardiographic with VividE9 .
Results: Cancer patients demonstrated slightly lower left ventricular ejection fraction (LVEF, 66±5%, range 42-78%) than control subjects (69±4%, range 62-79%, p<0.006), lower E/A ratio (1.1±0.4 vs 1.2±0.3, p=0.036), higher E/e' (9±3 vs 7±2, p=0.015), and higher estimated pulmonary artery systolic pressure (PASP, 29±9 vs 25±4mmHg, p=0.027). 96% of cancer patients and 100% of controls had a LVEF≥55%. 45% demonstrated diastolic dysfunction grade 1 (E/A<1.0), 30% grade 2 (E/e'≥8 with E/A≥1), 1% grade 3 (E/e'≥15), 24% had no diastolic dysfunction – in controls the distribution was 15, 19, 0, and 66%, respectively. Interventricular septal and posterior wall thickness were significantly elevated in cancer patients vs controls (10.4±1.7 vs 9.6±1.2 mm, p=0.022; 10.2±1.5 vs 9.6±1.1 mm, p=0.038). Subgroup analyses of treatment-naïve cancer patients vs healthy controls showed increased E/e' (9±4 vs 7±2; p=0.015), PASP (30±8 vs 25±4mmHg; p=0.016), interventricular septal thickness (10.8±2.0 vs 9.6±1.2mm; p=0.0073), and posterior wall thickness (10.5±1.7 vs 9.6±1.1mm; p=0.015). Not significantly different were LVEF (67±4 vs 69±4%; p=0.12) and E/A ratio (1.2±0.5 vs 1.3±0.3; p=0.50). Subgroup analysis of patients with prior chemotherapy known to be cardiotoxic and/or radiotherapy (n=16) vs treatment naïve cancer patients (n=37) showed lower LVEF (62±9 vs 67±4%; p=0.0046), lower interventricular septal thickness (9.8±1.0 vs 10.8±2.0mm; p=0.0498), and a tendency to lower posterior wall thickness (9.6±1.0 vs 10.5±1.7mm; p=0.057).
Conclusion: Cancer patients showed normal but slightly reduced left ventricular ejection fraction. 76% of cancer patients (all without relevant CV disease) demonstrated abnormal diastolic function.

P1161

Troponin T, NT-proBNP and CRP: prognostic markers of mortality in cancer patients

L-C Lueck[1]; A Lena[1]; S Hadzibegovic[1]; P Weinlaender[1]; A Letsch[1]; M Karakas[2]; U Landmesser[1]; SD Anker[1]; MS Anker[1]; S Von Haehling[3]
[1]Charite University Hospital, Berlin, Germany; *[2]University Medical Center Hamburg Eppendorf, Hamburg, Germany*; *[3]University Medical Center Gottingen (UMG), Gottingen, Germany*

Background: In modern day cardio-oncology cardiovascular (CV) blood biomarkers are frequently used. During anti-cancer treatment these biomarkers are considered prognostic markers of later cardiovascular dysfunction. Whether they are also prognostic markers for mortality is largely unknown.
Purpose: To test whether different CV blood biomarkers are significantly prognostic of all-cause mortality in cancer patients without significant CV disease at baseline.
Methods: From November 2017 until December 2018, we enrolled 138 unselected cancer patients without significant CV disease (age 63±14yrs, 55% female, body mass index (BMI) 25.5±7.7kg/m2) as well as 25 healthy controls (age 57±10yrs,

64% female, BMI 25.1±3.4kg/m2). The cancer group had the following histologically proven malignancies: 85 lymphoma patients (62%), 11 non-small cell lung cancer (8%), 10 colorectal cancer (7%), 25 breast cancer (18%), and 7 other types (5%). Cancer stages were I/II/III/IV 11/14/20/56%. Blood samples were taken for biomarker analyses.

Results: High-sensitive Troponin T (hsTnT), N-terminal pro brain natriuretic peptide (NT-proBNP) and C-reactive protein (CRP) were significantly increased in cancer patients vs healthy controls (89ng/L [IQR 85-93] vs 44ng/L [39-48], p<0.0001; 90ng/L [85-94] vs 40ng/L [35-45], p<0.0001; 84.3mg/L [78.8-89.7] vs 27.9mg/L [22.5-33.4], p<0.0001). During a mean follow-up time of 172 days (range 1–405), 29 cancer patients (21%) died (6-month mortality 23% [95%CI 15-32]). All three CV biomarkers predicted survival in univariable Cox analyses: hsTnT (per 1ng/L, HR 1.017 [95%CI 1.006-1.029], p=0.0017), NT-proBNP (per 100ng/L, HR 1.049 [1.013-1.085], p=0.0082) and CRP (per 1mg/L, HR 1.019 [1.009-1.030], p<0.0001). In multivariable Cox analysis including all three CV biomarkers, cancer stage, cancer entity and other clinical variables, all three CV biomarkers remained significant prognostic markers of mortality (hsTnT per 1ng/L, HR 1.017 [1.005-1.030], p=0.0067; NT-proBNP per 100ng/L, HR 1.044 [1.007-1.082], p=0.0211; CRP per 1ng/L, HR 1.017 [1.005-1.029], p=0.0047). The best cut-offs for the highest product of sensitivity and specificity for predicting survival were 12ng/L for hsTnT, 260ng/L for NT-proBNP and 9mg/L for CRP.

Conclusion: Plasma levels of the cardiovascular biomarkers hsTnT, NT-proBNP and CRP are elevated in cancer patients without significant cardiovascular disease compared to healthy controls. All three CV blood biomarkers are independent prognostic markers of short-term mortality in cancer patients.

Biomarkers and imaging modalities for the diagnosis of cardiotoxicity after chemotherapy; data from the greek multicenter cardio-oncology registry

A Ntalianis[1]; N Zografos[1]; E Roumpi[2]; A Tsiakou[3]; T Mpisxiniotis[4]; E Aggelopoulou[5]; M Marketou[6]; A Koutsoukis[1]; I Goudevenos[3]; I Kalafatis[4]; P Kalogeropoulos[5]; G Avgeropoulos[5]; F Parthenakis[6]; MA Dimopoulos[1]; I Paraskevaidis[1]

[1]University of Athens Medical School, Dept of Clinical Therapeutics, Alexandra Hospital, Athens, Greece; *[2]Sotiria Regional Chest Diseases Hospital, Athens, Greece*; *[3]University Hospital of Ioannina, Ioannina, Greece*; *[4]Aristotle University of Thessaloniki, Theagenio Hospital, Thessaloniki, Greece*; *[5]Hellenic Cardiological Society (HCS), Hospital Aghioi Anargyroi, Athens, Greece*; *[6]University Hospital of Heraklion, Heraklion, Greece*

Background/Introduction:: Cardio-oncology is an emerging field of cardiology that focuses on cardiovascular diseases in patients with cancer, especially the prevention and treatment of cardiotoxicity after chemotherapy (CARTOX).

Purpose: To record the current practice and the adherence to guidelines for the diagnosis of CARTOX in the Greek Multicenter Cardio-Oncology (GMCO) registry.

Methods: The GMCO registry is being conducted in 15 Cardio-Oncology outpatient clinics in Greece under the auspices of the Hellenic Cardiology Society. The following three groups of patients have been included: a) patients with CARTOX or patients with intermediate and high risk characteristics to develop CARTOX, b) patients with cardiac amyloidosis, and c) patients with primary or metastatic cardiac tumors. For each patient, history and predisposing factors for cardiotoxicity, previous and planned chemotherapy and radiotherapy and clinical and laboratory data were recorded.

Results: From June 2017 until June 2018, a total of 90 patients (mean age of 63 years, 44% females) were included in the GMCO. The majority of the patients were diagnosed with breast cancer (37%), 10% with cardiac amyloidosis and 3% with cardiac tumor. Forty six percent of the patients were screened before chemotherapy and 39% were included because of CARTOX. In patients with CARTOX, 34% presented with heart failure, 24% with angina, and 4% syncope. For the diagnosis of CARTOX, troponin was used in 52%, BNP in 40%, strain heart echocardiography in 5% and cardiac MRI in 10%.

Conclusions: According to GMCO registry a significant number of patients with CARTOX presented with symptoms of heart failure and angina. Sophisticated imaging techniques such as strain echocardiography and MRI were used only in the minority of patients with CARTOX.

P1163

Echocardiographic assessment of right ventricle function in HIV-infected patients during 1 year follow up.

N Kasinos[1]; A Antonios Destounis[1]; M Karakosta[1]; P Zahos[1]; CH Tountas[1]; K Englezopoulos[1]; M Vassaki[1]; S Mitsiadis[1]; E Grigoraki[1]; S Lygidakis[1]; K Yiangou[1]; A Theodosis-Georgilas[1]; G Chrysos[1]; D Beldekos[1]; E Pisimisis[1]

[1]Tzanio General Hospital, Department of Cardiology, Piraeus, Greece

Introduction: HIV-infected patients are at increased risk for cardiomyopathy and pulmonary hypertension, portending a poor prognosis. Right ventricular (RV) systolic and diastolic dysfunction are associated with worse outcomes in these conditions. Little are known about the possible effects of antiretroviral therapy in right ventricle cardiomyopathy. Early identification of these entities in course disease is crucial for further treatment of these patients.

Purpose: In this study we assessed in relatively newly diagnosed HIV young patients without known cardiovascular disease several indices of RV function at baseline and over 1 year follow-up

Methods: Echocardiograms were evaluated in 18 HIV-infected adults, with stable antiretroviral therapy (ART) and adequate CD4 count, at baseline and after 1 year. Measurements included several indices of HIV infection such as duration of infection, viral load and CD4 count along with echocardiographic indices of RV anatomy and function such as right ventricle (RV) area, right atrial volume, RV fractional area change (RVFAC), tricuspid annular plane systolic excursion (TAPSE), RV Tissue Doppler Imaging-derived IsoVolumic Acceleration time (IVA), and finally we assessed the right regional and global longitudinal strain.

Results: During over one-year follow-up we analyzed echocardiograms from eighteen relatively newly-diagnosed (mean duration of HIV infection 93±77 months), HIV-infected patients with stable antiretroviral therapy (mean age 47±12 years, 16 males, body mass index 26±4,5 kg/m^2, mean period of follow-up 16±4,5 months, mean CD4 at baseline 839±318 cells/mm and at follow-up 922±316 cells/mm.In HIV infected patients with stable antiretroviral therapy, adequate CD4 count and no change of viral load during 1 year follow up, we identified statistical significant changes to indices of diastolic function of RV such as right atrial indexed volume (RAVi) (mean difference -2,41±4,7, p<0,05). Additionally we were not be able to find any statistical significant change to systolic indices of RV function such as FAC (Fractional Area Change), STDI, IVA or regional and global longitudinal strain (RVGLS) during the follow-up period, although an improvement was noticed (FAC 42,9% vs 43,6%, STDI 13,6 vs 14,2 cm/sec, RV GLS -25,3 vs -26, baseline and 1 year later respectively) after 1 year of ART.

Conclusions: These data suggest that in early stages of HIV infection stable antiretroviral therapy. along with minimal viral load and sufficient CD4 count has minimal effects on right ventricle cardiomyopathy, except progression of right atrial dilatation. In right ventricle, the effect of HIV infection on its systolic function is minimal either assessed by traditional or newer echocardiographic indices, while effects on diastolic function of RV remain inconclusive. Probable more time is needed to assess effects of HIV infection and antiretroviral therapy upon right ventricle cardiomyopathy.

Chloroquin cardiomyopathy manifested as hypertrophic cardiomyopathy

H Hedvig Takacs[1]; V Nagy[1]; B Ivanyi[2]; T Forster[1]; R Sepp[1]

[1]University of Szeged, Second Department of Internal Medicine and Cardiological Center, Szeged, Hungary; *[2]University of Szeged, Department of Pathology, Szeged, Hungary*

Funding Acknowledgements: GINOP-2.3.2-15-2016-00039

Background: Chloroquine (CQ) traditionally has been used for the treatment and prophylaxis of malaria. Later, it was introduced for the long-term therapy of rheumatic diseases, particularly in the treatment of systemic lupus erythematosus (SLE). Severe toxicity in the form of irreversible retinopathy is well known under long-term treatment, however, cardiac complications including conduction disturbances [bundle-branch block, atrioventricular (AV) block] and cardiomyopathy -often with hypertrophy, restrictive physiology, and congestive heart failure- is less known. Aims:In our work we analyzed patients with CQ cardiomyopathy identified in our institution since 2013.

Patients and results: In the observational period 5 patients (all female, average age 57±12 yrs) were diagnosed with CQ cardiomyopathy. CQ therapy was initiated because of SLE, as underlying illness in all patients. CQ treatment duration was 10±6 yrs. Cardiac manifestation occurred in all patients, while skeletal muscle involvement, neurological involvement and GI involvement was observed in 3, 2 and 2 cases, respectively. Initial cardiac symptoms included syncope in 4 cases and sinus arrest in one case. IIIrd degree AV block occurred in 3 cases, while bifascicular block and LBBB was observed in one case each. Pace-maker implantation was necessary in three, ICD implantation in one case. Laboratory findings showed raised CK (363±185 U/l, CK-MB: 26±6 U/l) and LDH (978±120 U/l) levels, indicating skeletal muscle involvement. Cardiac phenotype was compatible with hypertrophic cardiomyopathy in one, and with restrictive cardiomyopathy in two cases, with preserved or slightly decreased LV ejection fraction (50±8%). NTpBNP levels were markedly increased (5858±3580 ng/ml). Cardiac biopsy was performed in all cases which showed histology findings compatible with CQ cardiomyopathy. Genetic screening for Fabry disease was negative in all cases. During the 14±11 month follow up we observed progression into heart failure in three cases, necessitating heart transplantation in one case. One patient died during follow up, due to rejection followed by a successful heart transplantation.

Conclusions: CQ therapy may be associated with severe cardiotoxicity, which is characterized by conduction disturbances and heart muscle disease with restrictive

diastolic dysfunction. Patients on CQ therapy should be monitored for cardiac manifestations on a regular basis.

P1165

Red cell distribution width: potential biomarker of the risk of right ventricular involvement in systemic sclerosis

S Sandra Jaksic Jurinjak[1]; D Delic Brkljacic[2]; I Jurin[1]; B Starcevic[1]; J Morovic Vergles[3]
[1]University Hospital Dubrava, Institute of Cardiovascular Diseases, Department of Cardiology, Zagreb, Croatia; *[2]University Hospital Sestre Milosrdnice, Cardiology clinic, Zagreb, Croatia*; *[3]University Hospital Dubrava, Immunology and rheumatology department, Zagreb, Croatia*

Introduction: Systemic sclerosis (SSc) is chronic disease marked by vascular inflammation and fibrosis. Primary myocardial involvement and pulmonary hypertension are common in SSc, and cardiac manifestations which include myocardial fibrosis and hypertrophy can lead to clinical complications as congestive heart failure. Impaired hemodynamic parameters of right ventricular (RV) function are predictors of poor outcome in patients with SSc, often begin in early stages of the disease and initially remain clinically asymptomatic. Identification of potential novel risk factors or markers could help clarify SSc pathophysiology, so red cell distribution width (RDW) which has been associated with different cardiovascular diseases as heart failure, pulmonary arterial hypertension and with overall cardiovascular mortality in different populations could lead to improved risk stratification in SSc.
Purpose: The aim of this study was to evaluate echocardiographic parameters of right ventricular function in patients with systemic sclerosis (SSc) without pulmonary hypertension and its correlation to red cell distribution width (RDW).
Methods: 27 consecutive SSc patients underwent echocardiography with tissue Doppler imaging to assess RV function. Of those enrolled, 21 study patients were investigated at baseline and 19 study patients in four visits of one year follow up. Echocardiographic measurements and RDW was assessed at each visit (zero month visit, 4th month visit, 8th month visit, 12th month visit).
Results: In the highest tercile RDW group (>14,25 for first follow-up visit) RV FAC was significantly lower 48,00 (45,00-51,00) compared to 50,80 (49,08-53,40); P=0,023., and in the highest tercile RDW group (>13,95 for second follow-up visit) PV Acct was significantly lower (P=0,007) in the follow-up at first and second visit respectively. In the highest tercile RDW group (>14,25 for first follow-up visit) RV FAC was significantly lower 48,00 (45,00-51,00) compared to 50,80 (49,08-53,40); P=0,023., and in the highest tercile RDW group (>13,95 for second follow-up visit) PV Acct was significantly lower (P=0,007) in the follow-up at first and second visit respectively. RDW showed a positive correlation with RIMP (rho=0,537, P=0,012) on the first visit and negative correlation with PV Acct on the first (rho=-0,495, P=0,023) and second (rho=-0,497, P=0,022) visit during the follow-up, respectively.
Conclusion: RDW in SSc may represent an integrative measure of multiple pathological processes including fibrosis and ongoing inflammation. RDW may indicate an impairment of cardiorespiratory function and right ventricular function in SSc but further investigation is needed.

P1166

Incidence of cancer in patients with heart failure with reduced ejection fraction: a single-center long-term follow up study.

VIRGILIO Martinez Mateo[1]; MJ Fernandez-Anguita[1]; L Cejudo Del Campo[1]; E Martin Barrios[1]; AJ Paule[1]
[1]Hospital Mancha Centro, Cardiology, Alcázar De San Juan, Ciudad Real, Spain, Spain

Introduction and objetives: Evidence linking heart failure (HF) with a higher incidence of cancer has been suggested previously in observational studies. However these epidemiological studies include patients with HF with reduced (HFr) and preserved ejection fraction (EF). Purpose/Methods: The aim of this study is to assess the incidence of cancer and all-cause mortality in patients with HFrEF followed prospectively in the HF Unit of a Spanish non-tertiary hospital. Results: Since the begin of Unit in 2010 until 2018, 485 patients with HFrEF have been followed (median 54 months, 79.2% men, mean age 66.5 ± 12.5 years [median 69]). 50 new cases of cancer have been identified, corresponding to an incidence rate of 21.5 per 1000 person-years (95% confidence interval [CI] 20.2–22.6) and a cumulative incidence of 1288.6 cases per 100000 person-year (vs 714.4 cases per 100000 person-year describe in general Spanish population). Median time from the diagnosis of HF to a diagnosis of cancer is 48 months (interquartile range 24–72). Patients with cancer are mainly males (90%) and compared with patients that do not have cancer in the follow-up, they are older (71.4 vs 66,0 years, p 0.004), an ischemic origin of cardiomyopathy is more frequent (60% vs 44.4%, p 0.00) and presented more comorbidity (smoking 68.7 vs 59.8%, p 0.04; arterial hypertension 66.5 vs 59.3%, p 0.03; chronic renal failure 30.0 vs 23.4%, p 0.05; and chronic obstructive pulmonary disease 44.1 vs 27.6%, p 0.00). Rate of treatment with beta blockers/ivabradine, angiotensin converting enzyme inhibitors/angiotensin receptor blockers/sacubitril-valsartan and aldosterone antagonists were similar between both groups although implantable electronic devices (ICD/CRT) were more frequently used in patients that were diagnosed of cancer in the follow-up (30 vs 21.4%, p 0.000). In multiple regression analysis predictors of cancer development have not been detected. Regarding the prognosis, mortality was higher in patients with diagnosis of cancer than patients without cancer (58% vs 26.2% with a survival median of 57.1+/- 2,2 vs 78.5 +/- 2.2 months respectively; log-rank X2 16.01 p 0.000) being the etiology of deaths mainly secondary to the malignancy (82.0% of cases) with a survival median since diagnosis of cancer until death of 12.0 +/-2.1 months. Diagnosis of cancer was an independent predictor of mortality (odds ratio 10.98, CI 95% 2.65-42.7; p 0.001). Conclusion: Incidence of cancer in patients with HFrEF is higher than general population and their prognosis is significantly worse compared with that of HF patients without cancer.

P1167

Usefulness of global longitudinal strain as predictor for sub-clinical left ventricular dysfunction and all-cause mortality among active cancer patients

LM Michal Laufer-Perl[1]; J Arnold[1]; L Mor[1]; N Amrami[1]; M Derakhshesh[1]; J Sherez[1]; G Keren[1]; Y Arbel[1]; Y Topilsky[1]; Z Rozenbaum[1]
[1]Tel Aviv Sourasky Medical Center, Cardiology, Tel Aviv, Israel

Background: Cardiotoxicity among cancer patients has become a leading cause of morbidity and mortality. The most commonly used definition is cancer therapeutic related cardiac dysfunction (CTRCD) defined as a left ventricular ejection fraction reduction of >10%, to a value below 53%. Global longitudinal systolic strain (GLS) has been shown to be more sensitive in detecting early sub-clinical systolic dysfunction. However, its role in routine follow up of cancer patients, and whether it is associated with all-cause mortality, haven't been established yet.
Objectives: To evaluate whether reduced GLS is associate with CTRCD development and all-cause mortality among active cancer patients.
Methods: Data were collected as part of the International Cardio-Oncology Registry (ICOR), enrolling prospectively all patients evaluated at the cardio-oncology clinic in our institution. Patients were divided into two groups – Reduced GLS vs. Preserved GLS. Normal GLS was defined as ≤-19% adhered to the standard benchmark set by previous studies.
Results: Among 277 consecutive patients, 91 (33%) patients had reduced GLS at first evaluated echocardiography. Patients with reduced GLS had higher prevalence of cardiovascular risk factors, including hypertension, diabetes mellitus and atrial fibrillation. There were no significant differences regarding the type of cancer treatment. Over a median follow-up period of 13.2 (7.2-19.3) months, 9 (3%) patients developed CTRCD and 35 (13%) patients died. For every 1-unit increment of GLS the risk of CTRCD increased by 25% (OR 1.25, 95%CI 1.09-1.43, p=0.002) and the risk of all-cause mortality by 16% (HR 1.16, 95%CI 1.08-1.25, p<0.001). After adjustment for baseline characteristic, including cardiovascular risk factors and systolic function, reduced GLS emerged as a significant predictor for CTRCD development (OR 6.6 95%CI 1.1-8.8, p=0.037) and all-cause mortality (HR 2.1 95%CI 1.1-4.4, p=0.037).
Conclusions: Reduced GLS is frequent among active cancer patients and can identify patients at increased risk for CTRCD development and all-cause mortality.

Cardiac immune related toxicity: a single center experience

N Salterain[1]; E Castanon[2]; P Rodeiro[2]; J Ibero[1]; E Iglesias[1]; JJ Gavira[1]
[1]University of Navarra, Cardiology, Pamplona, Spain; *[2]University of Navarra, Oncology, Pamplona, Spain*

Introduction: . Immunotherapy (IT), aimed at boosting an immune response against tumor cells and promoting an effective antitumor response, has provoked a paradigm shift in the treatment of cancer. Its impact on terms of progression free survival and overall survival is impressive, beeing approved in first line setting of metastatic disease for different tumors. Nevertheless, it has also caused concern regarding IT-related toxicity, since side effects are rather different to those associated to classical cytotoxic agents. Cardiac toxicity is one of the most concerning due to its potential lethality. So far, the real incidence on cardiac immunotoxicity remains unknown. We have studied the incidence of cardiac disturbances in an oncological population receiving IT as a part of their oncological treatment.
Methods: This is a retrospective study performed at our clinic between 2010 and 2017, including patients diagnosed with solid tumors and receiving IT. A joint database was created between Medical Oncology and Cardiology Departments. Characteristics of the patients (previous cardiological disease, cardiovascular risk factors, immunomodulatory treatment), and the development of cardiological complications during treatment were analyzed in a descriptive manner.

Results: 187 patients were studied. Cardiac toxicity was detected in 6 (3.2%) (Fig 1). Myocarditis was the most frequent adverse event (2.14%), and was only diagnosed in patients receiving IT agents in combination.
Conclusion: Further investigation is warranted in order to determine the real prevalence of cardiac toxicity in patients treated with IT. Multicentric studies should be encouraged in order to increase the sample size and thus, having enough power to detect possible prognostic factors for predicting the development of myocarditis and other cardiac toxic events in this setting.

Implementing a novel clinical scientist led cardio-oncology service in everyday clinical practice.

J Jenna Smith[1]; J Draper[1]; K Victor[1]; S Kapetanakis[1]
[1]Guys & St Thomas' NHS Foundation trust, Cardiology, London, United Kingdom of Great Britain & Northern Ireland

Introduction: Cardio-Oncology is a novel service that addresses cardiac complications from cancer therapies, the commonest of which is myocardial dysfunction, which is classified into Type 1 (irreversible) and Type 2 (reversible). Each type requires a distinct follow up pathway as described in international guidelines. The increasing number of patients require expert echocardiographic (TTE) and clinical surveillance which exerts significant pressure on Oncology and Cardio-Oncology services. We examine the feasibility and value of a clinical scientist-led cardio-oncology surveillance clinic designed to address these needs.
Methods: We assessed activity and outcomes of the first 25 months of a novel clinical scientist-led cardio-oncology clinic. This service is set up alongside a consultant led cardio-oncology service and independently assesses new referrals to the service, organises appropriate follow up and discharge from the service. New referrals are selected from direct referrals to the service and screening of all TTE requests. Once referred to the clinical scientist-led service, all subsequent cardiac follow up is arranged, with discharge according to predetermined criteria depending on the type of chemotherapy regime (fig. 1).
Results: 222 patients were referred to the scientist led cardio-oncology clinic during January 2016 – June 2018 (mean age 57 ± 15 years; 81% female). 27 patients had a cardiotoxic response to therapy and were subsequently referred to the consultant-led cardio-oncology clinic for medical therapy and further review. 3 patients were found to have incidental findings on echo that required referral to a Consultant Cardio-Oncologist (new atrial fibrillation [n = 2]; bicuspid aortic valve [n=1]). 7 patients died from other causes not related to heart failure. TTE and clinical surveillance undertaken within this service now account for 37.5% of the total cardio-oncology activity within our departments.
Conclusions: A clinical scientist led cardio–oncology service improves standard of care, is feasible and effective and may improve patient outcomes.

Background Treatment with trastuzumab has resulted in a remarkable response for some patients with HER2-positive metastatic breast cancer (MBC) and can be prolonged for over ten years. Since trastuzumab can be cardiotoxic, it is recommended to monitor the cardiac function during trastuzumab treatment. However, guidelines for frequency and duration of cardiac monitoring in these long term users of trastuzumab are unclear.
Purpose To study the incidence rates of cardiotoxicity over time and investigate the potential risk factors for developing cardiotoxicity in HER2-positive MBC patients receiving (long term) trastuzumab with the ultimate goal to establish guidelines for cardiac monitoring in this setting.
Methods Patients with HER2-positive MBC treated with more than one cycle trastuzumab-based therapy between January 2000 and December 2014 in eight Dutch hospitals and with LVEF >50% at start of treatment were eligible for the study. Patients were identified through the Netherlands Cancer Registry and linked to the institutes' tumour registries. Data were collected through medical records using case record forms. We investigated two co-primary endpoints: 1) total cardiotoxicity defined as a LVEF decline >10%-points from baseline to a LVEF <50% and 2) severe cardiotoxicity defined as a LVEF <40%. Multivariable cox-regression and mixed model analyses were performed to identify risk factors associated with total cardiotoxicity, severe cardiotoxicity and a continuous LVEF decline.
Results A total of 429 patients were included. The cumulative incidence of total cardiotoxicity during follow-up was 22% (94 out of 429 patients) and of severe cardiotoxicity 6% (25 out of 429 patients). The incidence rate of cardiotoxicity and severe cardiotoxicity in the first year of trastuzumab was 11.7% and 2.6%(Figure 1). The incidence rate of total cardiotoxicity decreased the following years (i.e. 8.9% in year two to 3.6% in year six), while the subsequent incidence rate of severe cardiotoxicity was lower than in the first year but remained stable over time. Smoking, low baseline LVEF (50-60%), cardiotoxicity during (neo)adjuvant treatment with anthracycline and/or trastuzumab and cumulative anthracycline dose are independently associated with an increased risk of developing total and severe cardiotoxicity. Mixed model analysis showed that low baseline LVEF (50-60%), cardiotoxicity during (neo)adjuvant treatment and cumulative anthracycline exposure resulted in an absolute lower LVEF of 9.19%, 5.14 and 0.24%.

Conclusion The incidence rate of total cardiotoxicity peaks in the first year of trastuzumab treatment and decreases to a lower rate (<5%) after four years of treatment. The incidence rate of severe cardiotoxicity peaks at a lower rate in the first year, and remains stable low thereafter. Based on these cardiotoxicity incidence rates, cardiac monitoring in MBC patients seems most important in the first 4 year of trastuzumab treatment.

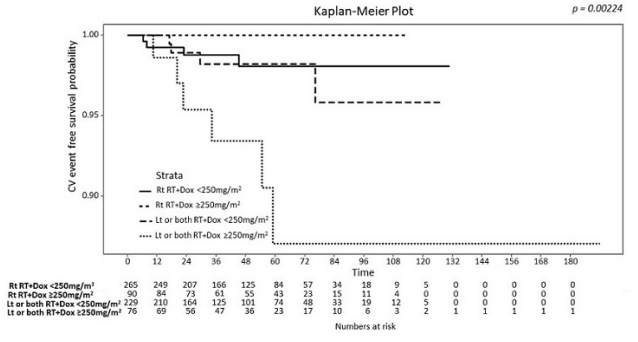
Funding Acknowledgements: This research was supported by the National Research Foundation of Korea (NRF-2018R1C1B6005448).

Background: Cancer treatment increases the risk of cardiovascular (CV) events. However, the long-term CV outcome of breast cancer patients who undergo radiotherapy and chemotherapy concomitantly is unknown. This study aimed to determine the incidence and risk factors of CV events among these patients.
Methods: Six hundred sixty consecutive breast cancer patients older than 50 years from November 2005 to September 2015, were enrolled in four university hospitals. The primary endpoint was CV events including CV mortality, myocardial infarction, heart failure, and stroke. CV events occurred in 14 (2.1%) patients during the follow-up period (median, 47.1 months).
Results: Left side irradiation was associated with increased risk of CV event in patients with doxorubicin dose ≥250 mg/m2 but not in patients with doxorubicin dose <250 mg/m2. On multivariable analysis, concomitant left-side irradiation with doxorubicin dose ≥250 mg/m2 and hypertension were independent risk factors for CV event.
Conclusion: The risk of CV event was further increased with concomitant left-side irradiation and doxorubicin ≥250 mg/m2 in breast cancer patients.



Cumulative K-M estimates of CV events

Optimal administration timing of thiazide diuretics for sequential nephron blockade in cardiovascular patients receiving loop diuretics

J Fallon[1]; M Roth[1]; SP Dunn[1]
[1]University of Virginia Health System, Charlottesville, United States of America

Background/Introduction: Volume overload poses a significant issue for many cardiovascular patients, particularly post-cardiovascular surgery or patients with heart failure faced with diuretic resistance. Sequential nephron blockade using a combination of loop and thiazide or thiazide-like diuretics (TZDs) offers a useful strategy for managing fluid accumulation through enhanced diuresis by blocking distal sodium reabsorption after the loop of Henle. A common practice is to administer TZDs 30 to 60 minutes prior to loop diuretic therapy in order to ensure maximal sequential blockade, though minimal evidence supports this practice.
Purpose: To evaluate the impact of administration timing of TZDs in relation to loop diuretics on urine output in a diverse cardiovascular population.
Methods A retrospective, single center study evaluated adult patients admitted to a cardiovascular floor who received at least one dose of a TZD (metolazone or chlorothiazide) in addition to a dose of bumetanide or furosemide. Patients were evaluated based on whether the TZD was administered early (30 minutes or more prior to the loop diuretic) or late (less than 30 minutes prior to the loop diuretic). The primary outcome was the urine output from the time of TZD administration until the next diuretic administration (maximum of 12 hours). Secondary outcomes included hospital length of stay, all-cause in-hospital mortality, and changes in electrolytes within 12 hours post-dose. The effect of TZD administration timing relative to loop diuretics was evaluated in different subgroups.
Results: A total of 1,114 patients were evaluated; 481 patients were in the early group (median TZD administration 46 minutes prior to the loop; interquartile range [IQR] 37-62) and 633 patients were in the late group (median TZD administration 0 minutes prior to the loop; IQR -1.8-1.2). Median urine output was similar with early administration at 1.68 mL/kg/h (IQR 0.93-2.5) compared to late administration at 1.55 mL/kg/h (IQR 0.91-2.33; P = 0.23). The majority of patients in the early and late groups received metolazone (97.3% vs. 92.3%; P<0.001) and furosemide (58.6% and 58.8%, respectively; P=0.96). There were no differences in hospital length of stay, all-cause in-hospital mortality, or 12-hour change in electrolytes. There was no difference in urine output between early and late TZD administration in subgroups of patients with diabetes, hypertension, left ventricular ejection fraction (LVEF) <40%, LVEF between 40-50%, LVEF >50%. Similarly, there was no difference in urine output between type of TZD given or loop diuretic route.
Conclusion(s): Early administration of TZDs prior to a loop diuretic does not appear to significantly increase urine output. Urine output after early or late administration of TZDs was not significantly influenced by subgroups based on LVEF, hypertension, diabetes, type of TZD, or route of loop diuretic.

Background: Sacubitril/valsartan (SV) reduced heart failure (HF) admissions and cardiovascular mortality in the PARADIGM. However, the response to the drug may vary between patients and there is no evidence yet on potential predictors of its efficacy.
Purpose: To identify the clinical predictors of super-response to SV.
Methods: Retrospective analysis of consecutive patients prescribed SV in a single tertiary HF-clinic between September 2016-February 2018. We have defined "super-responder" as a patient (i) without HF admissions and (ii) with a ≥50% reduction in NT-proBNP levels and/or an increase of ≥5 points in LVEF in a 6-month follow-up period after starting the drug.
Results: Out of 108 patients, 27 (25%) fulfilled the super-responder criteria. They were younger and have better NYHA class but similar blood pressure, creatinine and NT-proBNP levels and previous HF admission rate than the standard response group. After a logistic regression analysis, female sex (OR 9.1,95%CI: 2.2-37.9), NYHA II class (OR 8.8,95%CI: 1.9-40.6), sinus rhythm (OR 4.9,95%CI: 1.5-15.7) and initiation of the drug at intermediate doses (OR 5.2,95%CI: 1.7-16.2) were

independent predictors of super-response to SV.Conclusion: Female sex, NYHA II class, sinus rhythm and initiation of the drug at intermediate doses could identify a substantial group of patients super-responders to SV.

Who ARNI the best responders among patients with LVEF<35%?

J De Almeida[1]; S Martinho[1]; R Baptista[1]; F Franco[1]; S Costa[1]; M Ferreira[1]; M Robalo[2]; C Ferreira[1]; C Domingues[1]; P Alves[1]; M Costa[1]; M Costa[1]
[1]University Hospitals of Coimbra, Coimbra, Portugal; *[2]Hospital de Braga, Braga, Portugal*

Introduction: Although it is not a perfect surrogate in heart failure (HF), left ventricle ejection fraction (LVEF) is an important tool to guide therapy and evaluate ventricular function. The cutoff of 35% is of particular interest because it is helpful in guiding therapeutic decisions, pharmacological and device-related. Among patients on Angiotensin II Receptor Blocker Neprilysin Inhibitor (ARNI) with LVEF below this threshold, we wanted to identify which factors could help us predict a more favorable response to this therapy.
Methods: We retrospectively studied a population of 200 HF patients treated with ARNI. We selected patients with LVEF (evaluated with nuclear imaging) <35% and on maximum ARNI dose (n=78) and divided them into 2 groups: those who reached an EF>35% after at least 3 months of ARNI titrated up to maximum dose (optimal responders, n=14) and those who did not reach this threshold ("non-responders", n=64). There were no deaths. We characterized our population and looked for significant differences between groups.
Results: Our population had a mean age of 60.5 ± 11.9, baseline LVEF 24.9 ± 5.6%, medium blood pressure of 126.2 ± 16.2mmHg, creatinine 1.12 ± 0.38mg/dL, K of 4.55 ± 4.49mmol/L and NT-proBNP 128105 ± 1476.2pg/mL. 90.8% of patients were men and 55.1% had an ischemic etiology. Regarding symptoms, 56% were in NYHA Class II, 60% in NYHA Class III and 4% in NYHA class IV. The majority of patients had an implanted ICD (36.8%) or CRT-D (39.5%). Considering comorbidities, 40% of patients had diabetes, 38.7% AF and 30% had smoking habits. For previous events, 41.3% had a previous acute coronary syndrome and 65.8% a previous HF hospitalization. 98.7% of patients were on beta-blocker (30.7% reached maximum dose), 98.7% on angiotensin inhibitor (32% on maximum dose), 66.7% had aldosterone inhibitor on intermediate to high dose. 96% had furosemide.
There was a statistically lower rate of ischemic vs non-ischemic patients within the responder group (12.9% vs 28.5%, p=0.026) than within the non-responders (87.1% vs 61.5%, p=0.026) and a trend towards lesser rate of previous ACS (12.5% vs 34.4%, p=0.061) comparing to non-responders (87.5% vs 65.6%, p=0.061). Within ischemic patients, only 12.9% of patients reached EF>35%, compared with 38.5% of non-ischemic (RR=2.95, p=0.026). No other factors were statistically different between compared groups.
Conclusions: We observed that ischemic HF patients have an overall worse response to neuro-hormonal system modulator therapy, and this is in line with previous reports. The same remains true for this particular subset of patients, who already carry a poor prognosis and may benefit from other therapies, medical or structural. On the other hand, non-ischemic HF patients appear to be better responders and the expected favorable outcome could be helpful to better optimize the adequacy and timing of other therapies.

Etiology * LVEF>35 after 1 month with maximum dose

Rationale, design and baseline characteristics of the Personalised prospective comparison of ARni with ArB in patients with natriuretic peptide eLEvation (PARABLE) randomized controlled trial

M Ledwidge[1]; F Ryan[1]; C Watson[1]; J Gallagher[1]; M Ferre[1]; R Pharithi[1]; M Barrett[1]; D Murphy[2]; J Dodd[2]; K M Mcdonald[1]
[1]St Vincent's University Hospital, STOP-HF Unit, Dublin, Ireland; *[2]St Vincent's University Hospital, Department of Radiology, Dublin, Ireland*

On behalf of: STOP-HF Investigators
Funding Acknowledgements: Heartbeat Trust, European Commission, Novartis

Rationale: The STOP-HF study showed that asymptomatic patients with elevated B-type natriuretic peptide (BNP) levels are at higher risk of heart failure and other cardiovascular events. Genetic variants of the Nppb gene, which result in elevated BNP, have beneficial cardiovascular effects, including on progression of left ventricular dysfunction. This supports the hypothesis that elevated BNP is a protective response to volume and pressure overload as well as fibro-inflammation in asymptomatic patients. PARABLE will investigate the impact of sacubitril, a neutral endopeptidase inhibitor on progression of left atrial volume index (LAVI) using cardiac Magnetic Resonance Imaging (cMRI).
Design: PARABLE is an investigator-led, prospective, randomised, double blind, double dummy, phase II trial comparing sacubitril/valsartan versus valsartan treatment. The study will enroll 250 patients, aged over 40 years with hypertension and/or diabetes, with elevated BNP (20-280 pg/mL) or NTproBNP (100 to 1000 pg/mL) as well as LAVI above 28 mL/m2. Excluded are patients with a history of heart failure, left ventricular systolic dysfunction, haemodynamically significant mitral and /or aortic valve disease and persistent atrial fibrillation. Also excluded are those with hepatic dysfunction, severe renal insufficiency (eGFR <30 mL per minute per 1.73 m2) and any contra-indication to study therapy. The primary endpoint is change in LAVI measured by cMRI over 18 months. With 250 patients enrolled, the study has 80% power to detect a 2.5 mL/m2 difference between the groups with a two tailed α=5% and a drop-out rate of 15%. Other endpoints will assess the impact of sacubtril/valsartan versus valsartan on cMRI and Doppler-echocardiographic measures of cardiac structure and function, biochemical markers of fibro-inflammation and renal function, urinary cyclic-GMP and response to therapy based on genetic variants of Nppa, Nppb and Npra genes.
Baseline characteristics: Here we report on 203 randomised patients, 72 (35%) female, average age 72.0 ± 7.6 years. Hypertension and diabetes were present in 193 (95.1%) and 50 (24.6%) respectively. Population blood pressure was 134/75 ± 18/12 mmHg, heart rate was 63.4 ± 10.5 bpm and body mass index was 29.4 ± 7.3 kg/m2. Other baseline medical history included dyslipidaemia (n=165, 81.3%), coronary artery disease (n=95, 46.8%), stroke/TIA (n=17, 8.4%), paroxysmal atrial fibrillation (n=12, 5.9%) and chronic kidney disease (n=7, 3.4%). Median BNP was 66.2 pg/mL [IQR, 41.1, 106], average ejection fraction was 67.7 ± 6.6%, left ventricular mass index was 109.0 ± 25.6 g/m2, E/e' was 11.9 ± 7.4 and LAVI was 37.7 ± 5.0 mL/m2. To date more than 2,200 patient-months of data have accrued. PARABLE will complete in June 2020 and will define the impact of augmenting circulating BNP using sacubitril/valsartan versus valsartan alone

Effect of empagliflozin on hydroelectrolytic balance in patients with heart failure with reduced ejection fraction

M Maria Abellas Sequeiros[1]; S Del Prado[1]; G Alonso Salinas[1]; JM Vieitez Florez[1]; A Lorente Ros[1]; E Gonzalez Ferrer[1]; S Fernandez[1]; M Castillo Orive[1]; I Rayo Llerena[1]; JL Zamorano Gomez[1]
[1]*University Hospital Ramon y Cajal de Madrid, Madrid, Spain*

Introduction: Since the EMPAREG trial demonstrated a beneficial prognostic impact, reducing death from cardiovascular causes and hospitalization for heart failure, the use of inhibitors of the sodium-glucose transport protein 2 has raised. The main mechanism of action of empagliflozin is osmotic diuresis. Is there any risk of excess body-fluid loss and electrolyte disbalance?
Methods: To describe "real life" diuretic impact of empagliflozin, a series of patients with heart failure who initiated empagliflozin was prospectively assessed between December 2016-June 2017. Clinical characteristics, bioquemical parameters and diuretic doses before and after six-month treatment were collected. Wilcoxon test was conducted.
Results: Twenty patients were included; mean age was 72 years old; 14 (70%) patients were men and 60% had ischaemic etiology. Mean left ventricular ejection fraction was 36% and median estimated glomerular filtration rate (eGFR) was 70 ml/min. Regarding to optimal medical treatment: 79% were on angiotensin-converting-enzyme inhibitor, 21% sacubitril-valsartan, 84% beta-blocker and 75% mineralocorticoid receptor antagonist. Empagliflozin was discontinued in 1 patient because of persistent genital candidiasis.
During follow-up, haemoconcentration biomarkers such as osmolarity, haemoglobin and haematocrit did significantly rise (Table 1). Actually, there is a tendency to disminish diuretic doses. There were no significant changes in eGFR (p=0,222). Serum uric acid also decreased, explained because of a known uricosuric action of empagliflozin.
Conclusions: Glycosuric action of empagliflozin may have an important roll in heart failure patients, as this effect leads to a more concentrated state with lower doses of diuretics, without impairing renal function. Larger samples and longer periods of follow-up may be needed to corroborate this effect.

P1178

Iron therapy in heart failure with preserved vs depressed ejection fraction

GL Gonzalo Luis Alonso Salinas[1]; S Hernandez Jimenez[1]; S Del Prado Diaz[1]; E Gonzalez Ferrer[1]; M Castillo Orive[1]; S Fernandez Santos[1]; I Rayo Llerena[1]; JM Vieitez Florez[1]; JD Sanchez Vega[1]; M Abellas Sequeiros[1]; M Pascual Izco[1]; JL Zamorano[1]
[1]*Hospital Universitario Ramón y Cajal, Cardiology, Madrid, Spain*

Background Heart Failure (HF) with preserved Left Ventricular Ejection Fraction (LVEF) is a growing problem. Current therapies have not achieved prognostic benefit in preserved LVEF. The aim of this study was to assess the reduction of admissions in Iron Deficiency (ID) corrected and LVEF>and<45%.
Methods An ambispective cohort study was proposed. Patients were recruited once the ID was diagnosed. Previous 6-months admission rate and visits to Emergency Room (ER) were collected. The follow-up was 6.3±3.2 months. ID was described according current Clinical Guidelines.
Results
A total of 127 patients were included between June/2017 and July/2018. Of those, 63(49.6%) had LVEF>45%. Table 1 shows the baseline characteristics of the sample and treatment after the administration of Ferric Carboxymaltose. During the follow-up there were 11(8.8%) deaths.
Patients were analysed according their LVEF. The reduction of HF admissions 6 months before ID correction and after it was 79.3%(95% CI 60.5%-87.4%) in preserved LVEF group, and 50.0%(95% CI 7.5%-69.4%) in depressed group. Regarding ER visits, the reduction was 52.2%(95% CI 45.3%-54.8%) and 60.5%(95% CI 42.9%-72.9%) for preserved and depressed LVEF groups.

	Overall (n=127)	LVEF>45% (n=63)	LVEF≤45% (n=64)
Age (years)	77.7 ± 10.9	77.1 ± 10.5	78.3 ± 11.3
Female sex (n; %)	40; 32.3%	25; 42.3%	15; 23.1%
Ischaemic aetiology (n; %)	57; 44.9%	20; 31.8%	37; 57.8%
Previously-Corrected Valvopathy (n;%)	33; 25.8%	21; 33.3%	12; 18.5%
Uncorrected Valvopathy (n;%)	20; 15.8%	8; 12.7%	12; 18.8%
Glomerular Filtration Rate < 60 ml/min/1.73 m2 (n;%)	63; 49.2%	27; 42.9%	36; 55.4 %
Diabetes Mellitus (n; %)	60; 46.9%	26; 41.3%	34; 52.3%
LVEF (%)	47.0 ± 16.0	61.4 ± 8.0	33.1 ± 6.8
Treatment			
ACEI/ARBs/ANRI (n; %)	91; 71.1%	34; 54.0%	57; 87.7%
Beta-blockers (n; %)	94; 73.4%	39; 61.9%	55; 84.6%
MRA (n; %)	74; 57.8%	28; 44.4%	46; 70.8%
Furosemide daily dose (mg)	54.7 ± 45.6	56,9 ± 49.4	52.6 ± 42.0

ACEI: Angiotensin- Converter Enzyme Inhibitors; ARBs: Aldosterone Receptor Blockers; ARNI: Angiotensin Receptor and Neprilysin Inhibitors.

Conclusions In our HF Unit registry, patients showed a similar response to the correction of ID despite of their LVEF. Prospective and randomized trials are needed to confirm these data.

P1179

Acetazolamide as a potent chloride-regaining diuretic: its short- and long-term effects in cardiovascular patients

H Hajime Kataoka[1]
[1]*Nishida Hospital, Oita, Japan*

Background: The serum chloride concentration is an important therapeutic target according to the "chloride theory" of heart failure (HF) pathophysiology (AHA2015/ACC2016/ESC2016). The carbonic anhydrase inhibitor acetazolamide is a strong candidate as a potent chloride-regaining diuretic.
Purpose: This study was a retrospective analysis of the short- and long-term effects of acetazolamide on peripheral blood tests, serum electrolytes, and renal function.
Methods: The effects of low-dose Diamox (250-500 mg/d) were evaluated in 37 HF patients during the study period from February 2016 to September 2017. Patients with replacement (n=3) or combined usage (n=4) of this agent with other diuretic(s) were excluded. Thirty consecutive HF patients for whom Diamox was added as de-novo/add-on decongestion therapy for acutely worsening HF (n=18) or modification therapy for serum hypochloremia in stable HF (<100 mEq/L; n=12) were analyzed retrospectively. Peripheral hematologic tests were performed at baseline, and at short-term (≤10 days) and long-term (˜60 days) time-points.
Results: In all 30 study patients (Table), serum chloride concentrations increased during the short-term and decreased further over the long-term. Serum potassium concentrations constantly decreased throughout the short- and long-term study periods. Blood urea nitrogen and serum creatinine concentrations increased over the short-term, but returned to baseline levels over the long-term. Responders to Diamox (n=13, defined by HF resolution and body weight loss ≥1 kg) in the decongestion group had reduced serum b-type natriuretic peptide levels and markedly increased serum chloride concentrations, but the haemoglobin/haematocrit and serum creatinine levels did not change over the long-term after treatment.
Conclusions: Acetazolamide is a clinically potent candidate "chloride-regaining diuretic" for the treatment of HF patients under the "chloride theory". Its effect to enhance the serum chloride concentration occurs promptly within 10 days and

persists for long-term (˜60 days). Plasma volume and renal function are preserved under adequate diuretic treatment with acetazolamide.

Table Changes in peripheral blood test under acetazolamide treatment (n = 30)

Magnesium orotate for the treatment of heart failure in pregnant patients with unoperated atrial or ventricular septal defect

I Gaisin[1]; N Maximov[1]; L Shilina[2]; R Valeeva[1]; Z Vavilkina[2]; E Smirnova[2]
[1]Izhevsk State Medical Academy, Izhevsk, Russian Federation; *[2]Clinical Diagnostic Centre of the Udmurt Republic, Izhevsk, Russian Federation*

Background: Women with not closed atrial or ventricular septal defect (ASD/VSD) have small increased risk of maternal mortality or moderate increase in morbidity. Nevertheless, maternal cardiac complications occur in 12% of completed pregnancies. Offspring complications, including offspring mortality (4%), are more frequent than in the general population. Magnesium orotate (MO) is a non-steroidal anabolic orotic acid plus Mg2+ approved for pregnant patients.
Purpose: To evaluate the safety and efficacy of MO in pregnant women with unoperated ASD/VSD.
Methods: We studied 64 consecutive women with unoperated ASD (n=42) or VSD (n=22), aged 26±6 years. Patients were randomized to control group with conventional follow-up (n=32) and MO-group (n=32); in addition to standard therapy, they received MO from 2nd trimester 1000 mg t.i.d. for 1 week, followed by 500 mg t.i.d. The primary endpoints were a major adverse cardiovascular event (MACE), which included death, heart failure (HF), thrombo-embolic event, pulmonary arterial hypertension (PAH), and arrhythmias and pregnancy outcomes. Baseline and outcome data were analysed and compared for control patients vs. MO-group.
Results: At baseline, there were no significant differences between control and MO-group. NYHA functional class I had 21 (65.6%) and 20 (62.5%) patients, NYHA II had 4 (12.5%) and 5 (15.6%) patients, respectively (p>0.05). Atrial and/or ventricular ectopic beats had 28 (87.5%) and 29 (90.6%) patients (p>0.05).
No maternal mortality and no thrombo-embolic event occurred in both groups. In 17 control patients, at least one MACE occurred (53.1%): 7 developed HF (21.9%), 10 worsened HF (31.3%), 2 had atrial flutter (6.3%), 1 had a ventricular tachyarrhythmia (3.1%), and 1 patient developed PAH (3.1%).
In MO-group, no patient developed a MACE (p=0.005). MO reduced the HF occurrence (p=0.028) and HF worsening during pregnancy (p=0.015). Improvements were noted in control-adjusted changes in HF signs (−46.9%; p=0.005), cardiac hospital admissions (−40.6%; p=0.009) and in frequency of ectopic beats (−37.5%; p=0.022).
Perinatal mortality rate was 0 in the cohort, premature birth occurred in 8 controls (25%) followed by being small for gestational age (21.9%) vs. 0 in MO-group (p=0.028).
MO had no maternal and offspring adverse effects.
Conclusions: Long-term MO-therapy for pregnant patients with unoperated ASD/VSD prevents MACEs, improves HF status, and contributes to successful obstetric and foetal outcome. This study provides the evidence that metabolically acting MO is a promising therapy for pregnant patients with congenital heart disease.

P1181

Management of antithrombotic/antiplatelet therapy in patients with aortic stenosis undergoing transcatheter aortic valve replacement

M Munoz-Garcia[1]; E Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; JM Garcia-Pinilla[1]; L Morcillo-Hidalgo[1]; A Robles Mezcua[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; JJ Gomez-Doblas[1]
[1]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

Background: Many cardiac patients undergoing transcatheter aortic valve implantation (TAVI) required combined antithrombotic therapy consisting of an anticoagulant and inhibition of platelet function. Currently the optimal combination of anticoagulants and anti-platelet therapy is unknown, but it is well established that the combination increased bleeding rates.
The aim of this study was to analyze prevalence ischaemic and bleeding events in patients undergoing TAVI in according to management of antithrombotic therapy
Methods: A total of 637 consecutive patients with aortic stenosis undergoing TAVI were evaluated, between April 2008 and December 201, on base to antithrombotic/antiplatelet therapy received at discharge.
Results: The patients were characterized by had a HAS-BLED score 2.8± 1.1, CHADS2 3.35±1.0 and CHAD2-Vasc score 5.08±1.2. In 53 patiens (8.3%) were treated in monotherapy with an antiplatelet, dual antiplatelet in 424 (60.6%), (3.2%) triple therapy in 29 patients (4.6%) and 131 patients (20.6%) with oral anticoagulant plus a thienopyridine. We found not differences in mortality in according to antithrombotic therapy, respectively: 52.9% vs. 37.4% vs. 34.5% vs 47, [HR= 1.087 (95% CI 0.912-1.297), p=0.350], There were no differences in stroke 15.1% vs. 7.3% vs. 13.8% vs 10%, [HR=1.029 (95% CI 0.767-1.392), p=0.854], major bleeding 5.7% vs. 3.8% vs. 3.4% vs. 6.1% %, [HR=1.167 (95% CI 0.782-1.741), p=0.449], and myocardial infarction 1.9% vs. 3.8% vs. 3.4% vs. 0.8%, %, [HR=0.669 (95% CI 0.366-1.225), p=0.193].
Conclusions: in this study there was no differences in rate of mortality or isquemic and hemorragic events, although there were trend to higher rate of mortality in patients with only antiplatelet and anticoagulant plus thienopyridine.

Safety, pharmacodynamic and pharmacokinetic characterisation of vericiguat: key results from six phase I studies in healthy subjects

M-F Boettcher[1]; D Thomas[2]; W Mueck[1]; S Loewen[3]; E Arens[1]; K Yoshikawa[4]; J Liu[5]; C Corina Becker[1]
[1]Bayer AG, Clinical Pharmacology, Wuppertal, Germany; *[2]Bayer AG, Experimental Medicine, Wuppertal, Germany*; *[3]Chrestos Concept GmbH & Co. KG, Essen, Germany*; *[4]Bayer Yakuhin, Ltd, Clinical Sciences, Research & Development Japan, Osaka, Japan*; *[5]Bayer Healthcare Co. Ltd, Beijing, China*

Funding Acknowledgements: Funding for this research was provided by Bayer and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA

Background: Vericiguat is a once-daily oral soluble guanylyl cyclase (sGC) stimulator in clinical development for treatment of chronic heart failure (HF).
Purpose: To characterise safety, pharmacodynamic (PD) and pharmacokinetic (PK) properties of vericiguat in healthy males. Bioavailability (BA) and effect of food on vericiguat PK were also studied.
Methods: Vericiguat (oral solution/immediate-release [IR] tablet) was administered to healthy White, Chinese and Japanese men as single doses (SDs; 0.5–15 mg) or multiple doses (MDs; 1.25–10 mg; once-daily for 7 days) in six phase I studies. Safety, PD and PK profiles of vericiguat were assessed.
Results: Overall, 265 subjects were randomised and 255 completed their respective studies. There were no deaths or serious adverse events (AEs). Results from the first in human, single-ascending dose study (vericiguat oral solution, fasted state in White subjects) are presented here as representative data of the SD studies. In this study, the most common drug-related AEs in vericiguat-treated subjects were headache (5 [8.9%] vs 0 in placebo) and postural dizziness (5 [8.9%] vs 0 in placebo), consistent with the vasodilatory effect of vericiguat. Increases in heart rate (HR; <10 bpm), vasoactive hormones and changes in cardiac impedance were observed at ≥5 mg vericiguat relative to placebo. The 15 mg dose (oral solution, fasted) was not well tolerated due to exaggerated PD effects of orthostatic reactions in 3 of 4 subjects. Mean maximum vericiguat plasma concentration (Cmax) and area under the concentration-time curve (AUC) increased with dose in a linear fashion (0.5–15 mg: 17.2–430 μg L-1 and 273–7,900 μg*h L-1, respectively).
In a representative MD study in Japanese subjects, SDs and MDs of 1.25–10 mg vericiguat for 7 days were well tolerated. Effects of vericiguat on HR corresponded to compensatory increases in HR following expected vasodilation. Vericiguat (IR tablet, fasted state) was rapidly absorbed (median time to reach Cmax [tmax]: 1.0–2.5 h) with low inter-individual variability in exposure after the first dose and at steady state. Observed half-life was 18–27 h. No evidence for deviation from dose-proportionality was observed. Slight accumulation in AUC was observed with MDs (accumulation indices for AUC and Cmax were 1.40–1.66 and 1.16–1.44, respectively); no unexpected accumulation was observed. In White subjects, administration of vericiguat IR tablet with food increased BA by 19%, reduced PK variability and prolonged vericiguat absorption (median tmax: 1–1.5 h [fasted]; 4 h [fed]).
Conclusion(s): SDs and MDs of vericiguat up to 10 mg were generally well tolerated. AEs and PD changes were consistent with the mechanism of action. Vericiguat PK was linear with low inter-individual variability; the half-life indicated suitability for once-daily dosing. The PK, PD and safety profile of vericiguat was in line with the expected effects of an sGC stimulator and consistent across populations studied.

P1183

Pharmacodynamic and pharmacokinetic interaction profile of vericiguat

M-F Boettcher[1]; S Loewen[2]; M Gerrits[3]; C Corina Becker[1]

[1]Bayer AG, Clinical Pharmacology, Wuppertal, Germany; *[2]Chrestos Concept GmbH & Co. KG, Essen, Germany*; *[3]Merck & Co., Inc., Kenilworth, New Jersey, United States of America*

Funding Acknowledgements: Funding for this research was provided by Bayer and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA

Introduction: Vericiguat is an oral, once-daily soluble guanylate cyclase stimulator in development for the treatment of heart failure (HF) with reduced ejection fraction (HFrEF).

Purpose: A series of pharmacodynamic (PD) interaction studies with drugs often used to treat HF or with a narrow therapeutic index were conducted to support the development of vericiguat.

Methods: Three studies in healthy males investigated potential PD interactions between vericiguat and sacubitril/valsartan (SV), aspirin and warfarin (Table).

Results: Treatment with SV 97/103 mg at steady state together with vericiguat 2.5 mg as single and multiple doses was well tolerated. Generally, no significant PD interactions between SV and vericiguat were observed (Table). SV at steady state had no clinically relevant impact on the pharmacokinetics (PK) of vericiguat and vice versa.

In the aspirin study, no effect of vericiguat 15 mg as a single dose (SD), and no cumulative effect of vericiguat 15 mg with aspirin 1000 mg (up to 2 days prior to and concomitantly with vericiguat 15 mg) on bleeding time or platelet aggregation

P1183 Phase I vericiguat interaction studies

Short title	Study design and description	Inclusion criteria	Objectives
Sacubitril/valsartan interaction studyEudraCT2015-004809-16	Single-centre, randomised, single-blinded, placebo-controlledCo-administration of 2.5 mg vericiguat/placebo OD and sacubitril/valsartan 97/103 mg twice-daily over 14 days at steady state2.5 mg vericiguat dose was selected as this was to be the starting dose of the titration schedule in subsequent phase II and III studiesN=32 randomised, 29 completed	Healthy male subjects with a BMI ≥18.0 and ≤29.9 kg/m^2, 40 to 60 years, inclusive	Primary: Safety and tolerabilitySecondary: PD interaction (haemodynamic profiles: SBP, DBP, MAP and HR)PK interaction (maximum observed concentration [C_{max}] and AUC)
PD findings: Point estimates for the difference of sacubitril/valsartan+ vericiguat and sacubitril/valsartan +placebo for SBP, DBP, MAP and HR were -1.66 (90% CI:-4.22, 0.90), -1.80 (-3.24, -0.36), -1.70 (-3.77, 0.37) and -0.33 (-2.25, 1.58), respectively			
Aspirin interaction studyEudraCT2014-000765-52	Single-centre, non-blinded, non-controlledPilot part: Non-randomised (SD 15 mg vericiguat), N=11 valid for safety and PK analysisMain part: Randomised, 3-period, 3-sequence, 3-fold crossover. Treatments were: A: 15 mg vericiguat, (Day 1); B: 500 mg aspirin (Day -1, Day 1); C: 500 mg aspirin (Day -1) and SD 15 mg vericiguat + 500 mg aspirin (Day 1). Subjects were randomised to A-C-B, B-A-C or C-B-ABlood sampling in the fasted state was required for coagulation measurements. Given that bioavailability is lower in the fasted state, vericiguat 15 mg (fasted) was selected to investigate interactions relevant for 10 mg vericiguat (fed) N=14 valid for safety and PK analysis; 13 valid for PD analysis	Healthy male subjects with a BMI ≥18.0 and ≤30.0 kg/m^2, 18 to 45 years, inclusive	Main primary: PD interaction: influence of a combined treatment of a SD of 15 mg vericiguat (fasted) with aspirin on bleeding time and platelet aggregationSecondary: Effects of aspirin on PK of vericiguat, safety and tolerability
PD findings: Estimated differences between vericiguat + aspirin and aspirin alone were: 2.7 sec (95% CI: -90.4, 95.8) and 2.4% (-7.0, 11.8) for platelet aggregation, assessed by turbidimetry, respectively (both non-significant p>0.05)			
Warfarin interaction studyEudraCT2014-004880-19	Single-centre, randomised, double-blind, placebo-controlled, 2-fold crossover design10 mg vericiguat/placebo OD over 9 days; warfarin administered on Day 6N=23 completed treatment	Healthy male subjects with a BMI ≥18.0 and ≤30.0 kg/m^2, 18 to 55 years, inclusive	Primary: Investigate the influence of MDs of 10 mg vericiguat OD on PK and PD (clotting parameters) of a SD (oral) of 25 mg warfarin, administered on the sixth day of treatmentSecondary: Safety and tolerability of the combination
PD findings: Least squares mean ratios of AUC (0-96 h) for vericiguat + warfarin/ placebo + warfarin for prothrombin and factors VII, II and X were 1.00 (90% CI: 0.99, 1.01), 0.97 (0.95, 0.99), 1.00 (0.98, 1.02) and 1.00 (0.98, 1.03), respectively			

AUC, area under the concentration-time curve; BMI, body mass index; CI, confidence interval; DBP, diastolic blood pressure; HR, heart rate; MAP, mean arterial pressure; MD, multiple dose; OD, once-daily; PD, pharmacodynamics; PK, pharmacokinetics; SBP; systolic blood pressure; SD, single dose

was observed (Table). Co-administration of aspirin had no effect on vericiguat PK. Vericiguat was well tolerated alone and with aspirin.
In the warfarin study, no PD effect of multiple doses (MDs) of vericiguat on the coagulation inhibition elicited by an SD of warfarin was observed (Table). No PK interactions were observed after administration of MDs of vericiguat with warfarin compared to MDs of placebo with warfarin. Co-administration of MDs of vericiguat or placebo with an SD of warfarin was well tolerated.
Conclusion(s): Co-administration of vericiguat together with SV, aspirin or warfarin was well tolerated. No clinically relevant PD or PK interactions were observed. These findings support concomitant use of these commonly used drugs in HF together with vericiguat.

Parameter (unit)	Day (profile)	Vericiguat dose (mg)	Difference "Vericiguat–Placebo"	90% CI Lower	90% CI Upper

Background/Introduction: Vericiguat is a novel stimulator of soluble guanylate cyclase in development for treatment of chronic heart failure (HF) for once-daily oral administration. Guidelines recommend short- and long-acting nitrates for acute treatment and prophylaxis of angina in patients (pts) with coronary artery disease (CAD; a common comorbidity in HF). Co-administration of the short-acting nitrate nitroglycerin (NTG) with vericiguat in animal studies as well as in healthy volunteers (EudraCT 2014-001235-36) and in pts with CAD (NCT02617550) demonstrates that this combination is well tolerated.
Purpose: This study aimed to investigate the pharmacodynamic (PD) drug–drug interaction (DDI) between co-administered isosorbide mononitrate (ISMN) extended-release (ER) and vericiguat in pts with stable CAD (± HF).
Methods: The Vericiguat ISOsoRbide Mononitrate Interaction (VISOR) study (NCT03255512), a multicentre, double-blind, placebo (PBO)-controlled comparison study, investigated the co-administration of ER ISMN 60 mg with vericiguat in 41 pts. Pts were randomised to vericiguat + ISMN (n=28) or PBO + ISMN (n=13). Pts were administered ISMN once-daily for 2 weeks followed by co-administration with PBO/vericiguat. Up-titration of PBO/vericiguat from 2.5 to 5 to 10 mg once-daily was performed in 2-week increments; pts on PBO/vericiguat 10 mg + ISMN were monitored for 2 weeks. The primary objective was to evaluate PD DDIs between vericiguat and ISMN (assessed by blood pressure [BP] and heart rate [HR]); the secondary objectives were to evaluate safety and tolerability.
Results: In total, 35 pts completed treatment (n=12 and 23 for the PBO and vericiguat groups, respectively). Co-administration of vericiguat + ISMN led to mean baseline- and PBO-adjusted reductions in systolic BP (SBP) of 1.4–5.1 mmHg and diastolic BP (DBP) of 0.4–2.9 mmHg and changes in HR of 0.0 to 1.8 bpm (Table 1). These changes were not deemed clinically relevant. No consistent vericiguat dose-dependent PD effects were observed. Two discontinuations due to adverse events (AEs) occurred in the study; one patient terminated the study due to ISMN-related AEs; the other patient due to unstable angina; discontinuations were not related to PBO or vericiguat. The incidence of AEs was comparable between treatment groups (92.3% and 66.7% in the vericiguat + ISMN and PBO + ISMN groups, respectively).
Conclusion(s): Based on the lack of symptoms associated with the changes in BP and HR in pts taking vericiguat + ISMN, these changes were not considered to be clinically relevant. This combination was well tolerated and is supported by the consistency of results from previous preclinical and human studies. Concomitant use of short- and long-acting nitrates with vericiguat is unlikely to cause clinically significant AEs beyond those known for NTG and ISMN.

P1185

Observational study on the use of non antivitamin K anticoagulants in atrial fibrillation and deep vein thrombosis in the community

G Gheorghe[1]; CE Georgescu[1]; AS Hodorogea[1]; AG Florescu[1]; ACD Gheorghe[1]; IT Nanea[1]
[1]"Th. Burghele" Hospital, University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Aim: To assess the indication of the use of non antivitamin K anticoagulants (NOAC) in patients (pts) with nonvalvular atrial fibrillation (NAF) or acute deep venous thrombosis/pulmonary embolism (DVT/PE) admitted in a community hospital
Method: We studied the medical records of the pts with NAF, CHA2DS2-VASc ≥ 2 or acute DVT/PE admitted in our community hospital during three successive months. We noted the aria (rural or urban) from which the pts came, the type of anticoagulation (antivitamin K (AVK), NOAC or no anticoagulation at all) at admission and at discharge. In the AVK pts we noted the international normalized ratio (INR) at admission, considering non therapeutic values <2 or >3. The prescription of NOAC was decided according to the creatinine clearance, as indicated in the guidelines. We compared the type of anticoagulant between the admission and the discharge from the hospital in relation to the initial INR values, rural or urban aria the pts were coming from, age and sex. Statistical analysis was performed using EpiInfo 8.
Results. There were 194 pts, 94 men, mean age 72.26 +/-18 years, admitted in the hospital for NAF (147 pts) and DVT or PE (47 pts) during 3 successive months. 33% pts were from the rural aria. At the admission 51% pts with NAF had AVK, 8 % pts had NOAC and 40.8% pts did not receive anticoagulant, especially in rural aria. In 57.33% pts with AVK INR level was not within the therapeutic range, 60.4% from them being from the rural aria. At discharge 44.22% pts were prescribed AVK, 51% pts were prescribed NOAC and 4.7% pts were not prescribed any anticoagulant ($p<0.01$) (fig.1). The decision to initiate the treatment with NOAC was taken in 13.9% pts with uncontrolled INR on AVK and in 45.3% pts initially without anticoagulant

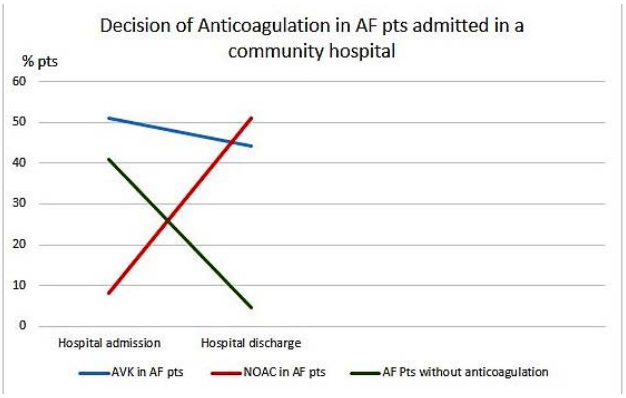

Fig. 1

treatment which lived in rural area. In the DVT/PE group 38.29% pts were prescribed NOAC especially those living in rural area and 61.7% pts were prescribed AVK. There were no differences between men and women or regarding the age. There were no bleeding or stroke during the hospitalization.
Conclusion: The rate of no anticoagulation in NAF pts in the community is still elevated. Despite their high prices, there is an increased tendency for the chronic use of NOAC in pts with NAF or DVT/PE in the community especially in those with non therapeutic INR on AVK or which cannot periodically determine INR. By respecting the contraindications, their usefulness and safety are good.

Determinants of non-pharmacological compliance in patients with heart failure

26/05/2019 08:30N Natalia Swiatoniowska[1]; A Szymanska-Chabowska[1]; J Gajek[1]; B Jankowska-Polanska[1]
[1]Wroclaw Medical University, Wroclaw, Poland

Introduction: The prognosis for patients with heart failure (HF) can be improved effectively by disorder-specific lifestyle modifications and optimized self-care. Apart from pharmaceutical treatment, sodium-restricted diet, fluid restriction, symptom monitoring by daily weighing and maintenance of physical activity are a significant part of HF patient care and management. Poor adherence to treatment recommendation is a common problem among heart failure patients.
The aim of the study was to evaluate the adherence to non-pharmacological recommendations in the treatment of chronic heart failure.
Material and methods. 475 patients (including 222 women), mean age 69.7±7.7, with HF were included. In the study was used the Revised Heart Failure Compliance Scale to assess non-pharmacological level of compliance. The socio-clinical data were obtained from medical records.
Results: The patients least often adhered to recommendations regarding physical activity (47.8% no active at all, and 19.4% very rarely). They similarly adhered to fluid intake restrictions (25.1% no restrictions at all, and 17.3% very rarely) and to salt intake restrictions in diet (12.8% at all, and 21.9% very rarely). They better adhered to drug intake and regular check-ups (57.5%). Having calculated the sum for total compliance, it was proved that only 6.9% of respondents adhere to recommendations totally. In univariate analysis the predictors negatively influencing the total compliance were: age >65 years old (rho=-0.165), loneliness (rho=-3.002), duration of the disease>4 years (rho=-0.179), higher stage of NYHA (rho=-1.612), co-morbidities (rho=-0.729), re-hospitalizations (rho=-0.729) and beta-blockers treatment (rho=-1.612). In multivariate analysis the independent predictors of total non-pharmacological compliance were: loneliness (β=-1.816), NYHA III and IV and number of co-morbidities (β=-0.676).
Conclusions: The level of adherence to non-pharmacological recommendations in treatment of heart failure (HF) is low, in particular as regards the salt and fluid intake restrictions in everyday diet. Loneliness, NYHA III and IV, number of co-morbidities are independent predictors of worse compliance.

P1187
Advanced practice providers' utilization of EUROMACS (european registry for patients with mechanical circulatory support) : single center experience

YA Ylenia Ann Quiaoit[1]; BL Lentz[1]; JL Lajoie[1]; MRM Molina[1]
[1]University of Pennsylvania, Philadelphia, United States of America

Background: EUROMACS was recently validated as an early predictor for post Left Ventricular Assist Device (LVAD) mortality due to right ventricular failure (RVF). Post LVAD RVF has been reported to be between 4% and 50%; and RVF associated mortality was seen in 29% of patients receiving an LVAD.
Purpose: The aim of this study is to describe advanced practice providers' role and utilization of EUROMACS predictive scores in patients requiring RVAD post LVAD implantation.
Methods: We performed a retrospective analysis of 56 (out of 63) patients who underwent LVAD implantation January 1, 2017 to May 31, 2018. Descriptive statistical analysis of the 56 cases with complete pre and post LVAD hemodynamics and echocardiograms data was performed. Cases with incomplete data was excluded from the analysis.
Results: Summary of demographics: 1. LVAD group (n-49): 40 males, 9 females, 14, 23 were for bridge to transplant (BTT), 27 were for destination therapy (DT), 3 for bridge to recovery (BTR), & 3 for bridge to intent (BTI). 2. BIVAD group (n-7): 7 males, 5 for BTI, 2 DT. All 56 patients were successfully implanted with LVAD. 12.5%(n-7) required RVAD support post implantation. 3.5% (n-2 /56) 30-days mortality rate post BiVAD implantation. Our analysis revealed that pre-LVAD, patients who required RVAD support (BIVAD group) had higher average RA (14.7 vs 11.8 for LVAD group) and PCWP30 vs 24.1 for LVAD group) ; required more inotropic (42% require 2 or more vs 4% for LVAD group) and mechanical support (71% had either ECMO, Impella orIABP pre implant vs. 16% LVAD group). Also, BiVAD group also had pre-LVAD echocardiogram noting moderate and severe RV dysfunction. In the post-operative phase, the BIVAD group also had higher average RA (13), PCWP (18), required 2 or more inotropic support (71%, n-5), and more RV dysfunction (moderate - severe RV dysfunction) on their post LVAD implant echocardiograms.
Conclusion/Implications: Advanced Practice Providers' (APP) understanding and utilization of EUROMACS as predictive tool in early intervention of BiVAD vs early RVAD support is pivotal in decreasing mortality in the first 30 days. Moreover, the echo-Doppler 'profile' of moderate to severe RV dysfunction is prevalent in patient requiring BiVAD support and immediate RVAD early post LVAD implantation. Moreover, APPs correlation of invasive hemodynamic data with the echo-Doppler provides a comprehensive assessment and a useful weaning tool of inotropes, vasodilators, and diuretic management.

P1188
LVAD-DT: The final destination

JE Hupcey[1]; L Kitko[1]; JH Gilchrist[2]; IC Gilchrist[3]
[1]The Pennsylvania State University, College of Nursing, University Park, United States of America; *[2]Duke University Medical Center, Durham, United States of America*; *[3]Penn State Hershey Medical Center, Heart & Vascular Institute, Hershey, United States of America*

Funding Acknowledgements: American Heart Association Beginning Grant-in-Aid (14BGIA18980022) and by the U.S. National Institutes of Health, National Institute of Nursing Resear

Background: LVADs can extend and improve quality of life for individuals with advanced heart failure. Fifty percent of LVAD implantations are destination therapy (DT), which is long-term support for non-heart transplant candidates.
Purpose: To investigate whether conversations about LVAD deactivation occurred with LVAD-DT recipients and their family caregivers (FCG) and whether device deactivation occurred prior to the recipient's death.
Methods: LVAD-DT recipients and their FCGs, from 2 longitudinal prospective studies, were individually interviewed and asked if discussions about device deactivation at end of life (EOL) occurred. Following the death of LVAD recipient, FCGs were interviewed about their loved one's death and about LVAD deactivation. Interviews were analyzed using a qualitative content analysis. Electronic medical records (EMR) were reviewed to determine device deactivation.
Results: Thirty-five LVAD-DT recipients and their FCGs were interviewed. There majority of the LVAD recipients were male (80%); while FCGs were female (86%). The mean time with an LVAD was 1.5 years (3 months to 5 years). During enrollment LVAD recipients had on average 6 readmissions. Six patients (17%) died during the study, no LVADs were deactivated. Seventeen percent (6/35) had advance decisions in the EMR: all completed prior to LVAD implantation; none included wishes regarding device deactivation. LVAD recipients did not recall conversations about device deactivation at the time of implantation or after implantation and only 1 FCG remembered having those discussions. During the post-death interviews, caregivers said: One doctor came and talked to me about it and I really didn't want to hear about it. I didn't even think you had to turn it off … and we have to turn the pacemaker off and to me that was like murder. I didn't want to hear about it. I said come back tomorrow.
The first I heard about it was when I was reading some of the literature … .I never give it any thought up till then … you mentioned it as part of the research study … the doctors never did.
At some point it should be shared a little bit more … what happens at EOL and this is a possibility [device deactivation] and what you may have to do. Because it's something that we never really talked about with anybody.
Conclusions: The pre-implantation period is a very busy time, if discussions about device deactivation at EOL occurred, they were not remembered.Despite an average of 6 hospitalizations post-implantation, discussions about device deactivation did not occur.Discussions about EOL decisions are important, particularly with a person with a life-limiting disease. These discussions and the advance decisions should be updated as a person's condition changes and advanced therapies are added to prolong life. The ultimate goal is for the terminal trajectory to be one that is peaceful and acceptable to the person who is dying and their family.

P1189

Socio-clinical variables affecting the level of self-care in elderly patients with heart failure and cognitive disorders

B Prochota[1]; K Szwamel[2]; I Uchmanowicz[3]
[1]*Olesno Health Care Center, Olesno, Poland*; [2]*Opole Medical School, Faculty of Medical Science, Opole, Poland*; [3]*Wroclaw Medical University, Faculty Of Health Sciences, Wroclaw, Poland*

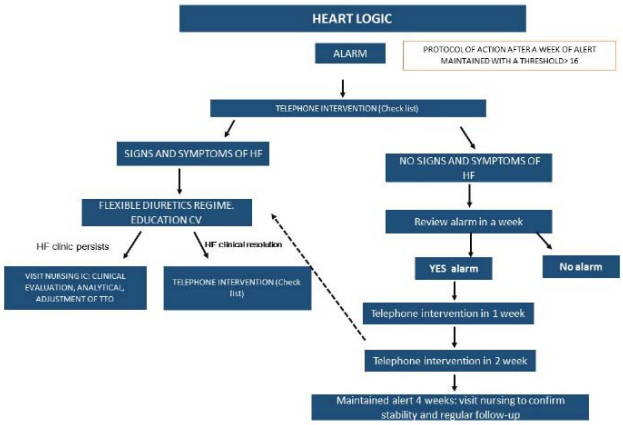
Introduction: Promoting self-care is the cornerstone of heart failure (HF) management. The number of hospitalizations and unscheduled visits could be reduced in elderly patients with heart failure by the patients' active involvement in self-care.
Objectives. To measure the level of self-care in elderly patients with heart failure, to examine the influence of socio-clinical variables on the level of self-care, and identify the socio-clinical variables that are predictors of self-care.
Material and methods: The study included 100 patients (48 female, 52 male) aged 60–88, diagnosed with HF, treated at the Internal Medicine Department of our Care Center. The European Heart Failure Self-care Behavior Scale 9 (EHFScB) and Mini-Mental State Examinaton (MMSE) were used.
Results: The total classic self-care score was 22.76 points (SD=8.49), and the standardized score was 61.78 (SD=23.59). Patients who were in a relationship, did not take digoxin or diuretics, were in NYHA classes I and II, and had normal scores or cognitive impairment with no dementia in the MMSE, had significantly higher levels of self-care. Self-care was also correlated with patient age (rs = −0.356, p <0.001) and LVEF (rs = 0.234, p = 0.019). Linear regression analysis demonstrated that only NYHA class has a significant impact on EHFScB scores. Compared to classes I and II, NYHA class IV decreases the standardized EHFScB score by a mean of 23.595 points.
Conclusions: Intensified self-care education should be provided to patients living alone, taking digoxin and diuretics, suffering from moderate dementia, and classified in NYHA class IV. These patients may require special educational strategies to gain the knowledge required for effective self-care.

P1191

Intervention algorithm for the heart logic device for nurse specialized in hf

M Monica Perez Serrano[1]; JGA Josebe Goirigolzarri Artaza[1]; DEV Daniel Enriquez Vazquez[1]; CNP Carlos Nicolas Perez[1]; MFE Marcos Fernandez Escarbajal[1]; RBF Ramon Bover Freire[1]; CMM Carlos Macaya Miguel[1]; CRR Concepcion Ramirez Ramos[1]; MGB Marcos Gonzalez Barja[1]; NRL Noemi Ramos Lopez[1]; AJB Adrian Jeronimo Baza[1]; EMG Eduardo Martinez Gomez[1]; IVC Isidre Vilacosta[1]; PMS Paula Martinez Santos[1]
[1]*Hospital Clinic San Carlos, HEART FAILURE, Madrid, Spain*

Purpose: HeartLogic is a diagnosis of heart failure implemented in ICD and CRT-D designed to detect early warning signs of worsening heart failure by combining data from 5 sensors in a single, with a specificity of 85.7% and a sensitivity of 70% allows to anticipate acute decompensation up to 34 days. The objective is to demonstrate that patients with the device and who are monitored by a nurse specialized in HF through a telephone intervention algorithm reduce the rate of IC readmission through early telephone intervention.
Methods: A prospective observational study will be conducted in all patients with this device and where an intervention and performance algorithm for specialized nursing in HF was designed, focused on early telephone intervention based on the diagnosis and detection of signs of decompensation and early application of the Flexible diet of diuretics. The activation of the protocol is carried out when the patient's device threshold is ≥16, at which time the nurse performs the telephone intervention and depending on whether or not symptoms are present, it is selected in one arm or another, to closer monitoring, this allows anticipating a possible income up to 34 days. Once the threshold <6 is stabilized, the patient leaves the algorithm.
Results: Since January 2018, 18 patients were enrolled in follow-up of alerts, of which 3 were women and 15 were men. The average age was 65.72 years. During the 6-month period, there were 11 alerts with threshold ≥ 16, to which telephone intervention was performed according to the algorithm. The cause of the alert was not found in two cases. There was a single admission related to HF in a context of severe anemia. Two of the patients lost track, and one device was cleared by infection. The rest of the case was resolved with treatment optimization.
Conclusion: The use of this algorithm allowed early intervention in most cases, with a single non-avoidable admission since the first cause that triggered it was not the CI. This algorithm will allow a greater follow-up of the patients and an early intervention in the case of decompensation



ALGORITHM

P1192

The HEART path, Help with Adaptation and Rehabilitation Trajectory

C J Caroline Wulffraat[1]; AC Hofman-Tanis[1]
[1]*ijsselland ziekenhuis, capelle aan den ijssel, Netherlands (The)*

Context: In the Netherlands today, there is a growing group of elderly patients with cardiac diseases who will not undergo cardiac surgical intervention. Cardiac surgery can technically be performed in fragile, older patients, but it is difficult for the individual patient to weigh the risks and benefits of such major surgery. A palliative approach is needed from the moment of deciding that there will be no intervention, since these patients are then confronted with a life limiting disease. Knowledge and cooperation from multi-disciplinary care professionals, who are involved in care for this patient category, is needed to develop a care pathway that supports these patients in adapting to a life limiting disease.
Method: The method of action research was chosen. Eleven patients, and one relative, with this specific cardiac condition were interviewed (semi structured). Two multidisciplinary heart teams gave input through patient assessments. Focus sessions with local cardiologists, NP's, GP's and homecare nurses provided a multi-faceted view on the concept of the care pathway. A care pathway was designed and implemented. Before discharge there is a shared decision on the treatment plan. Weekly home visits from a heart failure nurse with expertise in symptom recognition and relief are planned in the first month after discharge. This includes advanced care planning and, if necessary, continuing visits. A digital two-way patient file provides communication between home care and the heart failure clinic. At discharge the GP is informed by telephone and on paper and a home visit is planned.
Findings: At the time of the shared decision-making, patients rate honesty and expertise the highest. The cardiologists use hard data for decision-making, however, the widely used EuroSCORE does not cover this patient category. At discharge there was poor communication between care professionals, particularly with regards to symptom recognition and relief. Symptoms such as tiredness, fluid retention and weakness are experienced daily. There is a fear of acute, severe symptoms that often return at night, such as dyspnoea, chest pain and the feeling of suffocating/dying. In the first 18 months 83 patients were included in the pathway, 23 improved, 28 still have regular visits. Communication via the digital two way patient file is highly valued. Furthermore 32 patients died, 22 at home, 4 in a hospice and 4 in hospital, 2 places of death are still unclear. Re-admission data and data on symptom relief is currently being assessed.
Conclusions: Inclusion of frailty scores such as ISAR and KATZ ADL can provide a better patient assessment. Poor communication at discharge leads to inadequate symptom recognition and relief. The loss of mobility, due to symptoms and unpredictability of the disease and fear of returning symptoms can be addressed by a palliative approach. Since the start of the care pathway only 12,5% of the included patients died in hospital.

P1193

Health literacy, knowledge, treatment adhesion and self-care in heart failure in a middle income country

LL Pedraza[1]; SCS Pokorski[2]; BB Machado[3]; EB Ferro[3]; RH Souza[3]; FS Caetano[3]; ER Rabelo-Silva[4]
[1]Universidade Federal do Rio Grande do Sul, Programa de Pós-Graduação em Ciências da Saúde: Cardiologia e Ciências Cardiovasculares, Porto Alegre, Brazil; *[2]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*; *[3]Universidade Federal do Rio Grande do Sul, Nursing School, Porto Alegre, Brazil*; *[4]Universidade Federal do Rio Grande do Sul; HCPA, Programa de Pós-Graduação em Ciências da Saúde: Cardiologia e Ciências Cardiovasculares, Porto Alegre, Brazil*

Introduction: Studies show that the care of patients with heart failure (HF) in a multidisciplinary team contributes to improve knowledge, adherence and increased self-care practice. In addition, a few years of patient study and misunderstanding of common medical terms may interfere with their understanding of health concepts. Studies involving these themes are relevant to guide the practice of the multiprofessional team. Objective: To describe health literacy, knowledge on HF, adherence to treatment and self-care in patients linked to a recent implemented HF Management Program. Methods: Cross-sectional study with adult patients hospitalized for decompensated HF and who had follow-up with the multiprofessional team in a university public hospital in southern Brazil during the period from November 2017 to November 2018. To assess the level of literacy in health, the Short Assessment of Health Literacy scale was used, which evaluates the pronunciation and comprehension skills of common medical terms. It is composed of 18 questions and a score between 0 and 14 suggests inadequate health literacy. In order to assess the knowledge about HF, a questionnaire for knowledge of the disease was composed of 14 questions, which considers as appropriate 70% of assertions. Adherence to treatment was assessed with a questionnaire composed of 10 questions, in which a score of 18 points (70%) is considered adequate adherence. The skills for self-care were measured using the European Heart Failure Self-Care Behavior Scale, composed of 12 questions (lower scores indicate better self-care - maximum score 60 points). Results: 130 patients were evaluated, mean age of the participants was 64 $\pm$ 11 years. The health literacy questionnaire averaged 12 $\pm$ 4 hits; the knowledge about HF had a score of 69 $\pm$ 17; adherence to treatment had a score of 16 $\pm$ 4 and self-care of 32 $\pm$ 8. Conclusion: The results indicate that patients are unaware of common medical terms, knowledge about HF is close to adequate, and adherence to treatment. However, self-care behavior still lacks strategies for patients to achieve attitudes that impact clinical outcomes. Follow-up in a multidisciplinary team, especially after follow-up after hospital discharge, has benefits and should be implemented with a prospective evaluation of this behavior.

P1194

Evaluation of Self-Care Improvement after admission in a Heart Failure Clinic

A Ferreira[1]; A Neto[1]; D Seabra[1]; I Oliveira[1]; P Patricia Silva[1]; M Soares[1]; S Ferreira[1]; S Poiares[1]; M Meira[1]; A Andrade[1]
[1]Hospital Centre do Tamega e Sousa, Penafiel, Portugal

Introduction: Heart failure (HF) is a highly prevalent syndrome with significant morbimortality and great impact on patients (pts) and their family's quality of life. HF-related self-care behaviour reflects the actions that an HF patient undertakes to maintain life, healthy functioning, and well-being. The European Heart Failure Self-Care Behaviour Scale (EHFScB scale)is a validated scale considered easy to administer and practical to use. The scale is based on international guidelines for HF management and has been found to measure change in behaviour over time.
Aims: To evaluate the self-care capacity and its improvement over time in pts with chronic HF and reduced ejection fraction (HFrEF) in a HF Clinic (HFC).
Methods: Unicentric, retrospective analysis of pts followed in a HFC since 3/2011. Included pts with reduced ejection fraction (EF) (<50%) and previous diagnosis of HF for at least 6 months, who had completed the EHFScB scale in two different moments: the first moment (T1) before the nursing teaching session and the other (T2) 6 to 12 months after this intervention. This 12-item scale measures self-care behaviors on a 5-point likert scale ranging from 1 (strongly agree) to 5 (strongly disagree). A total score is calculated by summing responses from each item and lower score indicates better self-care.
Results: The sample consists of 58 pts with mean age of 63 +/- 12,4 years and male predominance (74%). 65% had ischemic etiology with median EF of 29.9% +/- 6,3 at admission in HFC. 62% had a prior HF hospitalization. Mean EHFScB scores in T1 and T2 was 37 +/-11 and 19 +/-5,8, respectively. All behaviours had a positive evolution in self-care capacity. The largest improvement was in the "asking for help" factor with a mean decrease of 1.8 points. The factor with the lowest evolution was 'adapting activities' with a mean increase of 1 point.
Conclusion: In this cohort, we concluded that pts adopts non-pharmacological measures in an easier way and follow the guidelines given by the professionals when properly instructed. The EHFScB scale can be used to assess self-care behaviours and as a baseline for the mutual decision between the patient and nurse or physician regarding self-care. It can also be used to improve patient compliance and empower nursing education sessions to address specific problems of heart failure patients.

P1195

Assessment of quality of life of patients followed in a heart failure clinic

P Patricia Silva[1]; D Seabra[1]; A Neto[1]; I Oliveira[1]; S Ferreira[1]; A Ferreira[1]; M Soares[1]; S Poaires[1]; M Meira[1]; A Andrade[1]
[1]Hospital Centre do Tamega e Sousa, Penafiel, Portugal

Introduction: Heart failure (HF) is a disease with a major impact in patients (pts) quality of life (QoL). It affects psychological, physical and social domains. Kansas City Cardiomyopathy Questionnaire(KCCQ) is an internationally validated questionnaire that describes social and functional limitations and quantifies symptoms and signs of HF (frequency, severity and stability) and QoL in the previous 2 weeks.
Aims: To assess the QoL of pts with chronic HF in a HF Clinic (HFC).
Methods: Unicentric, retrospective analysis of pts followed in a HFC since 3/2011. Included pts with previous diagnosis of HF for at least 1 year, who completed the KCCQ. This questionnaire has 23 questions regarding 5 fields: physical function, symptoms (frequency, severity and recent change),social function, self-efficacy and knowledge, and QoL.
Results: The sample consists of 88 pts, with mean age of 60 years, 78.4% male. 65% had ischemic aetiology and 68.2% had HF hospitalization in the previous year. Regarding the questionnaire, 60% of pts had no physical limitation in self-care activities, 25% had moderate limitation in medium-effort activities and 25% felt slightly limited. 69.3% of pts had no HF symptoms in the previous 2 weeks. Those who were symptomatic (30.7%), the majority underestimated symptoms relevance (with 32% describing symptoms as "stable" and 13.6% stated as "feeling better"). 60% regarded themselves as "satisfied" if they had to spend the rest of their lives as they were at the time of the questionnaire. No significant limitation in daily life activity was experienced by 45% of pts. 30% rarely experienced disappointment symptoms regarding the illness. Only 20% knew exactly which factors might decompensate HF. 45.4% stated that HF symptoms did not limit their lives, and 30% usually did not experience depressive feelings about it. Social limitations were felt in 25.3% of pts.
Conclusion: KCCQ allows appropriate assessment of pts symptoms and functional implications in different areas, allowing the HFC team to improve pts well-being and provide knowledge to achieve a better understanding of their condition. In this cohort, most pts had no physical significant daily-life limitations and considered themselves "satisfied", which might reflect that they have a good QoL. However, it also shows that there is room to reinforce the nursing teaching sessions mainly about the factors that can decompensate their health status.

P1196

The Dutch multidisciplinary guideline 'Palliative care for patients with heart failure'

MSA Aertsen-Van Der Kuip[1]; YMP Engels[2]; CMHB Lucas[3]; A De Graeff[4]; CW Middeljans-Tijssen[5]; R Starmans[6]; MWF Van Leen[7]; J Van Erp[8]; R Tabak[2]; L Bellersen[2]
[1]Diakonessen Hospital Utrecht, Utrecht, Netherlands (The); *[2]Radboud University Medical Centre, Nijmegen, Netherlands (The)*; *[3]Alrijne Hospital, Leiderdorp, Netherlands (The)*; *[4]University Medical Center Utrecht, Utrecht, Netherlands (The)*; *[5]Slingeland Hospital , Doetinchem, Netherlands (The)*; *[6]General Practice Center Vaillantplein, Den Haag, Netherlands (The)*; *[7]Ruitersbos, Elderly care, Breda, Netherlands (The)*; *[8]Dutch Heart Foundation, Den Haag, Netherlands (The)*

Purpose: Although the mean survival of patients with advanced heart failure is even shorter than of patients with cancer, and their symptom burden higher, less receive palliative care. Therefore, we developed a multidisciplinary guideline.
Methods: The guideline was developed by the Netherlands Comprehensive Cancer Organisation and experts, representing patients as well as all relevant professional associations. Using a survey, the most important barriers were collected from professionals and patients. This resulted in six topics, which were studied in depth. Based on systematic reviews, literature searches and consensus, recommendations were made regarding prognosis, palliative care provision, advance care planning, communication, organisation of care and medication in the terminal phase.
Results: There are no practically applicable prognostic models to estimate survival. The Surprise Question, SPICT indicators and RADPAC tools are recommended for timely identifying palliative care needs. Regarding advance care planning in end stage heart failure, specific attention is needed for ICD deactivation. The use of carefully titrated heart failure medication and morphine can be beneficial for symptom relief. In the organisation of care, the coordinating role can be taken by the heart failure nurse, who can also manage the contacts with the general practitioner and home care.

Conclusion: In February 2018, the multidisciplinary guideline for palliative care for patients with heart failure NYHA classification III and IV was published and is currently successfully implemented. This Dutch guideline might also inspire researchers and professionals from other countries. Therefore, an English summary is available.

P1197

Health status assessment of patients followed in a Heart Failure Clinic

P Patricia Silva[1]; I Oliveira[1]; A Neto[1]; D Seabra[1]; S Ferreira[1]; M Soares[1]; A Ferreira[1]; S Poaires[1]; M Meira[1]; A Andrade[1]
[1]*Hospital Centre do Tamega e Sousa, Penafiel, Portugal*

Introduction: Heart failure (HF) is a syndrome with significant morbidity and socioeconomical impact. Health status (HS) relates to pts perception of the functional impact of symptoms in daily life. The European Quality of Life Index (EuroQol) is an internationally validated questionnaire that reflects pts insight on their HS, improving their sensitivity and understanding of the disease.
Aims: To evaluate HS and assess its variation in pts with HF followed in a HF Clinic (HFC).
Methods: Unicentric, retrospective analysis of pts followed in a HFC since 3/2011. Included pts with diagnosis of HF for at least 1 year and with a HF hospitalization (HFH) within this period, who had completed the EuroQol questionnaire 6 months after the first nursing teaching session. EuroQol comprises 3 components: a visual scale measured from 0 to 100, with a higher number reflecting better HS perception on the day of the appointment; a question about pts perception of their HS comparing with 1 year before; 5 main fields related to mobility, self-care, daily life activities, pain/discomfort and depression/anxiety, according to the pt status.
Results: Included 88 pts, mostly men (78.4%), with a mean age of 60 +/-13,4 years. 65% had ischemic etiology. No significant differences in HS self-assessment were found between genders. There was an inverse correlation between HS and age. Pts living in urban areas and with higher education levels had better HS perception. The majority of pts had no limitations in the 5 fields assessed in the questionnaire. There was a high prevalence of anxiety/depression (46%), with 16% feeling extremely anxious/depressed. Regarding the visual scale, the mean HS perception in the moment of the appointment was 64.3 +/-17,59, ranging from 10 to 100. Considering the point "HS insight compared to one year before", there was an improvement in 54.5% of pts, while 16% felt worse and 29.5% had a similar HS.
Conclusion: The EuroQol is a useful tool to help pts recognise the functional impact of their disease on daily life and its evolution over time. By assessing various fields, it highlights important areas for intervention in nursing teaching sessions, in order to improve pts overall HS and decrease HFH. In our cohort, pts had high levels of anxiety/depression, emphasizing the need to develop interventions in this area. There was also an improvement in HS insight comparing with the previous year, which may reflect the impact of HFC and nursing teaching sessions in this disease.

P1198

New concept of triage in patients with heart failure due to specialized nursing

MPS Monica Perez Serrano[1]; JGA Josebe Goirigolzarri Artaza[1]; DEV Daniel Enriquez Vazquez[1]; CNP Carlos Nicolas Perez[1]; MFE Marcos Fernandez Escarbajal[1]; RBF Ramon Bover Freire[1]; CMM Carlos Macaya Miguel[1]; CRR Concepcion Ramirez Ramos[1]; MGB Marcos Gonzalez Barja[1]; NRL Noemi Ramos Lopez[1]; AJB Adrian Jeronimo Baza[1]; EMG Eduardo Martinez Gomez[1]; IVC Isidre Vila Costa[1]; PMS Paula Martinez Santos[1]
[1]*Hospital Clinic San Carlos, HEART FAILURE, Madrid, Spain*

Purpose: The pre-discharge is a fundamental step after an IC admission, a poor management of the transicon of care have been shown to increase the hopsitalar re-entry and the morbi-mortality.
The objective is to demonstrate that the realization of a new method of triage by specialized nursing, as it is done in the emergency services, allows to stratify the risk of the patient from discharge, until his / her entrance in the UIC, through the prealta .
Methods: A prospective observational study will be conducted in all patients admitted with a diagnosis of HF and compared with the standard pre-discharge method, based on an early visit to the unit.
The admitted patient will be assessed at 24-48 hours by the IC specialist nurse who will perform a comprehensive biopsychosocial assessment, as well as the pre-discharge, where he will define the "care route" in which the patient should be included, stratifying the risk and the patients. months of follow-up In this way, from the hospital discharge, a "triage" of referral to the UIC will be carried out by the nursing specialist according to the risk and the clinical profile.Triage method;
Low / medium risk patients (3-6 months follow-up / Yellow label):Preserved LVEF and absence of valvular heart disease / severe PHT and Absence of important cardiorenal sd or high diuretic requirements.
High-risk patients (12 months follow-up / Red label):First episodes of heart failure,Patients with ventricular dysfunction who require adjustment of medical treatment or are candidates for devices, Carriers of devices (DAI / DAI CRT or TAVI / mitraclip) especially to clinical stabilization, Revenue despite treatment optimization, Need for high doses of diuretics and / or important cardiorenal sd, In cases of previous strategy failure with high diuretic requirement, income despite treatment optimization and HDD visits. Advanced IC patients: (Prognostic study and close management / Black label): Patients admitted to UCOR by IC,Candidates to Tx / LAVD and Palliative patients.
Results: Since December 2018 a pilot is being carried out in the CI unit to assess the efficacy and safety of this new method described above compared to standard peraltas that are performed
We included 12 patients in the heart failure program of our center, 7 women and 5 men with an average age of ± 74.9 In the triage of the prealta 5 were stratified to the high risk arm, 6 in the low arm - medium risk and 1 patient in the advanced therapies that was referred to our referral center for transplantation. None of them re-enter since the discharge and continue in the established care route.
Conclusions: The nurse will carry out the pre-discharge, where she will define the care route with the aim of creating individualized care plans (NANDA) where she can perform interventions (NIC) and evaluate them (NOC). With the implementation of this method, the aim is to demonstrate the effectiveness and safety of the program in reducing re-entry rates and early intervention.

Clinical Cases

Acute hypertensive heart failure - when the etiology is misleading

A Burducea[1]; DO Geavlete[1]; L Predescu[1]; L Antohi[1]; I Kulcsar[1]; E Stoica[1]; R Radu[1]; S Balanica[2]; O Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania*; [2]*Fundeni Clinical Institute, Nephrology, Bucharest, Romania*

Introduction: Malignant hypertension is an important cause of acute heart failure (AHF) and left ventricle (LV) dilatation, as a result of abnormal response to pressure overload. Recent literature data suggest that the variability in the development of either a LV hypertrophic pattern or/and dilatation and failure is highly dependent on modulating factors less described so far. Associated myocarditis could explain a transitory severe LV dysfunction in patients with hypertensive heart disease.
Clinical case report: We present the case of a 44-y/o patient, with history of untreated arterial hypertension for 26 years and associated cardiovascular risk factors (dyslipidemia, central obesity), admitted for AHF. Physical examination upon admission revealed high blood pressure (260/140mmHg), bilateral pulmonary crackles, orthopnea, severe pedal edemas and high jugular venous pressure. Biological assessment showed NT-proBNP (11643pg/ml), hs-troponinI (217 ngl/L), newly diagnosed renal impairment (glomerular filtration rate 29 ml/min/1.73m2), hypokalemia and mild anemia. Echocardiography described severe dilated left ventricle, moderate systolic dysfunction (LV EF 35%), severe concentric hypertrophy, moderate functional mitral regurgitation.
Coronarography was performed and showed normal coronary arteries along with renal angiography which revealed normal renal arteries, therefore excluding a renovascular cause of hypertension. Abdominal ultrasonography excluded a renal parenchymal disease. Moreover, urinary and plasmatic metanephrines and normetanephrines, ACTH, cortisone, aldosterone, chromogranine A, thyroid tests and Fabry tests were normal.
As anamnesis was reassessed, the patient mentioned an upper respiratory tract infection with bronchitis 3 months prior to the admission, period in which symptoms progression occurred (bilateral pedal edema, shortness of breath), myocarditis was suspected. Cardiac-MR confirmed the diagnosis by showing T2-weighted focal myocardial enhancement (edema) and late gadolinium enhancement corresponding to the lateral and apical anterior walls, located mostly in the mid-wall to subepicardial layer.
The patient was discharged one week later with antihypertensive and evidence based HF maximal medical treatment. One month follow-up revealed normal BP values, normal LV diameters, important concentric hypertrophy, preserved global systolic function and mild mitral regurgitation.
Conclusions: AHF due to left ventricular dilation and severe LV dysfunction is reported to be the least frequent form of hypertensive heart disease, affecting patients with severe long-term overload. On a different matter, LV wall stress associated with hypertension may predispose to ensuing cardiac infection, thus overlapped myocarditis can be a cause of unexplained AHF. Early diagnostic work-up, recognition and characterization of myocarditis is important, as it may help to improve the treatment, LV function and future HF prognosis.

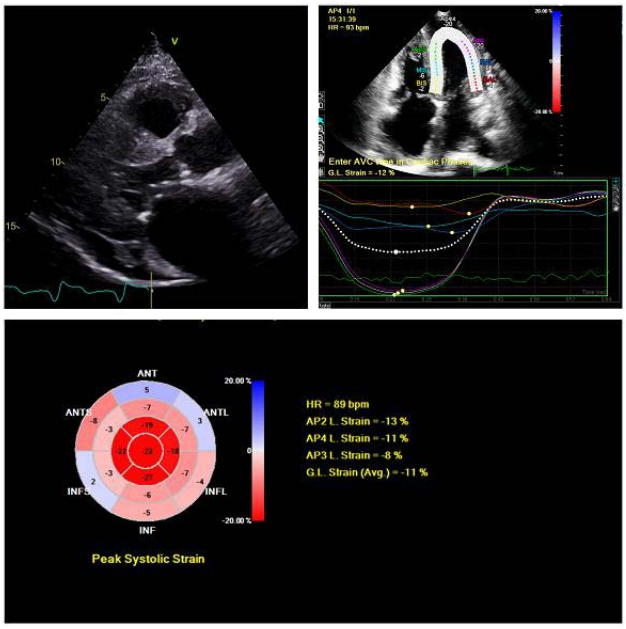
P1200

Wild type TTR amyloidosis disguised as concentric hypertensive left ventricular hypertrophy

A Siama[1]; S Giannitsi[1]; E Hamodraka[1]; A Athanasios Tsoukas[1]; AJ Manolis[1]
[1]*Asclepeion Voulas Hospital, Athens, Greece*

Funding Acknowledgements: No funding

Introduction: Amyloidosis is a great imitator and is paradoxially both over and under-diagnosed. Wild type TTR amyloidosis (previously called senile) has an estimated prevalence of approximately 8-16% in the elderly population and may co-exist with other pathologies such as hypertension and aortic stenosis, indicating common pathophysiologic pathways.
Case presentation: An 85 year old male was admitted to the Emergency Department of our hospital with symptoms of deteriorating dyspnoea. The patient was hospitalised two years prior due to complete atrioventricular block that required permanent DDDR pacemaker implantation. Echocardiography then revealed mild concentric left ventricular hypertrophy with good overall systolic function and grade I diastolic dysfunction, which was attributed to his hypertension. The present echocardiographic study revealed severe concentric hypertrophy (interventricular septum and posterior wall 20 and 18 mm respectively) with a sparkling quality, preserved ejection fraction, severe left atrial dilatation and a small pericardial effusion. Transmitral flow and lateral mitral annulus tissue doppler imaging demonstrated a restrictive physiology. Strain imaging further revealed reduced global longitutinal strain with reduced deformation in the basal and mid segments and preserved in the apical segments, so called cherry on the top (bulls eye) appearance. The patient underwent fatty tissue biopsy which manifested scattered infiltration by an amorphous eosinophilic substance identified as amyloid by Congo red stain with green birefrigence under polarized light and abscence of clonal plasmocytic series suggesting wild type TTR amyloidosis.Conclusion/Discussion: Amyloidosis is characterized by excessive infiltration of the heart affecting to varying degrees different structures such as the myocardium, the pericardium, the valves and the conduction system. Electrocardiographic findings are frequently preceding echocardiographic ones. In elderly patients presenting with unexplained concentric hypertrophy accompanied by abnormalities of signal production and conduction wild type TTR amyloidosis should be suspected. Newer imaging techniques such as strain, strain rate and deformation imaging may help in the diagnosis and follow up of such patients.

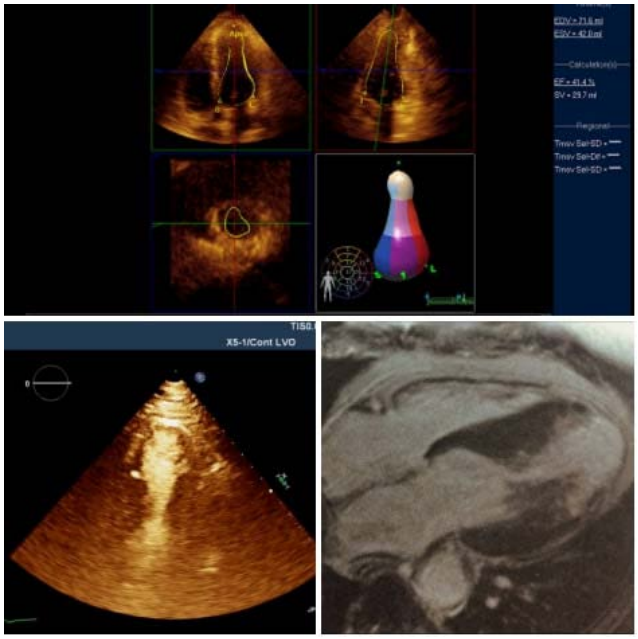


P1201

"Burned-out" hypertrophic obstructive cardiomyopathy presenting as acute coronary syndrome

A Siama[1]; E Hamodraka[1]; P Fountoulakis[1]; A Kalogeris[1]; A Athanasios Tsoukas[1]; AJ Manolis[1]
[1]*Asclepeion Voulas Hospital, Athens, Greece*

Introduction: Hypertrophic cardiomyopathy is defined as left ventricular hypertrophy not solely explained by abnormal loading conditions. Besides the macroscopic picture of tissue hypertrophy, the disease is microscopically characterized by disarray and fibrosis and associated with small vessel disease.
Case presentation: A 49 year old male was admitted to the Emergency Department of our hospital with symptomatic sustained ventricular tachycardia which converted to sinus rhythm in response to intravenous amiodarone administration. Cardiac enzymes were elevated and troponin showed a rise and fall pattern. Ultrasound examination revealed a non-dilated left ventricle with moderately reduced ejection fraction. Basal and mid wall hypertrophy was observed with pronounced apical thinning and akinesis resulting in hourglass left ventricular remodelling. Intracavitary mid-ventricular gradient of 30 mmHg at rest and upon Valsalva manoeuver was recorded. The patient underwent coronary angiography which demonastrated an atheromatous coronary network with minor non-obstructive lesions. Cardiac magnetic resonance confirmed the regional wall motion abnormalities described by the ultrasound; in particular an hourglass shaped left ventricle with hyperdynamic mid segments and thin akinetic to dyskinetic apical segments. Moreover subendocardial late gadolinium enhancement was demonstrated indicative of extensive fibrosis, compatible with "burned-out" hypertrophic cardiomyopathy that has entered a dilative phase. The patient was programmed for genetic family counselling and implantable cardioverter-defibrillator placement.
Conclusion/Discussion: Hypertrophic cardiomyopathy is a genetically and phenotypically heterogeneous disease with varied penetrance, ranging from asymptomatic "grey-zone" hypertrophy to severe left ventricular obstruction and/or end-stage dilated left ventricle with reduced ejection fraction. Prognosis and sudden cardiac death risk assessment takes into account several structural and functional parameters, including wall thickness, left atrial size, maximum left ventricular outflow tract gradient, episodes of non-sustained ventricular tachycardia, unexplained syncope and family history of sudden death. However physicians should be alert to recognize more atypical presentations of the disease.



Hourglass shaped left ventricle

Successful antiarrhythmic therapy with combination of quinidine and mexiletine in Purkinje-related ventricular arrhythmia, persistent atrial tachyarrhythmia and DCM associated with R814W SCN5Amutation

J Zakrzewska-Koperska[1]; ZT Bilinska[1]; GT Truszkowska[1]; M Franszczyk[1]; K Kalin[1]; K Guzek[1]; A Hasiec[1]; M Stepien-Wojno[1]; M Orczykowski[1]; R Bodalski[1]; P Urbanek[1]; R Baranowski[1]; L Szumowski[1]; R Ploski[2]; M Bilinska[1]
[1]*Instiute of Cardiology, Warsaw, Poland*; [2]*Medical University of Warsaw, Department of Medical Genetics, Warsaw, Poland*

Funding Acknowledgements: Prof. Zofia Bilińska is funded by the ERA-CVD grant: DETETCTIN-HF, The genetic examination was funded by the NCN grant No2011/01/B/NZ/03455 - R.Ploski

Background: SCN5A gene mutations are described in 2-4% of patients with dilated cardiomyopathy (DCM). In such cases DCM is associated with different arrhythmias like His-Purkinje-related ventricular contractions and atrial fibrillation/flutter (AF/AFL)

as well as symptomatic sick sinus and conduction disturbances. Arrhythmia often occurs in young age and is the first symptom of heart disease.
Family case:
We present cases of 56 year old man and 36 year old woman, father and daughter, with symptoms of heart failure (HF) in the course of familial DCM and complex ventricular tachyarrhythmias (VEBs/VT) with atrial fibrillation. Father has 20-year history of HF and ventricular arrhythmias, which constituted 50-60% of whole rhythm, and longstanding AF/AFL for 10 years with coexistent diabetes mellitus type 2, hypertension, coronary artery disease. Daughter stays symptomatic at the age of 32, after significant increase of ventricular and supraventricular arrhythmias. Both have ICD-VR implanted since 2006. There were two cases of sudden cardiac death and one case of heart transplantation among their siblings.
We found a heterozygotic mutation R814W in SCN5A by whole exome sequencing in the proband and confirmed its presence in all affected subjects.
In a father after quinidine treatment we observed significant reduction of ventricular arrhythmia with reduction of HF symptoms and elevation of LVEF from 35% to 55%. This effect was constant during 2 year observation. Adding mexiletine to quinidine therapy reduced the arrhythmia (VEBs/includingVT from 47 thousand/day to 6-8 thousand/day and reversion longstanding AF to sinus rhythm) and remains effective during 1,5 year follow-up. However, quinidine in monotherapy was unsuccessful and badly tolerated in daughter. In her case mexiletine and overdrive AAI/DDD stimulation were effective in ventricular arrhythmia treatment (VEBs decreased from 25 thousand/day to 50/day), reduced HF symptoms and improved of left ventricle function. Because of growing number of AF/AFL recurrences we used the combination of mexiletine with reduced dose of quinidine (then flecainide) with antiarrhythmic success in 6 month follow-up.
Questions: When in DCM patients genetic testing should be offered?
How to treat severe ventricular arrhythmia in SCN5A mutations?
Is it possible to avoid/delay heart transplant in this subgroup of DCM patients?
Conclusions: Treatment with quinidine combined with mexiletine for patients with SCN5A R814W associated disease leads to significant reduction of severe ventricular arrhythmia, reversal of long-standing persistent AF and improvement in myocardial function. Genetic screening should be performed in patients with His-Purkinje related ventricular arrhythmia and DCM. Our report highlights the role of genetic testing for perosnalized treatment in cardiology.

P1203
Clinical case of effective treatment of ventricular arrhythmias with ranolazine in a 32-year-old woman with unclear aetiology cardiac inflammation

MI Maria Chashkina[1]; MV Serova[1]; DA Andreev[1]; AA Bykova[1]; ZK Salpagarova[1]; DF Mesitskaya[1]; FY Kopylov[1]; AL Syrkin[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

A 32-year-old patient (pt) presented with dilated cardiomyopathy, frequent premature ventricular contractions (PVC) and unstable ventricular tachycardia (VT) first revealed in 2012. In echocardiography, there were diffuse left ventricular hypokinesis andreduced left ventricular ejection fraction up to 40%. With daily ECG monitoring, up to 17 thousand PVC with different QRS morphologies and up to 150 episodes of unstable VT were detected. According to a survey in 2012, coronary angiography revealed normal coronary anatomy without evidence of obstructive coronary artery disease; cardiac magnetic resonance detected no abnormalities except a diffuse hypokinesis and a midrange ejection fraction. Endomyocardial biopsy was obtained, inflammatory features of unclear aetiology were detected (myocardial stroma infiltration by lymphoid type cells, must cells with degranulation; immunohistochemistry detected cells containing macrophages, T-cells). A diagnosis of myocarditis was suggested, but diagnostic criteria were not fully met.It was also suggested that reduced left ventricular ejection fraction was triggered by frequent PVC. Antiarrhythmic therapy was recommended in this regard; 1 C class was ineffective, and severe thyrotoxicosis developed on amiodarone. The pt also takes ACE inhibitors and b-blockers in the maximum tolerated dose, as well as eplerenone. Given the lack of an appropriate antiarrhythmic therapy, the probable inefficiency of radiofrequency ablation due to significant polymorphism of PVC without any dominant focus, an attempt was made to treat with ranolazine. On 1000 mg / day the PVC decreased from 17 thousand to 10 thousand, just one unstable VT was detected. However, the pt developed severe dyspepsia and epigastric pain and ranolazine was stopped. After 2 months, the pt started ranolazine again, PVC decreased from 14 thousand to 9 thousand. However, even with the omeprazole intake, epigastric pain remained, so the pt was unable to continue taking this drug.
Discussion: ranolazine is a medication for the treatment of refractory angina. At the same time, it has also been reported as antiarrhythmic. It has been found to prevent acute myocardial infarction ventricular arrhythmias, as well as to cure drug-refractory ventricular arrhythmias. However, despite having effeciency, ranolazine caused side effects and significantly reduced the quality of life in this pt. The diagnosis of myocarditis cannot be ruled out. It is also possible that the pt has an arrhythmogenic inflammatory cardiomyopathy (a recent clinical description of patients with non-ischaemic cardiomyopathy who have ventricular arrhythmias and evidence of active unclear aetiology cardiac inflammation). Most probably, re-MRI/PET and endomyocardial biopsy are necessary. Taking into account the unpredictable course of both conditions, implantation of ICD should be considered, despite the moderately reduced left ventricular ejection fraction.

P1204
Young patient with syncope during exercise: should we be worried?

M L Barbu[1]; D Pasoiu[1]; B Suran[2]; M Buzoiu[1]; A Trandafir[1]; A Gurghean[1]; R Ciomag[1]; C Homentcovschi[1]; D Spataru[1]; C Siliste[2]; R Siliste[2]
[1]Coltea Clinical Hospital, Bucharest, Romania; *[2]University Emergency Hospital of Bucharest, Bucharest, Romania*

Although the etiology of syncopes in young patients is most frequently benign in nature, one should keep in mind that the cause might be a severe one, even in this age category. For this reason, the evaluation of a young patient should necessarily include some additional tests, useful in risk stratification, according to the current clinical guidelines.
We present the case of a 29-year-old male patient, without any significant medical or family history, who was admitted for recurrent episodes of palpitations, accompanied by hyperpyrexia and impaired tolerance for effort. The patient also describes a syncopal episode at age 19, during strenous exercise, preceded by rapid palpitations. He was not properly evaluated at the time.
The clinical exam, ECG and echocardiography raise the suspicion of an arrhythmogenic right ventricle cardiomyopathy (ARVC). The diagnosis was confirmed by performing a cardiac magnetic resonance exam, which showed biventricular dilation and dysfunction, right ventricle free wall aneurism and left ventricle fibrosis. 24-hour ECG monitoring records polymorphic ventricular extrasistoles and a few episodes of unsustained ventricular tachycardia.
ARVC is a progressive disease, with genomic substrate and initially electrical, afterwards morphological expression, with a serious risk of sudden death for the patient. Early diagnosis and appropriate treatment, often by implanting a defibrillator, are of crucial importance.

P1205
A case of brachial arteriovenous fistula secondary to venipuncture

TH Thai Hao Phan[1]
[1]Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam

Background: The common cause of an acquired arteriovenous fistula (AVF) is single or repeated diagnostic or therapeutic arterial or venous punctures. Its iatrogenic nature is somehow an obstacle to registering the accurate incidence because of the expected hesitation of the involved medical staff in reporting such cases. Nevertheless, it is generally considered rare. Under certain circumstances, an AVF can result in severe clinical consequences if it remains untreated. We report a case of brachial arteriovenous fistula secondary to venipuncture diagnosed by color Doppler ultrasonography.
Case presentation: A 19-year-old student with a palpable thrill on the medial aspect of left elbow was admitted to our clinic. He had no history of penetrating injury, coagulopathy; nevertheless, two year ago, he had been admitted to a hospital for 7 days, where he was treated for Dengue fever. At that time, he had received venipunctures in his arm for measurement of the complete blood count and fluid supply. Physical examination revealed a palpable thrill on the medial aspect of the left arm, 2 cm above the elbow, with a continuous murmur. Peripheral pulses were palpable, and arms were equal in length and width. Cardiac examination showed no abnormalities. Color Doppler ultrasonography of the left upper extremity revealed a large communication channel between the brachial artery and the vena comitans at the level of the antecubital fossa. The artery was markedly enlarged compared with the right side, and had a low-resistance waveform. One of the left pair of brachial veins accompanying the brachial artery was also markedly enlarged with arterialized flow. The original color Doppler ultrasonographic diagnosis was confirmed by computed tomography angiography. A diagnosis of brachial arteriovenous fistula secondary to venipuncture was made. He was treated surgically to repair the fistula to avoid long-term complications such as high-output heart failure and ischemic changes in the involved extremity.
Discussion: Iatrogenic AVFs are rare, are usually located at the level of femoral and antecubital vessels, and can even be diagnosed as late. Over the injury site, a palpable thrill and a continuous murmur are frequently found. The type of treatment depends on the cause, acute or chronic nature, location, and size of the AVF. There are 3 treatment options: surgical repair, exclusion with a covered stent, and transcatheter embolization. Finally, it is important that physicians be aware of this rare complication of venipuncture and avoid deep probing and running through with the needle. Conclusion: Iatrogenic AVFs are rare. Color Doppler ultrasonography is a valuable and safe diagnostic tool for peripheral AVFs. Physicians must be aware of

this rare complication of venipuncture and avoid deep probing and running through with the needle.

P1206

Patient and caregiver contribution in self-care heart failure - clinical case

MH Magdalena Hanna Lisiak[1]; M Wleklik[1]; I Uchmanowicz[1]
[1]*Wroclaw Medical University, Department of Clinical Nursing , Wroclaw, Poland*

Introduction: A 31-year-old male, with obesity, hypertension (untreated so far), a mild alcohol consumer without personal of family history of cardiovascular disease (CVD). He was admitted to the cardiology department for the symptoms of heart failure (HF) de novo. He complained for malaise, worsening shortness of breath which had been growing for two months (NYHA II/III), for resting dyspnea in the last days. For several weeks, he noticed a fast, irregular heart rate. During the physical exam the stagnation over the lungs (the chest X-Ray was done) with accompanying edema in the lower limbs was confirmed. Lab exams revealed: high NTproBNP (10475.0 pg/ml), slightly increased TnT (18.33 pg/ml) and D-dimers (2450.00 ng/ml). Electrocardiogram showed overload of the left chamber with significantly impaired ejection fraction (EF 25%) and features of high filling pressure, and a high probability of pulmonary hypertension. After the intensive HF treatment of HF was implemented, the patient response was good, but without his care and commitment. The patient was qualified for a further extension diagnosis of HF.
Identification of the problem: It is obvious that the assessment of HF patients' self-care is extremely important not only to involve the patient (P) but also his caregiver (CG). During the patient's hospitalization we wanted to check his and the CG' (his mother) contribution to HF self-care.
The evaluation included the analysis of data obtained from the completed socio-demographic, clinical data and questionnaires by the patient (Self Care Heart Failure Index, SCHFI) and the CG (the Caregiver's Contribution to Self-care of HF Index (CC-SCHFI)). At each stage of the self-care concept, the relations of the maintenance, symptom perception and management process was insufficient. The patient never or rarely takes prescribed medicines, visits health care provider, eats a low salt diet or avoids getting sick. Also in a situation when the symptoms of HF get worse, he would not do anything to reduce salt and fluid intake or even take an extra diuretic. The only thing he would probably do is contact the doctor. If he had any symptoms of HF, he was not sure to be able to control them.
The analysis of the data showed that the CG's contribution to the patient's self-care management was also low in identifying and monitoring symptoms. Despite the recognition of them, the CG only sometimes advised the patient to reduce salt and call the doctor or nurse, but rarely would order them to take an additional diuretic or reduce a fluids intake. Moreover, the CG would never or rarely recommend to check the weight or do some physical activity.
Conclusion: The assessment showed that neither the patient nor the CG showed a significant contribution to the HF self-care. Therefore, it seems obligatory to educate not only HF patients, but also their CGs. All interventions that increase CG confidence can potentially improve to contribute to the HF self-care.

P1207

Case report: peripherally inserted central catheter in patient with heart failure and cardiac implantable electronic device in catheterization laboratory

ER Rabelo-Silva[1]; M Junges[2]; RN Ceratti[2]; JA Augustin[2]; LA Hansel[2]; PMN Bairros[2]; PC Cardoso[2]; ID Brum[2]
[1]*Universidade Federal do Rio Grande do Sul; HCPA, PPG: Cardiologia e Ciências Cardiovasculares; Vasc. Access Program; Heart Failure Clinic/Transplant , Porto Alegre, Brazil*; [2]*Hospital de Clínicas de Porto Alegre, Vascular Access Program, Porto Alegre, Brazil*

BACKGROUND: Patients with heart failure have benefit from peripherally inserted central catheter (PICC) insertion because they require a safe catheter for a prolonged period, in view of the use of inotropic therapy, vasoactive drugs and diuretics. In a public teaching hospital in the south of Brazil, the patients eligible to use this device are hospitalized in units with telemetry monitoring, are listed for heart transplantation or palliative care. The use of PICC allows the patient to have greater comfort and safety, avoids innumerable venous punctures and blood collections; and allows the preservation of its venous patrimony, including the jugular veins by short term central venous catheter, protecting these vessels for possible biopsies after cardiac transplantation. Bedside peripherally inserted central catheter (PICC) insertion can be limited in cases of patients with cardiac implantable electronic devices due to the difficulty of catheter or wire guide's progression. In these cases, it is possible to ally different technologies to assist in the guidance of PICC insertion. Fluoroscopy is a safe and effective technique to guide the catheter to the optimal position. PURPOSE: To describe the case report of a patient with a cardiac implantable electronic device within which a peripherally inserted central catheter was inserted in an unusual way. CASE DESCRIPTION: Case report of a PICC insertion guided by fluoroscopy in a hemodynamic catheterization laboratory. The procedure was performed by PICC's team and interventional radiologist. Male patient, with right arm thrombosis history, with a cardiac implantable electronic device on the left arm and a difficult-to-access peripheral vasculature even under ultrasound guide, submitted to multiple unsuccessful bedside punctures. The wire guide didn't progress probably due to the cardiac implantable electronic device, so the procedure took place in a hemodynamic catheterization laboratory, with use of fluoroscopy technology. RESULTS: Puncture under local anesthesia in left basilic vein with catheter monitoring to the cavoatrial junction. Patient progressed without any PICC related complications, maintaining the catheter for 41 days until the end of therapy. Time of radiation exposure was as minimum as possible and there wasn't any kind of clinical complication during hospitalization. IMPLICATIONS AND
CONCLUSIONS: Despite of exposing patient to radiation, PICC insertion under ultrasound guidance and positioned by fluoroscopy is a safe and effective alternative in cases of hard vascular access. Therefore, the initiative to combine two technologies was determinant for patient safety.

P1208

An unusual case of infective endocarditis with Staphylococcus warneri, presenting as heart failure

R Rodica Diaconu[1]; V Ponomariov[2]; O Mirea[3]; I Donoiu[3]; O Istratoaie[3]
[1]*Emergency County Hospital, Craiova, Romania*; [2]*Southampton General Hospital, Southampton, United Kingdom of Great Britain & Northern Ireland*; [3]*University of Medicine and Pharmacy, Craiova , Department of Cardiology, Craiova, Romania*

Introduction: S. warneri a member of the coagulase-negative Staphylococcus (CoNS) group, has rarely been reported to cause disease in healthy people, because of a lack of aggressive virulence properties.
Case report : A 79-year-old Caucasian male presented to the emergency department with shortness of breath, bilateral leg edema and fatigue. He was known with hypertension and aortic valve stenosis that were treated medically. On physical examination he was afebrile, with lower limb pitting edema, HR 70/min, BP 180/80 mmHg; systolic murmur at the aortic and mitral area. His respiratory examination revealed decreased breath sounds bilaterally at lung bases with crackles, otherwise unremarkable. 12-lead electrocardiogram showed atrial fibrillation. Chest x-ray showed cardiomegaly with congestion and large bilateral pleural effusions. Blood results showed a BNP of 2000 pg/ml, mild anemia, increased impaired renal function (Creatinine 2 mg/dl), CRP 9 g/dl (normal <5 g/dl), ESR 30 mm/hour. Further blood tests were in the normal range. TTE showed mild left ventricle hypertrophy. Systolic function was normal. The aortic valve was trileaflet with severe stenosis (AVA 0.4 cm2) and moderate regurgitation. The mitral valve showed a mobile hyperechogenic formation of 12 mm seen on the atrial side of anterior mitral leaflet. Vegetation was confirm on TOE. Doppler examination showed severe mitral regurgitation due to perforation of the mitral anterior leaflet (figure 1). Three blood culture bottles grew gram-positive cocci in clusters, identified as methicillin-sensitive coagulase negative Staphylococcus (subsequently identified as S. warneri). We initiated therapy with Intravenous Oxacillin and Ciprofloxacin. The patient also received medication for heart failure and was anticoagulated with Acenocoumarol for his atrial fibrillation. The patient's clinical condition improved slowly, with gradual remission of congestion, and normalization of nonspecific inflammation markers, and improvement in kidney function. He was discharged after one month with a good clinical condition but with similar aspect of the TTE. The patient was referred for surgery - double valve replacement.

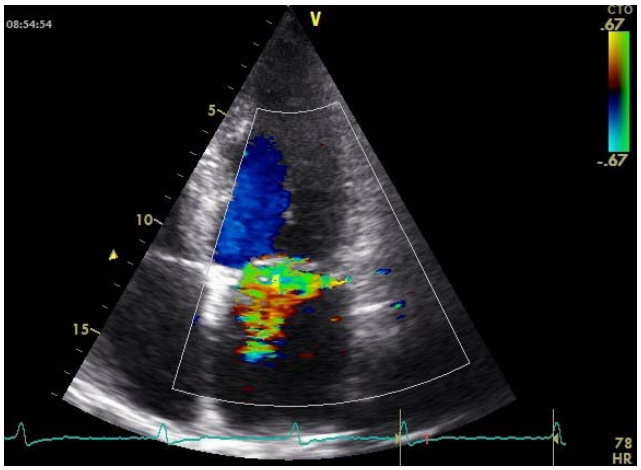

figure 1

Discussion: This represents the tenth case described in the English medical literature, being the second appearing in an immunocompetent individual without any history of infections or previous invasive procedure. Having a low virulence, the infection with Staphylococcus warneri can lack fever and other signs and symptoms of infection. The patients had no clinical signs of infection, only signs of heart failure. Heart failure represents the most frequent complication of infective endocarditis, being the most common indication for surgery. In our case patient's condition has deteriorated due to severe mitral regurgitation secondary to valve perforation.
Conclusion: Staphylococcus warneri is rare or underreported cause of native infective endocarditis in an immunocompetent individual.

P1209

Emerging cardio-oncology therapeutics: the role of ivabradine and levosimendan in acute heart failure reversible toxicity

G Georges El-Khoury[1]; A Bazarbachi[2]; H Skouri[1]
[1]American University of Beirut Medical Center, Internal Medicine-Cardiology, Beirut, Lebanon; *[2]American University of Beirut Medical Center, Internal Medicine-Hematology-Oncology, Beirut, Lebanon*

A 38 year old man, diagnosed to have Acute Myeloid Leukemia, s/p induction Idarubicin/Cytarabine followed by consolidation Idarubicin/Cytarabine with relapsed disease s/p re-induction with persistent disease. Patient was then started on vidaza + sorafenib. Reevaluation showed residual AML with 21% blasts. He continued cycle 2 vidaza + sorafenib.
He was initially admitted for severe left thigh, not controlled by medications and was shown to have bony infiltration. During his stay, he developed pancytopenia and complained of sudden onset chest pain. ECG showed sinus tachycardia with a rate of 110 bpm and no acute ischemic changes. Troponin was elevated. Urgent TTE showed severely impaired left and right systolic function with an estimated LVEF of 20% and severe MR/TR. Patient's condition rapidly deteriorated and became hypotensive requiring escalation in treatment (BP=82/55 mmHg, HR=130 bpm, T=39 degree C orally, RR=20/min. CXR showed bilateral patchy air space disease in the lower lobes and right middle lobe, compatible with an infectious process.
Patient was then transferred to the cardiac care unit and started on levosimendan/norepinephrine/IV furosemide and ivabradine. No invasive mechanical support /Swan Ganz instituted due to severe thrombocytopenia (37000) associated with elevated bleeding risk.
Patient's status improved markedly and was weaned off pressors. A repeat TTE 2 weeks later showed normalization of his LV and RV systolic function with an estimated ejection fraction of 55-59% with mild MR.
Discussion: Acute heart failure/cardiogenic shock in cardio-Oncology can be reversible. The cardiomyopathy can be secondary to one or combination of the following: chemotherapy, tachycardia and sepsis-induced. Heart Rate lowering medications and inodilators such as ivabradine and levosimendan are cornerstone in such conditions.

Echocardiograohic parameters			
	prior to admission	on presentation	2 weeks after admission
LVEF (%)	55	20	55
LVEDD (mm)	55	63	59
GLS (%)	-18	-11	-15
RV function	Normal	Severely Impaired	Normal
MR grade	Mild	Severe	Mild
TR grade	Mild	Severe	Mild
sPAP (mmHg)	26	46	38

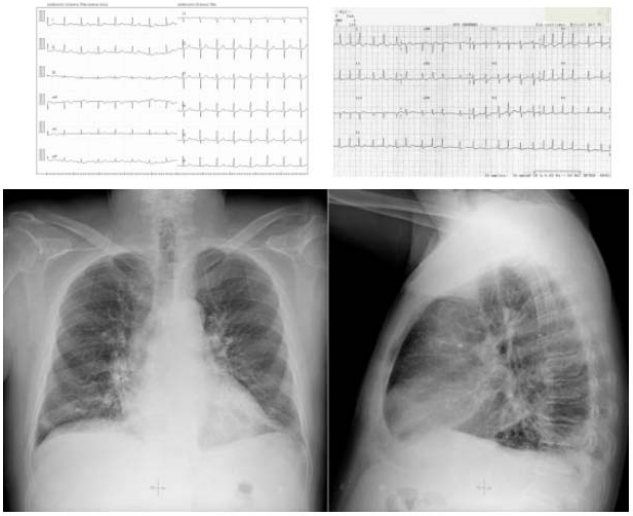
LVEF=left ventricular ejection fraction, LVEDD=left ventricular end diastolic diameter, GLS=global longitudinal strain, RV=right ventricle, MR=mitral regurgitation, TR=tricuspid regurgitation, sPAP=systolic pulmonary artery pressure

P1210

Heart failure and tachycardiomyopathy in a patient taking ibrutinib: a novel tyrosine kinase inhibitor.

M Codina[1]; G Ramirez-Escudero[2]; N Garcia Ibarrondo[2]; A Manzanal Rey[2]; I Bravo Martinez[3]; G Aurrekoetxea Bajeneta[3]; P Mendoza Cuartero[3]; C Asla Ormaza[3]; M Castellano Alcalde[3]; JA Uriarte Elguezabal[4]; JA Marquez Navarro[4]; R Martinez De Bourio Uriarte[5]; A Arregui Lopez[6]; MF Arcocha Torres[7]; L Ruiz Gomez[2]
[1]Hospital de Basurto, Noninvasive Cardiac Imaging Laboratory, Cardio-oncology, Bilbao, Spain; *[2]Hospital de Basurto, Noninvasive Cardiac Imaging Laboratory, Bilbao, Spain*; *[3]Hospital de Basurto, Department of cardiology, Bilbao, Spain*; *[4]Hospital de Basurto, Department of hematology, Bilbao, Spain*; *[5]Hospital de Basurto, Cardiac catheterization laboratory, Bilbao, Spain*; *[6]Hospital de Basurto, Cardiology intensive care unit, Bilbao, Spain*; *[7]Hospital de Basurto, Electrophysiology Laboratory, cardiology department, Bilbao, Spain*

We presented 71 y.o. patient (pt), male, former smoker with hyperuricemia, dyslipidemia. Pt was diagnosed with chronic lymphocytic leukemia (cll) in 2008 and he started treatment (tt) with complete remission (cr). In 2015 cll relapsed. After different tts cll early relapsed and Ibrutinib (ib) was started. The patient basal EKG and analysis were anodyne.
4 months after, pt presented to emergency room with a 1-week history of shortness of breath and mild limb swelling. Symptoms began 3 weeks ago. Pt did not notice palpitations. EKG showed rapid atrial fibrillation (af). Chest ray was consistent with heart failure (hf). Analysis showed mild hypoxemia, normal renal function without anemia, acidosis or dyselectrolytemia. Pt was diagnosed with rapid af and secondary hf. Hematologist proceed to ib discontinuation, patient was treated with i.v. loop diuretics and digoxin (dig). After stabilization he was hospitalized. Echo showed a mild dilated left ventricle (LV) with severe LV dysfunction (LVEF 20%), severe mitral regurgitation (MR), moderately dilated left atria. Coronary artery disease and endocrine disruption were excluded. Heart rate (hr) control strategy was chosen. Carvedilol (carv) was started and progressively increased, dig was discontinued. Eplerenone was associated. Ramipril was not initiated due to symptomatic hypotension. Stroke risk was assessed (CHADS2-VASc 2) and acenocoumarol was started. HASBLED was 1.After favourable evolution patient was discharged. In follow-up, pt complained of dyspnea persistence and symptomatic hypotension, he had no signs of congestion and good peripheral perfusion. Hr still elevated. Carv was reduced and low dose of dig was started. One week after, symptoms improved, hr was controlled.6 months later, pt was on Class I NYHA, echo showed normal LVEF and mild MR. In the other hand, cll aggressively relapse and pt finally deceased after a septic shock. An ib related af (ibraf) tachycardiomyopathy diagnoses can be made. Although ib has been linked to af, there are barely case-reports of an association with cardiomyopathy.
The ibraf incidence is 6-16%, usually appears in the first 6 months. Age ≥ 65 y.o, male, arterial ht, af background, diabetes and long ib tt are risk factors. Prior to ib initiation cvd, af, hormone or electrolytic alterations have to be excluded. Toxicity criteria ≥3 are uncommon and demands ib discontinuation (dis). Ib dis has been correlated to an inferior progression free survival. Ib has interactions (inter) with antiarrythmic and oral anticoagulant (oa) drugs: diltiazem, verapamil, amiodarone, dronedarone have to be avoid. Ibr increases dig and dabigatran levels and increases the risk of bleeding (40-69%) due to platelet inhibition effect. It is important to assess the pros and cons of oa before starting tt.
It is important to know the ibraf management to avoid unnecessary dis or inter. A multidisciplinary management in cardio-onco-hematology units is essential.



Basal and AF EKG and Chest Ray

The case of primary systemic amyloidosis with a clinical picture of congestive heart failure refractory to symptomatic therapy

I A Leonova[1]; S Boldueva[1]; I Yarmosh[1]
[1]*North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation*

A 55-year-old woman without a history of arterial hypertension, MI, heart disease for 1.5 years before was hospitalized with gradually progressive symptoms of biventricular CHF (recurrent bilateral hydrothorax with 2 thoracocentesis). The first manifestations of heart disease were paroxysms of atrial fibrillation (4 episodes in total, were stopped with medication) without antiarrhythmic and anticoagulant therapy. Further, the tendency to hypotension, the presyncope and syncopal states began to appear without any connection with arrhythmia. Then, exercise tolerance decreased due to general weakness and shortness of breath, and the edematous syndrome increased despite regular use of diuretics.

Patient had previous echocardiography with symmetric thickening of the left ventricular myocardium (up to 18 mm), which, in the absence of anamnesis of arterial hypertension, was regarded as hypertrophic cardiomyopathy. Smoking, drinking alcohol, drugs denied.

During patients' examination moderate jaundice, numerous scratching on the back and arms, acrocyanosis, moderate swelling of the face, feet and legs to the bottom third was found. BP was 95/70 mm. Hg, pulse was 78 per minute, rhythmic. On auscultation, heart sounds are deaf, in the lungs breathing was weakened in the lower sections on both sides. Tongue crimson, enlarged, with imprints of teeth. The abdomen was moderately enlarged due to subcutaneous fat and moderate ascites, enlargement of liver.

At a normal level of total protein in the blood, a decrease in albumin and an increase in α1- and γ-globulins were revealed. Urine protein was 0.40 g per day. Free light chains of immunoglobulins of lambda-type were increased both in serum up to 17 μg / ml (at a rate of up to 10 μg / ml) and in urine. Reducing of the amplitude of the R-wave in all leads was found on ECG. By EchoCG symmetric LVH was detected (up to 18 mm), the thickness of the RV was 5 mm, the ventricular cavities were not increased, LV was increased, LV EF was 39%, normal pressure in the pulmonary artery. CT of the chest: increased pulmonary pattern, signs of thromboembolism of a single small branches of the left pulmonary artery with infarction of the lower lobe in S9 of the left lung, a blood clot in the ear of the LP, fluid accumulation in the pleural cavity, pericardial cavity, in the abdominal cavity. MRI of the heart with contrast was confirmed restrictive type of myocardial dysfunction. The diagnosis of AL-type amyloidosis was verified on the basis of myocardial biopsy using histological and immunohistochemical methods. Despite the initiated pathogenetic therapy, the patient died within 6 months from her onset and 2 years from the onset of the first symptoms of the disease.

This clinical case draws the attention of doctors to the problem of differential diagnosis of hypertrophic cardiomyopathy, early diagnosis and pathogenetic treatment of primary amyloidosis.

Right ventricular failure and severe functional tricuspid regurgitation caused by atrial fibrillation

SARA Collins[1]; DONALD Haas[1]; REUBEN Azad[1]
[1]*Abington Hospital Jefferson Health, Internal Medicine, Abington, United States of America*

Background: Atrial remodeling associated with atrial fibrillation(AF) is known to be a risk factor for significant tricuspid regurgitation(TR). AF with secondary tricuspid annular dilatation leading to TR and right ventricular(RV) failure occurs in approximately 10-15 percent of patients with TR.

Case: 71 year old female with history of hyperthyroidism was admitted to the hospital with severely decompensated RV failure and was found to have severe TR on echocardiogram. She was recently diagnosed with AF and was started on metoprolol and rivaroxaban. Basic laboratory testing including thyroid function test was found to be within normal limits. Cardiac MRI ruled out infiltrative heart disease. She was started on diuretic with some symptomatic relief. She successfully underwent Cardioversion (DCCV) as an outpatient but subsequently reverted back to atrial fibrillation. She was not started on antiarrhythmic therapy after the DCCV. She was thought to be a poor candidate for amiodarone given her methimazole for hyperthyroidism. She continued to remain symptomatic and demonstrate severe tricuspid regurgitation on examination and decision was made to admit her to the hospital for sotalol loading followed by cardioversion. Her symptoms improved dramatically with restoration of sinus rhythm and her echocardiogram demonstrated normalization of the RV and severe tricuspid regurgitation.

Discussion: TR is caused by tricuspid valve systolic coaptation loss due to tricuspid annular dilation associated with atrial dilation. Functional TR (FTR) is rarely seen in patients with AF duration of less than 1 year; functional TR has been reported in one-fourth of patients with longstanding AF of more than 10 years. The prevalence of functional TR is growing due to the increased number of senior patients with longstanding AF in today's aging population. The exact determinants of functional TR remain uncertain. AF can lead to heart failure(HF), and their association brings a poor prognosis. In fact, cardiac death is more frequent than stroke- related death in AF patients, and a substantial proportion of the cardiac death results from HF. There is high probability of RV failure events in AF patients who have severe TR, thereby suggesting that more intensive therapy may be required to prevent HF events in AF patients.

Conclusion: Severe FTR leads to increased prevalence of right-sided heart failure underscoring the nonbenign nature of AF.

Our case is unique since the patient had atrial fibrillation duration of less than a year and presented with severe TR and right heart failure which is normally seen in patients with chronic atrial fibrillation. FTR is associated with poor prognosis in AF patients with preserved left ventricular ejection fraction and should be treated more intensively with the goal to restore normal sinus rhythm.

P1213

Left ventricular non-compaction and coronary artery disease: what's causing systolic dysfunction? a case report

C Chiara Rovera[1]; E Franco[1]; C Moretti[1]
[1]*Civil Hospital of Chivasso, Cardiology, Chivasso, Italy*

Background Left ventricular non-compaction is a rare cardiomyopathy, characterized by hypertrabeculations and deep recesses of the left ventricle.

Clinical manifestations range from no symptoms to progressive left ventricular systolic dysfunction and heart failure, atrial or ventricular arrhythmias and systemic thromboemboli.

The diagnosis of left ventricular non-compaction cardiomyopathy can be made by echocardiography as well as magnetic resonance imaging.

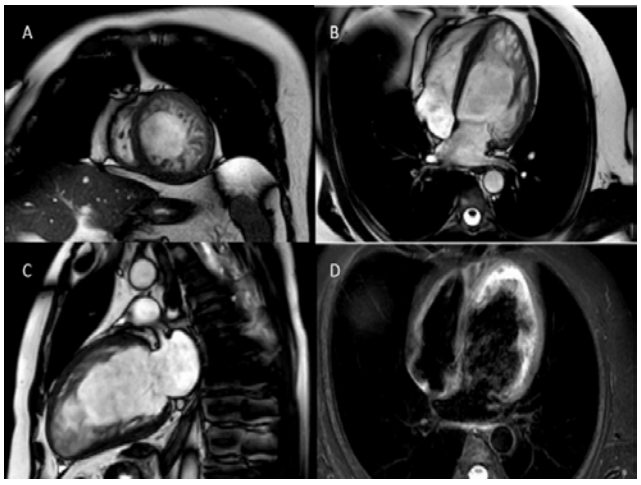
Case Summary We report a case of a 51-year-old man without cardiac risk factors referred to hospital after the finding of complete left bundle block on the ECG and a 6-month history of mild exertional dyspnea. Echocardiography showed a left ventricular ejection fraction of 25%, with prominent hyper-trabeculations, especially in lateral and apical wall.

Cardiac magnetic resonance imaging confirmed the diagnosis of left ventricular non-compaction cardiomyopathy (see Picture).

Coronary angiography showed an unexpected obstructive coronary artery disease: a severe stenosis of both the middle tract of left anterior descending artery and first diagonal branch. Lesions were treated with angioplasty and DES implantation.

One month after the revascularization and an adequate medical therapy, repeated echocardiogram confirmed the severe depression of left ventricular function, so an ICD-CRT device was implanted.

Discussion This is a rare case of coexisting left ventricular non-compaction and coronary artery disease in a young patient without cardiac risk factors. An explanation of this association might be that left ventricular compaction occurs simultaneously with the development of the coronary vessel system during gestation. So, the same genes might be involved both in left ventricular non-compaction and in the predisposition to coronary atherosclerosis even in patients without cardiac risk factors.



Cardiac magnetic resonance imaging scans

Haemochromatosis: an under-recognised and treatable cause of dilated cardiomyopathy

S Cesini[1]; A Kydd[1]; S Bhagra[1]; M Besser[1]; B Griffiths[2]; S Pettit[1]
[1]Papworth Hospital NHS Trust, Cambridge, United Kingdom of Great Britain & Northern Ireland; *[2]Addenbrooke's Hospital, Cambridge, United Kingdom of Great Britain & Northern Ireland*

A 27 year old male PhD student presented with a short history of breathless and fatigue. There was no past medical history and no background of smoking or substance misuse. There were signs of heart failure, including elevated central venous pressure and bilateral pleural effusions. An echocardiogram showed a non-dilated left ventricle (LV), severe biventricular dysfunction with an LV ejection fraction (LVEF) of 15%, moderate mitral regurgitation and severe tricuspid regurgitation. His cardiac Troponin-I was slightly elevated at 65 ng/L. There was concern about his outlook because of tachycardia and hypotension. He was transferred to our hospital for ongoing management.

On arrival at our hospital, he was treated with intravenous diuretics and required a period of inotropic support because of hypotension and renal dysfunction. We undertook a cardiac MRI scan to investigate the etiology of heart failure. The MRI showed a dark liver and mid wall late gadolinium enhancement, raising the possibility of an iron-overload cardiomyopathy (see figure). Iron studies were abnormal with serum Ferritin 6654 mcg/L and transferrin saturation (TSAT) 100%. We repeated the MRI scan with T2* sequences and this showed iron overload in the heart (T2* 10ms) and liver (T2* 2.1ms). We made a diagnosis of iron overload cardiomyopathy with probable juvenile form of haemochromatosis. Genetic studies have confirmed this with compound heterozygosis for 2 mutations in HJV gene.

He was treated with iron chelation therapy, comprising intravenous Desferrioxamine 50 mg/kg/day as a continuous infusion and oral Deferriprone 100mg/kg/day. We looked for endocrine manifestations of haemochromatosis and found evidence of hypogonadotrophic hypogonadism. He was started on Testosterone supplementation. As his heart failure settled, we were able to wean inotropic support and establish conventional oral medical therapy for heart failure. He was eventually discharged from hospital with a peripherally inserted central cannula and continuous IV Desferrioxamine.

There was a dramatic response over three months, with complete resolution of heart failure symptoms, improvement in biventricular function (LVEF 40%, normalization of RV function) and complete suppression of NTproBNP levels. As his Ferritin level reduced, we stopped Desferrioxamine and then Deferriprone, converting to regular venesection for control of iron overload. He has returned to his studies.

Conclusions: Reversible causes of heart failure must be considered in any case of new-onset heart failure. Iron-overload cardiomyopathies may be diagnosed by a combination of iron studies, cardiac MRI assessment and genetic testing. Correct diagnosis and treatment may lead to complete recovery of cardiac function, avoiding treatments such as ICD implantation, mechanical circulatory support and heart transplantation.

Cardiac MRI

Constrictive pericarditis: a forgotten cause of heart failure

C Pemberthy Lopez[1]; PJ Espinosa Martinez[1]; JC Rendon Isaza[2]; CI Saldarriaga Giraldo[2]
[1]Universidad Pontificia Bolivariana, Antioquia, Medellin, Colombia; *[2]Clinica CardioVID, Antioquia, Medellin, Colombia*

A 49 year old man with dyspnoea and lower extremities oedema was admitted the hospital. The past medical history was negative for cardiovascular disease. The physical exam was relevant for the presence of signs of congestive heart failure, the EKG showed atrial fibrillation. The echocardiogram showed an EF of 33%. Medical treatment for HFrEF was started. Coronary artery disease was rouled out with left cath and tachycardiomyopathy was considered the most probably aetiology.

After one year of treatment his clinical condition doesn´t improve, he developed worsening heart failure and had 2 more hospital admissions. A new echocardiogram showed an EF of 35%, with severe dilatation of atria, right ventricular dysfunction and a dense image compressing extrinsically both ventricles. A CT showed pericardial calcification and a MRI showed compression of both ventricles at the mid third by the pericardium. The diagnosis of constrictive pericarditis was confirmed by right heart cath that showed diastolic equalization of the right atrial pressure, right ventricular pressure, pulmonary artery pressure and pulmonary capillary wedge pressure. The myocardial biopsy was negative for infiltrative disease or myocarditis. An anterior pericardiectomy was performed. After surgery, our patient had a good evolution, with resolution of the heart failure symptoms and with an improve of the EF to 50%. The pericardium pathology reported degenerative changes with calcification and fibrosis, tuberculosis or malignancy were rouled out.

This patient did not have an evolution compatible with heart failure induce tachycardiomiopathy. This reveal the need of look for another cause of his symptoms. The new echocardiogram showed a dense image compressing cardiac chambers, which pointed to a restrictive pathology. The CT was very useful in order to identify the calcium in the pericardium and the right heart cath confirmed the presence of constrictive physiology and the only effective treatment was offered: pericardiectomy.

Constrictive pericarditis was not suspected at the beginning because he did not debuted with normal ejection fraction, which is more common in this pathology. This drive to a late diagnosis which can favour complications due to multiples episodes of decompensation, which turns in a worst prognosis. As a differential diagnosis there are toxic and hormonal cardiopathies and myocarditis; with further impairment, pulmonary thromboembolism, restrictive myocardiopathy and tumoral cardiac compression must be considered. In Colombia, tuberculosis is the main cause of constrictive pericarditis, however the pathological study ruled out this diagnosis.

Constrictive pericarditis is an important differential diagnosis in patients with heart failure with an unclear cause, in whom identification and treatment drives to a dramatic improvement in symptoms and ventricular function; therefore, a high grade of suspicion is required to make a prompt diagnosis.

Constrictive pericarditis

Difficult diagnosis of co-existence of constrictive pericarditis and cardiomyopathy due to rheumatoid arthritis

M Sugahara[1]; H Uemura[2]; K Azuma[1]; R Kawakami[3]; Y Okuhara[1]; M Asakura[1]; M Mitsuno[2]; M Ishihara[1]; S Hirota[3]; T Masuyama[1]
[1]Hyogo College of Medicine, Cardiovascular Division, Department of Internal Medicine, Nishinomiya, Japan; *[2]Hyogo College of Medicine, Department of Cardiovascular Surgery, Nishinomiya, Japan*; *[3]Hyogo College of Medicine, Department of Surgical Pathology, Nishinomiya, Japan*

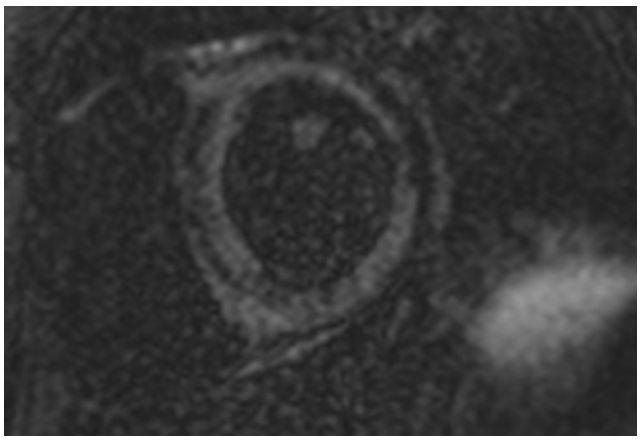
Introduction: Constrictive pericarditis (CP) is the most common cardiac involvement of rheumatoid arthritis (RA). Heart failure (HF) may develop due to CP through pericardial stiffening that hampers diastolic ventricular filling. Cardiomyopathy (CM) is another manifestation of RA and may also cause HF. RA-associated cardiomyopathy is complex and it is not necessarily easy to assess its association and the type of cardiomyopathy accurately. This is particularly true if the patients with RA had both CP and CM because these cause in similar hemodynamic alteration. We present such a case.
Case: A 62-year-old female patient with a history of RA was administered prednisolone and tacrolimus for 8 years, and was considered to have associated CP 5 years ago. Her pleural effusion (PE) and dyspnea on exertion (DOE) due to CP was incremental recent several months, and a work-up for surgical treatment was initiated. She was in sinus rhythm with a heart rate of 88. Her jugular venous pressure with sitting-up position increased to the level of the right earlobe. Laboratory findings showed normal renal function with brain natreutic peptide (BNP) of 345 pg/ml. The PE was transudative. Transthoracic echocardiography (TTE) revealed a septal bounce. Chest CT showed thickened pericardium. Invasive hemodynamics showed dip and plateau pattern in the bi-ventricles. According to these results, she underwent pericardiectomy. Histological finding of the resected pericardium was obviously fibrous thickening with calcification, supporting the diagnosis of CP. After the surgery, she had residual DOE with a further elevation in BNP (818 pg/ml). TTE showed a disappearance of the septal bounce without LV dilatation. Invasive hemodynamics was re-assessed a month after the operation. Mean pulmonary artery wedge pressure was 25 mmHg, mean right atrial pressure, 22 mmHg, right ventricular end-diastolic pressure, 23 mmHg, and left ventricular end-diastolic pressure, 29 mmHg, respectively. There was no ventricular interdependence by Valsalva maneuver. Histological finding of the myocardial biopsy showed moderate interstitial fibrosis with inflammatory cell infiltration, suggesting CM due to RA. Then, she received a titration of drugs for heart failure.
Discussion and
Conclusions: This case was initially considered to have only CP because there was clear evidence of CP in imaging modalities such as echocardiography and cardiac CT, and because hemodynamic alterations were explained solely by the presence of CP. However, there was little improvement in HF symptoms after surgical treatment, and the association of CM became evident. A slight increase in BNP level may have been only a clue of the association of CM with CP before surgery in this particular case. Future studies are definitely required to assess the presence or absence of CM and CP in a sophisticated fashion in patients with RA.

P1217

A cause of left ventricle dilatation and dysfunction which may benefit from aetiological therapy

G Crasmariu[1]; S Onciul[2]; L Calmac[1]; M Dorobantu[2]
[1]Emergency Clinical Hospital Floreasca, Cardiology, Bucharest, Romania; *[2]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*

A 54-year-old male presented with worsening dyspnoea and chest pain on exertion in the last 3 months. He denied any history of alcohol/drug abuse and no relevant family history of cardiovascular disease was identified. His blood pressure control was optimal on a combination of 5/1.25/5mg perindopril/indapamide/amlodipine. Physical examination revealed fine bibasilar crackles and no cardiac murmurs. Initial laboratory data showed elevated NT-proBNP (2013 pg/ml) and hs-Tn (68.6 ng/l), normal renal and hepatic function. The invasive angiography revealed normal epicardial coronary arteries.
The echocardiography showed a dilated left ventricle (LV), with asymmetrical septal hypertrophy (19mm) and severe systolic dysfunction due to global hypokinesia (ejection fraction 38%, with severely impaired global longitudinal strain of the mid and basal myocardial segments with apical sparing). Both atria were severely dilated and the transmitral Doppler showed a restrictive pattern. Despite LV dilation and hypertrophy, the ECG showed low voltage rather than LV hypertrophy.
In this context an infiltrative myocardial disease was suspected and a CMR was pursued, which confirmed both LV and right ventricle dilation, hypertrophy and systolic dysfunction. Moreover, a diffuse transmural myocardial hyperenhancement was seen on LGE sequences typical for cardiac amyloidosis (figure). T1 mapping was suggestive of a highly expanded interstitium with an extracellular volume fraction of 67%, while the T2 imaging showed no evidence of oedema.
A complete work-up for systemic amyloidosis revealed high blood values of free lambda chains with a free kappa/free lambda ratio of 0.01. The abdominal fat biopsy was positive for amyloid deposition while the genetic testing was negative for TTR mutations. A diagnosis of AL cardiac amyloidosis (CA) was made and targeted chemotherapy with a triple regimen of bortezomib/cyclophosphamide/dexamethasone was initiated.
Cardiac involvement in amyloidosis usually presents as a nondilated cardiomyophathy with concentric hypertrophy and restrictive diastolic pattern. We hereby report the case of a patient who presented with LV dilatation, asymmetrical septal hypertrophy and severe systolic dysfunction, in which the diagnosis work-up indicated amyloid deposition to be the etiologic process.
Although the endomyocardial biopsy is considered to be the gold standard for diagnosing CA, CMR provides a pathognomonic pattern which accurately differentiates CA from other specific cardiomyopathies such as the hypertrophic cardiomyopathy, hypertensive heart disease or Fabry disease.
Early diagnosis is imperative in CA since both AL and ATTR forms benefit from specific aetiological therapy. While the classical heart failure drugs are inefficient or may be even dangerous in patients with CA due to a susceptibility to orthostatic hypotension, the development of targeted therapies improved the prognosis to a median survival >5 years.



figure

P1218

Coronary artery disease in a systemic sclerosis sine scleroderma female patient

I Ioan Tilea[1]; A Varga[1]; CF Suciu[1]; DN Petra[1]; DG Iancu[2]
[1]University of Medicine, Pharmacy, Sciences and Technology, Targu Mures, Romania; *[2]County Emergency Hospital of Targu Mures, Second Internal Medicine Clinic, Targu Mures, Romania*

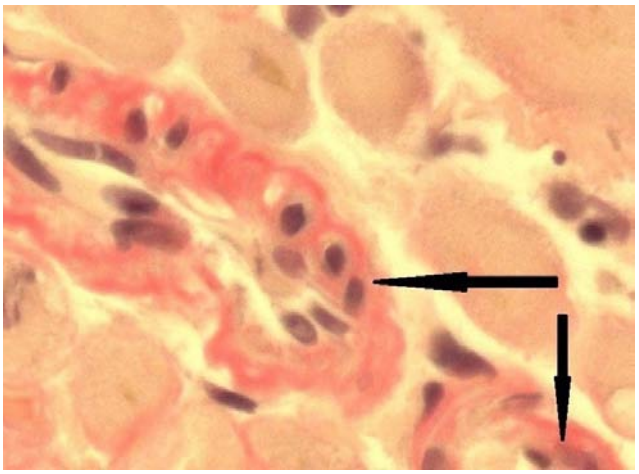
INTRODUCTION: Scleroderma sine scleroderma is part of the scleroderma spectrum of diseases. Skin involvement is lacking in this subtype, however, typical scleroderma internal organ involvement is present. Cardiac involvement in scleroderma is characterised by fibrosis extended to the endocardium, conducting tissue, myocardium and pericardium, resulting in rhythm and conduction disturbances, pericarditis, valvular regurgitation and/or heart failure. Myocardial fibrosis has a focal distribution involving both ventricles and can be distinguished from coronary atherosclerosis using cardiac magnetic resonance: fibrotic lesions are inconsistent with the coronary distribution, immediate subendocardial layers are affected, and hemosiderin deposits typical for atherosclerosis are absent.
Coronary artery disease in scleroderma patients is known to have an unremarkable prevalence that could be comparable to general population, as inflammation is less important in scleroderma when compared to other rheumatic diseases. However, recent reports highlight the possibility of subclinical silent involvement of the coronary arteries that might be detected using imaging studies such as single-photon emission computed tomography, magnetic resonance and computed tomography.
CASE PRESENTATION: We report the case of a 58 year old woman with a history of inflammatory arthritis with an undetermined cause nor an underlying specific treatment. The patient developed a non-ST elevation myocardial infarction (NSTEMI), 2 month prior to admission. She had no documented history of heart disease, or a notable dyslipidemic profile.
At admission, the patient presented dyspnoea, dysphagia, dry cough, Raynaud's phenomenon, important bilateral ankle synovitis. An extensive panel of imaging (echocardiography, computed tomography and cardiac magnetic resonance

scans), respiratory (spirometry) and digestive (, abdominal ultrasound, upper digestive endoscopy) studies were performed. Laboratory tests were negative for specific rheumatic disease antibodies, including scleroderma, nonetheless, she did present high erythrocyte sedimentation rate, positive C-reactive protein. Data collected rise the suspicion of scleroderma sine sclerodema, with ischemic heart disease, myocardial and subendocardial fibrotic lesions suggestive of a primary cardiac involvement, mild pulmonary hypertension, interstitial lung disease, esophageal dysmotility.
CONCLUSIONS: Our patient's case highlights the importance of early sensitive investigations and is an advocate for the possibility of coronary artery involvement as a result of scleroderma spectrum of diseases.

P1219
The clinical case of cardiac amyloidosis associated with multiple myeloma

E Ekaterina Tsoi[1]; YUV Rogovskaya[1]; SV Demyanov[1]; VV Ryabov[1]
[1]State Research Institute of Cardiology of Tomsk, Emergency cardiology, Tomsk, Russian Federation

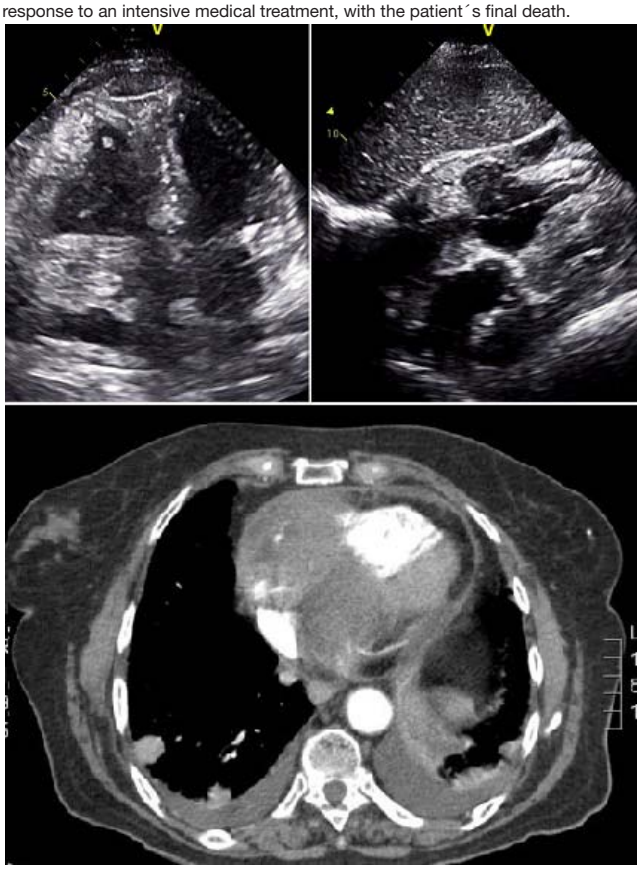
Nowadays, amyloidosis is a group of diseases with diverse clinical signs characterized by extracellular deposition of insoluble pathological fibrillar proteins leading to development and progression of heart failure. Clinical manifestations are very diverse which leads to late diagnosis and the only method for determining the type of amyloidosis is a biopsy followed by histochemical research. We present a clinical case of cardiac amyloidosis associated with myeloma and confirmed by a morphological study. The case describes a 67-year-old patient complaining of irregular heartbeat, alopecia for 3 years and a 13 kg weight loss in the last 6 months. She suffered from acute myocardial infarction with complications: pulmonary edema, bilateral hydrothorax; peripheral edema. After 1 month she was hospitalized with blood pressure of 90/60 mm of mercury, hepatomegaly and peripheral edema. Blood analysis: hypoproteinemia. Urinalysis: Bence-Jones protein. Electrocardiography showed sinus tachycardia with a heart rate of 104 beats per min. In laboratory tests data for myeloma were obtained. Invasive coronary angiography was performed, no coronary atherosclerosis was detected. Magnetic resonance imaging showed both ischemic and non-ischemic (amyloidosis/ glycogenosis) damage in the background of myocardial degeneration (Fig. 1). An endomyocardial biopsy of the right ventricle was performed: positive periodic acid Schiff substance in the interstitium and in the endocardium, amyloid deposits are determined.
Based on all the data it was possible to verify the diagnosis of primary cardiac amyloidosis, probably of the AL type associated with myeloma. During therapy with beta - adrenergic blocker, ACE inhibitor, diuretics hydrothorax was stopped but hypotension, severe weakness, insomnia and lack of appetite persisted. The patient was transferred to the Department of Nephrology and chronic hemodialysis where bone marrow trepanobiopsy was performed and the diagnosis of myeloma and renal amyloidosis was confirmed. Hydrothorax and hydropericardium in the hospital recurred, weakness increased, cachexia, hypotension, pulmonary edema recurred. The patient died in the intensive care unit in two weeks.
This clinical case demonstrates the complexity of timely in vivo diagnosis of amyloidosis and the selection of adequate drug therapy which is associated not only with the limited ability to establish an accurate diagnosis and the lack of specific treatment in most cases but also with the late visit of patients for medical care. Thus, the development/ improvement of non-invasive screening methods of examination will allow to identify pathology at earlier stages with the possibility of selecting effective drugs and in some cases – heart transplantation.



P1220
Numb Chin syndrome, intracardiac mass in right ventricle and pulmonary nodules as metastasis of diffuse large B-cell lymphoma (DLBCL) of non-germinal center (non-GC) type

AM Culebras Lopez[1]; C Ganan Gomez[1]; B Munoz Calvo[1]; P Rodriguez Doyaguez[1]; JA Garcia Lledo[1]
[1]University Hospital Príncipe de Asturias, Medicina Interna y Cardiologia, Alcala de Henares, Spain

A 74-year-old female patient diagnosed with myelodysplastic syndrome (MS) with 1,5 years of follow-up, presented heart failure with a NYHA III functional class for last 2 months, dyspnea and bimalleolar edema, bibasal lung crackles on auscultation, high BNP levels (1500 pg/ml) and cardiac enzymes levels not elevated, with a first episode of hypoesthesia and pain over the chin in the region supplied by mental nerve and its branches or Numb Chin Syndrome (NCS).
Angiotomography of the chest showed pulmonary segmentary thromboembolism, pulmonary nodules, bilateral hiliar and mediastinal adenopathies, pericardial and bilateral pleural effusion and heterogeneous and irregular solid thickening of the cardiac base/right ventricle (RV). The ECG showed ST depression in leads V1 to V3 and negative T wave in leads III and aVF. Echocardiography showed LA dilated, LV showed mild diastolic dysfunction with preserved ejection fraction (70%), with large mass at the tricuspid valve ring and posterior interventricular sulcus that includes the right coronary artery, of smooth profile, which captures contrast and extends with infiltrating aspect to the entire RV free wall, that is thick and heterogeneous in appearance, no pericardial effusion and normal flows.
Ultrasound-guided lung nodule biopsy was diagnostic of suspected non-Hodgkin lymphoma B. Waiting to transesophageal echocardiography biopsy, the patient presented complete atrioventricular block. It was then decided by cardiac and thoracic surgery, pacemaker implantation and open lung wedge biopsy to establish the correct histological diagnosis prior to treatment.
This one was from diffuse large B-cell lymphoma (DLBCL) of non-germinal center (non-GC) type, stage IV (pulmonary and possible cardiac metastasis) with a high risk international pronostic index (IPI).
In this moment, evidence of worsening heart failure was observed. Treatment was started with rituximab plus chemoteherapy regimen including liposomal adriamycin (lower cardiotoxicity) and prednisone. After 4 days, the patient presented severe acute respiratory failure with distress that required admission to an intensive care unit. The evolution was torpid, requiring invasive mechanical ventilation and without response to an intensive medical treatment, with the patient´s final death.



NCS is an uncommon underappreciated though well documented neurological manifestation of metastatic malignancy. Together with the pulmonary involvement and cardiac mass, the first possibility is metastasis of a primary tumor (solid organ, hematologic-lymphoma,..).DLBCL is aggressive and fast-growing (60% diagnosed in advanted stages). The extranodal involvement (40%) in our patient was cardiac, pulmonary and peripheral nerves. Due to the type and stage of the lymphoma, IPI, affected organs and cardiotoxicity of treatment, it is an entity of difficult diagnosis, poor prognosis with serious complications and a high mortality, as occured in this case.

P1221

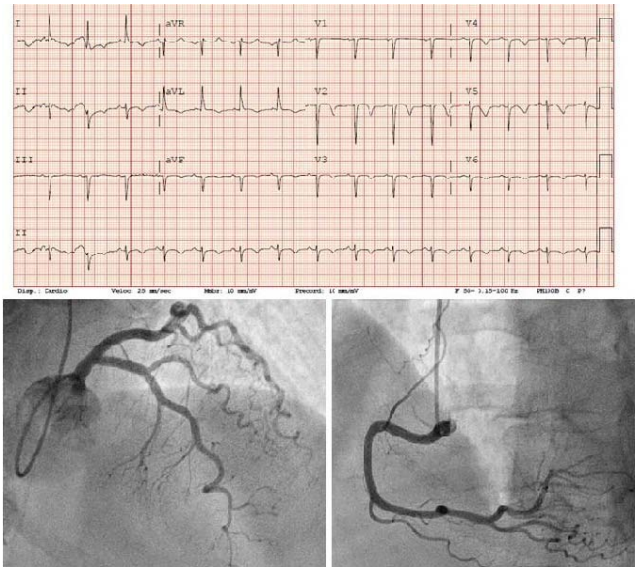
Takotsubo-like syndrome in a patient with BRAF mutated metastatic lung cancer

LC Belarte Tornero[1]; A Taus Garcia[2]; M Ble Gimeno[3]; T Martos Cardenas[4]; S Servitja Tormo[4]; E Gimeno Vazquez[5]; A Salar Silvestre[5]; X Sanz Latiesas[6]; F Martinez Medina[3]; A Miguel Gutierrez[7]; E Sole Gonzalez[7]; S Ruiz Bustillo[7]; N Farre Lopez[7]; J Marti Almor[8]

[1]Hospital del Mar, Cardiology Department, Heart Failure Unit, Cardio-Hemato-Oncology Unit, Barcelona, Spain; *[2]Hospital del Mar, Oncology Department, Barcelona, Spain*; *[3]Hospital del Mar, Cardiology Department. Cardio-Hemato-Oncology Unit, Barcelona, Spain*; *[4]Hospital del Mar, Oncology Department, Cardio-Hemato-Oncology Unit, Barcelona, Spain*; *[5]Hospital del Mar, Hematology Department, Cardio-Hemato-Oncology Unit, Barcelona, Spain*; *[6]Hospital del Mar, Department of Radiation Oncology, Cardio-Hemato-Oncology Unit, Barcelona, Spain*; *[7]Hospital del Mar, Cardiology Department, Heart Failure Unit, Barcelona, Spain*; *[8]Hospital del Mar, Head of Cardiology Department, Barcelona, Spain*

A 72 year-old woman was admitted to hospital with dysnea. She had a history of lung adenocarcinoma with liver metastasis and bilateral carcinomatous lymphangitis diagnosed one year before. She received treatment with carboplatin and pemetrexed and nivolumab without response. Initial molecular testing revealed a BRAF V600E mutation so treatment with trametinib/dabrafenib was initiated 4 months before admission.The patient complained of progressive shortness of breath, orthopnea and intermittent opressive chest pain the last 4 days before admission. Heart failure was diagnosed based on bilateral pulmonary crackles on examination, an X-ray that showed bilateral pulmonary oedema and NT-pro-BNP of 7339 pg/mL. The treatment with trametinib/dabrafenib was stopped because of suspected cardiotoxicity. High-sensitivity cardiac troponin was elevated (peak level 261.5 ng/L) with ischemic kinetic and ECG showed left axis with profound negative anterolateral T waves and prolonged QT. A coronary angiography was performed and showed coronary arteries without stenosis. The echocardiogram revealed normal left ventricle (LV) size with severe systolic dysfunction due to extensive anterolateral and apical akinesia with hyperkinetic basal LV. Thus the diagnosis of Takotsubo-like syndrome was established. In the following hours the patient progress to cardiogenic shock with elevated serum lactate and inotropic support with levosimendan was required. Rapid improvement was observed with hemodynamic recovery and resolution of heart failure. Treatment with B-blockers and ACE inhibitors was started. A cardiac magnetic resonance, done 1 week after, evidenced normal LV function without regional wall motion abnormalities. No myocardial oedema or late gadolinium enhancement was proved. The ECG after 1 week was normal.

To our knowledge this is the first case report of tramefinib cardiotoxicity presented as Takotsubo-like syndrome. The treatment with BRAF and MEK inhibitors is usually used in melanoma. However, as persistent hyperactivation of the RAS-RAF-MEK-ERK pathway is common in solid tumours; their use is being extended. Tramefinib is a selective inhibitor of MEK 1/2. Cardiac adverse events include elevated blood pressure, prolonged QT duration, LV dysfunction and myocarditis. LV systolic dysfunction incidence varies from 3 to 9% and although it is not very frequent it can be life-threating. The specific effect of trametinib over cardiac cells is not well studied. It is likely the result of suppression of ERK1/2 activation in the heart; a receptor with cardioprotective effects. As MEK/ERK receptor is inhibited with tramefinib beta-adrenergic signalling shunts toward the cardiotoxic p38 MAP kinase pathway. That's why levosimendan was preferred instead of other inotropics with beta-adrenergic effect as dobutamine. Periodic cardiac function monitoring must be implemented in patients treated with tramefinib for early detection of cardiotoxicity.



ECG and coronary angiography

P1222

Acute heart failure in patient with cervical cancer

S Dakova[1]; K Ramshev[1]

[1]Military Medical Academy of Sofia, Cardilogy and Intensive care unit, Sofia, Bulgaria

Introduction

The frequency of cardiac tumors –primary or secondary- is very low. The heart is an uncommon site of metastasis due to relatively less vascularity of endocardium, continuous movement of myocardium, striated cardiac muscle,rapid blood flow circulation, and the lack of lymphatic communication of between the surrounding tissues. If the metastatic cancer is observed, the most common involved side is right, but lesions could be located everywhere.

The presence of cardiac metastasis from cervical carcinoma is extremely rare 1.23% based on autopsy findings.The distant metastases are most frequently spreads to liver, lungs, bones, brain and supraclavicular lymph nodes.The usual spreading route of these cervical carcinomas is hematogeneous through the cervical plexus, inferior vena cava into right atrium finally right ventricle.

Case report We report a case of 51 years old woman, with known cervical carcinoma since 1,5 year/T3N1M1/, after many courses of chemo and radiotherapies. She presented in intensive care unit, because of signs of acute heart failure one day prior hospitalisation. She had a severe dyspnea, central cyanosis, pulmonary edema, low blood pressure and extremities edema.

Her vital signs were poor: BP 70/40 mmHg, pulse rate 113 BPM/AF, respiratory rate of 43/min, PO2 65mmHg, PCO2 30mmHg and SpO2 of 83% on 3 L/min Oxygen via nasal canula.

ECG- atrial fibrilation 113 BPM, no signs of acute coronary disease. The chest X ray was with signs of pulmonary congestion.

The laboratory results were out of range: Hb 85 g/l, Plt 113 g/l , WBC 14,5 109/l, CRP 145 mg/l, ASAT 77,ALAT 68, Total protein 55 g/l, Alb 21 g/l,NT proBNP 1250 pg/l.

The heart ultrasound found a huge tumor of the free wall of right ventricle with dimensions -6/5cm. The lesion was 3.7cm wide, penetrate 3cm in the cavity of ventricle and almost 3cm in pericardium.There was an obstruction of the cavities both left and right due to the mass compression, poor LVEF 41%, RVEF 15% and pericardial effusion 250ml.

The abdominal echo showed multiple metastases in liver.

The patient refused either any CT scan or MRT.

The therapy was:oxygen (nasal canula),diuretics,antibiotics,cardio inotropic medications,pain reliefs, hemotransfusion, protein substitution, hepato and gastroprotection,LMWH. Our patient refused any cardiac surgery and chemo-or radiotherapies. She was discharged on the 9th day in better condition, but with poor short time prognosis.

Do you think this patient needs anticoagulation?

Our desicion was to left her 1 month on LMWH but low doses.

Conclusion Cardiac metastases may cause many different symptoms heart failure, arrhythmias, intracardiac obstruction, pulmonary embolism and many others.The prognosis is extremely poor and it is important to suspect them in patient with history

of any malignant disease. There is no specific treatment but surgery and aggressive therapy may lengthen patients survival and quality of life.

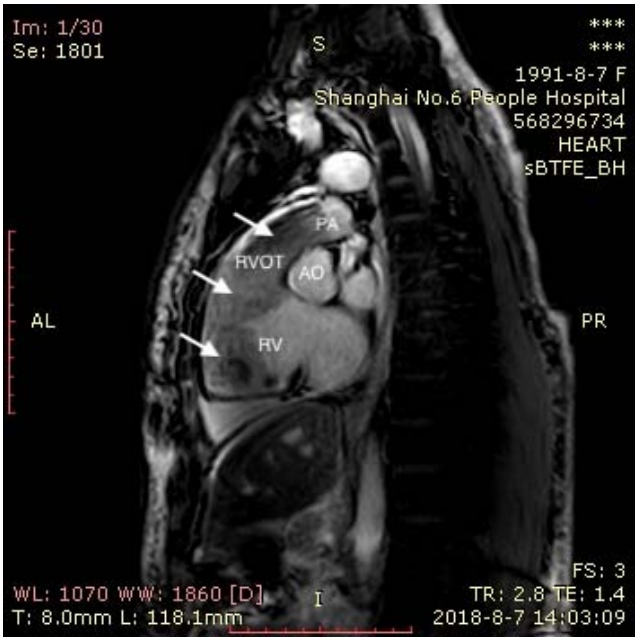
The obsessional synovial sarcoma

J Jingwei Pan[1]; CJ Gao[1]; H Tang[2]; YG Wang[1]
[1]Shanghai Sixth People's Hospital of Shanghai Jiaotong University, Shanghai, China; *[2]Shanghai Hospital of Second Military Medical University, cardio-thoracic department, Shanghai, China*

On behalf of: Shanghai No.6 Hospital Heart Center

A 25-year-old girl, suffering from persistent left upper abdominal pain, was diagnosed as left renal mass. Computed tomography (CT) showed the mass at the inferior of the left kidney with ipsilateral renal vein embolus. Histopathology demonstrated well-differentiated spindle cell tumor. Three months after the surgery, ICV embolus was found by follow-up CT angiography (CTA). The embolectomy was performed and ICV was replaced by artificial blood vessel. Relapse of the synovial sarcoma was confirmed by pathology. Six months later, complaining of dyspnea and palpitation, she was diagnosed as right ventricular mass by echocardiography. Further cardiac magnetic resonance (CMR) demonstrated a huge mass taking up 2/3 space of the right ventricle, striding over the tricuspid annulus and obstructing the right ventricular outflow tract (RVOT) . The mass was removed and her tricuspid valve was replaced emergently for fish like tumor eroded the valve. Spindle cell tumor was confirmed by histopathology again . Unfortunately, the patient died of infection and disseminated intravascular coagulation 45 days after the third operation. Radical nephrectomy and lymphadenectomy remain the most positive and effective approach to treat renal carcinoma, while the postoperative recurrence rate in 2 years is up to 50%. It is very urgent to find effective measures to prevent relapse of sarcoma.



CMR-RVOT

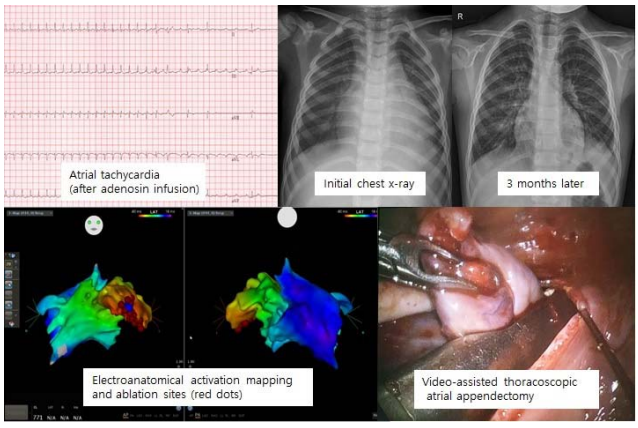
Successful video-assisted thoracoscopic atrial appendectomy for a 4-year-old child with intractable atrial tachycardia with tachycardia-induced cardiomyopathy

HW Kwon[1]; EJ Bae[1]; JG Kwak[2]
[1]Seoul National University, Pediatrics, Seoul, Korea (Republic of); *[2]Seoul National University, Cardiothoracic surgery, Seoul, Korea (Republic of)*

Case report: A 4-year-old boy visited the Emergency Department due to prolonged abdominal pain. His pulse rate was 208 bpm, blood pressure was 96/56 mmHg, body temperature was 36.5 °C, and oxygen saturation by pulse oximeter was 97%. He did not complain of palpitation, however, his mother said she could notice his precordial heaving since several days ago. His body weight was 22kg, and his weight has recently increased by 2kg. Chest x-ray showed cardiomegaly with pleural effusion. Echocardiography showed dilated all cardiac chambers and left ventricular ejection fraction (LV EF) was around 30%. Plasma level of B-type natriuretic peptide (BNP) was 3296 pg/mL. An EKG showed narrow QRS tachycardia without normal P wave. After adenosine infusion, ectopic P waves were apparent during atrioventricular conduction block. He was admitted to the pediatric intensive care unit for management of incessant ectopic atrial tachycardia (AT) and associated heart failure. Because he was not tolerated to even very low dose beta-blockers, he started amiodarone infusion. However, amiodarone infusion was discontinued because he showed recurrent Torsade pointes and non-sustained ventricular tachycardia with prolonged QT interval. We tried radiofrequency catheter ablation for ectopic AT using CARTO® system. There were multiple origins of AT in the left atrial appendage; anterior apex, inferior side, and posterior base. Even though we attempted multiple RFCA, AT was terminated and then frequently recurred at other sites. Finally, we decide to perform video-assisted thoracoscopic atrial appendectomy for refractory AT. Immediate after the appendectomy, AT was terminated and restored to sinus rhythm. Immediate postoperative LV EF was 40%, and it increased to 53% the day after the operation. Two months after treatment, LV EF was measured as 57% and BNP level decreased to 31 pg/mL. He had no arrhythmia during the 4-month follow-up.

Conclusions: In children, heart failure can present with atypical symptoms such as abdominal pain. Heart failure associated with incessant tachycardia can be improved by aggressive treatment of arrhythmias. Arrhythmia surgery should be considered for malignant arrhythmia that is not responding to drugs or radiofrequency ablation.

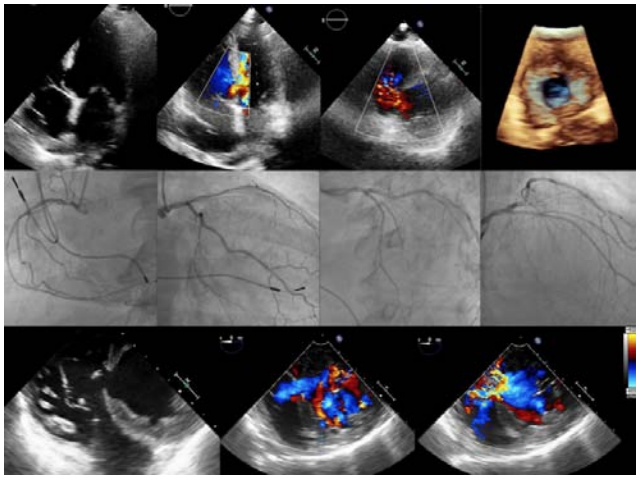


P1225

High degree AV block and ventricular septal rupture unmasking silent myocardial infarction.

D Cocco[1]; D Congia[1]; A Pani[1]; G Binaghi[1]; E Serra[1]; GS Fele[1]; M Melis[1]; PP Orru[1]; G Zedde[1]; M Manconi[2]; A Boi[3]; EM Cirio[4]; P Manca[4]; M Corda[1]; M Porcu[1]
[1]G. Brotzu Hospital, SC Cardiologia con Unità di Terapia Intensiva Cardiologica, Cagliari, Italy; *[2]G. Brotzu Hospital, SSD Cardioanestesia, Cagliari, Italy*; *[3]G. Brotzu Hospital, SC Cardiologia Interventistica, Cagliari, Italy*; *[4]G. Brotzu Hospital, SC Cardiochirurgia, Cagliari, Italy*

Ventricular septal rupture (VSR) is a rare mechanical complication of acute myocardial infarction (MI). An early diagnosis is necessary because of high mortality rates. Surgical or percutaneous repair is generally required but the timing is still a matter of debate. We report the case of a 79-year-old man affected by hypertension, who was implanted with a PM for a 2:1 atrioventricular (AV) block symptomatic for syncope. At that time transthoracic echocardiography (TTE) and laboratory analysis were not consistent with MI. Two weeks later he presented complaining dyspnea. At physical examination a new 3/6 systolic murmur, pulmonary rales, mild jugular distension, hepatomegaly and ankle oedema were present. BP was normal. ECG showed sinus tachycardia, first degree AV block, right bundle-branch block and left posterior fascicular block. Chest X-ray showed cardiomegaly and congestion. Diuretics and oxygen were started, but soon after the clinical picture deteriorated to pulmonary edema. TTE showed a dilated left ventricle with normal systolic function (EF 60%.) Unexpectedly, the exam revealed a ventricular septal rupture (VSR) in the infero-basal segment of the interventricular septum (14 mm), close to the tricuspid valve, with a left-to-right shunt. The septum showed a paradoxical movement as for right ventricle overload. The interrogation of the PM reported normal functioning. Coronary angiography showed a complete occlusion of the first septal branch of the left anterior descending artery. Right heart catheterization confirmed a left-to-right shunt with increase of pulmonary pressures. An intra-aortic balloon pump (IABP) was positioned. A diagnosis of recent silent MI complicated by high degree AV block and VSR was made. After Heart Team discussion, surgery was delayed to permit healing of the myocardium. In the ICU hemodynamic remained stable with i.v. diuretics and IABP. After 14 days, despite the challenging anatomy, a surgical repair with bovine pericardium patch was successfully performed with no residual shunt. This case singularly shows a AV block followed by a VSR as the sole signs of a silent MI. The diagnosis was challenging for the unusual presentation. The new systolic murmur heralded the mechanical complication and brought to the correct diagnosis. Echocardiography played a pivotal role in both diagnosis and surgical planning. VSR is still a hot topic because the optimal timing and type (surgical vs percutaneous) of repair is debatable.



Ventricular septal rupture following MI

P1226

Takotsubo cardiomyopathy as a rare complication of guillain-barre' syndrome

R Rok Stopar[1]; B Rojc[2]; B Mahne[1]; T Ravnikar[1]; N Cernic-Suligoj[1]; A Kupresan[1]; S Kariz[3]
[1]Izola General Hospital, Cardiology, Izola, Slovenia; *[2]Izola General Hospital, Neurology, Izola, Slovenia*; *[3]Izola General Hospital, Medical Intensive care unit, Izola, Slovenia*

Takotsubo cardiomyopath is defined as reversible left ventricular dysfunction mainly triggered by physical or emotional stress in postmenopausal women. It may be associated with different neurologic conditions such as intracranial hemorrhages, strokes and multiple sclerosis.
In following case report we will present Takotsubo cardiomyopathy secondary to severe
form of Guillain Barre syndrome and preceded by PRES syndrome
64 year old woman, without any previous serious medical condition, presented with hypertension, acute confusion and disorientation followed in next days by upper and lower extremity weakness. CT and MR scans disclosed patchy lesions in parietooccipital lobes which were consistant with posterior reversible encephalopathy (PRES) syndrome . CSF examination and EMG were in line with acute demyelinating polyneuropathy According to clinical, neurological and neurophisyological findings, diagnosis of Guillain Barre' syndrome (GBS) was established. In the meantime, muscular weakness progressed to quadriplegia and respiratory failure, accompanied by hypotension. Intubation and mechanical ventilation were needed. Treatment by intravenous immunoglobulin was introduced. Due to elevated troponin, ECG changes and heart failure signs with elevated BNP and congestion on lung x rey an acute coronary sindrom was suspected. Transthoracic echo revealed apical akynesia with hyperkinesia of basal segments and moderately reduced systolic function (EF 42%), without apical thrombus or left outflow tract obstruction. CT coronary angiogram ruled out sever coronary disease. Upon haemodinamic stabilisation, therapy with ACE inhibitor and β was commenced. After introduction of immunoglobulin therapy there was a substantial clinical improvement with successful weaning from mechanical ventilation. Blood pressure was in normotensive range. Repeated transthoracic echocardiogram performed 4 weeks later demonstrated normal systolic function, without any regional wall motion abnormality, confirming diagnosis of takotsubo cardiomyopathy. 6 months later patient was symptom free, without any neurological sequelae.
Takotsubo cardiomyopathy is usually reversible and self-limited. Nevertheless sever complicatons may develope in acute stage. Recognition and treatment of precipitating factors and predisposing disease is fundamental and may have an impact on improving prognosis and in preventing recurrence.

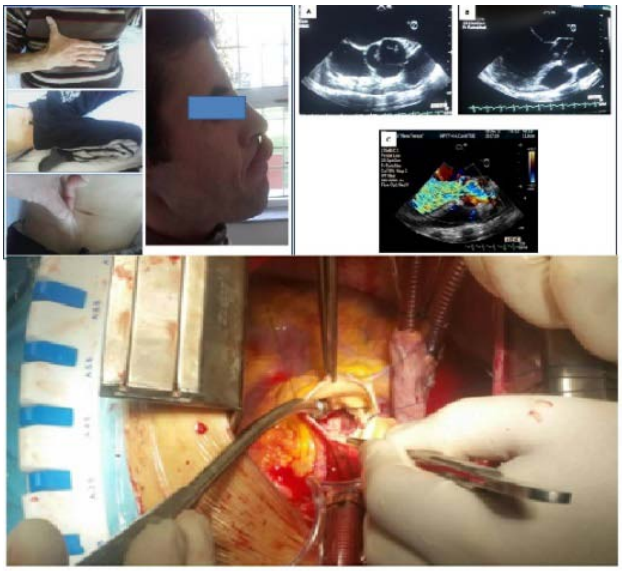
Native aortic valve endocarditis mimicking meningitis in a rare setting

I Refatllari[1]; A Banushi[1]; E Rapushi[2]; E Ramosaco[3]; K Krakulli[4]; E Bejko[4]
[1]University Hospital Center Mother Theresa, Cardiology, Tirana, Albania; *[2]University Hospital Center Mother Theresa, Rheumatology, Tirana, Albania*; *[3]University Hospital Center Mother Theresa, Infective Diseases, Tirana, Albania*; *[4]University Hospital Center Mother Theresa, Cardiac Surgery, Tirana, Albania*

Introduction: The Ehlers-Danlos syndromes(EDS) are a group of connective tissue disorders that can be inherited,generally characterized by joint hypermobility,skin hyperextensibility,tissue fragility.Some of these pt have cardiac involvement which management is a challenge
Case report:A 38y.o male presented to the ER with viral infection signs(temperature, myalgia and respiratory symptoms),followed by headache,nucal rigidity.A cerebrospinal fluid analysis showed normal glucose,mild elevation of protein levels and a small number of cells,mostly neutrophils.Nasal culture and HIV test negative.The head CT normal.Considering a viral meningitis iv acyclovir was initiated.Because of constitutional findings(hypermobility of the big and small joints,hyperelastic skin,facial features,thoraco-lumbar kyphoscoliosis,long neck),the pt was consulted by a rheumatologist and an EDS diagnose was made based on Beighton Score(7/9) and Gorlins sign.A temp of 39.5°C persisted,dyspnea,cough,subcrepitant rales at the right lung base appeared.High levels of WBC and thrombocytopenia were present,negative hemocultures,high CRP(81.7mg/L).ANA(+++);IGA-(N);IGM-(5.65mg/dl);C3-(N).Ceftriaxon+levofloxacin were started.A diastolic aortic murmur was present,BP 120/50mmHg,HR 100/min.ECG had signs of LV hypertrophy and sinus tachycardia.The pt was evaluated by a cardiologist.TTE suggested an infective endocarditis(IE) of the native tricuspid aortic valve with several small vegetations on the noncoronary and right coronary cusp,aneurism of the noncoronary cusp(NCC) with probable perforation and severe aortic regurgitation(AR),LV dilation(74mm),normal EF(66%),mild MR,PFO,moderate TR,severe PAP(70 mmHg).A TEE(a week later)confirmed the NCC rupture,massive AR(2 jets),no visible vegetations and no perivalvular abscess.Vancomycin was added.After 10 days the pt was afebrile,dyspnea improved(NYHA 2),normal WBC,mild decline of Hb and RBC.CRP 36mg/dl,negative hemocultures.Antibiotics continued 4 weeks,afebrile pt with HF signs thus intervention was scheduled.A small abscess at the NCC level was noticed during cardiac surgey which reconfigured the aortic annulus through pericardial patch and replaced the valve with a mechanical prosthesis without complications.The pt recovered well,without HF signs
Conclusion:We present a case of IE mimicking initially a viral meningitis,diagnosed during a degenerative syndrome course similar to Marfan.The indication for surgery was HF.Despite valve destruction,VM dilation from fluid overload,a good tolerance of HF suggest a preexisting lesion of the aortic valve that can classify our pt in the

cardio-vascular form of EDS,rare and characterized by progressive cardiovascular lesions.Because of increased vascular fragility there is a high risk for severe bleeding and hematomas.Special care is needed during intubation and central venous catheters insertion.In case of valve replacement, suture dehiscence or aortic rupture during cannulation can happen more often.



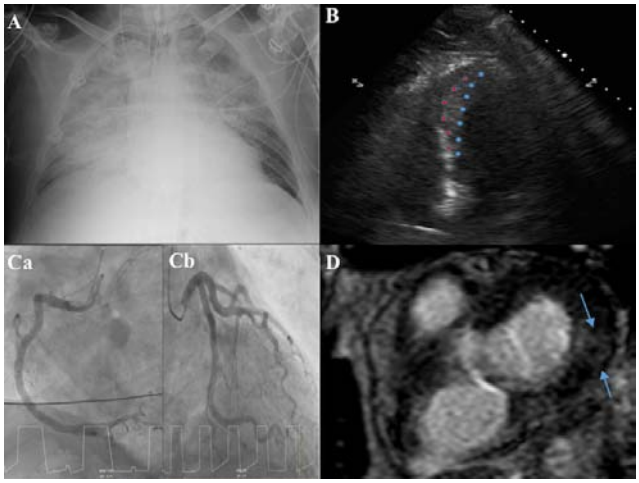
EDS clinical features, aortic valve IE

P1228

A case of acute myocarditis due to 5-fluorouracil cardiotoxicity.

JD Juan Diego Sanchez Vega[1]; E Rajjoub Al-Mahdi[1]; GL Alonso Salinas[1]; M Pascual Izco[1]; JM Vieitez Florez[1]; M Plaza Martin[1]; R Hinojar Baydes[1]; C Fernandez-Golfin[1]; A Urena[2]; A Garcia De Vicente[2]; MA Fernandez[2]; M Sanmartin Fernandez[1]; JL Zamorano[1]
[1]*University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain*;
[2]*University Hospital Ramon y Cajal de Madrid, Radiology, Madrid, Spain*

We present a case of a 56 years-old male, with stage III colorectal cancer (T3N2M0) undergoing chemotherapy treatment one month following surgical resection, without other medical history. The patient was receiving a cycle of chemotherapy, with intravenous oxaliplatin and 5-fluorouracil (5FU).
During treatment, the patient presented with chest pain, discomfort and perspiration. The first electrocardiogram (ECG), troponine levels and echocardiogram were normal. After a few hours, the patient developed respiratory failure due to acute pulmonary edema (image A) and cardiogenic shock, in need of orotraqueal intubation and vasoactive drugs. In the sequential ECG, ST segment elevation from V2 to V5 and I-II-aVF was appreciated, indicating an infarction code.
The coronary angiography demonstrated no lesions (Image Ca-Cb). That, joined with a new moderate systolic dysfunction of the left ventricle, made us consider a myocardial infarction with non-obstructive coronary arteries as a probable diagnosis. Cardiogenic shock progress to an INTERMACS 1 situation, led us to implant a venoarterial extracorporeal membrane oxygenation (ECMO) as a bridge to a definitive treatment decision. Furthermore, the patient presented arrhythmic storm with fast ventricular tachycardia and ventricular fibrillation, requiring 27 electric shocks, amiodarone, and finally propranolol to control the rhythm. After the initial stabilization, our patient presented with severe dysfunction of the left ventricle, without the possibility of opening of the aortic valve and the presence of an apical thrombus (image B: red line indicates the endocardium, blue line indicates the thrombus surface), requiring an increase of the dosage of inotropes.
With the suspicion of 5FU cardiotoxicity, we contacted with the oncology service, which recommended the use of uridine triacetate as an antidote. Upon administration the patient showed a gradual improvement, descending the need of vasoactive drugs and mechanical support. In a cardiac magnetic resonance image, we observed inferior-lateral-basal non-ischemic contrast pattern, which supported the diagnosis of acute myocarditis (image D).
Following 16 days of hospital admission, the patient recovered a normal left ventricular function and was discharged. Five months later, the patient continued to be stable, without any signs of heart failure and sustained normal left ventricular function.
The cardiotoxicity from chemotherapy drugs is a common complication that may appear during the treatment of different types of cancers. 5FU cardiotoxicity is a known adverse affect of this drug, however the mechanism of which this toxicity occurs in not clear. Uridine triacetate has been considered an effective antidote for the most severe cases of toxicity.



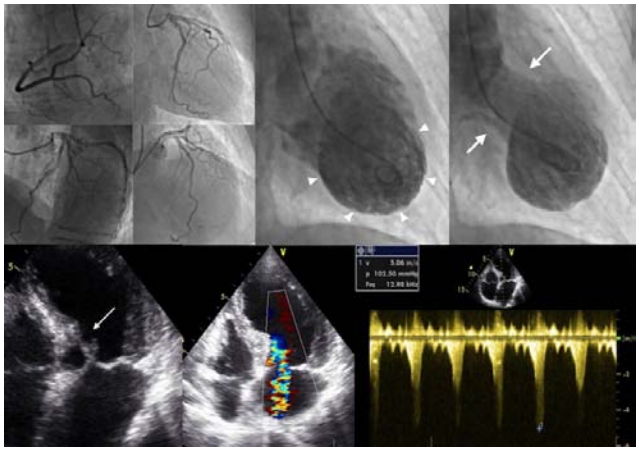
Images of the case

P1229

Takotsubo syndrome complicated by left ventricular outflow tract obstruction in a woman with chronic beta-blocker therapy

G Garau[1]; D Cocco[1]; C Soro[1]; CS Centorbi[1]; L Craba[1]; R Montisci[1]; L Meloni[1]
[1]*University of Cagliari, Clinica Cardiologica, Policlinico Universitario Duilio Casula, Cagliari, Italy*

Takotsubo syndrome (TS) is characterized by acute and transient left ventricular (LV) regional systolic dysfunction. Although in most patients the myocardial dysfunction is reversible, the prognosis may be poor because serious life-threatening complications can occur, such as acute heart failure and cardiogenic shock.A 60-years-old smoker woman presented to the emergency department (ED) for sudden chest pain. She had a history of hypothyroidism and hypertension treated with bisoprolol 2.5 mg once daily. Vital signs were normal. On cardiac auscultation a 3/6 olosystolic murmur was audible in all the auscultatory areas, lung sounds were clear. ECG showed sinus rhythm and ST-segment elevation in the inferior leads and in V4-V6 leads. Intravenous nitroglycerin (NTG) was started in the ED and she was transferred in the cath lab. At the angiography the coronary arteries were normal, while ventriculography showed an apical ballooning of the apex with severe mitral regurgitation (MR). A diagnosis of TS complicated by severe MR was made and the patient was admitted to the Intensive Coronary Unit. Soon after, she developed hypertensive pulmonary edema (BP 160/100 mmHg) which was treated with repeated bolus of loop diuretic and increased nitrate infusion. Unexpectedly, she presented abrupt hypotension (BP 70/50 mmHg), tachycardia (HR 110 bpm), worsening dyspnea and diaphoresis with mild elevation of serum lactates (2.5 mmml/L). The transthoracic echocardiography (TTE) showed severe functional MR secondary to systolic anterior motion of the mitral valve (SAM), with severe dynamic left ventricular outflow tract obstruction (LVOTO), peak gradient > 100 mmHg. NTG and diuretics were immediately stopped. After administration of intravenous methoprolol and fluid, BP normalized and LVOTO decreased. The subsequent course was uneventful: oral bisoprolol was continued and TTE documented progressive improvement of the LV systolic function, with disappearance of SAM, dynamic LVOTO and MR.The present case shows how TS can occur during chronic beta-blockade. Treatment of hypertensive pulmonary edema by intravenous loop diuretics and nitrate can exacerbate the LVOTO in the setting of TS and trigger cardiogenic shock. Despite severe hypotension, the intravenous administration of a beta-blocker, by reducing the LV basal hyper-contractility, may remove the dynamic LVOTO and the associated MR with stabilization of the hemodynamic conditions.



Takotsubo syndrome complicated by LVOTO

P1230

Fulminant myocarditis: should we wait for recovering? Biopsy says no

S Sara Vazquez[1]; B Keller[1]; JM Dominguez[1]; G Spitaleri[1]; F Loiacono[1]; F Perez Villa[1]; M Farrero[1]; A Castel[1]
[1]Hospital Clinic de Barcelona, Cardiology, Barcelona, Spain

We report the case of a healthy 24-year-old woman who presented to the Emergency Department of another Center with a two-days history of fever (38°C), nausea, vomiting, diarrhea and epigastric pain. Hemodynamic instability and signs of general hypoperfusion were observed.

Laboratory analysis revealed leukocytosis, impaired renal and hepatic function and a marked elevation of CKs, CK-MB and troponin. ECG (Figure 1-a) showed ST elevation in aVR and V1-V2, with a diffuse ST depression in other leads. Initially diagnosed with STEMI, she was treated with heparine and double antiplatelet therapy, and emergently transferred to our hospital for coronary angiography, which showed no artery disease. Initial echocardiogram showed severe biventricular dysfunction and diffuse hypertrophy suggesting edema. Swan-Ganz measurements showed cardiac index 1.3L/min/m2. An intra-aortic balloon pump was implanted and inotropes and vasopressors were initiated due to cardiogenic shock.

She quickly developed severe multiorgan dysfunction, with hypertransaminasemia (peak ASAT 44711U/L) and anuria. Two hours after admission, while she was being transferred to the OR for central biventricular support implant, she presented a cardiac arrest from ventricular tachycardia and was placed in veno-arterial ECMO. In the following hours, heart rhythm changed from persistent ventricular tachycardia to an agonic rhythm and asystole (Figure 1-b). After 24hours, mechanical cardiac support was converted into a mini-thoractomy biventricular assist device, associated to an oxygenator due to pulmonary edema. An endomyocardial biopsy was then obtained, which showed a diffuse lymphocytic T-type infiltrate (Figure 1-c), with diffuse and severe myocardial destruction, confirming the diagnosis of myocarditis. Considering her fast progression and the diffuse tissue damage on biopsy, she was placed in the highest priority list for emergent heart transplantation, which was successfully performed 4 days later. Post operative heart transplantation course was uneventful, with progressive organ recovery. She was discharge to a rehab facility 3 weeks after surgery.

Explanted heart pathological report became available 2 weeks after transplant. The histopathological evaluation of the explant specimen revealed a diffuse and dense interstitial lymphocytic infiltrate, which immunohistochemically consisted of CD3+ T lymphocytes with very few accompanying CD20+ B lymphocytes. Immunohistochemical staining for C9 exhibited extensive necrosis of the myocardial fibers (Figure 1-d). Severity of these results perfectly matched the aggressive clinical presentation, and confirmed the scarce possibility of myocardial recovery.

P1231

Rare cause of acute heart failure in a young patient

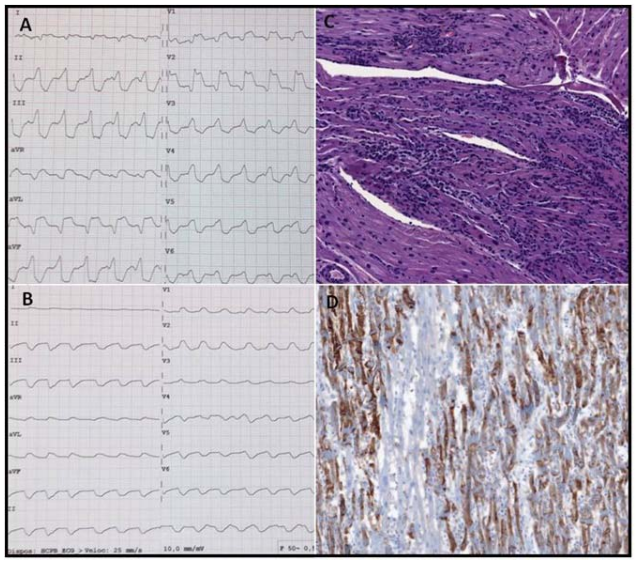
E Han[1]; B Oeztuerk[1]; S Kufova[1]; GJ Wengert[2]; R Badr Eslam[1]; J Bergler-Klein[1]
[1]Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria; *[2]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Vienna, Austria*

Introduction: Primary cardiac lymphoma (PCL) is extremely rare and accounts for 5-6 % of primary malignant cardiac tumors and 1-2% of all primary cardiac tumors, and mainly manifests over the 5th age decade, and in immunocompromised patients or in HIV. PCL generally emerges in the right atrium or right ventricle and has a poor prognosis.

Results: This is an unusual case of a 23 year old male referred to our hospital with increasing severe dyspnea, chest pain, palpitations, signs of upper venous congestion and elevated NT-proBNP (395.5 pg/ml). Echocardiography and cardiac MRI findings revealed a large cardiac mass infiltrating the right atrium (tumor diameter 5.5 cm), right ventricle (tumor 3 cm) and tricuspid valve (Figure 1a). Cardiac surgery was performed with tumor resection and bioprosthetic tricuspid valve replacement. Histological assessment yielded diffuse large B-cell lymphoma. Additionally, the patient underwent four cycles of chemotherapy (CHOP: cyclophosphamide, doxorubicin, vincristine, prednisone), without further metastasis. Two years post surgery, the patient is asymptomatic, but has elevated cardiac enzymes with troponine and NT-proBNP. Echocardiography displayed normal LV ejection fraction, but impaired global systolic longitudinal strain (GLS) as subclinical sign of heart failure (Figure 1c and 1d). Assessment by MRI showed normal right ventricular function and normal function of the tricuspid valve bioprothesis also in echocardiography (Figure 1b).

Conclusion and implications for clinical practice: Rapid imaging in heart failure is crucial to differentiate the etiology. Cardiac tumors causing heart failure need urgent surgical treatment. Patients undergoing chemotherapy require cardio-oncology follow up with echocardiography for detection of cardio-toxicity and early start of heart failure therapy.

Figure 1a Pre-surgery: MRI demonstrates an inhomogeneous enhancing mass (arrow on four chamber SSFP-sequence in systole), arising in the region of the



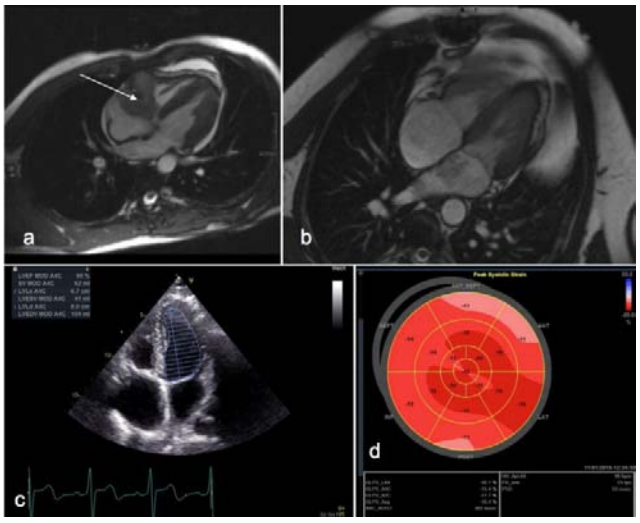


Figure 1

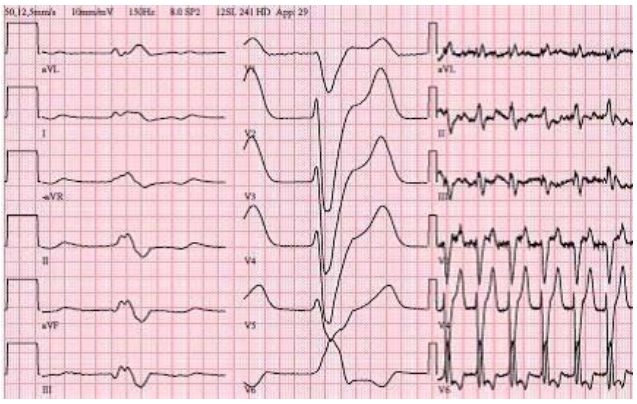
right atrium and right ventricle with tricuspid valvular involvement. The mass has polylobulated shape and does not infiltrate into the anterior mediastinum. There is a moderate pericardial effusion, indicating acute heart failure.
b Follow-up: right ventricular function assessment by cardiac MRI two years after surgery.
c Assessment of left ventricular ejection fraction by echocardiography.
d Assessment of global longitudinal strain of left ventricle by echocardiography.

P1232

Leptospirosis: an unusual cause of multiorgan failure and severe cardiac involvement with impressively wide QRS complex

A Kissopoulou[1]; M Carlsson[2]; S Kyrama Nijm[1]
[1]Ryhov County Hospital, Department of Internal Medicine and Cardiology, Jonkoping, Sweden; [2]Ryhov County Hospital, Department of Infectious Diseases, Jonkoping, Sweden

Case Report: A 64 years old male patient presented to the Emergency Department with complains of fatigue, malaise and anorexia. The patient also gave a history of diarrhea and vomiting one-week prior. He worked as a fish dealer and gave no history of significant past illness. On presentation, he had no fever, was hemodynamically stable with mild tachypnea. The ECG showed sinus tachycardia with left bundle branch block (LBBB) and QRS duration of 258 msec. Clinical features revealed icterus, peripheral cyanosis, no signs of congestion and a normal neurological status. Bedside Echocardiography showed: a dilated left ventricle with generally, moderate impaired function without any pericardial effusion. The blood samples revealed elevated infection parameters and severe metabolic acidosis with elevated lactic acid. Additionally, he had an acute renal failure with electrolyte disturbances and even acute liver failure as well as sings of acute myocardial injury. As his clinical status deteriorated, he was immediately shifted to the intensive care unit, where he received inotropes, fluids, antibiotics, and was put on hemodialysis. A temporary pacemaker was also implanted because of tachy-brady arrhythmias. The infectious disease consultant suggested examining serology for Leptospira and even considered mushroom poisoning as an alternative diagnosis, because the patient mentioned consumption of self-collected mushrooms. Therefore, he was transferred to the liver transplantation center for further investigation. Coronary angiography ruled out coronary disease, cardiac magnetic resonance showed signs of myocarditis and severely impaired biventricular systolic function. Thus, he was a poor candidate for a liver transplant and was treated conservatively. Fungal poisoning could be excluded, as the mushroom sample was innocuous. However, leptospira-specific immunoglobulin M (IgM) turned out to be highly positive, confirming the diagnosis of Leptospirosis. Further interrogation revealed that he was exposed to rats in his workplace. On subsequent days, the patient showed significant clinical recovery with normalization of biochemical parameters. He was discharged after 75 days of hospital care with only a mild degree of heart failure and an ECG showing normal sinus rhythm and LBBB with QRS duration of 150 msec.
Discussion: Here, we present a case of Leptospirosis with multiorgan dysfunction (Weil´s disease) including acute renal and liver failure and non-ischemic biventricular heart failure with cardiac arrhythmias. The ECG showed LBBB with an unusually wide QRS complex attributed to electrolyte disturbances and myocarditis. Cardiovascular involvement in Leptospirosis tends to predict poor outcome.
Conclusion: Cardiac manifestations in leptospirosis are variable ranging from myocarditis and heart failure to severe cardiac arrhythmias. Meticulous intensive care management and prompt antibiotic therapy are crucial, as laboratory confirmation can be delayed.



The patient´s ECG on admission

P1233

Postpartum acute heart failure in a patient with bicuspid aortic valve

N Avram[1]; GD Baltag[1]; S Guberna[1]; R Brezeanu[1]; A Lacraru[1]; A Avram[1]; I Dimitriu[1]; V Chioncel[1]; I Calangea[1]; A Catana[1]; A Teasa[1]; A Ion[1]; CJ Sinescu[2]; CL Andrei[2]
[1]Bagdasar-Arseni Emergency Hospital, Cardiology, Bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania

A 27-year-old woman was hospitalized for orthopnoea and major legs swelling progressively aggravated in the last month. Medical history: caesarean delivery 5 weeks before, bicuspid aortic valve (BAV) with moderate stenosis and minimal regurgitation incidentally discovered during pregnancy. She had been monitored until birth with no significant changes of the aortic valvular dissease (AVD) or LV function (LVEF the day before cesarean- 50%). At admission: orthopnea, subcrepitant rales, decreased oxygen saturation (75%), systemic congestion, BP= 100/60 mmHg, sinus tachycardia (126 bpm), ejection aortic murmur, small suprapubic postoperative dehiscent wound, pallor of teguments and mucous membranes. Laboratory test: elevated NTproBNP level, mild anemia and hepatic cytolysis syndrome. ECG: sinus rhythm, QRS axis +30 degrees, no change of repolarization, no rhythm or conduction disorders. Transthoracic echocardiography: eccentric LV hypertrophy, severe global systolic LV dysfunction, LV apical trombus, BAV: severe stenosis (aortic valve area (AVA) = 1 cm2), mild regurgitation, RV dysfunction. Transesophageal echocardiography: BAV, severe aortic stenosis (AVA= 0.95 cm2); two hyperecogenic structures, in the left atrium (LA) and LV apex suggestive of thrombi. Clinical and paraclinical data concluded the diagnosis of acute congestive heart failure with LV severe dysfunction, BAV with low-flow low-gradient stenosis and minimal regurgitation. To find the precipitating factors that led to acute heart failure we incriminated three potential causes: peripartum cardiomyopathy, myocarditis, infective endocarditis. Repeated hemocultures had negative results, cardiac MRI excluded myocarditis and confirmed echocardiographic findings. Diagnosis: Acute HF with LV severe systolic dysfunction. BAV with low-flow low-gradient stenosis and minimal regurgitation. Peripartum cardiomyopathy with postpartum late onset. The patient received conventional treatment for acute heart failure and her evolution was favorable. Betablocker and ACE inhibitor were added in titrated doses after hemodynamic stabilization, with good tolerance. 6 months after this acute event ecocardiography showed systolic LV improvement (LVEF= 40%). Particularity of the case: BAV with moderate stenosis and minimal regurgitation, asymptomatic for 27 years, incidentally diagnosed with the occasion of cardiac examination during pregnancy in a patient that developed cardiomyopathy with severe LV dysfunction 2 weeks after child birth. Discussions: 1. Counseling of a nulliparous pregnant woman without other cardiovascular risk factors who was incidentally diagnosed with moderate congenital aortic valvular disease during pregnancy regarding the maintaining or not of the pregnancy before the correction of valvular disease. 2. Counseling the same patient for future pregnancies in relation to the risk of recurrence of cardiomyopathy.

HFWM: - Title: Selenium deficiency impairs mitochondrial function in human cardiomyocytes and is associated with worse clinical outcomes in patients with heart failure

N Bomer[1]; N Grote Beverborg[1]; MF Hoes[1]; J Ijmker[2]; DJ Touw[2]; AA Voors[1]; P Van Der Meer[1]
[1]University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands (The); [2]University Medical Center Groningen, Clinical Pharmacy and Pharmecology, Groningen, Netherlands (The)

On behalf of: BIOSTAT-CHF
Funding Acknowledgements: FP7-242209-BIOSTAT-CHF; EudraCT 2010–020808–29

Background: Selenium is an essential trace element involved in the antioxidant defense mechanism. Extreme selenium deficiency can lead to dilated cardiomyopathy. However, whether modest deficiency have an impact on outcome in patients with heart failure (HF) is currently unknown. Here, we investigate the involvement of selenium deficiency in worsening of HF symptoms and outcome, at a clinical and molecular level.
Methods: BIOSTAT-CHF is a multinational, prospective, observational study cohort that included patients with worsening heart failure. Serum selenium levels were measured by mass spectrometry. Primary outcome was a combined outcome of all-cause mortality and hospitalization for HF, secondary outcome was all-cause mortality alone. To investigate the direct effects of Se deficiency on cellular level, human cardiomyocytes were cultured selenium deficient. Mitochondrial metabolic function and distribution, cellular ROS levels, mRNA expression of cellular stress and metabolic markers were assessed.
Results: In the 2382 HF patients included in this study, selenium deficiency (<70 ug/L) was found in 485 (20.4%) of all patients. Selenium deficient patients were older,

more often women with a higher NYHA class, more severe signs and symptoms of HF and a lower exercise capacity (6-Minute Walk Test [P <0.001]) and quality of life (Kansas City Cardiomyopathy Questionnaire [P <0.001]). Selenium deficiency was independently associated with higher rates of the primary combined outcome (Hazard ratio [HR] 1.23; 95%CI 1.06-1.42) and all-cause mortality alone (HR 1.52; 96%CI 1.26-1.86). Finally, in human cardiomyocytes, low selenium reduced mitochondrial function and therewith oxidative phosphorylation and increased intracellular ROS levels.

Conclusions: Selenium deficiency in heart failure patients is independently associated with an impaired exercise tolerance, a 50% higher mortality rate and an impaired mitochondrial function in human cardiomyocytes. Clinical trials are needed to investigate the potential role of selenium supplementation in patients with worsening HF and low selenium levels. Translation of our findings towards clinical application of selenium as a low cost "nutraceutical" should be initiated.

HFWM: - Title: Gene therapy with phosphodiesterase 4B in a murine model of pressure overload-induced cardiac hypertrophy

N Nikoleta Pavlaki[1]; VO Nikolaev[1]

[1]University Medical Center Hamburg Eppendorf, Hamburg, Germany

Funding Acknowledgements: DZHK, ERA-CVD

Background: Heart failure (HF) is characterized by chronic neurohormonal hyperactivation and increased production of the second messenger 3',5'-cyclic adenosine monophosphate (cAMP) which regulates force of contraction, cardiac relaxation, and beating frequency. Specific hydrolysing enzymes phosphodiesterases (PDEs) tightly regulate intracellular cyclic nucleotide levels and generate multiple functionally relevant cAMP microdomains. In HF, protein levels of several PDEs are altered, resulting in a dramatic downregulation of PDE3 and PDE4 activities. Furthermore, the interplay between β-adrenergic receptors (β-ARs) and PDEs is compromised leading to disease-associated alterations in cAMP compartmentation.
Purpose: To restore cyclic nucleotide compartmentation in the sarcoplasmic ryanodine receptor (RyR) microdomain by cardiac-specific overexpression of PDE4B in a mouse model of pressure overload-induced heart failure.
Methods: Transgenic (TG) mice expressing a cAMP biosensor localized in the RyR microdomain were subjected to Transverse Aortic Constriction (TAC) and gene therapy with adeno-associated virus type 9 (AAV9) expressing the phosphodiesterase PDE4B. At different time points, echocardiography was performed to assess heart dimensions and contractile function. Eight weeks after TAC, the hearts were excised and freshly isolated ventricular cardiomyocytes were subjected to Förster Resonance Energy Transfer (FRET)-based cAMP imaging. FRET measurements were performed upon β-AR stimulation with the non-selective β-AR agonist isoproterenol (ISO) and subsequent pharmacological inhibition of PDE2, PDE3 or PDE4.
Results &
Conclusions: In the RyR microdomain of healthy cardiomyocytes, PDE4 tightly controlled cAMP levels, especially after a saturating dose of ISO. After submaximal β-AR stimulation, the effect of PDE4 inhibitor was less pronounced, suggesting cAMP-dependent protein kinase (PKA)-dependent phosphorylation and increase in PDE4 activity. However, the PDE4 contribution was dramatically reduced in failing cardiomyocytes. AAV9-PDE4B treatment resulted in PDE4B overexpression at the protein level and partial improvement of hypertrophy and contractile function, as measured by echocardiography. Interestingly, gene therapy led to increased PDE4 inhibitor-like effects in the RyR microdomain. This strategy might be promising to restore altered cAMP compartmentation and to improve cAMP dynamics at the microdomain specific level.

Trace ions in failing hearts: only iron, or also others?

B Kozlowska[1]; B Sochanowicz[2]; H Polkowska-Motrenko[2]; M Kruszewski[2]; M Kusmierczyk[3]; P Leszek[1]

[1]Institute of Cardiology in Anin, Department of Heart Failure and Transplantology, Warsaw, Poland; *[2]Institute of Nuclear Chemistry and Technology, Warsaw, Poland*; *[3]Institute of Cardiology in Anin, Department of Cardiac Surgery and Transplantology, Warsaw, Poland*

INTRODUCTION: Micronutrients and trace ions play the complex and multiple physiological and pathophysiological role in myocytes function. Their balanced levels are essential for adequate physiological functioning, whereas dysregulation can cause harm.
AIM: The aim of this study was to assess the content of selected ions (iron – Fe; zinc- Zn, selenium-Se, cobalt-Co) in the failing left ventricle also with regard to the severity of heart failure (HF).
METHODS: The study group consisted of 27 HF patients (21 men and 6 women), aged 50.23±13.13 yrs, referred to heart transplantation with advanced HF. Mean ejection fraction values was 26 ±16%. Mean NT-pro BNP levels was- 6076 ± 5083 pg/ml. The main aetiology was ischemic cardiomyopathy 18 pts. whereas nonischemic in 9pts. Myocardium samples were collected during a heart transplantation. The control group consisted of 7 non-failing hearts (NFH) of male subjects aged 22-47 years who had died from head trauma and were unsuitable for heart transplantation. Instrumental Neutron Activation Analysis (INAA) was used to assess the concentration of selected ions: Fe, Zn, Se, Co in failing left ventricles (FH and NFH). STATISTICS: Test for normality of each analysed parameter was performed by Shapiro-Wilk test. Comparisons between groups (FH vs. NFH) were performed with the ANOVA or Wilcoxon tests. Spearman's rank test was used to assess the correlation between the severity of HF based on the ejection fraction and NT-pro BNP and the concentration of individual ions.
RESULTS: We found in FH vs NFH left ventricle a significant reduction in myocardial Fe load (186.34 ug/g ± 58.77vs 267.89 ug/g ±129.1; p= 0.031) and increased Zn concentration (136,17 ug/g ± 26,76 vs 108.6 ug/g ±34.55; p=0.029). The concentration of the remaining ions Se, Co - did not differ between FH vs NFH. HF aetiology and gender did not modify ions concentration.
With regard to HF severity we found correlation with Se concentration: positive EF (p=0.033, r=0.42); negative NT pro BNP (p=0.033, r=-0.49), without significant correlation with other ions.
CONCLUSIONS: Our study confirm the multidirectional disturbances in the ion balance in FH. We found not only reduction in Fe but also increase in Zn concentration in FH. Both changes were not related to gender, aetiology or HF severity. Moreover we found an important correlation between reduced Se and HF severity. The importance of our finding with relation to Zn/Se and requires further investigation.

P1238

HFWM: - Title: Rescue of a proarrhythmic CaMKII-transgenic heart failure mouse model by selective knock-out of sodium channel NaV1.8

P Philipp Richard Felix Bengel[1]; C Krekeler[1]; S Ahmad[1]; P Tirilomis[1]; K Toischer[1]; N Dybkova[1]; LS Maier[2]; G Hasenfuss[2]; S Sossalla[2]

[1]University Medical Center Gottingen (UMG), Department for Cardiology and Pneumology, Gottingen, Germany; *[2]University Hospital Regensburg, Clinic and Polyclinic for internal medicine II, Regensburg, Germany*

Background: An enhanced late sodium current (INaL) as a determinant of electrical remodeling is present in several cardiac pathologies such as heart failure and is associated with proarrhythmogenic cellular triggers like early-(EADs) and delayed afterdepolarizations (DADs). We have recently shown that the neuronal sodium channel isoform NaV1.8 is involved in formation of INaL in human in heart failure. Therefore, we tested if selective inhibition or knock-out of NaV1.8 could reverse proarrhythmogenic triggers in settings of enhanced INaL. Additionally, we examined if this antiarrhythmic potential is potent enough to improve survival in a heart failure mouse model with increased CaMKII-expression.
Methods/Results: To investigate cellular proarrhythmogenic triggers we isolated cardiomyocytes from Wild-Type (WT) and SCN10A-knock-out (SCN10A-/-) mice. After pharmacological enhancement of INaL with anemone toxin II (ATX-II, 5nmol/L) we measured action potentials (AP) with whole cell patch clamp technique in voltage-clamp mode. Application of the respective NaV1.8-specific blockers A-803467 (30 nmol/L) or PF-01247324 (1µmol/L) significantly reduced EADs in ATX-II treated cells. Further, ATX-II treated cells from SCN10A-/–mice showed less

EADs than cardiomyocytes from WT. We further measured cellular arrhythmias such as diastolic Ca2+-waves using confocal microscopy (Fluo4-AM). Significantly less Ca2+-waves occurred in cells treated ATX-II and additionally with either A-803467 or PF-01247324.
For investigation of possible in-vivo effects of NaV1.8-depletion we crossbred SCN10A-/–mice with CaMKIIδc transgenic mice exhibiting a proarrhythmogenic heart failure phenotype. Our preliminary data indicate a strong trend towards improved survival in CaMKIIδc transgenic mice crossbred with SCN10A-/- (CaMKII+/T & SCN10A-/-) compared to CaMKIIδc transgenic (CaMKII+/T) mice (93 vs 71.5 days, n=68 p=0.06). Heart weight to body weight ratio was not significantly different between the two groups. In addition, confocal line scan measurements of isolated cardiomyocytes from these mice showed no significant differences in Ca2+-transient characteristics. However, preliminary data indicate that cells from CaMKII+/T & SCN10A-/- mice exhibited less diastolic Ca2+-waves as cellular proarrhythmogenic events. Additionally, cells from CaMKII+/T & SCN10A-/- mice showed less EADs or DADs during AP-recordings. Therefore, we hypothesize that this crossbreeding of CaMKII+/T & SCN10A-/- has no relevant effect on heart failure progression but significantly reduce the arrhythmogenic burden.
Conclusion: We hereby demonstrate that inhibition of NaV1.8 reduces proarrhythmogenic cellular triggers such as EADs and DADs. Most importantly, the selective knock-out of NaV1.8 improved survival in a proarrhythmogenic mouse model phenotype with CaMKII-overexpression. Taken together, our findings imply an antiarrhythmic potential of NaV1.8-inhibition that needs further investigation in vivo.

Funding Acknowledgements: Supported by a NHF Grant 2007B024 and CVON-ARENA (CVON2011-11).

Introduction: DNA in every cell is continuously being damaged and DNA repair systems are essential for protection against DNA damage-induced aging-related diseases. Evidence indicates that DNA damage is associated with heart failure. We have shown that unrepaired endogenously generated DNA damage drives the early onset of progressive heart failure. Here we studied the effects of physiological as well as pathological stimuli on cardiac function in a mouse model with deficient DNA repair. Methods: To increase the burden of DNA damage, we generated mice with cardiomyocyte-restricted inactivation of DNA repair endonuclease XPG (αMHC-Xpgc/-). To induce physiological left ventricular (LV) hypertrophy, mice were exposed to 11 wks of voluntary wheel running. Another subset of mice was subjected to 8 wks of pressure overload by transverse aortic constriction (TAC) to produce pathological LV hypertrophy. LV function was assessed at age 16 wks. Results: Cardiomyocyte-restricted inactivation of Xpg resulted in systolic as well as diastolic LV dysfunction, demonstrated by decreases in fractional shortening (49%), LVdP/dtP40 (36%) and LVdP/dtmin (42%) compared to WT (all $p<0.05$), while LV end-diastolic lumen diameter (LVEDD) was markedly increased (36%; $p<0.05$). Physical activity has been shown to be beneficial for maintaining and improving cardiac function in mice after myocardial infarction . In contrast, exercise failed to ameliorate LV remodeling and dysfunction in αMHC-Xpgc/-, as it produced further increases in LVEDD (9%) and relaxation time constant tau (41%) compared to sedentary αMHC-Xpgc/- (both $p<0.05$). Moreover, myocardial collagen content was increased (159%) and the number of γH2A.X-positive nuclei, an indicator of DNA damage, was elevated (45%; both $p<0.05$). TAC-induced LV hypertrophy was similar in both groups (WT 38%, αMHC-Xpgc/- 34%; both $p<0.05$) compared to corresponding control. In WT, LV hypertrophy was accompanied by minimal LV dilation (14%; $p<0.05$) and modest changes in LV function. Conversely, TAC in αMHC-Xpgc/- produced severe LV dysfunction and resulted in overt congestive heart failure, demonstrated by aggravation of LV dilation (24%) and marked increases in LV end-diastolic pressure (286%), lung fluid weight (102%) and myocardial fibrosis (338%; all $p<0.05$). Interestingly, TAC resulted in a reduction of γH2A.X-positive nuclei (28%; $p<0.05$). However, TUNEL staining revealed elevated levels of cell loss (96%; $p<0.05$). Conclusion: Cardiomyocyte-restricted loss of DNA repair protein Xpg increases cardiac vulnerability to develop heart failure in response to exercise training and particular to pressure overload. These findings underscore the importance of genomic stability for maintenance of cardiac function, not only during basal conditions, but also in response to physiological and pathological stimuli.

Review of the protective effects of Compound 21 and valsartan in iso-induced heart failure in rats

ZEYNEP Ulutas[1]; TARIK Kivrak[1]; ONURAL Ozhan[2]; NIGAR Vardi[3]; HAKAN Parlakpinar[2]; BURHAN Ates[4]; NECIP Ermis[5]
[1]Firat University, Department of Cardiology, Elazig, Turkey; *[2]Inonu University, Department of Pharmacology, Malatya, Turkey*; *[3]Inonu University, Department of Histology, Malatya, Turkey*; *[4]Inonu University, Department of Chemistry, Malatya, Turkey*; *[5]Inonu University, Department of C ardiology, Malatya, Turkey*

Aim: The study aimed to research the protective effects of Compound 21, the first specific non-peptide AT 2receptor agonist, from cardiac injury in the rats with isoproterenol-induced heart failure in vivo and compare it with valsartan, AT 1 receptor antagonist.
Materials and Method: In this study, 56 Wistar albino race male rats (estimated body weights250 to 400 g) were used. They were divided into 8 groups of 7. Group 1 (SHAM group) was not given any drug while Group 2 (ISO group) was injected with two doses of İsoproterenol (180 mg/kg s.c) at intervals of 24 hours. Group 3, Group 4, and Group 5 were administered with Valsartan (30 mg/kg per oral), C21 (0.03 mg/kg intraperitoneal), and the combination of Valsartan and C21 for 30 days respectively. Group 6, Group 7, and Group 8 were subjected to the same administration mode, duration, and dose and in the 29th and 30th day of the experiment, İsoproterenol (180 mg/kg s.c) was given. Transthoracic echocardiography was performed in the rats at the beginning and end of the experiment. The blood pressure, heart rate, and EKG alterations were monitored via the carotid artery cannula before ending the experiment. The histopathological and biochemical measurements were made on the cardiac tissue of the rats.
Results: In our study, the protective effect of C21 from heart failure is found to be superior to that of Valsartan. According to the echocardiographic and biochemical measurement results, C21 and Valsartan showed the protective effect from heart failure. In the histopathological findings, the treatment with C21 and the combination of Valsartan and C21 statistically reduced the heart failure progression more than the administration of Valsartan alone did.
Conclusion: These results support the hypothesis that Ang II plays a key factor in heart failure via AT 1 and AT 2 receptors. The mechanisms of antagonist action of Valsartan at AT 1 receptor and of agonist action of C21 at AT 2 receptors protect the heart from the harmful effects of AII.

P1241

Distinct signalling pathways mediated phosphorylation of sarcomere proteins in the right and left ventricle contribute to diverse cardiac dysfunction in the failing heart

A Kovacs[1]; S Pabel[2]; M Herwig[1]; D Kolijn[1]; M Waddingham[3]; E Robinson[4]; S Van Linthout[5]; J Barta[6]; Z Csanadi[6]; A Toth[7]; Z Papp[7]; S Heymans[4]; C Tschope[5]; S Sossalla[2]; N Hamdani[1]
[1]Ruhr University Bochum (RUB), Department of Cardiovascular Physiology, Bochum, Germany; *[2]University Hospital Regensburg, Klinik und Poliklinik für Innere Medizin II, Regensburg, Germany*; *[3]VU University Medical Center, Department of Physiology, Amsterdam, Netherlands (The)*; *[4]Cardiovascular Research Institute Maastricht (CARIM), Department of Cardiology, Maastricht, Netherlands (The)*; *[5]Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany*; *[6]University of Debrecen, Faculty of Medicine, Department of Cardiology, Debrecen, Hungary*; *[7]University of Debrecen, Faculty of Medicine, Department of Cardiology, Division of Clinical Physiology, Debrecen, Hungary*

Background: Altered signalling pathways play a central role in sarcomere dysfunction in the pathophysiology of heart failure (HF). Treatment options for HF are still limited perhaps because of the distinct remodelling processes and molecular mechanisms in the right (RV) and left (LV) ventricle of the failing heart.
Purpose: Our purpose was to reveal interventricular differences of cardiomyocyte signalling pathways that lead to heterogenous sarcomere dysfunction in HF.
Methods: HF patients with reduced ejection fraction (<40%, HFrEF) and post-ischemic rats were studied, and compared to non-HF and sham-operated controls, respectively. Human cardiac biopsies were obtained and studied from both the LV and RV of the same heart. Activities of protein kinases, levels of oxidative and inflammation parameters, gene expressions, protein expressions and phosphorylation were assessed. Cellular mechanical performance was measured in single skinned cardiomyocytes.
Results: In HF vs. control, oxidative and inflammation parameters were high in both LV and RV, but more pronounced in the LV. HF cardiomyocyte passive tension was increased in both RV and LV. This increase was restored by CaMKII treatment in the RV, but there was no effect of CaMKII treatment in the LV. This could be explained by the fact that CaMKII activity was decreased in the RV, but increased in the LV. While PKG lowered passive tension in both LV and RV, but the effect was more pronounced in the LV vs. RV, which goes along with decreased PKG activity in

both ventricles. Despite CaMKII and PKG activity were reduced in the RV, total titin phosphorylation was preserved in the RV, but reduced only in the LV, perhaps because of increased PKC activity. Phosphorylation of titin at CaMKII phospho-site Ser-4062 was reduced in the LV, but unaltered in the RV. Ca2+-sensitivity was higher in both LV and RV in HF vs. controls, but Ca2+-sensitivity was higher in the LV vs. RV. However, Ser-23/24 phosphorylation of cTnI was decreased in both LV and RV. While Ser-282 phosphorylation of cMyBP-C was decreased only in the LV, but unaltered in the RV. Gene expression of CaMKII-targeted HDAC4, NFAT and MAPK1 genes were all increased in both LV and RV in HF vs. control, as well as PKG-targeted genes such as PDE2 and PDE9, while PDE1 and PDE5 were increased only in the LV, but unaltered in the RV. In addition, we also found increased sGC, CG-A, and CG-B in the LV, but unchanged in the RV.

Conclusions: Our data suggest different mechanical modulation of cardiomyocytes due to distinct changes of signalling pathways in the LV and RV in the failing heart. Such interventricular differences in sarcomere dysfunction may have important therapeutic relevance when uniformly targeting cardiomyocyte signalling pathways in HF.

HFWM: - Title: Single cell mechanics in failing heart: role of microtubules and mitochondria re-arrangement

P Pamela Swiatlowska[1]; J Sanchez-Alonso[1]; P Wright[1]; S Bello[1]; P Novak[2]; J Gorelik[1]

[1]Imperial College London, National Heart and Lung Institute, London, United Kingdom of Great Britain & Northern Ireland; [2]Queen Mary University of London, Institute of Bioengineering, London, United Kingdom of Great Britain & Northern Ireland

Funding Acknowledgements: NHLI Imperial College London PhD Studentship

Background and Purpose

Myocardium experiences considerable mechanical stress throughout its lifespan. As a result cardiac tissue is very adaptive to the mechanical load. In the failing heart, mechanical properties differ from the normal heart. Modified extracellular matrix, in particular increased collagen deposition, corresponds to an increased stiffness of the failing heart. At the cellular level, increased stiffness is observed in isolated myocytes after a myocardial infarction. We aimed to further study how the cell mechanics changes in cardiomyocytes in different heart disease models.

Methods Using high resolution Scanning Ion Conductance Microscopy in combination with pressure application we obtained a map of Young's modulus (YM) and a map of cell surface of adult rat and human cardiomyocytes isolated from healthy hearts. Inhibition of several cytoskeleton networks was used to investigate the contribution of cellular proteins to cell stiffness. The stiffness of normal cells was compared to Myocardial Infarction (MI) and partial mechanical unloaded rat models, as well as human cardiomyocytes isolated from patients with dilated and ischemic cardiomyopathy.

Results Our data confirm that mechanics of adult cardiomyocytes change in the cardiac pathology, displaying higher stiffness in MI compared to control cells. Similarly, human healthy cardiomyocytes are softer when compared to dilated/ischemic cardiomyopathies. Interestingly, the surface of the sarcolemma (crest) becomes significantly stiffer than the z-groove in failing rat cells. On the other hand, mechanical unloading of the failing hearts reduces the YM to control values. Mitochondria-specific staining shows bigger submembrane mitochondria areas in the MI model (due to clustering). Also, unloaded hearts showed a decrease in size and number of mitochondria. Inhibition of actin-myosin cross bridging interaction using blebbistatin, decreases cell YM, showing incomplete actin-myosin relaxation in the MI model. Blocking actin assembly with cytochalasin D also decreases cell YM, as does blocking the microtubules polymerization with vinblastine. Further investigating microtubules post-translational modifications, inhibition of detyrosination or deacetylation with parthenolide and HDAC6 inhibitor respectively, reduces cell stiffness.

Conclusions Our findings show that both mechanical stimulation and intracellular elements significantly contribute to the cell mechanical properties and they are modified under pathological conditions.

Specifically, mitochondria may contribute to a stiffer crest domain of the sarcolemma, whereas microtubules are critical in maintaining mechanical resistance.

Circulating NEP concentrations and activity in the low-, medium- and high-renin HFrEF phenotypes

S Prausmueller[1]; H Arfsten[1]; JF Novak[1]; A Cho[1]; G Goliasch[1]; PE Bartko[1]; N Pavo[1]; M Huelsmann[1]

[1]Medical University of Vienna, Department of Internal Medicine, Division of Cardiology, Vienna, Austria

Background. Previous investigations of plasma Renin-Angiotensin-System (RAS) fingerprints of patients with heart failure with reduced ejection fraction (HFrEF) revealed the existence of low-, medium- and high-renin HFrEF phenotypes independently of disease severity. Plasma renin indicates RAS-activation and serves as surrogate for total angiotensin metabolite levels including AngII, which exerts deleterious effects thereby triggering disease progression. Neprilysin (NEP) inhibition has been proven to be effective with marked clinical benefits within angiotensin-receptor neprilysin-inhibitor (ARNI) therapy in HFrEF. NEP is implicated in the homeostasis of vasoactive peptides, suggesting a relationship between RAS and NEP regulation. The study aimed to investigate the relationship between plasma NEP concentrations (sNEP) and activity and different HFrEF phenotypes based on plasma renin levels.

Methods. We prospectively enrolled 369 consecutive patients with stable HFrEF, who were clinically followed-up routinely. Laboratory markers including NT-proBNP and active renin concentration (ARC) were assessed. sNEP and NEP activity were measured by a specific ELISA (R&D systems, UK) and a fluorimetric peptide cleavage assay. The association of all three measures on all-cause mortality was assessed. The correlation between sNEP and NEP activity was determined. sNEP and NEP activity between low-, medium- and high-renin phenotypes (i.e. <15. percentile, 15.-85. percentile and >85. percentile of ARC) was compared.

Results. Median age was 65 (IQR 53-73) years, 75% of patients were male. Median NT-proBNP levels were 1936 (IQR 855-4126) pg/ml. Median ARC levels in the low-, medium- and high-renin HFrEF phenotypes were 4.2 (IQR 2.0-7.8) µIE/mL, 155.1 (IQR 43.3-353.5) µIE/mL and 2360 (IQR 1483-3250) µIE/mL (p=<0.001), respectively. No correlation could be shown between sNEP and plasma NEP activity [r=0.09, p=0.088]. In the univariate analysis plasma ARC, but not sNEP levels and NEP activity, were associated with outcome. This association remained significant after adjustment for age, gender, kidney function and NT-proBNP [adj. HR per 1-IQR increase of ARC 1.27 (95%CI 1.04-1.22), p=0.003]. Similarly, there were no differences in sNEP levels and NEP activity between the low-, medium- and high-renin HFrEF phenotypes (Figure 1).

Conclusions. ARC is a risk factor for mortality in HFrEF patients, independently of NT-proBNP. Circulating sNEP levels and NEP activity neither correlated with each other nor were associated with outcome. Similarly, neither sNEP nor NEP activity was related to RAS-activation, suggesting either that there is no simple direct relationship between RAS and NEP regulation or that plasma NEP measures are not potent biomarkers appropriately reflecting systemic NEP regulation.

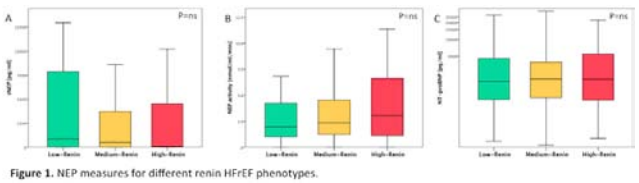

Figure 1. NEP measures for different renin HFrEF phenotypes.

Inhibition of apoptosis signal-regulating kinase 1 ameliorates cardiac dysfunction by reducing hypertrophy and fibrosis in a rat model of cardiorenal syndrome

F Savira[1]; BH Wang[1]; AJ Edgley[2]; H Krum[3]; DJ Kelly[2]; AR Kompa[2]
[1]Baker IDI Heart and Diabetes Institute, Biomarker Discovery Laboratory, Melbourne, Australia; [2]St Vincent's Hospital, Department of Medicine, Melbourne, Australia; [3]Monash University, Centre of Cardiovascular Research and Education in Therapeutics, Melbourne, Australia

Funding Acknowledgements: This research was supported by National Health and Medical Research Council of Australia (Program Grants 1092642 and Project Grant 1087355).

Background: Cardiorenal syndrome (CRS) is a global health burden with suboptimal treatment options requiring novel therapeutic strategies. Previously, we reported that inhibition of apoptosis signal-regulating kinase 1 (ASK1), using a small molecule inhibitor (GSK2261818A, G226), attenuated pathological cardiac hypertrophy and cardiac and renal collagen synthesis in vitro. The present study assessed the therapeutic potential of ASK1 inhibition in a rat model of CRS.
Methods: Adult male Sprague-Dawley rats underwent surgery for myocardial infarction (MI) (week 0) followed by 5/6 subtotal nephrectomy (STNx) at week 4 to induce CRS. At week 6, MI+STNx animals were randomized to receive either 0.5% carboxymethyl cellulose (Vehicle, n = 13, Sham, = 10) or G226 (15mg/kg daily, n = 11). Cardiac and renal function was assessed by echocardiography and glomerular filtration rate (GFR) respectively, prior to treatment at week 6 and at endpoint (week 14). Haemodynamic measurements were determined at week 14 prior to tissue analysis.
Results: G226-treated animals demonstrated an improvement in absolute change in left ventricular (LV) ejection fraction, fractional shortening, preload recruitable stroke work and reduced LV end-diastolic and end-systolic volume and LV posterior wall thickness compared to Vehicle group. CRS-induced increase in myocyte cross sectional area, cardiac interstitial fibrosis, immunoreactivity of cardiac collagen-III and TGF-β1 and cardiac TIMP-2 activation, were also significantly reduced by G226. G226 ameliorated renal interstitial fibrosis, diminished renal collagen-I, -IV and kidney injury molecule-1 immunoreactivity and macrophage infiltration as well as renal p-SMAD2 activation, with no effect on GFR.
Conclusion: Inhibition of ASK1 ameliorated LV dysfunction and diminished cardiac hypertrophy and cardiorenal fibrosis in animals with CRS. This suggests that ASK1 is a critical pathway with therapeutic potential in the CRS setting.

Polymorphic variants and the expression level of the Ca(2+)-ATPase SERCA2a and ryanodine receptors genes are associated with systolic myocardial dysfunction

E Muslimova[1]; T Rebrova[1]; SH Ahmedov[1]; S Afanasiev[1]
[1]Cardiology Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation

Funding Acknowledgements: This work was supported by the Russian Foundation for Basic Research 17-04-01450.

Purpose. To study the association of polymorphic variants rs1860561, rs3766871 and expression level of ATP2A2, RYR2 genes with the severity of chronic heart failure (CHF). Methods. The sample included 174 patients aging 64 (59; 70) years with CHF of ischemic origin. The distribution of CHF class I (NYHA), II, III was 25 (14.4%), 97 (55.7%), 52 (29.9%). The left ventricular ejection fraction was 62% (52; 66). The expression level and polymorphic variants rs1860561 (110345436G>A) of the ATP2A2 gene encoding Ca(2+)-ATPase SERCA2a, and rs3766871 (5656G>A; Gly1886Ser) of ryanodine receptor RYR2 gene were determined. Results. An association of variant rs1860561 with CHF class (p = 0.041) and the frequency of type 2 diabetes mellitus (DM2) (p = 0.027) was detected. Among the AA homozygotes, CHF of severe class III and cases of DM2 were more common. Among women, carriers of the AA genotype had a higher frequency of left ventricular hypertrophy (p = 0.040), the left ventricular ejection fraction was reduced (p = 0.032), and the end-systolic volume was increased (p = 0.030). An increase in the expression level of ATP2A2/GAPDH and ATP2A2/ACTB was observed in DM2, but the expression level was not dependent on the rs1860561 variant. In the studied sample there was no association of the variant rs3766871 with the severity of CHF. But in the presence of DM2, the expression level of RYR2/GAPDH was higher (p = 0.009) than in the case of impaired glucose tolerance or in the absence of disturbances in carbohydrate metabolism. There was a relationship between the worsening of CHF class and a decrease in the expression level of the RYR2/GAPDH (p = 0.023). Conclusion. The polymorphic variant rs1860561 was associated with systolic myocardial dysfunction. Expression level of ATP2A2 and RYR2 genes was increased in patients with CHF and DM2. Expression level of RYR2 gene was reduced in patients with CHF class III.

Clinical, humoral and hemodynamic predictors of cardiac fibrosis in advanced heart failure

K Katarzyna Kodziszewska[1]; S Szymanska[2]; A Drohomirecka[1]; W Smigielski[1]; P Leszek[1]
[1]Institute of Cardiology, Warsaw, Poland; [2]Children's Memorial Health Institute, Warsaw, Poland

Funding Acknowledgements: Institute of Cardiology Research Grant

Background: Cardiac fibrosis is one of the key features of remodeling in heart failure (HF). Modern pharmacotherapy is aimed at halting/reversal of these pathological changes through effects on renin-angiotensin-aldosterone axis, beta receptor blockage and, more recently, augmenting the natriuretic peptide action.
Aim: To identify humoral, hemodynamic, echocardiographic or clinical factors, including pharmacological agents, influence the degree of cardiac fibrosis in patients with advanced HF referred for heart transplantation (HTx).
Methods: We collected left ventricular tissue samples from 66 patients with advanced HF at the time of HTx (2013-2015). Tissues were fixed in formaldehyde and parafin, and subsequently stained with H&E stain. Histological assessment was performed and the extent of cardiac fibrosis was assessed according to the following criteria: mild or no fibrosis (fibrosis encompassing $\leq$30% of tissue section), moderate (30-70%), or severe ($\geq$70% of tissue section). All patients underwent through clinical, biochemical, hemodynamic, and echocardiographic evaluation at the time of qualification for HTx and the data were used to create a discriminant analysis model determining predictors of cardiac fibrosis. Chi-square test was used to evaluate the predictive value of therapy with pharmacological agents constituting the gold standard of HF therapy on the degree of fibrosis. Rank-Spearman test was used to establish the direction of the correlation.
Results: The best discriminant analysis model ($p<0.001$ for the entire model) included biochemical parameters such as: red blood cell count (RBC) serum glucose concentration and white blood cell count (WBC), which predicted the degree of cardiac fibrosis (p=0.004, 0.026, and 0.053, respectively). In case of glucose and WBC the relationship was positive, while RBC correlated negatively with the severity of fibrosis. Also, the use of mineralocorticoid receptor inhibitors influenced the degree of cardiac fibrosis.
Conclusions: Clinicians should be aware that certain hematological and biochemical (RBC, WBC, serum glucose) parameters are important predictors of cardiac fibrosis in HF. The rationale behind this relationship (inflammation, disorders of glucose metabolism or iron turnover) requires further investigation. We corroborated the value of mineralocorticoid receptor inhibitors as an important factor influencing the extent of cardiac fibrosis.

Activation of Toll Like Receptor 4 (TLR4) promotes cardiomyocyte apoptosis and fibrosis through SIRT2-dependent p53 deacetylation

P Parmeshwar Katare[1]; H Nizami[1]; P Bugga[1]; A Dinda[2]; S Banerjee[1]
[1]Translational Health Science and Technology Institute, FARIDABAD, India; [2]All India Institute of Medical Sciences (AIIMS), Department of Pathology, New Delhi, India

Background: Cardiomyocyte inflammation followed by apoptosis and fibrosis are common mechanism for the development and progression of heart failure. As a key regulator of inflammation, toll like receptor 4 (TLR4) plays an important role in pathogenesis of cardiac diseases. However, the precise mechanism of TLR4 mediated cardiac complications is still elusive. Therefore, the present study was designed to find the role of TLR4 in cardiac fibrosis and apoptosis, and molecular mechanism thereof.
Method: Rats were treated either with saline or TLR4 agonist (LPS 12.5ug/kg/day) through osmotic pump for 14 days. To simulate the same condition in vitro, H9c2 cells were treated with LPS (1ug/ml). Similarly, H9c2 cells were transfected with TLR4 ORF plasmid for overexpression. Cardiac inflammation, oxidative stress, fibrosis and mitochondrial parameters were evaluated both in vitro and in vivo. Expression and acetylation of p53 and its downstream proteins BAX, caspase 7 were evaluated.
Results: Cardiac inflammation after LPS treatment was confirmed by increased TNF alpha and IL-6 expression in rat heart. There was a marked increase in oxidative stress along with mitochondrial dysfunction in LPS treated group. Histopathology study showed the presence of cardiac fibrosis after LPS treatment. Protein expression of nuclear p53 and cleaved caspase 7 was significantly increased in LPS treated heart. Similar to in vivo study, nuclear translocation of p53, mitochondrial dysfunction and cellular apoptosis was significantly increased in H9c2 cells after LPS treatment. Our data also indicate that decrease expression of SIRT-2 was associated with increased acetylation of p53 and its increased nuclear translocation after LPS treatment.
Conclusion: TLR4 activation in rats promotes cardiac inflammation, mitochondrial dysfunction, apoptosis, and fibrosis. p53 and caspase 7 were found to play an

important role TLR4 mediated apoptosis. Reducing TLR4 mediated fibrosis and apoptosis could be a novel approach in the treatment of heart failure, where TLR4 mediated inflammation plays a major role.

Inhibition of myeloperoxidase in an obese/hypertensive mouse model attenuates obesity and liver damage, but not cardiac remodeling

A Arnold Piek[1]; W Du[1]; Z Wang[2]; DPY Koonen[2]; E Lindtstedt[3]; E Michaelsson[3]; RA De Boer[1]; HHW Sillje[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The); *[2]University Medical Center Groningen, Pediatrics, Section Molecular Genetics, Groningen, Netherlands (The)*; *[3]AstraZeneca, Heart Failure Bioscience, Cardiovascular and Metabolic Diseases, IMED Biotech Unit, Gothenburg, Sweden*

Funding Acknowledgements: This work was supported by a grant from AstraZeneca.

Background: Heart failure with preserved ejection fraction (HFpEF) is a major health problem for which no proven therapy exists. Low-grade systemic inflammation caused by obesity, diabetes and hypertension is believed to contribute to HFpEF development and progression. The enzyme myeloperoxidase (MPO), involved in inflammation, has been linked to HFpEF and obesity.
Purpose: In this study, the effect of a novel MPO inhibitor, AZM198, on cardiac remodeling was investigated in an obesity/hypertension mouse model with HFpEF characteristics.
Methods: Male C57BL/6J mice aged 8 weeks were subjected for 16 weeks to either low fat diet (LFD) or high fat diet (HFD) with or without AZM198. During the last 4 weeks this was combined with angiotensin II (AngII) or saline (control) infusion. Just before sacrifice, body mass composition was determined, and cardiac magnetic resonance imaging (MRI) measurements and left ventricular (LV) pressures were recorded. The heart and other tissues were investigated at the molecular and histological level.
Results: A combination of HFD and AngII infusion did not reduce left ventricular ejection fraction (LVEF%), but did result in mild, but significant, elevated pathological cardiac hypertrophy and fibrosis and in diminished LV relaxation, all characteristics of HFpEF. MPO plasma levels were significantly elevated in this HFpEF model and this was driven by the HFD. AZM198 treatment significantly reduced the elevated MPO levels to control, LFD, levels. No adverse AZM198 effects were observed in any of the AZM198 mouse groups and AZM198 treatment had no significant effect on any of the measured cardiac parameters, including fibrosis, hypertrophy and relaxation (dP/dtmin; Tau). AZM198, however, significantly attenuated adipose tissue accumulation and reduced inflammatory crown-like structures and inflammatory gene expression in adipose tissue. Liver ballooning degeneration was also significantly less prominent in AZM198 treated HFD groups.
Conclusions: AZM198 treatment normalized MPO levels in obese/hypertensive mice, but did not improve functional and structural cardiac parameters. However, AZM198 did reduce adipose inflammation, fat deposition and liver degeneration. These positive effects could be important for the obese human HFpEF population.

Background: During the development of pressure overload (PO)-induced pathological left ventricular (LV) myocardial hypertrophy (LVH) and its progression to heart failure distinct alterations could be observed both in LV contractility and myofilament function. However, whether the dynamic alterations on the two levels (contractility on the global ventricular level and myofilament function on the cellular level) correspond to each other has been not studied.
Purpose: Therefore, we aimed at investigating the relation between LV contractility and myofilament function in PO-induced LVH.
Methods: PO was evoked by abdominal aortic banding (AB) in male, Sprague-Dawley rats for 6, 12 and 18 weeks. Control animals underwent the same surgery without constricting the aorta (Sham). Characteristic PO-induced alterations were investigated by serial echocardiography, histology, quantitative real-time PCR and western blot. LV function was assessed by pressure-volume analysis. Force measurement was carried out in permeabilized cardiomyocytes.
Results: Sustained PO resulted in the development of pathological LVH in the AB groups as indicated by macroscopic (increased heart weight-to-tibial length ratio and LV mass index), microscopic (increased cardiomyocyte diameter) and molecular markers (reactivated fetal gene program: increased atrial natriuretic peptide and β-to-α myosin heavy chain expression). These alterations were already present at early stage of LVH (AB-week6). Furthermore, at more advanced stages (AB-week12, AB-week18), interstitial fibrosis and chamber dilatation were also observed. The detailed analysis of the pressure-volume loops revealed that the AB-wk6 group was associated with increased LV contractility (as indicated by increased end-systolic elastance [ESPVR]: 1.74±0.22 vs. 3.28±0.36 mmHg/µl, preload-recruitable stroke work [PRSW]: 104±8 vs. 140±8 mmHg and preload-adjusted maximal slope of systolic pressure increment [dPdt-EDV]: 33±2 vs. 53±6 (mmHg/s)/µl Sham-week6 vs. AB-week6, $P<0.05$), maintained ventriculo-arterial coupling (VAC) and preserved systolic function. In the same experimental group, increased myofilament Ca2+ sensitivity (pCa50) and hyperphosporylation of cardiac troponin-I (cTnI) at Threonin-144 was detected. In contrast, in the AB-wk12 and AB-wk18 groups, the initial augmentation of LV contractility, as well as the increased myofilament Ca2+ sensitivity and cTnI (Threonin-144) hyperphosphorylation diminished, resulting in impaired VAC and reduced systolic performance. Strong correlation was found between LV contractility parameters (ESPVR, PRSW and dP/dtmax-EDV) and myofilament Ca2+-sensitivity (pCa50) among the study groups.
Conclusion: Changes in myofilament Ca2+ sensitivity might underlie the alterations in LV contractility during the development and progression of PO-induced LVH.

P1250

HFWM: Circulating relaxin-1 is a surrogate marker of myocardial fibrosis and left ventricular diastolic function in HFrEF

E Edit Gara[1]; J Simon[1]; GY Csiko[1]; T Radovits[1]; G Foldes[1]; A Nemes[1]; M Husveth-Toth[1]; J Skopal[1]; B Merkely[1]
[1]Semmelweis University, Heart Center, Budapest, Hungary

Recently relaxin-1 (RLX-1) has emerged as a possible therapeutic tool or target in myocardial fibrosis due to its anti-fibrotic effect on the failing myocardium. Previous randomised clinical trials investigated the therapeutic role of exogenous relaxin in patients with acute-on-chronic heart failure with reduced ejection fraction (HFrEF) and failed to meet clinical endpoints. Here we aimed to assess endogenous, circulating RLX-1 levels in patients with HFrEF of ischemic origin. Furthermore, we analyse the relation of RLX-1 levels and left the ventricular diastolic function, left

and right ventricular remodeling and fibrosis. The unique feature of our study is the availability of ex vivo human myocardial samples.
Human myocardial samples were available from the Heart and Vascular Centre Heart Transplantation Biobank System (Semmelweis University) upon local ethical authorisation and informed consent of all participants (n=55). Human myocardial tissue was collected immediately after heart explantations, peripheral blood was collected before the induction of anesthesia. Myocardial sections were stained for Masson's trichrome and Picrosirius red staining in order to quantify fibrosis rate. Medical records of all participants were analysed (ECG, anthropometry, blood tests, medication, echocardiography, and invasive hemodynamic tests).
Our patients were divided into a low- and high-RLX-1 group; on average, RLX-1 levels were comparable with those measured in pregnant women. (702±283 pg/ml in HFrEF vs. 560-1060 pg/ml in pregnancy (literature data)). Age and gender-matched healthy control human subjects had low levels of circulating RLX-1 (44±27pg/ml). In the HFrEF patient population circulating RLX-1 was independent of age, gender, hypertension, diabetes mellitus, BMI and BSA. Eight participants required mechanical circulatory support (IABP+LVAD) before heart transplantation, which did not influence RLX-1 levels or outcomes. We found a moderate inverse correlation between RLX-1 levels and myocardial fibrosis rate of both ventricles (r=-0.493, p=0.0005 in the right ventricle vs. r=-0.487, p=0.0006 in the left ventricle). Parallel, a moderate correlation was found in left ventricular diastolic function (E/A r=0.456, p=0.0025) and RLX-1 levels. RLX-1 levels showed moderate correlation with RLX-2 levels (r=0.453, p=0.0003).
Increased RLX-1 levels were accompanied by lower myocardial fibrosis rate, which is a novel finding in a small patient population with HFrEF of coronary artery disease etiology. Interestingly, our results suggest that RLX-1 can have a biomarker role and may be targeted in anti-fibrotic therapeutics.

HFWM: Natural compound-derived small molecules to target fibrosis

FP Kreutzer[1]; A Meinecke[1]; J Fiedler[1]; F Perbellini[2]; S Mitzka[1]; QT Do[3]; CM Terracciano[2]; T Thum[1]
[1]Hannover Medical School, Institute for Molecular and Translational Therapeutic Strategies (IMTTS), Hannover, Germany; *[2]Imperial College London, Imperial Centre for Translational and Experimental Medicine, National Heart and Lung Institute, London, United Kingdom of Great Britain & Northern Ireland*; *[3]Greenpharma S.A.S., Orléans, France*

Funding Acknowledgements: The starting study was supported by grants of the EU-project Fibrotarget (7th Framework Project; to T.T.)

Introduction One of the main causes for heart failure with preserved ejection fraction (HFpEF) is the increasing stiffness of the heart due to proliferation and activation of cardiac fibroblasts (HCF), which leads to accumulation of excess extracellular matrix (ECM). In search of a pharmacological treatment option, we previously identified the natural compounds bufalin (toad exudate) and lycorine (Amaryllidaceae) as promising anti-fibrotic effectors for in vitro and in vivo models. The aim of this study was to generate chemical derivatives of these substances to further improve their efficacy and toxicological profiles.
Methods and results
Using primary human cardiac fibroblasts (HCFs) we screened 26 derivatives (15 for bufalin and 11 for lycorine) for inhibition of primary HCF proliferation by BrdU incorporation. 15 out of these generated derivatives showed activity below 10μM and potently reduced fibroblast proliferation, also validated by WST-1-derived metabolic activity. 12-point dose-response curves determined EC50s in the range of 5 to 500nM. One derivative showed over 100× increased potency over its natural precursor lycorine. Parallel to the evaluation of newly synthesized small molecules, we additionally compared performance towards the already available anti-fibrotic drugs Nintedanib and Pirfenidone (approved for idiopathic pulmonary fibrosis). In addition to efficacy measurements, physicochemical properties, pharmacokinetics, drug- and lead-likeness, as well as bioavailability were predicted in silico and used as additional ranking dimension.
The highest ranked candidates were assessed for further functional outcome in HCF culture by applying a model of scratch wounding. Moving towards relevant in vivo testing, rat myocardial slices, a living multicellular ex vivo cardiac model, were used to test these shortlisted candidates for cardiotoxicity and potential effects on contractility. Early results indicated maintained contraction force for favorite candidates.
Conclusions In summary we screened chemical derivatives of the natural compounds bufalin and lycorine. Favorite small molecules showed promising efficacy and safety in vitro and ex vivo. Thus we speculate on their therapeutic use for fibrosis-underlying cardiac disease such as HFpEF or in the setting of other organ-related fibrosis.

Fibroblasts as inflammatory supporter cells-a matter of tissue origin?

K Pappritz[1]; M El-Shafeey[1]; C Tschoepe[2]; S Van Linthout[1]
[1]Berlin-Brandenburg Center for Regenerative Therapies (BCRT), Berlin, Germany; *[2]Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany*

Background: Heart failure is a syndrome not solely affecting the heart, but also other organs like the skeletal muscle. We previously have shown how transforming growth factor (TGF)-ß1 and interferon (IFN)-γ affect cardiac fibroblast activation and the attraction of pro- and anti-inflammatory monocyte subsets. However, how cardiac and muscle fibroblasts intrinsically and in response to TGF-ß1 and IFN-γ differ from each other, has not been investigated before.
Purpose: The study aimed to investigate the responsiveness of heart- and muscle-derived fibroblasts towards TGF-ß1 and IFN-γ, mimicking an inflammatory environment.
Methods: Therefore, primary fibroblasts were obtained from the left ventricle (LV) and muscle of C57BL6/j mice by outgrowth culture. Cells were stimulated with TGF-β1 (5 ng/mL), IFN-γ (10 ng/mL) or both for up to 72h. mRNA expression of extracellular matrix proteins was examined by real-time PCR. Supernatants were used to analyze chemokine release by ELISA or to perform migration assays followed by flow cytometry to characterize the migrated pro- (Ly6Chigh) and anti-inflammatory (Ly6Clow) monocyte subsets.
Results: In LV fibroblasts, TGF-ß1 induced myofibroblast differentiation, as obviated by higher collagen I, III, lysyl oxidase (Lox)-1 and lysyl oxidase-like (LoxL)-2 mRNA expression levels compared to controls, respectively. IFN-γ suppressed the TGF-ß-induced myofibroblast differentiation, as indicated by lower collagen I, III, and LoxL2 mRNA expression levels compared to sole TGF-ß1 administration, respectively. Similar observations were found in muscle fibroblasts. Furthermore, both LV and muscle fibroblasts stimulated with sole TGF-β1 or IFN-γ displayed a higher CC-chemokine ligand (CCL) 2, CCL7 and chemokine C-X3-C motif ligand (Cx3CL1) release compared to control fibroblasts. The induction in the expression of the chemokines CCL2 and CCL7, attracting pro-inflammatory monocytes, was hereby the most pronounced upon IFN-γ stimulation and was further elevated by TGF-β1+IFN-γ co-stimulation in LV fibroblasts as well as in muscle fibroblasts. In general, muscle-derived fibroblasts displayed lower CCL2, CCL7 and Cx3CL1 production, but higher CCL2/Cx3CL1 and CCL7/Cx3CL1 ratios compared to LV fibroblasts. Subsequent analysis of monocyte migration towards TGF-β1-conditioned media from LV fibroblasts further revealed a higher Ly6Clow/Ly6Chigh monocyte ratio compared to control media. Combination of IFN-γ with TGF-ß1 reduced the Ly6Clow/Ly6Chigh monocyte ratio. Compared to all corresponding LV conditioned media, supernatant of muscle-derived fibroblasts attracted more Ly6Chigh monocytes, indicative for a more inflammatory phenotype.
Conclusion: LV and muscle fibroblasts differ in their responsiveness towards pro-inflammatory and pro-fibrotic stimuli in terms of their potential to attract pro-inflammatory monocytes, suggesting fundamental differences in subsequent remodelling under disease conditions between heart and muscle.

P1253

The secreted matrix glycoprotein ADAMTSL3 is up-regulated in heart failure and mediates anti-fibrotic effects in cardiac fibroblasts

KB Rypdal[1]; ME Strand[1]; AO Melleby[1]; M Gelazauskaite[1]; CP Dahl[2]; T Tonnessen[2]; L Gullestad[2]; G Christensen[1]; IG Lunde[1]
[1]Oslo University Hospital, Institute for Experimental Medical Research, Oslo, Norway; *[2]Oslo University Hospital, Department of Cardiology, Oslo, Norway*

Funding Acknowledgements: Norwegian Research Council

Background/Introduction
Fibrosis is a central remodelling process in heart failure where cardiac fibroblasts (CFB) become activated, transdifferentiate into myofibroblasts, and produce excessive amounts of extracellular matrix (ECM) constituents. The ADAMTSL (a disintegrin and metalloproteinase with thrombospondin motif like) protein family consists of seven glycoproteins secreted into the ECM. They are structurally similar to the matrix metalloproteinase and ADAMTS protein families, yet lack a catalytic domain. Despite suggested roles in ECM microfibril formation and connective tissue disorders, the function of ADAMTSL proteins remain largely unknown, including in the heart.
Purpose
The purpose of this study was to investigate the regulation and role of ADAMTSL3 in heart failure.
Methods Expression level of ADAMTSL3 was examined in myocardial biopsies from patients with aortic stenosis (AS) and ischemic dilated cardiomyopathy (iDCM). ADAMTSL3 levels were also examined in mouse hearts after aortic banding (AB) and in primary cultures of CFB and cardiomyocytes (CM) from neonatal rats. Finally, adenoviral overexpression of ADAMTSL3 was performed in CFBs to investigate the effects of increased ADAMTSL3 levels on fibrosis.

Results
In cardiac biopsies from patients with AS and iDCM, ADAMTSL3 mRNA was increased 2-fold and 1.5-fold, respectively, compared to controls, suggesting that ADAMTSL3 levels are increased in the heart of patients with heart failure. Similarly, mice subjected to AB showed elevated left ventricular mRNA levels of ADAMTSL3 during concentric hypertrophic remodelling and dilated, end-stage heart failure (1.5-fold and 2-fold, respectively). In rat heart cell cultures, mRNA expression of ADAMTSL3 was 3-fold higher in CFB than in CM, suggesting that CFBs are the main producers of ADAMTSL3 in the heart. CFBs overexpressing ADAMTSL3 showed reduced mRNA levels of the stiff fibrillar collagen type I (70% of control) and reduced total collagen protein synthesis to 50% of controls, measured by radioactive proline incorporation, suggesting anti-fibrotic effects. In line with this, ADAMTSL3 overexpression reduced mRNA levels of the collagen cross-linking enzyme lysyl oxidase (80% of control). Furthermore, expression of the ECM scaffold proteins fibrillin-1 and fibronectin was reduced to 80 and 50% of control, respectively, and the myofibroblast signature gene, alpha smooth muscle actin, was reduced to 80% of control. These anti-fibrotic effects of ADAMTSL3 overexpression was likely mediated through reduced TGFb-signaling, as ADAMTSL3 overexpressing CFB showed reduced phosphorylation of the TGFb-directed transcription factor SMAD2.
Conclusion
Our results suggest that ADAMTSL3 mediates anti-fibrotic effects in the heart. This will be investigated further in ADAMTSL3-knock out mice subjected to heart failure.

P1254
Sepsis-induced myocardial dysfunction is associated with epigenetic modulation of parkinson susceptibility gene DJ-1/PARK7

J James Tsoporis[1]; H Amatullah[1]; K Teichert-Kuliszewska[1]; S Izhar[1]; G Kabir[1]; TG Parker[1]; C Dos Santos[1]
[1]St. Michael's Hospital, Toronto, Canada

Funding Acknowledgements: Canadian Institutes of Health Research, Heart and Stroke Foundation of Canada

Introduction: Myocardial depression and associated hemodynamic collapse are among the major causes of death in severe sepsis. Management of severe sepsis is largely supportive.
Purpose: Emerging evidence suggests that the antioxidant DJ-1 (PARK7) may have a role in resistance to sepsis; however, a role of DJ-1 in severe sepsis-induced myocardial dysfunction remains uninvestigated.
Methods: Using both in in vivo (murine model of cecum ligation and puncture) and in vitro (lipopolysaccharide (LPS) treatment of cultured murine cardiac myocytes) approaches we determined whether DJ-1 is a putative novel target for sepsis.
Results: In response to cecum ligation and puncture (CLP) for 48hrs, wild type (WT) mice developed bacterial peritonitis, a marked inflammatory response (3-5 fold increases in serum interleukin-1β and tumor necrosis factor-α), myocardial dysfunction (20-35% decreases in dp/dt and echo-derived % ejection fraction and % fractional shortening), a 20-fold increase in serum DJ-1, 1.5-3 fold increase in left ventricular (LV) DJ-1 mRNA and protein and a 55-70% decrease in LV mRNA and protein of the transcriptional repressor Jarid-2 compared to WT-sham. Targeted deletion of DJ-1 rendered the mice resistant to CLP-induced bacterial peritonitis resulting in improved cardiac function and survival despite a similar hyper-inflammatory response to WT mice. In adult cultured cardiac myocytes derived from WT mice, basal DJ-1 is transcriptionally repressed by binding of Jarid-2 to A/T-rich target sequences in the DJ-1 promoter as determined by gel-shift assay. Chromatin immunoprecipitation demonstrated that basal DJ-1 repression is also associated with increased H3 methylation (H3K9me3 and H3K27me3) facilitating complex formation with Jarid-2 at A/T-rich sequences of the promoter. Treatment of WT adult cardiomyocytes with the endotoxin LPS (1 μg/mL) for 24 h, decreased Jarid-2 and histone marker formation resulting in a 1.7 fold increase in DJ-1 expression.
Conclusions: These findings reveal that the loss of DJ-1 enhances bacterial clearance and inflammatory responses resulting in improved cardiac function and survival following CLP-induced sepsis.

Empagliflozin modulates GTP enzyme cyclohydrolase 1 in chronic heart failure

MC Asensio Lopez[1]; P Lopez-Herrera[2]; L Oltra-Rodriguez[2]; N Garcia-Carrillo[2]; E Saura-Guillen[3]; A Hernandez-Vicente[1]; MCA Sanchez-Perez[1]; N Fernandez-Villa[3]; DA Pascual-Figal[3]; AM Antonio Manuel Lax[2]
[1]Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain; *[2]University of Murcia, El Palmar, Spain*; *[3]University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain*

Purpose. Empagliflozin (EMPA), a drug approved for type II diabetes management, reduced cardiovascular death. The cardioprotective effect of EMPA may be mediated by anti-oxidative mechanisms that prevent cardiac remodeling and slowdown HF progression; however, the molecular mechanisms have not been well elucidated. The present study aimed to analyze whether EMPA modulates the cardiac GTP enzyme cyclohydrolase 1 (cGCH1), a key protein in the development of remodeling in HF.
Material and methods. First, male Wistar rats (6-8 weeks old, 180-250 g) were used to undergo an experimental condition of diabetes (50 mg/kg streptozotion, i.p) and then MI was induced by permanent ligation of the left anterior descending coronary. Animals were randomly assigned to not receive treatment or to receive EMPA (10 mg/kg/day, oral) from the day of surgery and for 4 weeks. A sham group was used as control. The infarcted and border areas of the left ventricle were processed at 4 weeks. The mRNA and protein expression of cGCH1 and other remodelling markers (Galectin 3, collagen I, collagen III, TIMP1) were analyzed by qRT-PCR and western blot. In parallel, regulation of nitric oxide synthase (NOS) isoforms were evaluated using western blot. BH4 levels were measured by HPLC. Each value is expressed as fold of control.
Results. Compared with sham group, MI group, showed lower levels of cGCH1 in both the infarcted ($p<0.01$) and border areas ($p<0.001$). cGCH1 was increased by treatment with EMPA ($p<0.001$) in both areas. MI group also showed higher levels of galectin-3, collagen I, collagen III and TIMP-1 than the sham group in the infarcted area ($p<0.001$, in all cases); whereas in the border area, only the galectin 3 and TIMP-1 were increased ($p<0.01$). The treatment with EMPA significantly reduced the expression levels of all these remodeling markers in both areas ($p<0.001$, in all cases). When we evaluated the effect of EMPA on NOS isoform, compared with sham group, MI group, showed an increase in nNOS, eNOS and iNOS, in both the infarcted ($p<0.001$, in all cases) and border areas ($p<0.001$, in all cases). EMPA treatment prevented this deleterious effect ($p<0.001$, in all cases). EMPA treatment induced an up-regulation in BH4 levels in comparison with MI group ($p<0.01$).
Conclusions: Our results suggest that the overexpression of cGCH1 may be an important mechanism involved in the cardioprotective action of EMPA in the context of post-infarction HF. Its cardioprotective effect could be related to an improvement in oxidative damage following MI.

P1258
The myocardial metabolism shift results to cardiomyocyte dedifferentiation in dilated cardiomyopathy and chronic heart failure.

OV Stepanova[1]; AD Voronova[1]; TG Kulikova[1]; MP Valikhov[1]; IV Reshetov[2]; SN Tereshchenko[1]
[1]Cardiology Research and Production Center, Cardiology, Moscow, Russian Federation; *[2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Funding Acknowledgements: RFBR:18-015-00198 "Studying of energy cardiac metabolism and cardiomyocyte dedifferentiation in chronic hert failure"

Background: One of the main cause of chronic heart failure (CHF) is dilated cardiomyopathy (DCM). The CHF progression is accompanied with a metabolic remodeling characterized by shifting from cardiac fatty acid oxidation as a primary energy source to glucose oxidation. Cardiac energy metabolism is under the transcriptional control of nuclear receptors, such as peroxisome proliferator activated receptor alpha (PPARα). PPARα plays a critical role in controlling cardiac energy. The high level of PPARα expression is observed in differentiated cardiomyocytes. So we propose that myocardial metabolism shift results to cardiomyocyte dedifferentiation. Dedifferentiated cardiomyocytes may take part in regenerative processes in DCM and CHF. Formation of new functional cardiomyocytes may come both of dedifferentiation and proliferation of pre-existing cardiomyocytes without complete reversion to a cardiac progenitor state, or by cardiac differentiation of stem cells (embryological or dedifferentiated origin). Aim: The aim of the work to determine PPARα expression level in DCM and CHF, to detect dedifferentiated cardiomyocytes in DCM and CHF.
Methods: RT-qPCR was used to assess PPARα and ANP expression levels in endomyocardial biopsies (EMB) in15 patients with CHF and DCM. Atrial natriuretic peptide (ANP) was used in this work as well-known marker of the dedifferentiated cardiomyocytes. Resident cardiomyocyte progenitors and dedifferentiated cardiomyocytes were found by the immunofluorescence approach and the electron microscopy.
Results: The PPARα expression level decrease was detected in EMB in CHF in comparison with the myocardial samples without cardiovascular pathology. Significant ANP expression level increase was detected in EMB in CHF in comparison with the myocardial samples without cardiovascular pathology. We detected the cardiomyocyte progenitor cells which express c-Kit and Nkx-2.5, other cells express Mdr-1 and GATA-4. Revealed the cardiomyocyte progenitor cells may be of the embryological or dedifferentiated origin. Cardiomyocytes with hallmarks of dedifferentiation have been found in our study. Revealed cardiomyocytes have main features of dedifferentiated cardiomyocytes - sarcomere disorganization and mitochondria disposition.

Conclusions: PPAR-alpha expression level decrease shows shift from oxidative phosphorylation to glycolysis, a transition to dedifferentiated state of cardiomyocytes. Elevated ANP expression levels are associated with cardiomyocyte dedifferentiation. Identified dedifferentiated cells can participate in revealed the shift from oxidative phosphorylation to glycolysis. Metabolism modulating by acting on PPARα gives an opportunity to govern by cell differentiation and dedifferentiation and therefore it is an attractive therapeutic avenue in regenerative medicine.

P1259

Empagliflozin ameliorates post-infarction cardiac remodeling through overexpression of GTP enzyme cyclohydrolase 1

AM Antonio Manuel Lax[1]; P Lopez-Herrera[1]; L Oltra-Rodriguez[1]; N Garcia-Carrillo[1]; E Saura-Guillen[2]; MCA Sanchez-Perez[3]; A Hernandez-Vicente[3]; M Veas-Porlan[2]; DA Pascual-Figal[2]; MC Asensio Lopez[3]
[1]University of Murcia, El Palmar, Spain; *[2]University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain*; *[3]Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain*

Purpose. Empagliflozin (EMPA) have profound benefits on reducing heart failure (HF) and mortality in patients with type II diabetes, although the mechanism(s) of this benefit remain poorly understood. A plausible mechanism could be relate to its action on oxidative damage. Here we evaluated whether EMPA improves adverse cardiac remodeling following MI, through modulation of the cardiac GTP enzyme cyclohydrolase 1. (cGCH1), a key protein in the development of cardiac adverse remodeling in HF.
Material and methods. A rat model of type II diabetes (50 mg/kg streptozotocin, i.p.) was subjected to MI by ligation of the left anterior descending coronary artery. Animals were randomly divided into two groups treated with placebo (PL) or EMPA (10 mg/kg/day) from the day of surgery and for 4 weeks. Additional controls consisting of sham-operated rats with diabetes (DS) and sham-non-operated rats with diabetes treated with EMPA, were used. The mRNA and protein expression of cGCH1 and other remodeling markers were analyzed by qRT-PCR and western blot. Both phospholamban (PLN) as well as protein phosphatase 1 α (PP1α) activation were evaluated by western blot. Adult primary cardiomyocytes (CMs) under normal or high glucose (Glc) conditions (25 mM Glc, 24 h) and untreated or treated with EMPA (500 nM, 2 days), were then subjected to a simulate ischemia/reperfusion (I/R). CMs were used: (1) to measurement of [Ca2+]cyt and sarcoplasmic reticulum (RS) Ca2+ release by spectrofluorometry; (2) To study the role of cGCH1 through its specific silencing (siRNAs) and (3) To measurement NO and O2.- levels by chemioluminiscence analyzer.
Results. Compared with sham group, cGCH1 is degraded in both infarcted and border areas ($p<0.001$). EMPA treatment prevented this degradation ($p<0.01$), significantly reduced the expression of all remodeling markers evaluated ($p<0.001$, in all cases) and improved echocardiographic and hemodynamic parameters. In addition, infarcted and border areas from rats treated with EMPA showed higher NO levels ($p<0.05$) and lower O2.- ($p<0.001$) compared to sham group. A significant down-regulation in the phosphorylation state of PLN ($p<0.001$), as well as an increase in phosphorylation of PP1α ($p<0.01$) was observed in MI group. EMPA reversed these effects ($p<0.001$, in all cases). CMs treated or not with EMPA under I/R, showed similar results to those obtained in vivo. Moreover, I/R induced a significant increase of [Ca2+]cyt and a decrease in [Ca2+] inside sarcoplasmic reticulum (SR). Similarly, EMPA reverted these effects ($p<0.001$, in all cases). Silencing of cGCH1 in CMs reversed all cardioprotective effects related to EMPA treatment.
Conclusion. Our results suggest, for first time, that the overexpression of cGCH1 may be an important mechanism involved in the anti-remodeling effect of EMPA in the context of HF. Furthermore, our results highlight an EMPA mechanism of action on calcium metabolism, establishing clear pharmacological targets

P1260

Pharmacological mitochondrial stabilization to prevents adverse cardiac remodeling following MI using empagliflozin

MC Asensio Lopez[1]; L Oltra-Rodriguez[2]; N Garcia-Carrillo[2]; E Saura-Guillen[3]; MCA Sanchez-Perez[1]; A Hernandez-Vicente[1]; M Martinez-Herrera[3]; P Lopez-Herrera[2]; DA Pascual-Figal[3]; AM Antonio Manuel Lax[2]
[1]Biosanitary Research Institute of Murcia (IMIB-Arrixaca)., Cardiology, Murcia, Spain; *[2]University of Murcia, El Palmar, Spain*; *[3]University Hospital Virgen de la Arrixaca, Department of Cardiology, Murcia, Spain*

Purpose. The oxidative damage associated with cardiac dysfunction following myocardial infarction (MI), is related to a mitochondrial dysfunction in the cardiomyocyte. Although empagliflocin (EMPA) has showed to prevent cardiac remodeling and slowdown heart failure (HF) progression, the molecular mechanisms have not been well elucidated. Cardiac GTP enzyme cyclohydrolase 1 (cGCH1), a key protein in the development of remodeling in HF, is down-regulated in MI and could be a therapeutic target for EMPA. Here we evaluated whether EMPA improves mitochondrial dysfunction following MI, through the modulation of cGCH1.
Material and methods. Diabetic rats (50 mg/kg streptozotocin, i.p.) were used to induce MI by ligation of the left anterior descending coronary artery. Animals were then randomly divided into two groups treated with placebo (PL) or EMPA (10 mg/kg/day, oral) from the day of surgery and for 4 weeks. Additional controls consisted of sham-operated rats with diabetes (DS) and sham-non-operated rats with diabetes treated with EMPA, were used. The mRNA and protein expression of GCH1 and other remodeling markers were analyzed by quantitative RT-PCR and western blot. The effect of MI on mitochondrial performance was characterized by analyzing Complex I activity by ELISA, ATP synthesis by HPLC (AMP/ATP ratio) and the mitochondrial membrane potential ($\Delta\Psi$m) using JC-1 as a fluorescent indicator. Apoptosis was characterized by analyzing cytochrome c release and caspase 3 activation by Western blotting. The involvement of GCH1 was determined via siRNA-mediated knockdown using adult primary cardiomyocytes (CMs) under normal or high glucose (Glc) conditions (25 mM Glc, 24 h) and untreated or treated with EMPA (500 nM, 2 days), were then subjected to a simulate ischemia/reperfusion (I/R).
Results: Acute-MI to cause a significant decrease in cGCH1 levels ($p<0.001$) mitochondrial function, as quantified by a depression of Complex I activity ($p<0.001$), diminution of $\Delta\Psi$m ($p<0.01$) and the increase in AMP/ATP ratio ($p<0.05$), both infarcted as well as border areas. In these areas, EMPA treatment attenuated the decrease of cGCH1 ($p<0.001$), complex I activity ($p<0.01$) and $\Delta\Psi$m ($p<0.05$) and prevented the increase in AMP/ATP ratio ($p<0.05$). Interestingly, treatment with EMPA prevented cytochrome c release and caspase 3 activation induced by MI ($p<0.001$, in all cases). Similar results were obtained in an experimental model of diabetes under simulated I/R. When CMs under I/R were knock-down for cGHC1, the cardioprotective effects induced by EMPA, were eliminated ($p<0.001$, in all cases).
Conclusions: This study shows that cGHC1 is the main mediator of mitochondrial protection, in the prevention of MI-induced cardiomyopathy by EMPA. These results suggest that therapeutic strategies based on cGHC1 modulation could protect cardiomyocytes from mitochondrial dysfunction in the setting of oxidative stress.

P1261

Age-specific features of cardioprotective action of meldonium under the experimental severe hypoosomolar hyperhydration

N Nadiia Demikhova[1]; O Yarmolenko[1]; O Prykhodko[1]; V Bumeister[1]
[1]Sumy State University, Medical Institute, Sumy, Ukraine

The aim of our study was the determination of morphological changes in the rat's heart of different age under the experimental severe hypoosmolar hyperhydration and attempt to correct the identified changes by means of cardioprotector.
Materials. The experiment was performed on 54 white laboratory rats, which were divided into 2 experimental and 1 control series. The first experimental series included 6 rats in the prereproductive period at the age of 3 months, 6 rats in the reproductive period at the age of 8 months and 6 rats of the elderly age of 22 months. Animals were modeled a severe degree of hypoosmolar hyperhydrylion by introduction of distilled water and a synthetic analogue of ADH (vasopressin) "Minirin" twice a day at a dose of 0.01 mg trough the probe.The second experimental group included rats of all age groups (6 in each), which morphofunctional changes were corrected by meldonium. Rats of the control series were injected with "Minirin" twice a day at 0.01 mg, taking into account the potential effects of the drug onthe cardiovascular system. Cardiometry and statistical methods were used to assess the effect of hyperhydration on the morphofunctional state of the heart.
Results. In the 3-month-old rats of the first experimental series, the weight of the atria (AW) increases by21.98% ($p<0.0001$), the left ventricular weight (LVW) - by 28.65% ($p<0.0001$), the right ventricular weight (RVW) - by 25.77% ($p<0.0001$), and the area of the endocardial surface of the right ventricle (AESRV) - by 18.05% ($p=0.0099$) as compared with the control series.In the young rats of the secondexperimental series it is noted increasing of LVW by 23.03% ($p<0.0001$), RVW – by 20.1% ($p<0.0001$), AW – by 18.68% ($p=0.0003$) as compared with the control.The area of the endocardial surface of both ventricleschanges insignificantly. In the 8-month-old rats of the first experimental series AW is greater than the control by 25.35% ($p<0.0001$), LVW-by 15.4% ($p=0.0002$), RVW – by 48.13% ($p<0.0001$). The AESLV increases insignificantly, while AESRV increasesby 29.28% ($p<0.0001$). In mature rats of the second experimental series the AW is greater than control by 22.46% ($p<0.0001$), LVW – by 17.22% ($p<0.0001$), RVW – by 23.88% ($p<0.0001$), AESRV increases by 13.63% ($p=0.0499$). In the 22-month-old rats the AW increases by 22.89% ($p=0.0001$), LVW - by 24.48% ($p< 0.0001$), RVW – by 45.88% ($p<0.0001$), AESLV– by 31.35 % ($p<0.0001$), AESRV – by 35.12% ($p<0.0001$) as compared with the control. In old rats of the second experimental series we observe increasing of LVW by 25.45% ($p<0.0001$), RVW – by 37.28% ($p<0.0001$), AW – by 20.33% ($p=0.0002$), AESLV– by 18.33% ($p=0.0013$), and AESRV – by 22.68% ($p=0.0012$).
Conclusion. Under the influence of hypoosomolar hyperhydration was observed a significant increase of massometric indices in both experimental groups. At the same time, the application of meldonium slows growth of the mass of the right ventricle and its dilatationin all age categories.

The mitochondrial permeability transition pore (mPTP), located on the inner mitochondrial membrane, has become an important goal in investigating initiation and signalling pathways involved in cardioprotection. Metabolic preconditioning (MP) is an experimental cardioprotective model that has demonstrated sufficient protection to compensate for the mitochondrial energy of the heart under pathological conditions. A suitable method for elucidating the molecular structure and regulatory components of the multienzyme mPTP complex is shown to be proteomic analysis. Our attention was also concentrated on mitochondrial creatine kinase (mtCK) as one of the proposed mPTP regulators, whose function is particularly important from the energy conservation position.

The isolated Wistar rat heart mitochondria on the MP model represented by acute 8-day streptozotocin-induced diabetes mellitus (65 kg/mg i.p.) versus the healthy control group were examined. Proteomic analysis by nano-liquid chromatography and mass spectrometry were preceded by separation of mitochondrial proteins by 1D gel electrophoresis and digestion of proteins in gel by using trypsin.

At the level of using proteomic analysis, we have focused on proteins currently considered as structural and regulatory components of mPTP. The abundance of the investigated proteins as a whole was significantly lower in the MP-affected group ($p = 0.048$). However, in the individually analysed proteins of the MP-treated group, we did not observe statistically significant differences except from the ATP synthase β subunit, which was significantly reduced. The remaining identified mPTP proteins retained expression at the level of healthy mitochondria without significant change. Also, the mtCK enzyme activity was preserved in MP.

The results of mPTP proteomic analysis and unchanged mtCK activity under MP conditions indicate the positive effect of mPTP-regulated mechanisms present in the state of increased calcium influx into the mitochondria, thereby contributing to the maintenance of the energy of the pathologically affected myocardium.

Funding Acknowledgements: The study was financed by the National Academy of Science of Ukraine. No additional funding sources were used.

Introduction . Mitochondria are the key organelles that regulate the vitality of cells, the central hub for metabolic reactions and the main source of cellular ATP. In addition, mitochondrial dysfunction is one of the main causes of cardiovascular disease in various pathological conditions and aging. It is known that the protective effect on the cardiovascular system can be carried out by a gas transmitter - hydrogen sulfide (H2S). The aim of the current work was to study the effect of H2S-synthesizing enzymes cofactor pyridoxal-5-phosphate (PLP) on the sensitivity of mitochondrial permeability transition pore (MPTP) opening to Ca2+ as natural inducer in old rat heart, as well as the H2S content and cNOS activity in heart mitochondria.

Materials and Methods. Wistar male rats were divided into 3 groups: adult (6 months), old (24 months) and old+PLP. PLP was administered per os in dose of 0,7 mg per kg daily for 2 weeks. MPTP opening was registered spectrophotometrically as mitochondrial swelling. Additionally, the content of H2S, cNOS and iNOS activity, was measured in heart mitochondria.

Results. Our results show that H2S content and cNOS activity was 2 times lower in old rat heart mitochondria comparing to adult ones. However, PLP administration induced the increase of endogenous H2S content and cNOS activity in 4,2 times and 1,9 times respectively, compared with those in older animals. Additionally, iNOS activity was 2,5 times higher in old rat, but the administration of PLP caused decreasing of this parameter in 4,6 times. It has also been shown that PLP application prevents Ca2+-induced MPTP opening by reducing the sensitivity to the inductor in old rat heart.

onclusions. Overall, our results showed that H2S acts as a regulator of MPTP opening, increasing activity cNOS and recoverability of enzyme coupled state, indicating the importance of this gaseous transmitter in the pathology of the cardiovascular system. Thus, the 2 weeks administration of PLP might be used for stimulation of endogenous H2S synthesis and restoration of cNOS activity in heart mitochondria of old rat.

Inflammatory state and the development of low triiodothyronine syndrome in advanced heart failure.

M Kabat[1]; M Fraczek-Jucha[1]; K Zbierska-Rubinkiewicz[1]; R Rychlak[1]; J Nessler[1]; A Gackowski[1]

[1]John Paul II Hospital, Department of Coronary Disease and Heart Failure, Krakow, Poland

Background: Inflammatory state may accompany heart failure and lead to disturbed function of deiodinases. The aim of the study was the evaluation of the prevalence and clinical significance of low T3 syndrome in HF in relation to hsCRP - inflammatory state marker.

Methods: The study group consisted of 59 consecutive patients hospitalized due to decompensated HFrEF NYHA III or IV.

Exclusion criteria: thyroid dysfunction, severe systemic disease, treatment with amiodarone, steroids or propranolol.

We included all 59 consecutive patients hospitalized due to decompensated HFrEF. Group A included 9 patients with low fT3 concentration below 3.1 pmol/L. Group B consisted of the remaining 50 patients with normal fT3 levels.

Laboratory tests and echocardiography were performed.

Results: The prevalence of low T3 syndrome was 15.3%. We demonstrated correlations between free T3 (fT3) and main clinical variables (Table 1.). Kaplan-Meier survival analysis showed lower survival probability in patients with low fT3 ($p<0.001$).

Conclusions: Low T3 syndrome is frequently found in patients with HFrEF and is associated with a poor outcome. We found correlation between hsCRP and fT3.

Table 1. Correlation analysis.

Variable	Byvariable	Correlation	p-value
fT3	hsCRP	-0.4505	0.0003*
fT3	NT-proBNP	-0.5368	<0.0001*

Altered fatty acid oxidation and mitochondrial function and structure in skeletal muscle of patients with preserved and reduced ejection fraction compared to healthy controls

T Bekfani[1]; M Bekhite Elsaied[1]; M Westermann[2]; S Nietzsche[2]; S Derlien[3]; A Hamadanchi[1]; J Nisser[3]; E Froeb[1]; D Haase[1]; T Kretzschmar[1]; UC Smolenski[3]; G Lehmann[4]; G Wolf[4]; S Moebius-Winkler[1]; PC Schulze[1]

[1]University Hospital of Jena, Department of Cardiology, Jena, Germany; [2]University Hospital of Jena, Centre of electron microscopy, Jena, Germany; [3]University Hospital of Jena, Institute of Physiotherapy, Jena, Germany; [4]University Hospital of Jena, Department of Endocrinology, Nephrology and Rheumatology, Jena, Germany

Background: Several studies suggested altered metabolism and mitochondrial function in skeletal muscle of patients with heart failure (HF).

Purpose: To compare mitochondrial structure and function in skeletal muscles of symptomatic outpatients with preserved (HFpEF) and reduced ejection fraction (HFrEF) and age-matched healthy controls (HC) and its relationship to exercise capacity.
Methods: 55 participants were recruited prospectively in our University Hospital, Germany: 17 HFpEF, 18 HFrEF, 20 HC (Age: 71±6 vs. 68 ±9 vs. 66±7 years, p=0.1; sex (m/f): 8/9 vs. 3/15 vs. 7/13, p=0.0001; BMI: 28.7±4.6 vs. 27.9±5.3 vs. 26.4 ±4.2 kg/m2, p=0.2). All participants underwent echocardiography, cardiopulmonary exercise test, muscle function tests, and muscle biopsies from the vastus lateralis. Total RNA was prepared (10 HFpEF, 13 HFrEF, and 11 HC) and expression levels of fatty acid translocase (CD36), carnitine palmitoyltransferase IB (CPT1ß), medium-chain acyl-CoA dehydrogenase (ACADM), uncoupling protein (UPC-3) and Mitofusin (Mfn2) was measured using real-time polymerase chain reaction. CPT1ß-protein was evaluated using Western Blot. Mitochondrial number and size were analysed using an electron microscope and measured in pictures with enlargement of 13.000x. Serum samples were analyzed for SuPAR by means of ELISA.
Results: Comparing patients with HFpEF and HFrEF to HC gene expression of fatty acid uptake [CD-36: (0.17±0.10 vs. 0.22±0.14 vs. 0.34±0.12, p=0.01)], transportation across the mitochondrial membrane [CPT1ß: (1.79±0.71 vs. 2.27±1.24 vs. 4.38±1.49, p<0.0001), degrading medium-chain fatty acids [(ACADM: 3.99 ±0.79 vs. 3.90±1.71 vs. 5.48 ±1.66, p=0.03)], Uncoupling proteins [UPC-3: 0.9±0.5 vs. 0.5±0.3 vs. 1.2±0.5, p<0.0001], Mitochondrial fusion [(MFN2: 0.2±0.07 vs. 0.2±0.1 vs. 0.4±0.1, p<0.0001)], protein level of CPT1ß (0.5±0.2 vs. 0.5±0.2 vs. 0.7±0.2, p=0.03)], number of mitochondria (15.8±8.2 vs. 14.0±4.6 vs. 30.5±9.8, p=0.003) and size (1487±640 vs. 2524±1114 vs. 5612±4242, p=0.008) were reduced in skeletal muscles. Mitochondrial size was associated with higher levels of ACADM, MFN2-gene expression and CPT1ß-protein (r=0.7, p=0.003; r=0.5, p=0.03; r=0.6, p=0.04, respectively), PVO2 (r= 0.5, p=0.02), muscle strength (Knee flexion: r=0.53, p=0.01), and with distinct cardiac structure abnormalities: left atrial volume index (r=-0.74, p=0.004), intraventricular septum thickness (r=-0.5, p<0.0001), and with e´ lateral (r=0.76, p=0.003), and inversely with the level of an inflammatory biomarker SuPAR (r=-0.44, p<0.05). Logistic regression showed MFN-2 to be an independent factor for predicting a reduced PVO2 adjusted for LVEF, CD36, ACADM (odds ratio: 1.1, p=0.04).
Conclusion: Distinct alterations of mitochondrial structure and function were observed in patients with HF, especially those with HFpEF, compared to HC. These changes were associated with reduced exercise capacity, muscle strength, and elevated levels of inflammatory Biomarkers.

P1266
Effects of phosphodiesterase-5A inhibition on right ventricular cardiomyocyte function in diabetic cardiomyopathy

L Lilla Martha[1]; B Bodi[1]; J Tamas[1]; C Matyas[2]; A Toth[1]; B Merkely[2]; T Radovits[2]; Z Papp[1]
[1]University of Debrecen, Division of Clinical Physiology, Department of Cardiology, Faculty of Medicine, Debrecen, Hungary; *[2]Semmelweis University, Heart and Vascular Center, Budapest, Hungary*

Elevated intracellular cyclic guanosine monophosphate (cGMP) levels have been shown to prevent the development of diabetic cardiomyopathy. Here we studied the effect of the phosphodiesterase-5A (PDE-5A) inhibitor, vardenafil in a rat model of diabetic cardiomyopathy on cardiomyocyte function of the right heart.
Experiments were performed in male Zucker Diabetic Fatty (ZDF) and ZDF Lean (ZDFL) rats (as controls). Seven-weeks-old animals received either vehicle (ZDFL, ZDF) or 10 mg/bwkg vardenafil per os (ZDFLV, ZDFV) for 25 weeks. Permeabilized cardiomyocytes from right ventricle (RV) were used during isometric force measurements. Maximal Ca2+-activated active force production (Fmax), its Ca2+-sensitivity (pCa50), and Ca2+-independent passive force (Fpassive) were monitored. Western immunoblotting was applied to assess site-specific phosphorylation status of cardiac troponin-I (cTnI) and cardiac myosin binding protein C (cMyBP-C). Total phosphorylation status of titin protein was probed by ProQ Diamond phosphoprotein kit. Fpassive values were significantly higher in ZDF rats (1.95±0.08 kN/m2, n=6-7) than in the ZDFL (1.38±0.12 kN/m2, n=6-7), ZDFLV (1.30±0.11 kN/m2, n=6-7) and ZDFV (1.13±0.16 kN/m2, n=6-7) groups (P<0.05). No significant differences were observed in Fmax among the four groups (ZDF: 14.20±1.40 kN/m2, ZDFL: 11.15±1.17 kN/m2, ZDFLV: 12.36±0.97 kN/m2, ZDFV: 10.96±0.50 kN/m2, n=6-7). pCa50 values were significantly lower in ZDFV groups (ZDF: 5.84±0.02, ZDFL: 5.85±0.02, ZDFLV: 5.83±0.02, ZDFV: 5.67±0.02, P<0.05, n=6-7). Cardiac troponin-I (cTnI) was hyperphosphorylated at Ser-22/23, Ser-43 and Thr-143 sites in ZDFV groups when compared to ZDF animals (ZDFV: 1.08±0.13, 1.45±0.19 and 2.32±0.32, ZDF: 0.95±0.07, 0.98±0.05 and 1.04±0.21; in relative units, respectively, P<0.05, n=6). No significant differences in the site specific phosphorylation status of cMyBP-C at Ser282 and in the total phosphorylation status of titin between the groups were observed.
Increased passive force production developed in RV cardiomyocytes of rats with type 2 diabetes mellitus which could be limited by chronic phosphodiesterase-5A inhibition through markedly increased protein phosphorylation.

P1267
Mitochondrial dysfunction results from the loss of ERK5 in diabetic cardiomyopathy

W Wei Liu[1]
[1]University of Manchester, Manchester, United Kingdom of Great Britain & Northern Ireland

Funding Acknowledgements: British Heart Foundation

The prevalence of cardiomyopathy from metabolic stress has increased dramatically; however, its molecular mechanisms remain elusive. Here, we show that extracellular signal-regulated protein kinase 5 (Erk5) is lost in the hearts of obese/diabetic animal models and that cardiac-specific deletion of Erk5 in mice (Erk5-CKO) leads to dampened cardiac contractility and mitochondrial abnormalities with repressed fuel oxidation and oxidative damage upon high fat diet (HFD). Erk5 regulation of peroxisome proliferator-activated receptor γ co-activator-1α (Pgc-1α) is critical for cardiac mitochondrial functions. More specifically, we show that Gp91phox activation of calpain-1 degrades Erk5 in free fatty acid (FFA)-stressed cardiomyocytes, whereas the prevention of Erk5 loss by blocking Gp91phox or calpain-1 rescues mitochondrial functions. Similarly, adeno-associated virus 9 (AAV9)-mediated restoration of Erk5 expression in Erk5-CKO hearts prevents cardiomyopathy. These findings suggest that maintaining Erk5 integrity has therapeutic potential for treating metabolic stress-induced cardiomyopathy.

P1268
Post-rest inotropic reaction of the myocardium in dependence on SERCA2a expression level and metabolic enzyme activity in patients with coronary artery disease and diabetes mellitus

[1]Cardiology Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation; *[2]Siberian State Medical University, Tomsk, Russian Federation*

Funding Acknowledgements: This work was supported by a grant the RFBR 17-0401450 and by the Russian State Projects "Science" No. AAA-A15-115123110026-3.

Background. Contractile dysfunction in heart failure (HF) and diabetes mellitus is tightly associated with the abnormal excitation-contraction coupling, associated with sarcoplasmic reticulum (SR) dysfunction. The role of changes in the intracellular calcium handling in the pathogenesis of HF associated with diabetes remains poorly understood. The inotropic behavior of isolated preparation of myocardium of patients with coronary artery disease (CAD) and CAD combined with type 2 diabetes mellitus (DM2), its relation with the expression SERCA2a and enzyme activity of the energy suppling metabolism were evaluated.
Methods. The study included patients with chronic CAD and patients with CAD combined with DM2 undergoing coronary artery bypass grafting. Inotropic reaction on rest period was studied on isolated trabeculae of the right auricular myocardium of patients. Post-rest reaction of myocardium assessed for analyze the sarcoplasmic reticulum function (4 - 60 sec). The protein levels of SERCA2a in myocardium were determined by Western blotting. Oxygen consumption by mitochondria was measured using a Clark-type oxygen electrode. The activity of lactate dehydrogenase and succinate dehydrogenase were determined by histochemical method.
Results. It was shown that potentiation and decay of post-rest contraction force of myocardium was observed in both CAD patients with and without DM2. The potentiation of post-rest contractions of myocardium corresponds to the "high content" of the SERCA2a expression, and the decay of post-rest contractions coincides to the "low content" of the SERCA2a. In the combined development of CAD and DM2 with short duration of the disease, the potentiation of post-rest contractions is manifested to a greater degree and corresponds to a higher of SR SERCA2a expression than in CAD patients. Activity of the enzymes of the energy suppling metabolism succinate dehydrogenase (SDH) and lactate dehydrogenase (LDH) was higher in the myocardium of CAD patients while the rate of oxygen uptake by cardiomyocyte mitochondria was higher in the myocardium of patients with combined pathology.
Conclusion. In CAD with and without DM2 the potentiation of post-rest contractions of isolated muscle strips of human myocardium corresponds to 'high level' of SR SERCA2a expression, while the decay of post-rest contractions is associated with 'low level' of SR SERCA2a expression. In combined development of CAD and DM2 with short-term duration of disease the potentiation of post-rest contractions is manifested to a greater degree and corresponds to a higher level of SR SERCA2a

expression than in CAD alone patients. In CAD ATP synthesis is realizes mainly in result of glycolytic processes and Krebs cycle and, opposite, the mitochondrial oxidative phosphorylation prevail in comorbid development of CAD and DM2 in the production of ATP.

P1270

HFWM: - Title: CaMKII-HDAC4 interplay governs the function of the diabetic heart

J Grosso[1]; M Kronlage[2]; M Dewenter[1]; AR Saadatmand[1]; U Oehl[1]; AR Sickmann[3]; HA Katus[2]; J Backs[1]
[1]University Hospital of Heidelberg, Internal Medicine VIII, Department of Molecular Cardiology and Epigenetics, Heidelberg, Germany; *[2]University Hospital of Heidelberg, Internal Medicine III, Department of Cardiology, Heidelberg, Germany*; *[3]Leibniz-Institut für Analytische Wissenschaften - ISAS - e.V., Dortmund, Germany*

Worldwide, diabetes mellitus (DM) and heart failure (HF) are frequent co-morbidities with constantly growing prevalence. DM patients not only have a higher lifetime risk of developing HF, cardiovascular complications also represent a major cause of death in these patients. However, clinical evidence exists that intensive glucose lowering treatment in patients with DM paradoxically increases the risk of hospitalization due to HF. These findings raise the question whether glucose might even possess protective effects. In the current project, we investigated hyperglycaemic signalling in DM with respect to detrimental versus protective effects to the heart. DM was induced in HDAC4 deficient mice and cells were transfected with plasmids encoding either HDAC4, its inactivating upstream regulator CaM Kinase II (CaMKII) or its activating upstream regulator protein kinase A (PKA) in low versus high glucose conditions. We found that diabetic HDAC4-KO mice develop impairment of systolic function, whereas control littermates were protected. We now found that addition of O-linked b-N-acetylglucosamine (O-GlcNAc) at S642 of histone deacetylase 4 (HDAC4) is essential for its proteolysis and production of a cardioprotective N-terminal fragment, which we named HDAC4-NT. In a series of biochemical experiments, we provide additional evidence that O-GlcNAcylation of HDAC4 at S642 is not only essential for HDAC4-NT production but also reduces HDAC4 inactivation through detrimental CaMKII-mediated phosphorylation of S632. Vice versa, CaMKII phosphorylation of HDAC4 triggered decreased levels of HDAC4-NT production. Altogether, this suggests that O-GlcNAcylation at S642 and phosphorylation at S632 are mutually exclusive events and that HDAC4 contains a molecular domain that decides about protective and detrimental downstream signaling. Thus, we propose a new model potentially explaining the ''diabetic paradox'': HDAC4 serves as a molecular checkpoint in diabetic metabolism consisting of S632 (target of detrimental CaMKII signaling) and S642 (target of protective O-GlcNAcylation) and thereby controls cardiac function. Further investigation is necessary to identify mechanisms that control specificity of O-GlcNAcylation in the diabetic heart and might be suitable as potential drug targets in the future.

Circulating micrornas associated with c-type natriuretic peptide in childhood obesity

M Cabiati[1]; V Bianchi[2]; C Salvadori[1]; E Randazzo[2]; G Federico[2]; S Del Ry[1]
[1]Institute of Clinical Physiology of CNR, Pisa, Italy; *[2]University of Pisa, Unit of Pediatric Endocrinology and Diabetes, Dep. Clinical and Experimental Medicine, Pisa, Italy*

Background: Circulating microRNAs (miRNAs) are biomarkers of metabolic disease implicated in the pathogenesis of obesity and C-type natriuretic peptide (CNP) was recently indicated as important natural regulator of adipogenesis during pediatric obesity. At present, no data are available on a possible contribution of CNP-linked miRNAs to childhood obesity.

Purpose: Our aims were to 1) perform a detailed in silico analysis to identify miRNAs targeting CNP gene through the use of bioinformatic algorithms; 2) recognize CNP-linked miRNAs associated with obesity; 3) characterize their circulating profiling in normal-weight (N) and obese adolescent (O).
Materials & Methods: A clinical examination was performed in 26 N and 50 O adolescents aged 13.5±0.4 years. CNP plasma levels were detected by immunometric assay while miRNA expression was carried out on peripheral blood using Real Time PCR.
Results: Plasma CNP resulted significantly lower in O than in N (5.58±0.62 vs. 14.78±1.35 pg/ml, $p<0.0001$). In silico analysis disclosed several specific circulating CNP-linked miRNAs with miR-33a-3p, miR-223-5p and miR-142-5p being also associated with obesity. MiR-199 and miR-4454, known to be associated with obesity but not with CNP, were also studied. Only circulating miR-223 and miR-33a expression resulted significantly ($p=0.05$) higher in O (0.97±0.1; 0.85±0.1, respectively) than in N (0.66±0.11; 0.51±0.08, respectively). Plasma CNP correlated inversely with miR-33a (r= -0.25, $p=0.036$), miR-223 (r= -0.33, $p=0.004$), miR-199 (r= -0.35, $p=0.003$) and miR-4454 (r= -0.48, $p<0.0001$). Significantly positive correlations were observed between miR-33a and miR-223 ($r=0.35$, $p=0.002$) and between miR-199 and miR-4454 ($r=0.45$, $p=0.0001$). Applying a multivariate logistic regression analysis, miR-199 ($p=0.016$) and miR-142 ($p=0.006$) resulted significantly associated with CNP in pediatric obesity.
Conclusions: Our data confirm miR-199, previously reported as an important player in early childhood obesity, as a key regulator of CNP expression in pediatric population. Nevertheless, further investigations are needed to validate the differential expression of miRNAs in childhood obesity. The regulation of CNP-mediated miRNA may contribute to better understand the potential action of miRNAs in childhood obesity by fine-tuning target gene expression, as CNP.

P1272

HFWM: Endothelial-to-mesenchymal transition contributes to aortic stiffness in type 2 diabetes mellitus

M S Melanie Hulshoff[1]; IN Schellinger[2]; X Xu[1]; H Wong[1]; U Raaz[2]; EM Zeisberg[1]
[1]University Medical Center Göttingen, Cardiology and Pneumnology, Göttingen, Germany; *[2]University Heart Center, Göttingen, Germany*

Background/introduction – In the past decades, the prevalence of diabetes mellitus has risen considerably and is currently affecting more than 422 million people worldwide. Cardiovascular diseases including myocardial infarction and heart failure represent the major cause of death in type 2 diabetes. Diabetes patients exhibit accelerated aortic stiffening which is associated with myocardial infarction and heart failure. Importantly, aortic stiffening is an independent predictor of cardiovascular disease and mortality in diabetes mellitus patients. We recently showed that aortic stiffness precedes hypertension in a mouse model of diabetes (db/db mice), making aortic stiffness an early contributor to cardiovascular disease development.
Purpose – Elucidating how aortic stiffening develops is a pressing need in order to halt the pathophysiological process at an early time point. We now identified the endothelial-to-mesenchymal transition (EndMT) as a novel regulator of aortic stiffness.
Methods – To assess the occurrence of EndMT, we performed co-immunofluorescent staining of an endothelial marker (CD31) with mesenchymal markers (α-SMA and S100A4) in aortic sections from db/db mice. Moreover, we performed qRT-PCR to analyze the mRNA expression of the EndMT transcription factors (Snail, Slug and Twist) in aortic sections of db/db mice as well as diabetic patients with aortic stiffness. To identify the underlying mechanism by which EndMT contributes to aortic stiffening, we overlapped the Micronome of aorta's from db/db mice and high glucose treated human umbilical vein endothelial cells (HUVECs).
Results – We demonstrate robust co-localization of CD31 and α-SMA or S100A4 in aortic sections of db/db mice which was almost absent in control mice. Moreover, we demonstrate a significant upregulation of the EndMT transcription factors in aortic sections of both db/db mice and diabetic patients with aortic stiffness. We also show co-localization of CD31 and α-SMA or S100A4 and upregulation of EndMT transcription factors in high glucose treated HUVECs. As underlying regulator, we identified miR-132-3p as the most significantly downregulated miR in both the micronome of db/db mice and of high glucose treated HUVECs. Indeed, miR-132-3p was also significantly downregulated in aortic tissue from diabetic patients with aortic stiffness. We identified Kruppel-like factor 7 (KLF7) as a target of miR-132-3p and show a significant upregulation of KLF7 in aortic sections of both db/db mice and diabetic patients as well as in high glucose treated HUVECs.
Conclusion(s) – To the best of our knowledge, this is the first report to demonstrate that EndMT contributes to aortic stiffening in the context of type 2 diabetes. We identified miR-132-3p and KLF7 as novel regulators of EndMT in this context. Altogether, this gives us new insights in the development of aortic stiffening in type 2 diabetes.

Background: The prevalence of heart failure with preserved ejection fraction (HFpEF) is increasing, and there are no evidence based therapies for this condition. The main molecular defect in HFpEF is reduced activity of the nitric oxide-cyclic GMP-protein kinase G (NO-cGMP-PKG) pathway, which appears to be triggered by low-grade inflammation-induced endothelial dysfunction, secondary to cardiometabolic comorbidities frequently associated with HFpEF (e.g. hypertension, diabetes, obesity). Omega-3 polyunsaturated fatty acids (n-3 PUFA) have pleiotropic beneficial cardiovascular effects, including improvement of diastolic and endothelial function, anti-inflammatory effects and a positive cardiometabolic profile.
Purpose: We hypothesized that n-3 PUFA supplementation could prevent the development of HFpEF in a preclinical model.
Methods: Male Dahl salt sensitive (DSS) rats were fed a high salt diet (8% NaCl) without supplementation of n-3 PUFA from 7 weeks of age (HFpEF group), whilst another cohort received a high salt diet supplemented with 1.2% fish oil (n-3 PUFA group). Another cohort of DSS rats was fed a low salt diet (0.3% NaCl) throughout the duration of the study protocol until 19 weeks of age (Control group). Blood pressure was evaluated by the tail cuff method. A complete echocardiographic evaluation was performed at baseline and repeated every 2 weeks thereafter, which included evaluation of diastology parameters, such as mitral valve inflow velocities, and tissue Doppler evaluation of myocardial tissue relaxation velocities. Fatty acid content was measured in plasma, red blood cells and myocardium, and the omega-3 index was also calculated.
Results: Rats in both the HFpEF and the n-3 PUFA groups developed severe hypertension, whilst the control group remained normotensive. Only the HFpEF group developed signs of heart failure (e.g. reduced activity, laboured respiration, weight loss), and deterioration of health status, which was associated with higher indices of cardiac hypertrophy and pulmonary congestion (Figure 1A). Of note, all groups exhibited normal left ventricular ejection fraction throughout the study. Significantly, only the HFpEF group presented diastolic dysfunction (elevated E/e' ratio, reduced e', increased a', and reduced e'/a' ratio), whilst the n-3 PUFA and Control groups exhibited normal diastolic function (Figure 1B-C). Taken together, the above results suggest that n-3 PUFA supplementation prevented the development of HFpEF. The protective effect of n-3 PUFA was associated with substantial enrichment of n-3 PUFA content in the myocardium and concomitant elevation of the omega-3 index in the n-3 PUFA group, compared to the HFpEF and Control groups (Figure 1D).
Conclusion: Our data suggest that chronic supplementation of n-3 PUFA through the diet prevents the development of HFpEF in the DSS hypertensive model, and therefore may be a promising therapeutic option for HFpEF patients.

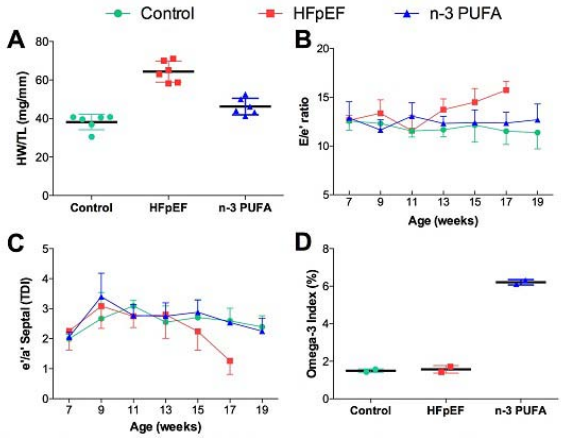

Figure 1. A. Heart weight/tibia length (HW/TL) ratio suggest attenuated cardiac hypertrophy in the n-3 PUFA group compared to the HFpEF group. **B-C.** HFpEF group exhibits diastolic dysfunction as indicated by alterations in the E/e' and e'/a' ratios. The Omega-3 Index (% of EPA+DHA fatty acids in red blood cells) was only increased in the n-3 PUFA group. Data shown as mean ± SEM.

Heart failure with preserved ejection fraction (HFpEF) is a major public health concern, characterized by normal heart ejection fraction but with inability of the myocardium to relax normally. It lacks effective therapies, and is worsened by obesity, diabetes and hypertension epidemics in an ageing population.
Recent advances in HFpEF pathophysiology were possible due to the development of the ZSF1 obese rat model, which display HFpEF phenotype, including preserved systolic function and diastolic dysfunction . Mounting evidence suggest that these associated comorbidities prime a systemic pro-inflammatory milieu and microvascular endothelial activation which trigger subsequent myocardial dysfunction .
Targeting the immune response has been proposed as an effective strategy to prevent cardiovascular dysfunction in HFpEF. However, a comprehensive analysis on immune alterations and the subsequent implications to endothelial and organ dysfunction are yet to be reported. This work aimed to characterize systemic immune cell populations in a HFpEF animal model, and their crosstalk with endothelial cells. Flow cytometry characterization of immune cell populations in blood, spleen and lymph nodes of ZSF1 obese rats showed a variation in their proportions, when comparing with lean animals, namely an increase in CD11b/c+ myeloid cells accompanied by a decrease in T and B cells. These data indicate that systemic immune alterations occur in HFpEF and suggest a higher involvement of innate immunity in the disease. We also detected higher expression levels of the senescence marker p21 in peripheral blood mononuclear cells which is a scenario compatible with chronic inflammation.
Although we observe that endothelial activation correlates with augmented inflammatory infiltration in ZSF1 obese animals, their association is yet to be defined. Based on this, we studied the interaction between immune cells, namely bone marrow-derived macrophages, with microvascular endothelial cells (MVEC), stimulating MVEC with extracellular vesicles isolated from cultures of macrophages from obese and lean ZSF1 rats. Preliminary results suggest an involvement of macrophage secretome in MVEC activation status. In conclusion, our findings suggest that in HFpEF alterations in the immune system precede endothelial dysfunction. However, further studies are required to advance current understanding on the role of the immune system in disease pathophysiology, and to translate this knowledge in the identification of effective therapeutic targets.

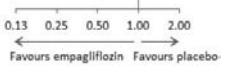
Introduction – Atrial fibrillation (AF) is a frequent comorbidity in heart failure (HF), and it worsens the outcome, reflecting a more advanced myocardial disease. AF confers an additional risk associated with HF, and HF treatments, such as beta blockers, have not demonstrated reductions in mortality in patients with AF. In the EMPA-REG OUTCOME study, empagliflozin led to a reduction in HF hospitalisations (HHF), cardiovascular (CV) death, CV death or HHF, and incident or worsening nephropathy in patients with type 2 diabetes (T2D) and established CV disease.
Purpose: This post-hoc analysis of the EMPA-REG OUTCOME study aimed to examine (1) classical and expanded HF outcomes in a T2D population with and without pre-existing AF, and (2) the effect of empagliflozin in patients with AF compared with those without AF.

Figure 1: Impact of empagliflozin on HF outcomes by AF at baseline

	Empagliflozin n/N (%)	Placebo n/N (%)	HR (95% CI)	HR (95% CI)	p-value for interaction
Hospitalisation for HF					0.7509
AF Yes	21/247 (8.5)	18/142 (12.7)	0.60 (0.32, 1.12)		
AF No	105/4440 (2.4)	77/2191 (3.5)	0.67 (0.50, 0.90)		
CV death					0.5570
AF Yes	21/247 (8.5)	21/142 (14.8)	0.52 (0.29, 0.96)		
AF No	151/4440 (3.4)	116/2191 (5.3)	0.64 (0.50, 0.81)		
Hospitalisation for HF or CV death					0.5630
AF Yes	38/247 (15.4)	33/142 (23.2)	0.58 (0.36, 0.92)		
AF No	227/4440 (5.1)	165/2191 (7.5)	0.67 (0.55, 0.82)		
Introduction of loop diuretics					0.9716
AF Yes	29/157 (18.5)	23/90 (25.6)	0.61 (0.35, 1.06)		
AF No	311/3805 (8.2)	239/1879 (12.7)	0.62 (0.52, 0.73)		
Oedema					0.1344
AF Yes	14/247 (5.7)	23/142 (16.2)	0.32 (0.16, 0.61)		
AF No	237/4440 (5.3)	212/2191 (9.7)	0.53 (0.44, 0.64)		
Incident or worsening nephropathy					0.1987
AF Yes	26/207 (12.6)	29/118 (24.6)	0.44 (0.26, 0.74)		
AF No	499/3917 (12.7)	359/1943 (18.5)	0.62 (0.54, 0.71)		



AF, atrial fibrillation; CV, cardiovascular; HF, heart failure.

Figure 1

Methods: In total 7020 patients with T2D and CV disease were treated with empagliflozin 10 mg, 25 mg or placebo, and followed for a median of 3.1 years. We explored the association between investigator-reported history of AF at baseline and time to first HHF, CV death, HHF or CV death, first introduction of loop diuretics, first occurrence of oedema and incident or worsening of nephropathy. We also assessed the consistency of the effect of empagliflozin treatment in patients with and without AF at baseline. Differences in the risks between treatment groups were assessed using a Cox proportional hazards model with factors for age, sex, baseline body mass index (BMI), baseline glycated haemoglobin (HbA1c), baseline estimated glomerular filtration rate (eGFR), region, treatment, AF and treatment by AF interaction. All analyses were performed on a nominal two-sided alpha of 0.05 without adjustment for multiplicity.
Results: A total of 389 patients had investigator-reported AF at baseline. Patients with AF were more often male (78.1 vs 71.1%), older (mean age 68.4 vs 62.8 years), had higher BMI (mean 31.7 vs 30.6 kg/m^2), and lower eGFR (mean 67.4 vs 74.4 ml/min/1.73 m^2). Furthermore, patients with AF vs without AF at baseline had higher rates of HHF or CV death on placebo (Plac) and empagliflozin (Empa): (Plac/Empa 23.2%/15.4% vs Plac/Empa 7.5%/5.1%). Increased risks were also detected for HHF (Plac/Empa 12.7%/8.5% vs 3.5%/2.4%), introduction of loop diuretics (Plac/Empa 25.6%/18.5% vs 12.7%/8.2%), first occurrence of edema (16.2%/5.7% vs 9.7%/5.3%) as well as incident or worsening of nephropathy (24.6%/12.6% vs 18.5%/12.7%). Empagliflozin consistently reduced HHF, CV death, HHF or CV death, introduction of loop diuretics, occurrence of oedema and incident or worsening of nephropathy in patients with and without AF (Figure).
Conclusion – In patients with T2D and CV disease, AF is associated with an increased risk of CV and HF outcomes and mortality. The treatment effects of empagliflozin are consistent in patients with and without AF.

1279

Eligibility for EMPEROR trials in a real-world heart failure population: data from the Swedish heart failure registry

T Thorvaldsen[1]; LH Lund[1]; U Dahlstrom[2]; G Savarese[1]
[1]Karolinska Institute, Department of Medicine, Stockholm, Sweden; *[2]Linkoping University, Department of Medical and Health Sciences and Department of Cardiology, Linkoping, Sweden*

Background Randomized controlled trials (RCT) populations may use inclusion/exclusion criteria for trial-specific reasons, e.g. to enrich for higher cardiovascular (CV) risk, in order to establish the benefit of the investigational compound in a practically feasible manner. Generalizability of RCT results to real-world settings is an important question.
Purpose To investigate the eligibility criteria for the Empagliflozin outcome trial in patients with chronic heart failure (HF) with preserved ejection fraction (EF)(EMPEROR-Preserved) and reduced EF (EMPEROR-Reduced) in a real-world HF population.
Methods Patients enrolled as out- or as in-patients at discharge in the Swedish HF Registry (SwedeHF) in 2000-2012 were included. Inclusion criteria in EMPEROR trials were applied, specifically NYHA class II-IV and being outpatient on stable HF therapy. Considered exclusion criteria were systolic blood pressure (SBP)≥180 or <100 mmHg, liver disease, and eGFR<20 ml/min/1.73m2 or dialysis. Patients with EF≥40% and <40% were considered eligible for EMPEROR-Preserved and -Reduced, respectively. NT-proBNP>300 pg/ml for patients without atrial fibrillation (AF) or >900 pg/ml for those with AF was inclusion criterion in EMPEROR-Preserved, whereas NT-proBNP>600 pg/ml and ≥1200 pg/ml, respectively, was applied for patients with EF <40%.
Results (Figure): Of 24,002 patients with EF<40% and 19,727 with EF≥40%, 68-69% could not be screened due to missing NT-proBNP measurements. Of 7,158 patients with EF<40% and 6,026 with EF≥40%, 38.6% and 34.0% would have been eligible for EMPEROR-Reduced and -Preserved, respectively. Major unmet inclusion criterion was sufficiently high NT-proBNP levels and major exclusion criterion was in-patient status. SBP<100 mmHg limited eligibility for EMPEROR-Reduced. Comorbidity burden was similar in eligible vs non-eligible, except for more AF, anemia and hypertension in the eligible patients regardless of EF, and less COPD in EMPEROR-Preserved eligible vs. non-eligible patients. Eligible patients were less likely to have NYHA IV class and more likely to be followed-up in specialist care, to receive RASi and beta-blockers. In outpatients, risk of CV death/HF hospitalization, of any and HF hospitalization was higher in eligible patients.
Conclusions In SwedeHF, eligibility for EMPEROR trials was around 35%, which is higher compared with other contemporary trials in HF, and mainly determined by the NT-proBNP cut-off. Using NT-proBNP for eligibility is a common approach in heart failure RCTs to optimize the evaluation of the benefit of the investigational compound

in a manageable trial setting. The likelihood of receiving empagliflozin in real-world practice may be influenced by factors other than trials' inclusion/exclusion criteria (i.e. frailty, life expectancy, access to care, patients' willingness). Further analyses exploring factors influencing eligibility are needed at the time empaglifozin will become available for HF treatment.

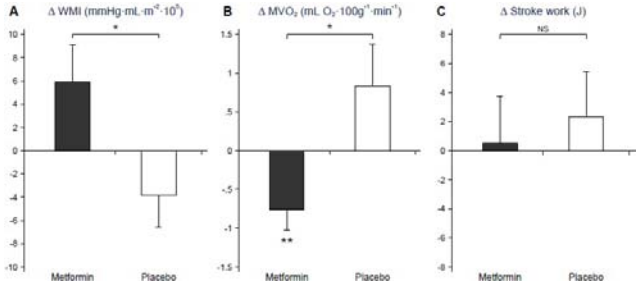
Funding Acknowledgements: Danish Diabetes Academy; Arvid Nilsson Foundation; Aarhus University; Danish Heart Foundation; Kirsten Anthonius Fund; Augustinus Foundation

Background Heart failure (HF) is characterized by myocardial mitochondrial dysfunction and reduced myocardial efficiency (stroke work / oxygen consumption). Metformin has direct mitochondrial effects and is associated with improved survival in HF registry studies. The present study investigated the effects of metformin on myocardial oxygen consumption and myocardial efficiency in pre-diabetic HF patients.



Efficiency, Oxygen consumption, Work

Methods In a double-blinded design, 36 pre-diabetic HF patients with reduced ejection fraction (EF ≤ 45%; HbA1c 37-47 mmol/mol) were randomized to three months of metformin treatment (n = 19) or placebo (n = 17) in addition to standard HF therapy. All patients underwent 11C-acetate positron emission tomography (PET), comprehensive transthoracic echocardiography, and cardiopulmonary exercise testing. The primary endpoint was change in myocardial efficiency expressed as work metabolic index (WMI) derived from 11C-acetate PET and echocardiography.
Results The median age was 66 (interquartile range 58-69); 81% were men, and the mean EF was 37 ± 8%. Compared with placebo, metformin treatment (1,450 ± 550 mg/day) reduced myocardial oxygen consumption (MVO2) by -1.6 mL O2/100g/min (95% confidence intervals [CI]: -2.8 to -0.4; p = 0.014) and increased WMI by 1.0 mmHg·mL·10^6/m^2 (95% CI: 0.1 to 1.8; p = 0.03), equivalent to a 20% relative myocardial efficiency increase. Cardiac stroke work was preserved, -1.8 J (95% CI: -10.9 to 7.3; p = 0.69). Metformin treatment reduced glycated hemoglobin levels, HbA1c, by -1.7 mmol/mol (95% CI: -3.0 to -0.3; p = 0.02) and reduced body weight by -2.2 kg (95% CI: -3.6 to -0.8; p = 0.003). Changes in EF, global longitudinal strain, and exercise capacity (VO2max) did not differ between groups.
Conclusions Metformin treatment in pre-diabetic HF patients with reduced EF improved myocardial efficiency by reducing myocardial oxygen consumption. These energy-sparing effects of metformin encourage further large scale investigations in pre-diabetic HF patients.

1281

Effects of combined uptitration of ACE-inhibitors and beta-blockers in heart failure with reduced ejection fraction

W Ouwerkerk[1]; THK Teng[1]; J Tromp[1]; WT Tay[1]; I Anand[2]; AM Richards[3]; AA Voors[4]; CSP Lam[1]
[1]National Heart Centre Singapore, Singapore, Singapore; *[2]Veterans Affairs Medical Center, Minneapolis, United States of America*; *[3]National University Heart Centre, Cardiovascular Research Institute, Singapore, Singapore*; *[4]University Medical Center Groningen, Groningen, Netherlands (The)*

Background: Both Angiotensin-converting enzyme(ACE)-inhibitors/Angiotensin receptor blockers (ARBs) and beta-blockersare guideline-recommended first line therapies in patients with heart-failure and reduced ejection–fraction (HFrEF); yet in real-world practice many patients are not on optimal combination treatment at target doses. We aimed to investigate the effect of combined uptitration of ACE-inhibitors/ARBs and beta-blockers on outcomes in real-world patients with HFrEF.
Methods: We studied 4,704 patients with HFrEF from the prospective longitudinal multinational European (BIOSTAT-CHF; n=2,100) and Asian (ASIAN-HF; n=2,604) studies. Patients were analyzed according to achieved % guideline-recommended doses (GRD) of combination ACE-inhibitor/ARB and beta-blocker therapy, with adjustment for indication bias by inverse probability weighting.
Results: Only 4% (n=190) and 21% (n=981) patients achieved 100% and 50% for both ACE-inhibitor/ARB and beta-blocker, respectively. The risk of death/HF hospitalization was lowest with achieving 100% guideline-recommended doses of both ACE-inhibitor/ARB and beta-blocker (hazards ratio [HR] 0.5; 95%CI 0.41-0.6), and highest with no therapy (HR 2.39; 95%CI 1.42-4) compared to those achieving at least 50% GRD of both) (Table). In combination therapy, increasing doses of ACE-inhibitors/ARBs resulted in greater reductions in risk of death/HF hospitalization, compared to increasing doses of beta-blockers. In fact, uptitration of beta-blockers in combination with suboptimal doses of ACE-inhibitors/ARBs was associated with increased risk of adverse outcomes (figure).Conclusion: While combined therapy with ACE-inhibitors/ARBs and beta-blockers at guideline-recommended target doses is associated with the best outcomes in HFrEF, our multinational real-world data suggest that when patients are on ACE-inhibitors/ARBs and beta-blockers, uptitrating ACE-inhibitors/ARBs may be of greater prognostic benefit than uptitrating beta-blockers.

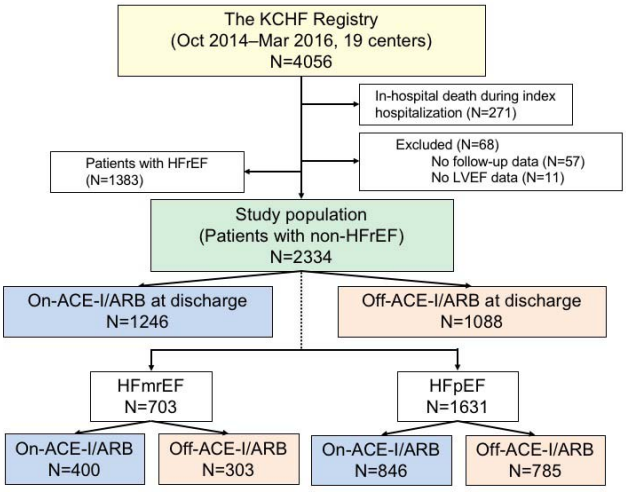
Angiotensin-converting enzyme inhibitors and angiotensin receptor blockers in heart failure patients with mid-range and preserved ejection fraction and clinical outcomes: from the KCHF Registry

Y Yoshikawa[1]; Y Tamaki[2]; H Yaku[1]; E Yamamoto[1]; N Ozasa[1]; Y Inuzuka[3]; T Morimoto[4]; T Kato[1]; T Kimura[1]

[1]Kyoto University Graduate School of Medicine, Department of Cardiovascular Medicine, Kyoto, Japan; *[2]Tenri Hospital, Department of Cardiology, Tenri, Japan*; *[3]Shiga General Hospital, Department of Cardiology, Moriyama, Japan*; *[4]Hyogo College of Medicine, Department of Clinical Epidemiology, Nishinomiya, Japan*

On behalf of: The KCHF Registry Investigators

Background Angiotensin-converting enzyme inhibitors/angiotensin receptor blockers (ACE-I/ARB) is an established medical treatment for heart failure with reduced ejection fraction (HFrEF), whereas it remains to be elucidated who derive merit from ACE-I/ARB in heart failure (HF) patients with left ventricular ejection fraction (LVEF) ≥40%. In the current guidelines, LVEF ≥40% has been divided into the following categories; heart failure with mid-range ejection fraction (HRmrEF) and preserved ejection fraction (HFpEF).
Purpose The aim of this study is to assess the association between ACE-I/ARB and clinical outcomes of HF patients with LVEF ≥40%.



Study flowchart

Methods The Kyoto Congestive Heart Failure (KCHF) Registry a multicenter registry without any exclusion criteria which included consecutive patients hospitalized for congestive HF in Japan. We classified the patients into the two groups according to medication status at discharge: those on ACE-I/ARB and those without ACE-I/ARB. We compared these two groups and their 1-year clinical outcomes. The primary endpoint was defined as a composite of all-cause death and re-admission for HF. We assessed hazard ratios (HRs) by the Cox regression model for the primary endpoint. Then, we subdivided the population into those with HFmrEF and HFpEF, and assessed HRs in each group and the interaction of the LVEF category. We also performed a sensitivity analysis by propensity score-matching method in each of the LVEF categories group for the primary endpoint.
Results A total of 4056 patients were enrolled, where 2334 patients had LVEF ≥40%. The study population was divided into those who were prescribed ACE-I/ARB at discharge (N=1246) and those not (N=1088). The multivariable analysis showed the adjusted hazard ratio (HR) of those on ACE-I/ARB relative to those without for the primary endpoint was marginally significant (adjusted HR 0.86 [95% confidence interval (CI) 0.74–1002], P=0.053). The subgroup analysis showed the HR was significant in HFmrEF group (N=703, adjusted HR 0.61 [95% CI 0.45–0.82], P=0.001), whereas the HR was not significant in HFpEF group (N=1631, adjusted HR 0.95 [95% CI 0.80–1.14], P=0.61); the interaction was statistically significant (P interaction=0.039). The propensity score-matched analyses showed a marginally significant HR in HFmrEF group (HR 0.73 [95% CI 0.50–1.07], P=0.10) and an insignificant HR in HFpEF group (HR 0.98 [95% CI 0.79–1.21], P=0.86).
Conclusions In the HF patients with LVEF ≥40%, ACE-I/ARB as discharge medication was associated with a lower HR for death and HF admission, especially in those with HFmrEF. ACE-I/ARB has a potential to be a treatment option for HFmrEF.

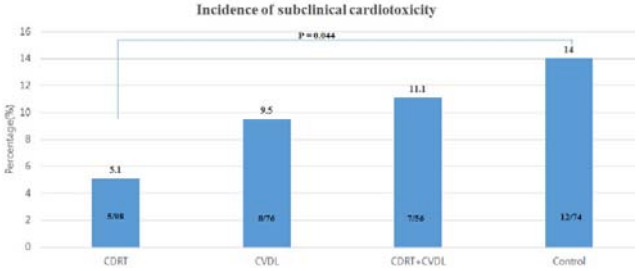
1283

The role of candesartan or carvedilol for prevention of anthracycline induced subclinical cardiotoxicity in breast cancer patients.

MH Myun-Hee Lee[1]; WB Chung[1]; BJ Song[2]; WC Park[2]; BJ Chae[2]; HJ Youn[1]

[1]Seoul St. Marys Hospital, Division of Cardiology, Department of Internal Medicine, Seoul, Korea (Republic of); *[2]Seoul St. Marys Hospital, Department of Breast Surgery, Seoul, Korea (Republic of)*

Background Despite of its effectiveness among breast cancer patients, anthracycline is associated with irreversible cardiotoxicity. But the effectiveness of prevention with angiotensin receptor blocker and/or beta blockers remains controversial.
Purpose: The Aim of this study is to investigate the preventive effect of concomitant therapy with candesartan and/or carvedilol in the anthracycline-induced subclinical cardiotoxicity (SC).
Methods We identified 485 patients with breast cancer with normal ejection fraction before receiving anthracycline chemotherapy at our institution between Dec,2013 and Nov,2017, randomly assigned to receive candesartan 4mg daily(n=98), carvedilol 3.125mg daily(n=84), candesartan 4mg daily plus carvedilol 3.125mg daily(n=63) and control(n=86). Cardiac functions of patients were evaluated by transthoracic echocardiography (TTE) before and after chemotherapy. Primary outcome was detection of SC (defined as either decreased left ventricular ejection fraction (LVEF) more than 10% or the LVEF declines under 55% from baseline without heart failure symptoms) after anthracycline chemotherapy. Secondary outcomes were effects of candesartan and/or carvedilol on diastolic dysfunction, left atrium (LA) size and left ventricle (LV) dimension.
Results: Primary endpoint occurred in 5 patients (5.1%) in the candesartan group, 8 patients (9.5%) in the carvedilol group, 7 patients (11.1%) in the candesartan plus carvedilol group and 12 patients (14.0%) in the control group. (Figure.1) A significant absolute difference in LVEF observed between chemotherapy (-0.85%, -2.11%, -1.81%, -1.45%, candesartan, carvedilol, candesartan+carvedilol, control, respectively). Compared to control, candesartan showed significant lower incidence of SC (p=0.04, OR=0.33(98% CI: 0.11-0.98)) (Figure.1) and demonstrated lesser decline of LVEF (-0.95% vs. -1.45%, p=0.054). Additionally, candesartan noted more protective effect against prevention of SC (p=0.266, OR=0.51(95%CI: 0.16-1.64)) and early decline in LVEF compared to carvedilol (-0.95% vs. -2.11%, p=0.024). No significant effect on diastolic dysfunction and overall change in LA size and LV dimension were observed in all study groups.
Conclusions In our trial, concomitant administration of low dose candesartan with chemotherapy significantly reduce incidence of SC and prevent LV dysfunction compared to control. Compared to carvedilol, candesartan also resulted in lesser decline of LVEF. However, there are no significant difference in terms of diastolic dysfunction and left heart chamber size.



Incidence of subclinical cardiotoxicity

Background: Initiation of sacubitril/valsartan (S/V) in hospitalised patients with heart failure (HF) with reduced ejection fraction (HFrEF), stabilized after admission for decompensated HF (ADHF), was associated with superior NT-proBNP reduction compared to enalapril in the PIONEER-HF study. Treatment effect was the same in patients with and without a prior diagnosis of HFrEF.

Table 1

Event	De novo HFrEF (N=286), n (%)	Previous diagnosis of HFrEF (N=705), n (%)	P-value
At least one AE	178 (62.2)	478 (67.8)	0.103
Selected AEs of interest			
Hyperkalemia	24 (8.4)	85 (12.1)	0.116
Hypotension	26 (9.1)	108 (10.9)	0.263
Cardiac failure	13 (4.5)	58 (8.2)	0.042

Temporary interruption due to AE	22 (7.7)	87 (12.3)	0.034

AE, adverse event

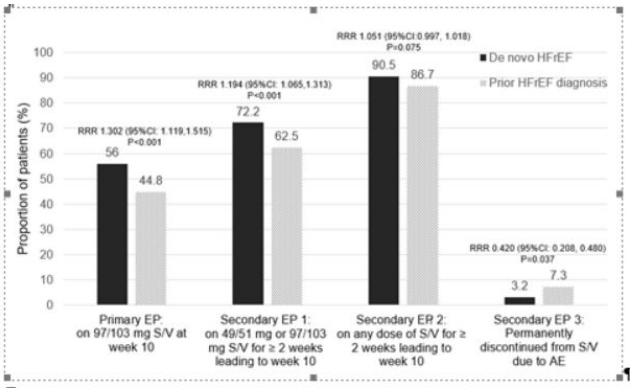

Figure 1. Primary endpoint (EP)

Methods: In TRANSITION (NCT02661217), 1002 patients with HFrEF, hospitalized for ADHF, after hemodynamic stabilization, were randomized 1:1 to start open-label S/V either pre-discharge or during days 1–14 post-discharge. Primary endpoint was the proportion of patients achieving the target dose of 97/103 mg S/V bid at 10 weeks. Endpoints, adverse events (AE) were compared by HF history status in the combined pre- and post-discharge arms.

Results: 286 patients (28.8%) had de novo HFrEF and 705 (71.0%) had a previous diagnosis of HFrEF. At baseline, de novo HF patients were younger, had lower systolic blood pressure, higher pulse rate, more non-ischemic HF, lower serum creatinine, higher e-GFR, lower high-sensitive Troponin T levels, and fewer had comorbidities. More de novo HF patients achieved the target dose compared to subjects with a prior HF diagnosis (56.0% vs. 44.8%, RRR 1.30, 95% CI 1.12, 1.52, P<0.001) and 90% were able to achieve and maintain any S/V dose (Figure 1). Serious AEs, temporary and permanent discontinuation of S/V due to AEs were lower in patients with de novo HFrEF (Table 1).
Conclusion: Patients with de novo HFrEF can be safely initiated on S/V and are more likely to achieve the target dose and maintain S/V treatment by week 10, compared to patients with a previous diagnosis of HFrEF.

Funding Acknowledgements: Netherlands Cardiovascular Research Initiative and a grant from the European Commission [FP7-242209-BIOSTAT-CHF; EudraCT 2010–020808–29]

Background: Guideline-recommended doses of angiotensin-converting-enzyme (ACE) inhibitors/angiotensin-receptor blockers (ARBs) and beta-blockers are similar for men and women with heart failure with reduced ejection fraction (HFrEF), even though there are known sex differences in pharmacokinetics of these drugs. We hypothesized that there may be sex differences in the optimal dose of ACE-inhibitors/ARBs and beta-blockers in patients with HFrEF.
Methods: We performed a post-hoc-analysis of BIOSTAT-CHF, a prospective study of HF patients in whom initiation and up-titration of ACE-inhibitors/ARBs and beta-blockers was encouraged by protocol. Findings were validated in an independent cohort (ASIAN-HF) of 3,539 men and 961 women with HFrEF.
Results: Among 1,308 men and 402 women with HFrEF from BIOSTAT-CHF, women were older (74 vs. 70 years, p<0.001), and had lower body weight (72 vs. 85 kg, p<0.001) and height (162 vs. 174 cm, p<0.001) than men. A similar % of men and women reached guideline-recommended target doses of ACE-inhibitors/ARBs (25 vs. 23%; p=0.61) and beta-blockers (14 vs. 13%; p=0.54). The lowest hazards of death and/or HF-hospitalization occurred at 100% of the recommended dose of ACE-inhibitors/ARBs and beta-blockers in men, but at only 50% of the recommended doses in women. These sex differences were still present after adjusting for clinical covariates including body surface area. In ASIAN-HF, similar patterns were observed for both ACE-inhibitors/ARBs and beta-blockers, with women having a better clinical outcome at significantly lower doses as compared to men.
Conclusion: The optimal doses of ACE-inhibitors/ARBs and beta-blockers may be lower in women than in men with HFrEF.

Background: Systolic ejection time (SET) is the phase of systole, during which blood is ejected from the left ventricle (LV). In heart failure with reduced ejection fraction (HFrEF), SET decreases (Weissler et al., Circulation1968). However, SET closely depends on heart rate and the data on SET in HFrEF stem from a time, when patients with HFrEF were naïve to HR-lowering drugs. In the general population, decreased SET was associated with increased risk of incident heart failure independent of cardiovascular risk factors and systolic LV function (Biering-Sørensen et al., Eur J Heart Fail2017). Together, it remains unresolved, whether SET is an epiphenomenon of tachycardia in HFrEF or might be per se a promising therapeutic target for advancing substances.Hypothesis: We hypothesized that ivabradine increases SET in patients with HFrEF through two mechanisms, 1) by lowering HR and 2) by improving LV systolic function.
Methods: We analysed data from the echocardiography substudy of the randomised, double-blind SHIfT trial (n=411 patients), which evaluated the effect of ivabradine on LV remodelling compared to placebo in HFrEF. Complete echocardiographic data were available at baseline and at 8 months after ivabradine treatment. Values are shown as means ± SD.
Results: At baseline, HR and SET were similarly distributed in patients assigned to placebo or ivabradine (HR: 71±12 bpm in both groups; SET: placebo, 284±34 ms; ivabradine, 291±38 ms; p=n.s.). SET inversely correlated to HR in both groups (placebo, r=-0.58; ivabradine, -0.55; p<0.0001, respectively), but without any differences of the slopes between groups (placebo, -1.63; ivabradine, -1.81; p=n.s.). After 8 months of treatment, HR decreased and SET increased in ivabradine, but not in the placebo group (HR: placebo, 69±13 bpm; ivabradine, 61±10 bpm; p<0.001; SET: placebo, 289±34 ms; ivabradine, 310±39 ms; p<0.001). If SET improvement was explained only by HR reduction, then the slope between HR and SET would be unchanged. However, the slope between HR and SET steepened in ivabradine-, but not placebo-treated patients (ivabradine, -2.58; placebo, -1.51; p<0.01). Especially in patients with HR <70 bpm, SET was increased by ivabradine versus placebo at any given HR, with the strongest improvements in those patients with the lowest HRs. Conclusions: Ivabradine increases SET by two mechanisms, one that is explained by the HR lowering per seand one that is independent of the HR-lowering effect. Both mechanisms are synergistic. The HR-independent effect may be related to the known effects of ivabradine on LV function, with improvements of LVEF and decrease in LV end-diastolic volumes.

1287

The importance of optimal dosing of ferric-carboxymaltose to treat iron deficiency

P Pieter Martens[1]; L Minten[1]; M Dupont[1]; W Mullens[1]
[1]Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium

BACKGROUND
Treatment with ferric carboxymaltose (FCM) beneficially influences symptomatic well-being and exercise capacity in heart failure with reduced ejection fraction (HFrEF) and iron deficiency (ID). However, the maximal dose of FCM during one administration is limited to 1gram, which is insufficient in patients with a higher body weight or low hemoglobin (Hb). The clinical relevance of sub-dosing remains unstudied, yet is common in clinical practice.
METHODS
We retrospectively assessed all HFrEF patients with ID receiving ambulatory daycare treatment with intravenous FCM between October 2015 and December 2017. This time-frame was chosen as during this time-frame we employed a treatment protocol of 1-gram FCM for all patients (unless Hb=14-15mg/dl, than 500mg). We compared the actual given dose (by protocol) versus the calculated target dose, based on Hb and weight, as calculated based on the dosing calculation in the SmPC of FCM (and tested in the CONFIRM-HF study; see figure panel A). The difference between the calculated target dose and the actual dose was calculated (termed dose deficit). Patients were typically followed-up after 12 weeks for clinical and laboratory re-assessment. We assessed the impact of dose deficits on clinical (NYHA-class) and biochemical (change in TSAT and ferritin) status.
RESULTS A total of 211 HFrEF-patients with ID (ferritin <100 µg/L or between 100-300 µg/L if TSAT<20%) received treatment with FCM during study follow-up. The actual given dose FCM was 918±188mg, while the calculated target dose was 1308±470mg. In 121(61%) patients a standard of 1-gram resulted in a dose-deficit, of whom 93 had a dose deficit of 500mg and 35 had a dose deficit of 1000mg. Clinical and laboratory follow-up was available in 81% of patients at a median of 12 weeks (IQR=9-16 weeks). A dose deficit of 500mg was associated with a 4.93 higher odds, while a dose deficit of 1000mg was associated with a 7.78 higher odds of residual ID at follow-up (figure panel B). After adjusting for baseline NYHA-class in an ANCOVA-model, a dose deficit was associated with less symptomatic improvement (figure panel C). During 442±292 days of follow-up, 68 patients were readmitted with heart failure and 15 patients died. In an univariate model, a dose deficit was associated with adverse clinical outcome. However, the significance of this association was lost after multivariate correction (figure panel D).
CONCLUSION
A majority of HFrEF patients with iron deficiency require doses exceeding 1 gram of FCM, and thus require follow-up appointments to correct a residual dose deficit. A residual dose deficit is associated with less functional and biochemical improvement.

Medical treatment of octogenarians with chronic heart failure: data from CHECK-HF

G Linssen[1]; J Veenis[2]; A Kleberger[1]; HP Brunner-La Rocca[3]; AW Hoes[4]; JJ Brugts[2]
[1]Hospital Group Twente, Almelo, Netherlands (The); *[2]Erasmus Medical Center, Cardiology, Rotterdam, Netherlands (The)*; *[3]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands (The)*; *[4]Julius Health Center - Julius Gezondheidscentra, Utrecht, Netherlands (The)*

On behalf of: CHECK-HF Investigators
Funding Acknowledgements: Servier, the Netherlands, funded the inclusion of data and software program.

Background/introduction: Elderly heart failure (HF) patients are underrepresented in clinical trials, though comprise a substantial number of patients in real-world practice. Particularly, data in octogenarians on actual use of HF therapies are scarce.
Purpose: to evaluate practice-based medical treatment of chronic HF patients aged >80 years, from a large registry at HF outpatient clinics.
Methods: We analyzed 3,490 octogenarians with chronic HF at 34 Dutch outpatient clinics in the period between 2013 and 2016. The mean age was 84.7 ± 3.6 years. Forty-nine percent were females. The study patients were divided into HF with preserved ejection fraction (HFpEF) (LVEF≥50% (n= 911 (26.1 %) and HF with reduced ejection fraction (HFrEF, LVEF <50% (n= 2,579 (73.9%)), according to the 2012 ESC HF Guidelines.
Results: Most HFrEF patients aged >80 years received a beta-blocker and a RAS-blocker, i.e. 77.0% and 71.6% respectively. An MRA was prescribed in 51.4% of patients and diuretics in 90.4%. All three of the HF medication (beta-blocker, RAS-inhibitor and MRA) were given in 28.7% of octogenarians with HFrEF. In total 65 patients (2.5%) received ivabradine, which represents 77% of them received those where it was indicated. At least 50% of target doses of beta-blockers, RAS-inhibitor and MRA were prescribed in 36.9%, 40.4% and 50.1% of the total group of octogenarians with HFrEF, respectively. In HFpEF, beta-blocker, RAS-inhibitor and MRA were used by 74.3%, 62.0% and 44.6% of patients, respectively.

Conclusion: The majority of octogenarians received guidelines-recommended HF medication. However, target doses of beta-blockers and RAS-inhibitor were prescribed in the minority. Although, it is unclear whether very elderly patients benefit to a similar extent from HF medication as compared to younger patients.

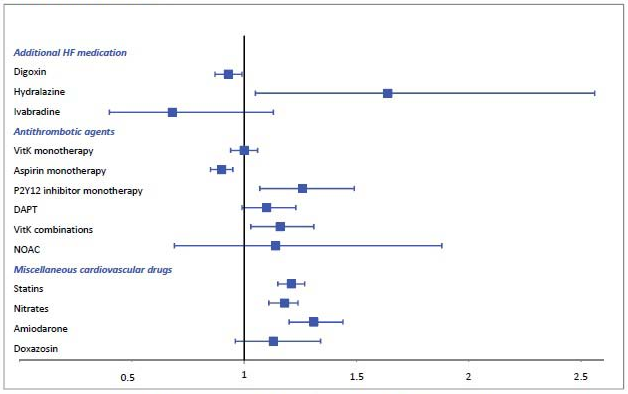
Association between cardiovascular medication and readmission in heart failure patients

W J Willemien Kruik-Kolloffel[1]; GL Linssen[2]; HJ Kruik[2]; EM Heintjes[3]; KLL Movig[4]; CJM Doggen[5]; J Van Der Palen[5]
[1]*Röpcke-Zweers Hospital, Clinical Pharmacy, Hardenberg, Netherlands (The)*; [2]*Hospital Group Twente, Cardiology, Hengelo, Netherlands (The)*; [3]*Pharmo Institute, Utrecht, Netherlands (The)*; [4]*Medical Spectrum Twente, Clinical Pharmacy, Enschede, Netherlands (The)*; [5]*University of Twente, Enschede, Netherlands (The)*

Introduction and purpose
Patients discharged after an admission for heart failure (HF) have a high risk of HF readmission. The aim of this population-based cohort study was to compare hospital readmission rates of HF patients using additional HF medication and/or non-HF cardiovascular (CV) medication versus patients not using the particular additional HF medication and/or non-HF CV medication in a real-world scenario.
Methods and results
Medication at hospital discharge was determined on the basis of dispensing data from the Dutch PHARMO Database Network including 22,476 patients with a diagnosis of HF between 2001 and 2015. Median follow-up was 29.3 months. Thirty percent of patients were readmitted for HF. Propensity scores were calculated as a proxy for comorbidities and hazard ratios were adjusted (HRadj) accordingly. The prescription of digoxin was associated with a decreased readmission risk (HRadj 0.93; 95%CI 0.87-0.99), aspirin monotherapy with a decreased risk (HRadj 0.90; 95%CI 0.85-0.95) and P2Y12 inhibitor monotherapy with an increased risk (HRadj 1.26; 95%CI 1.07-1.49) and. The risks of readmission for statins, nitrates and amiodarone were all significantly increased, with HRadj between 1.18 and 1.31.
Conclusion: Use of digoxin, added in selected HF patients on top of core HF medication according to the guidelines, was associated with a lower risk of HF readmission. On account of the lower risk of HF readmission, aspirin monotherapy should be preferred to P2Y12 inhibitor monotherapy. The risk of readmission for patients on statins, nitrates and amiodarone is increased, compared to patients not prescribed these drugs.

Figure 1 Forest plot for adjusted hazard ratios* associated with cardiovascular medication in heart failure patients



*HR versus non-use adjusted for age, gender, number of drugs (excl particular drug), year of admission, propensity score of particular medication (based on baseline covariates and co-medication)
DAPT: dual antiplatelet therapy (aspirin and P2Y12 inhibitor)

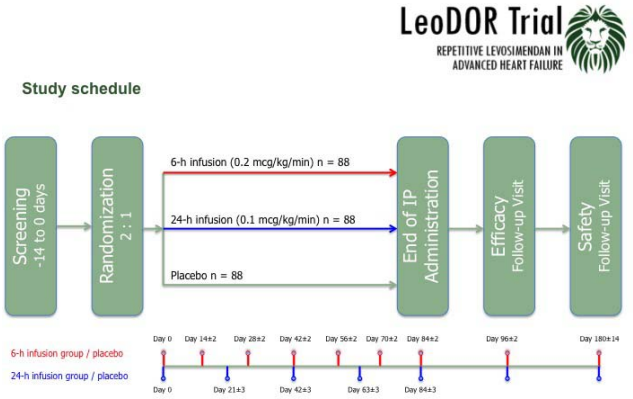
Funding Acknowledgements: Unrestricted grant from Orion Pharma

Background Readmission and mortality rates are high during the vulnerable period following an episode of acute heart failure. Experience in several clinical studies has indicated that administration of intravenous levosimendan in intermittent cycles may be effective in patients with advanced HF. We here describe the rationale and protocol of the LeoDOR study that will assess the efficacy and safety of intermittent levosimendan therapy during the vulnerable phase after a recent hospitalisation for acute HF in advanced HFrEF patients. The overarching hypothesis is that, compared with placebo, repetitive administration of levosimendan during the post-acute phase will be associated with greater clinical stability over a follow-up period of 14 weeks.
Methods The LeoDOR study is a randomised, double-blind, placebo-controlled, three-armed trial designed to evaluate the efficacy and safety of intermittent levosimendan therapy, administered in addition to standard therapy for a period of 12 weeks either as a 6-h continuous infusion at a rate of 0.2 μg/kg/min every 2 weeks or as a 24-h continuous infusion at a rate of 0.1 μg/kg/min every 3 weeks. The primary endpoint will be evaluated after 14 weeks. Information on safety events will be obtained after 6 months. The study that was started in March 2018 intends to include 264 patients in 30 centres in nine European countries.
The primary efficacy assessment will be made using a global rank endpoint in which all participants are ranked across three hierarchical groups: (i) time to death or urgent heart transplantation or implantation of a ventricular assist device (VAD); (ii) time to non-fatal HF requiring i.v. vasoactive therapy; and (iii) time-averaged proportional change in N-terminal pro-brain natriuretic peptide (NT-proBNP) from baseline to week 14 with (i) as the most important event. Secondary efficacy endpoints include individual components of the primary endpoint at short- (14 weeks) and intermediate-term (26 weeks) follow-up, as well as changes in functional status.
Conclusion The LeoDOR trial will test efficacy and safety of intermittent levosimendan therapy in patients with "very" advanced but not acute heart failure with the highest short- and long-term mortality and rehospitalisation rates. The study is configured to examine evidence of efficacy of an intensified therapy using clinically relevant endpoints for severely ill patients managed on an outpatient basis.



Study design of the LeoDOR Trial

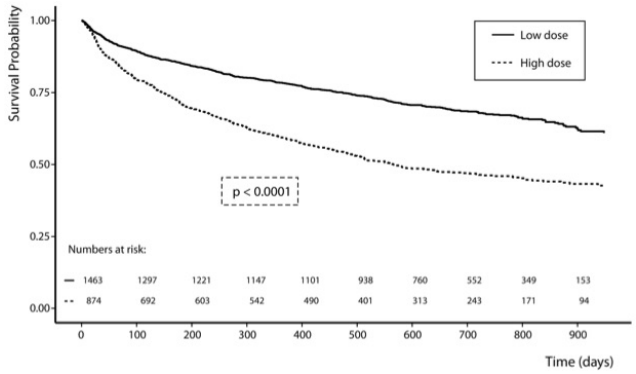
Higher doses of loop diuretics limit uptitration of inhibitors of the renin-angiotensin system in patients with heart failure and reduced ejection fraction

J M Jozine Ter Maaten[1]; P Martens[2]; K Damman[1]; AA Voors[1]; W Mullens[2]
[1]University Medical Center Groningen, Groningen, Netherlands (The); *[2]Hospital Oost-Limburg (ZOL), Department of Cardiology, Genk, Belgium*

Introduction Loop diuretics are frequently prescribed to patients with heart failure and reduced ejection fraction (HFrEF) for the treatment of congestion, however these might hamper the uptitration of inhibitors of the renin-angiotensin system.
Purpose We aimed to assess the effect of loop diuretic dosage on the ability to uptitrate patients to guideline recommended doses of inhibitors of the renin-angiotensin system, as well as to assess the association of loop diuretic dosage with outcome.
Methods Loop diuretic dose at baseline was recorded in 2,338 patients with HFrEF enrolled in BIOSTAT-CHF, an international study of HF patients on loop diuretic therapy who were eligible for uptitration of angiotensin-converting-enzyme inhibitors (ACEi)/mineralocorticoid receptor antagonists (MRA). The association between loop diuretic dose and uptitration of ACEi/MRA to percentage of target dose was adjusted for a previously published model for likelihood of uptitration and propensity score adjustment was performed.
Results Baseline median loop diuretic dose was 40 [40-100] mg of furosemide or equivalent. Higher doses of loop diuretics were associated with higher NYHA class and higher levels of NT-proBNP, more severe signs and symptoms of congestion, more frequent MRA use and lower doses of ACEi reached at 3 and 9 months (all P<0.01). The results remained statistically significant after adjustment for potential confounders. After propensity adjustment, higher doses of loop diuretics remained significantly associated with poorer uptitration of ACEi (beta per log doubling of loop diuretic dose: -1.66,P=0.021), but not with uptitration of MRAs (P=0.758). Additionally, higher doses of loop diuretics were independently associated with an increased risk of all-cause mortality or heart failure hospitalization (HR per doubling of loop diuretic dose: 1.06 (1.01-1.12), P=0.021).
Conclusions Patients with HFrEF and higher doses of loop diuretics had a worse uptitration of ACEi and a higher risk of death and/or heart failure hospitalization, independent of their lower likelihood of uptitration and higher baseline risk. These data support the recommendation that unnecessary high doses of loop diuretics should be avoided in order to uptitrate inhibitors of the renin-angiotensin system.



KM loop diuretic dose and outcome

Background: Renal replacement therapy is an addition to enhanced diuretic therapy, but there are no widely accepted indications for its use and timing of initiation.
Purpose: We intended to explore use of renal replacement therapy in heart failure population with diuretic resistance and figure out risk factors predicting a renal replacement therapy application in the end.
Methods: We searched the Multiparameter Intelligent Monitoring of Intensive Care Database III Version 1.4 (MIMIC-III v1.4) and identified heart failure patients with an ejection fraction of less than 40%. Diuretic resistance was defined as in need of more than 2 loop diuretic units per day. The primary outcome was application of renal replacement therapy. Secondary outcomes included in-hospital mortality, 30-day mortality, 90-day mortality, intensive care unit and hospital length of stay, total fluid intake, total fluid output, total urine output and total fluid overload. Models based on patient demographics, comorbidities, vital signs and laboratory results at addmission and occurrence of diuretic resistance was developed by logistic regression and random forest analysis to predict RRT application.
Results: We identified 1217 heart failure patients with an ejection fraction lower than 40% and diuretic resistant. Among them 7.6% ended up with renal replacement therapy. Cox proportional hazards models showed no difference of mortality between renal replacement therapy group and non renal replacement therapy group. Renal replacement therapy group showed shorter hospital stay and more total fluid output. AUCs of models including oxygen saturation and glomerular filtration rate at admission, albumin level, level of creatinine and glomerular filtration rate when diuretic resistance appears and so on were nearly 90%.
Conclusions: Renal replacement therapy did not increase mortality of moderate or severe heart failure patients with diuretic resistance. Models include oxygen saturation and glomerular filtration rate at admission, albumin level, level of creatinine and glomerular filtration rate when diuretic resistance appears are predictable of nearly 90% of renal replacement therapy application. Earlier use of renal replacement therapy in diuretic resistant moderate or severe heart failure patients might be acceptable.

Clinical Case Corner 4 - Have you seen this before? Rare presentations

Acute heart failure in pregnancy, do not forget zika and the pericardium.

K Gonzalez Carta[1]; I Morr[2]; IJ Mendoza Britto[3]; Y Meza[2]; JA Marques[2]; C Terzic[1]; F Lopez-Jimenez[4]; T Allison[4]; IJ Mendoza Mujica[2]
[1]*Mayo Clinic, Rochester, United States of America*; [2]*Central University of Venezuela (UCV), Tropical Cardiology, Caracas, Venezuela (Bolivarian Republic of)*; [3]*Jackson Memorial Hospital, Electrophisiology, Miami, United States of America*; [4]*Mayo Clinic, Cardiovascular Diseases, Rochester, United States of America*

Background. Acute heart failure (HF) during pregnancy is one of the most important complications, causing maternal and foetal morbidity and mortality. It is usually related to preeclampsia, rarely to myocarditis or pericarditis and it has not been associated to Zika virus infection (ZVI), considered the worst outbreak of the XXI century. There is only one report of HF associated with ZVI and none in pregnant women.
Case report . A 22-year-old G2P1 developed low-grade fever, conjunctivitis, polyartralgias, widespread pruritic maculopapular rash and mild myalgia at 36 weeks of gestation, five days after the onset of this acute episode was admitted to the hospital emergency with rapidly progressive dyspnoea NYHA IV. She had no appreciable past history before pregnancy and had normal blood pressure. The patient also experienced an episode of mild substernal chest pain. The electrocardiogram showed sinus tachycardia with low voltage. Chest X-ray exhibited bilateral pulmonary congestion and cardiac dilatation (cardiothoracic ratio 2:1, figure A). Echocardiogram revealed a moderate pericardial effusion with normal ejection fraction 61%. Zika induced pericarditis was diagnosed based on the following criteria: 1.) Zika RNA was detected in serum with the use of RT-PCR and ZV specific IgM antibody; 2.) Potential simultaneous infection including Dengue, Chikungunya, and other viral or parasitic infection were ruled out; 3.) Clinical, ECG, echocardiographic evidence of myocarditis was detected. The patient was treated with intravenous furosemide and aspirin as a holistic therapy. She had a favourable outcome with disappearance of symptoms, ECG improvement, normalization of X-ray findings, and resolution of pericardial effusion on echo control. Two weeks later she developed pre-eclampsia and caesarean section was performed. Her new born, male weighed 2600 mg and Apgar score was 3/5, uneventful development and without microcephaly.
Discussion. Zika virus infection is usually mild with non-specific symptoms. Cardiovascular (CV) complications might be underdiagnosed in clinical practice. Therefore the importance of CV screening in suspected cases, and awareness of the possibility of cardiac involvement in patients with Zika.
Conclusion. This is the first report of cardiac involvement with acute HF and pericardial effusion in a pregnant patient with Zika. This case is unique since the patient previously known to have normal cardiac function developed rapidly progressive acute HF. Future research is needed to determine the incidence of cardiovascular involvement of Zika virus infection.

Right heart failure related to diffuse large b cell lymphoma

AG Florescu[1]; A Bouali[1]; G Salles[2]; P-Y Courand[1]
[1]*Civils Hospices of Lyon, Cardiology Department, Hôpital de la Croix-Rousse et Hôpital Lyon Sud, Lyon, France*; [2]*Civils Hospices of Lyon, Hematology Department, Hôpital Lyon Sud, Lyon, France*

Isolated right heart failure requiring a specific work-up regarding the etiology: We report the case of a 76 year-old man admitted in our department for the clinical presentation of the aforementioned condition. His past medical history included refractory diffuse large B cell lymphoma (currently treated with Rituximab and Lenalidomide), type A thoracic aortic dissection surgically treated with a Tirone-David procedure (bioprosthetic aortic valve), complete atrio-ventricular block implanted with dual-chamber pace-maker (PM), a successful ablation for atrial flutter and deep vein thrombosis on left internal jugular Port-a-Cath.
Clinical examination: at admission in our department, we observed major bilateral edema, systolic murmur heard in all auscultation sites and diastolic murmur on the left sternal border. 12-lead ECG demonstrated right ventricle pacing. Transthoracic echocardiography showed: a preserved systolic left ventricular function (LVEF at 55%), mild aortic and mitral regurgitations. The right atrium and ventricle were severely dilated (RV/LV ratio > 1). Right systolic function was reduced (TAPSE 9 mm, DTI S' velocity 9 cm/s) and color Doppler indicated a severe tricuspid regurgitation. Right atrial pressure was estimated above 15 mmHg. Transeosophageal echocardiography (TEE) noticed: no left to right shunt, tricuspid valve infiltration with a nodular lesion, spontaneous contrast in the right atrium and multiple abnormal masses in the lateral wall of the right atrium and ventricle. Pace-maker leads and valves were cautiously observed and no sign of infective endocarditis was retained. Treatment with intravenous diuretics was started with a progressive regression of fluid overload.
We discuss the potential differential diagnosis of the intra-cardiac masses observed. Many hypotheses were supposed: thrombi (echogenicity, spontaneous contrast in the right ventricle), infective endocarditis (IE) (presence of a pace-maker and immunosuppression due to chemotherapy) and infiltration by the lymphoma (multiple sites of infiltration already present on previous PET-CTs and history of lymphoma). Infective endocarditis was ruled out by a complete biological check-up (blood cultures, serology). We also analyzed the differential diagnosis that could explain the right heart failure: tricuspid regurgitation induced by a PM lead, left to right shunt induced by the aortic surgical procedure, pulmonary hypertension other than the one classified as WHO Group II, other diseases in relationship with the masses showed by the TEE, infiltration by lymphoma and pulmonary embolism (PE). The final diagnosis was made with PET-CT which demonstrated an infiltration of the anterior wall of the right atrium adjoining the tricuspid valve, of lymphomatous nature and no argument for IE, PE or intra-cardiac thrombi.

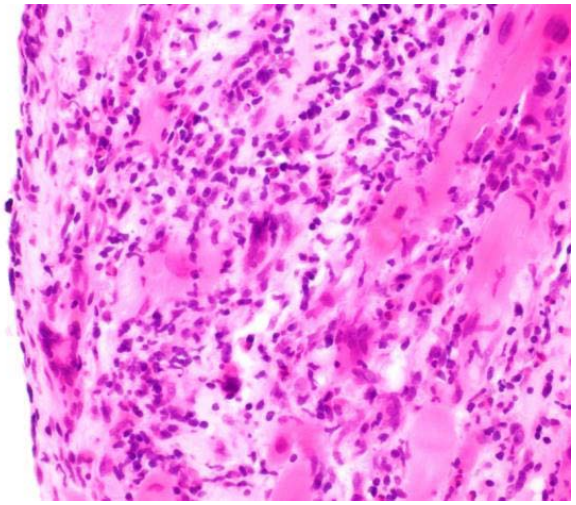
1325

P-wave asystole in a 26-year-old male; a complex clinical course

PF Brennan[1]; O King[2]; J Coburn[1]; LJ Dixon[1]
[1]*Royal Victoria Hospital, Cardiology, Belfast, United Kingdom of Great Britain & Northern Ireland*; [2]*Royal Victoria Hospital, Pathology, Belfast, United Kingdom of Great Britain & Northern Ireland*

A 26 year-old male, with a history of ulcerative colitis (UC), presented acutely with syncope, 8 days after returning from travelling in Thailand. An initial 12-lead electrocardiogram (ECG) demonstrated complete heart block with a broad (RBBB) escape rhythm. He was normotensive.
He had an elevated high sensitivity cardiac troponin T (cTnT) at 2949mg/L and NT-proBNP of 900pg/L. Due to episodes of P-wave asystole, a temporary pacing wire was inserted. An initial transthoracic echocardiogram (TTE) revealed severe left ventricular (LV) systolic impairment (LVEF 20%) with multiple regional wall motion abnormalities.
A cardiac MRI (CMR) was performed which showed biventricular dilatation and severely reduced biventricular function (LVEF 25%, RVEF 30%). Myocardial oedema

was present in the anterior septum and there was extensive delayed gadolinium enhancement, some of which was transmural, within both ventricles. These findings were suggestive of myocarditis and we opted to perform an endomyocardial biopsy (EMB) for definitive diagnosis (Picture 1). Cardiac sarcoid and atypical viral myocarditis were among the differential diagnoses.
The EMB demonstrated prominent multinucleated giant cells (GC) confirming a diagnosis of giant cell myocarditis (GCM). He was treated with oral prednisolone and cyclosporine. Due to ongoing pacing requirements with marked RBBB and NYHA II symptoms, despite optimal heart failure therapy, we implanted a cardiac resynchronisation device (CRT-D), after which his LVEF increased to 40% on TTE.
22 months later he was readmitted in cardiogenic shock. Cyclosporine had recently been switched to azathioprine after a flare of colitis. His cTnT and NT-proBNP were elevated at 236mg/L and 3462pg/L respectively. Repeat TTE demonstrated severe global biventricular dysfunction. We decided to perform cardiac catheterisation and repeat the EMB. His mean capillary wedge pressure (MCWP) was elevated at 24mmHg, with reduced cardiac output (3.1L/min) and index (1.4L/min/m2), respectively. An intra-aortic balloon pump was inserted and he was commenced on inotropes. Repeat EMB confirmed recurrent GCM. We commenced oral prednisolone, after methylprednisolone, and restarted cyclosporine. He received a single dose of the monoclonal antibody alemtuzumab. He was transferred, acutely, for transplant/ventricular assist device assessment but his condition stabilised and he was discharged 4 weeks later.
At 5years after recurrence of GCM he remains admission and arrhythmia free. He is NHYA class I on cyclosporine, mercaptopurine, sacubitril/valsartan, eplerenone and nebivolol. His NT-proBNP is 743ng/L.
The management of recurrent GCM often warrants cardiac transplant, but 5-year transplant-free survival is possible with medical therapy. In this case, we report the successful management of recurrent GCM with temporary mechanical ventricular support and inotropy, followed by cyclosporine-based immunotherapy which remains the gold standard treatment for GCM.



Endomyocardial biopsy (EMB)

Old therapies of new fashion: a better way to use diuretics and normal saline in acute decompensated heart failure

M Mapelli[1]; N Cosentino[1]; A Del Torto[1]; C Vignati[1]; V Mantegazza[1]; A Dalla Cia[1]; F De Martino[1]; J Campodonico[1]; G Marenzi[1]; PG Agostoni[1]
[1]Cardiology Center Monzino IRCCS, Milan, Italy

Clinical case: A 40 years old man was admitted for acute decompensated heart failure (ADHF). He was known for Arrythmogenic Right Ventricle dysplasia (ARVD) since 12 years. 3 years before admission a Cardiac Magnetic Resonance was performed showing RV dilatation with moderate biventricular dysfunction (RVEF 36%, LVEF 44%) and RV fibrosis (LGE+ with non-ischaemic pattern). Two years before admission he was hospitalized for ADHF with dyspnea. During hospitalization episodes of sustained ventricular tachycardia occurred. A coronary angiography was normal and a permanent ICD was implanted. On admission he was symptomatic for dyspnea (NYHA class III/IV), he reported reduced urine output and a weight increase of +12 Kgs in the last 4 weeks. On examination: respiratory rate 23/min with slight orthopnea, jugular vein distension at 45°, pitting edema at both legs and hepatomagaly. ECG showed sinus rhythm, atrial enlargement, small complexes in the peripheral leads with incomplete right bundle branch block and RV strain. An epsilon wave was noted in the anterior precordial leads (Fig.1A).
A cardiac echo showed a severe LV and RV dilatation and dysfunction (Fig.1B) while a cardiopulmonary exercise test showed exercise cardiogenic limitation with a peak Vo2 of 39% of the predicted and oscillatory breathing. Patient was treated with i.v. furosemide (40 mg bolus followed by continuous infusion) with matched de-hydration to obtain a more controlled and physiologically-oriented dehydration. This was achieved with the RenalGuard System. Current evidences on its use comes from studies on acute kidney injury prevention in patients undergoing intravascular contrast exposure. In this specific field, furosemide-induced high-volume diuresis with concurrent maintenance of intravascular volume through matched hydration, by the RenalGuard, is now considered a recommended strategy. In this patient we set an estimated daily targeted negative fluid balance of 2.4 liters (-100 ml/h, Fig.1C). Results are shown in Fig.1D.
In summary the patient was successfully treated with i.v. diuretics and normal saline matched with RenalGuard with a 7.5 Kgs weight reduction and NYHA class improvement. During the treatment kidney function didn't worsen (a mild improvement in creatinine and BUN was noted).
After one month he was on stable clinical condition with stable kidney function and he was started on Sacubitril/Valsartan according to the guidelines. He was also referred to a transplant center.

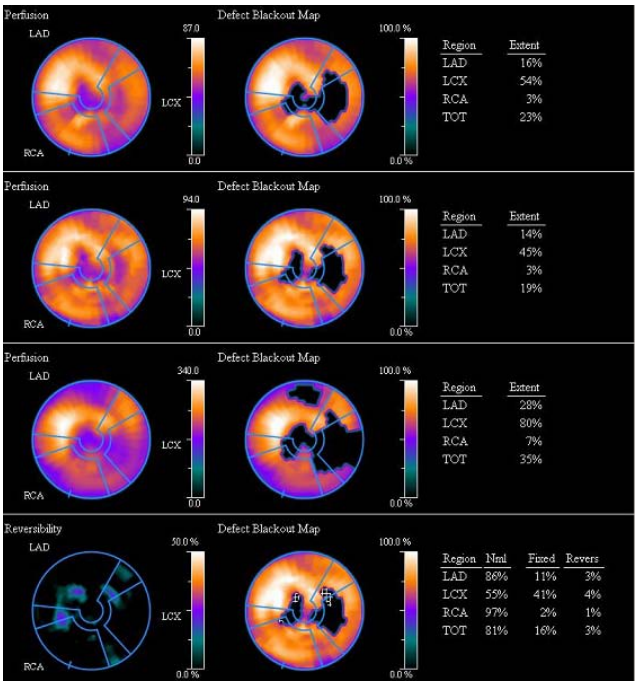
A new mutation causing arrhythmogenic right ventricular cardiomyopathy with atypical presentation

A Aimo[1]; A Barison[2]; GD Aquaro[2]; U Startari[2]; G Vergaro[2]; C Passino[3]; M Emdin[3]
[1]Azienda Ospedaliero-Universitaria Pisana, Scuola di Specializzazione Malattie dell'Apparato Cardiovascolare, Pisa, Italy; [2]Gabriele Monasterio Foundation, Pisa, Italy; [3]Sant'Anna School of Advanced Studies, Pisa, Italy

A 38-years old woman with referred familiarity for myocardial infarction (MI) was admitted to an Emergency Department because of chest pain. While biomarkers of myocardial necrosis and B-type natriuretic peptide were normal, and the electrocardiogram showed only a right ventricular (RV) conduction delay, transthoracic echocardiogram revealed diffuse left ventricle (LV) wall motion abnormalities and an apical aneurism. A coronary angiography demonstrated a normal coronary tree, leading to the diagnosis of "unstable angina with normal coronary arteries, possible prior MI."
A rest and stress myocardial perfusion imaging with 99mTc-sestamibi was negative for inducible ischemia, but showed "evidence of prior myocardial infarction (MI) in the anterior and apical regions of the LV." Even the findings at cardiac magnetic resonance (CMR) were deemed "compatible with previous MI" because of late gadolinium enhancement in the apical and inferolateral LV segments, and the thinning of LV apex. The RV was overlooked.
After discharge, a re-evaluation of CMR findings at another institution raised the suspicion of arrhythmogenic right ventricular cardiomyopathy (ARVC). Gene sequencing allowed to find homozygosity for the c.428 T>A mutation in the desmoglein gene (DSG2). Although not previously reported, this was considered a pathogenic variant as it produces a stop codon, which blocks protein synthesis after inclusion of 143 amino acids instead of 1119. A definite diagnosis of ARVC was then made (two major criteria: CMR findings and a pathogenic mutation).
Considering the ventricular ectopic burden (over 6000 ectopic beats during the 24 hours, with 100 couplets), the patient underwent mapping and ablation of an arrhythmogenic focus located into the LV apex. She then repeated the CMR

examination. The reader found "diffuse regional wall motion abnormalities and alterations of signal intensity within both ventricles, suggesting multiple, large areas of fibrofatty replacement." A single chamber defibrillator was eventually implanted for primary prevention. Cardiologic assessment and genetic screening of other family members is currently underway; the c.428 T>A mutation and CMR abnormalities have already been found in the patient's sister.
This is the first report of the c.428 T>A mutation as the cause of ARVC. It also demonstrates that the clinical and imaging presentation of ARVC may be misleading, so that a high index of suspicion is needed to come to the correct diagnosis.



1328

Clinical case of heart failure and atrial fibrillation due to long persistent migrated cava-filter in the right ventricle and tricuspid valve

A Yakushev[1]; O Paratsii[1]; B Kravchuk[1]; V Onishchenko[1]; A Rusnak[1]; R Maliarchuk[1]
[1]Amosov Institute of Cardiovascular Surgery AMS of Ukraine, Cardiac arrhytmias, Kiev, Ukraine

Introduction Cardiovascular diseases occupy leading positions in the structure of morbidity and mortality of the world's population. One of the problem areas is venous thrombosis, which includes thrombosis of deep veins of the lower extremities and it frequent life-threatening consequence - pulmonary artery thromboembolism (PAE). The main option of treating of venous thrombosis is anticoagulant therapy with additional strategies like the implantation of cava-filter (CF). Implantation of CF carries some risk of complications, one of which is the device dislocation which extremely rare can lead to heart failure (HF).
Aim of the work: to analyze the clinical case of dislocation and migration of the CF in the right ventricle with the development of HF
Results and discussion
Patient M. 71 y.o. come to our National Institute of Cardiovascular Surgery with NYHA III HF. From the anamnesis it became known that 10 years ago CF was implanted due to thrombosis of deep veins of the lower extremities and recurrent PAE, after which the patient did not undergo any medical examination at his will. In echocardiogram: severe tricuspid regurgitation and echo negative shadow of unknown etiology in the area of the tricuspid valve.
Performed CT revealed that the shadow of unknown etiology is migrated CF, most of which body is intimately adherent to endocard of the right ventricle and presses the septal leaflet of the tricuspid valve, leading to severe regurgitation. Patient undergone open heart surgery, during which CF was removed (Figure 1) tricuspid valvular anuloplasty was done, left atrial appendage was cut and MAZE-IV procedure was performed; sinus rhythm was restored.
The postoperative period was unremarkable. Control echocardiography showed an adequate function of the valves. To maintain the sinus rhythm, the patient was given amiodarone at a dose of 200 mg twice daily. At the examination 3 months after surgery, the patient have no complains no signs of HF. His ECG showed sinus rhythm, echocardiography - minimal tricuspid regurgitation.
The dislocation of implanted CF is a known complication of this procedure, which occurs in 10-12% of cases according to literature data. Migration of cava-filter into the cavity of the right ventricle with symptomatic tricuspid insufficiency is an extremely rare phenomenon, which is devoted to isolated publications of clinical cases in the world . Our clinical case is unique because the cava-filter has been in the right ventricle cavity for a long time (probably up to 9-10 years) and has been tightly entwined to the endocardium, which has led to the choice of open heart surgery in this patient.
Conclusion This clinical case broadens the understanding of possible complications of cava-filter implantation and emphasizes the need and importance for regular medical control of the position and function of medical implants.

Macropreparation of cava-filter

1329

A defect never comes alone. How many anomalies discovered by chance can hide a single heart?

R-D Robert-Daniel Adam[1]; A Nicula[2]; S Albu[1]; C Ginghina[1]; BA Popescu[1]; R Jurcut[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; *[2]University Emergency Hospital of Bucharest, Radiology, Bucharest, Romania*

Cardiomyopathies (CM) are a heterogenous group of myocardial diseases associated with mechanical and/or electrical dysfunction due to various causes that are most frequently genetic. Left ventricle (LV) noncompaction is a rare nonclassified CM affecting the LV or both of the ventricles consisting in the persistence of the fetal spongiform structure of the ventricular walls. The purpose of this presentation is to illustrate the importance of imaging techniques in the diagnosis of associations in a rare CM and the importance of family screening (FS) in genetic cardiovascular diseases.
We present the case of a 19-y-o patient with no significant medical history who was sent to our clinic for evaluation after an abnormal ECG finding that showed left atrial anomaly and a slight fragmentation of the ORS complex, lacking significant terminal phase anomalies. The patient is asymptomatic, with normal clinical examination, except for the lower limbs blood pressure which was with 10 mmHg lower than in the upper limbs. The lab work-up was also unremarkable, except for a slight elevation of the BNP levels (48 pg/mL).
Transthoracic echocardiography revealed normal LV dimensions and a noncompacted myocardium, especially in the apex, mild LV sysyolic dysfunction (LVEF 45%) with restrictive filling pattern, severe longitudinal dysfunction with particular apical sparing aspect of the GLS. Furthermore, a large interatrial septum aneurism, which protrudes towards the right atrium and a bicuspid aortic valve with a relatively normal function were discovered. Also, the thoracic descending aorta presented a turbulent flow, with a maximum velocity of 2.4 m/s (continuous Doppler) suggesting a large aortic coarctation. Echocardiographic findings were confirmed using cardiac MRI and thoracic aorta angioCT.
FS included both parents and his 10-y-o sister. On one hand, the patient's mother showed a slight trabeculated LV myocardium in the apex, but with a normal global and longitudinal systolic function, as well as an IAS aneurysm. The patient's sister was however intensely symptomatic (dyspnea at low-moderate physical activity and frequent respiratory infections) and was diagnosed with restrictive CM with

LV dysfunction due to myocardial noncompactation, associated with 2 small atrial septal deffects and pulmonary hypertention.
Although a rare cause of heart failure, noncompactation CM remains a notable diagnosis, especially in young patients with significant symptoms or ECG anomalies. In addition, reports show possible associations with other congenital heart defects such as atrial septal defects or bicuspid aortic valve. We stress the importance of FS and the significant intrafamilial phenotypic variability of the disease, as shown by the presence of different forms of severity in the same family, especially in its youngest members.

Right heart failure in basedow-graves disease: a tricky diagnosis

I Iacopo Casella[1]; M Buffa[1]; F Patti[1]; E Ubertini[1]; M Gravellone[1]; A Giubertoni[1]; C Piccinino[1]
[1]*University of Eastern Piedmont, Novara, Italy*

The thyroid function has a fundamental role in controlling cardiovascular system. Thyropathies can be associated with many patterns of cardiovascular disfunction, as heart failure and pulmonary vascular disease. The most common presentation of hyperthyroidism is high cardiac output biventricular heart failure; rarely it presents as isolated right heart failure associated with pulmonary hyperthension. A 69-year-old Caucasian man with a history of recent deep vein thrombosis of the legs in discontinuative anticoagulant therapy was hospitalized in another clinical division for heart failure. He was symptomatic for dyspnoea, the physical examination suggested right heart failure, brain natriuretic peptide was 2338 pg/ml. Transthoracic echocardiography showed an important dilatation of right heart chambers, moderate tricuspidal rigurgitation with severe pulmonary hypertension (pulmonary artery systolic pressure 62 mmHg), left ventricular ejection fraction was normal. He underwent a computed tomography angiography of the chest which ruled out pulmonary thrombosis. A right heart catheterization was performed and led to the diagnosis of a mild precapillary pulmonary hyperthension (pulmonary artery mean pressure 27 mmHg, wedge pressure 15 mmHg, cardiac index 3,9 L/mq, pulmonary vascular resistance 1,8 WU). These alterations were attributed to a referred chronic obstructive pulmonary disease, without any other investigations, and he was discharged after medical therapy. The next month he had a new episode of heart failure and he was admitted to our pulmonary hyperthension ambulatory for further investigations: pulmonary functional tests excluded a relevant pneumopathy, the rheumatological tests were negative, the endocrinological profile showed a basedow graves disease. A specific antithyroid therapy was started with a significant clinical and laboratoristic improvement, stable during time. Thyroid hormones may cause cardiovascular disfunction in many ways: blood volume increase and excessive preload, endothelial damage (due to inflammation, high cardiac output and autoimmunity), increased metabolism of intrinsic pulmonary vasodilators (prostacyclin and nitric oxide), decreased metabolism of vasoconstrictors (serotonin, endothelin-1 and thromboxane), stimulation of the sympathetic nervous system causing pulmonary vasoconstriction. Hyperthyroidism is associated with an increased risk of cardiac death. Even if pulmonary hypertension due to thyroid diseases has long been known, it is still underdiagnosed. Our case report demonstrates how important is to follow the recommended algorithm in order to achieve the correct diagnosis and to start as soon as possible the specific therapy. Nowadays there are no scientific evidences for using specific pulmonary vasodilators drugs in pulmonary hypertension associated to thyroid diseases. Antithyroid drugs are the therapeutic choice for these patients, with good long term prognosis.

1331

A sporadic or a familial case of left ventricular noncompaction?

D Bursacovschi[1]; R Negru-Cemortan[1]
[1]*Institute of Cardiology, Chisinau, Moldova (Republic of)*

Introduction: Left ventricular noncompaction (LVNC) is a rare congenital disorder that can be sporadic, but familial recurrence and associated dysmorphism has been reported. Diagnosis is challenging and often with a predilection for overdiagnosis. Progressive heart failure, ventricular arrhythmias and systemic embolic events are the classical triad of complications.
Clinical case description: We report a case of a 41-year-old male patient with signs of congestive heart failure during the previous 2 months. He had no chest pain, palpitations, or syncope. Physical examination revealed bilateral crackles in the lower-lung fields and edema of the lower extremities. The electrocardiogram showed a sinus rhyth, 85 beats/min and a few premature ventricular contractions. Ambulatory ECG (Holter) monitoring (24h) registered frequent premature ventricular contractions. Transthoracic echocardiography (TTE) showed a severe dilatation of all heart chambers, a severe reduced ejection fraction (EF 25%), diffuse hypokinesia and a lot of trabeculae located on the posterolateral wall of the left ventricle (LV) and apex (Picture 1, 2). The blood flow into the intertrabecular recesses. The Jenni (2001) criteria for the diagnose of LVNC where positive. The lateral wall of right ventricle was highly trabeculated and the contraction was poor. Third degree LV diastolic disfunction, moderate regurgitation of mitral and tricuspid valves, severe signs of pulmonary hypertension. The CMR analysis showed non-compact myocardium at the level of left and right ventricles, the ratio of non-compacted myocardium to compact myocardium was 5:1 at the postero-lateral wall and of 8:1 at the apex of the LV. From first-degree relatives, patient's father has no cardiac pathologies. Patient's mother was diagnosed with dilatative cardimyopathy (DCM) 7 years ago. The remodeled LV examined through repetead TTE made it difficult to exclude DCM. Further, we examened the patient's daughter (14 years old, asymptomatic), through TTE we identified small trabeculation localized on posterolateral wall and apex of the LV. The girl's CMR ratio of non-compacted myocardium to compact myocardium at the end of systole was 1:2.5 and the mass of trabeculation was 33% with a slightly decreased EF (47%). Patient's brother and nephew showed no cardiac abnormalities. Medical management of the patient included: β-blockers, ACEI, a loop diuretic, spironolactone, digoxin and warfarin. We obtained a significant improvement in dyspnea and a reduction of peripheral congestion at one month follow-up.
Questions: LVNC is a distinct cardiomyopathy or a morphological expression of different cardiac diseases? Still no gold standard exists for diagnosis and the applied criteria lack specificity, especially in children. So there is a large diagnostic 'grey area' between LVNC, DCM and even normal myocardium. It is unknown whether the prognosis could be improved by early diagnosis and treatment.

Objective: When genetic mutations or teratogenic effects occur on the fetus in the early stages of embryogenesis, a three-compartment heart can develop, considered as severe congenital defect. This clinical case demonstrates the patient with a single ventricle of the heart who reached 56 years old without surgery.
The patient K., female, 56 years old, was admitted to our cardiological intensive care unit with complaints of hemoptysis. It was known that the patient had a congenital heart defect - single left ventricle, accompanied by the secondary

erythrocytosis, congenital complete proximal atrioventricular block and history of nasal bleeding caused by thrombocytopenia. The patient underwent a multispiral computer arteriotomography (MCTA) of the chest. MCTA revealed: Defects of contrasting in the subsegmental arteries A1, A2, A6, A8, A9 (red arrows) of the right lung and A9, A10 of the left lung; in the lower lobes of the lungs areas of infiltration of the pulmonary parenchyma were determined ("frosted glass" type). It was noted that there were venous collaterals of the mediastinum, more to the left. Those vessels allowed bypath blood flow to the right atrium through the v.azygos, v.hemiazygos (system of the vena cavasuperior) and vv. lumbales (system of the vena cavainferior) (Yellow arrows).

Echocardiography revealed single LV with eccentric hypertrophy and dilatation, with preserved global contractility of their function, EF - 57%, no areas of local LV discontractility were detected. Mitral valve cusphas diffuse thickening and tightening with severemitral regurgitation (degree III), the calculated bloodpressure in the pulmonary artery was not increased. (Picture 1)

Haematology: Haemoglobin 251 g/l, RBC - 7.83 x 1012 / l, Haematocrit 73.7%, Platelets 39.15 x 109 ESR - 0 mm / h. Coagulation profile: APTT 118.8 seconds, PT 26.9 seconds, INR 2.56 D-dimer was 2311.13 ng / ml (normal range - 0-250 ng / ml).

The patient underwent daily ECG monitoring: bradycardia with a heart rate of 34 to 51 (average 41) beats / min., complete AV-blockproximal type), episodes of replaced rhythm from the AV-node, numerous atrial extrasystoles were observed.

Summary. Single ventricle is a condition characterized by poor prognosis. Most patients (75%) without treatment die during the first months of life from rapidly progressive complications, such as severe heart failure, fatal cardiac arrhythmias, pulmonary embolism, and severe pneumonia. The average life expectancy of such patients is about 6-7 years [1]. Our clinical case describes the only left ventricle in a 56-year-old woman without pulmonary stenosis. It is known that the survival rate of persons with pulmonary artery stenosis is higher, due to the slower development of congestion in the pulmonary circulation. Only isolated cases of survival of such patients up to 50 years old were described.

On behalf of: EPICTER investigators group

Introduction Palliative care in patients with advanced heart failure (HF) is strongly recommended by Clinical Practice Guidelines. However, limited data exist on the real use of End-of-life care in patients admitted for acute HF.
Purpose To calculate the prevalence of end-stage HF in patients admitted for decompensation and to describe their characteristics, treatments, procedures and management.
Method A total of 3153 patients admitted with acute HF in 74 spanish hospitals were consecutively included in 2 different periods (winter and summer), and followed up for 6 months. Hospitals began collecting data on the same day, in which all patients admitted for HF should be included. Each hospital continued to include patients on subsequent days until the required number was completed. Patients were classified into 2 groups according to whether or not they met criteria for end-stage HF. To define end-stage HF, a combination of cardiac and general criteria was used (including functional class, left ventricular ejection fraction (LVEF), physical and functional deterioration, multiple readmissions, estimated survival less than 6 months...). The groups were compared.
Results 23.4% of patients (739) met criteria for end-stage HF. They were more likely to be women, older and to have a history of anaemia, chronic kidney disease and cognitive impairment. Compared to patients that did not meet criteria, they had more often reduced LVEF and higher levels of natriuretic peptides. The most frequent symptom among these patients was dyspnea (90.7%), followed by insomnia (48.7%) anxiety (46.8%) and erratic pains (37.7%). For the management of acute HF, furosemide infusion (29.6%) and vasodilators (21.0%) were mainly used. Refractory symptoms were treated with intravenous and subcutaneous opioids (46.9%), benzodiazepines (44.1%), phenothiazines (21.8%) and anticholinergics (6.2%). A multidisciplinary approach, involving Palliative Care specialists was only sought in 15% of the end-stage HF patients. The use of invasive procedures was: angiography (10.1%), central venous catheters (10.7%), reservoirs (14.6%) and bladder catheters (57.2%). Although in more than half of the patients there was an agreement to avoid unnecessary tests and not to resuscitate (Figure 1), in 47.8% of the patients palliative care were only provided on the agony. Patients with end-stage HF had significantly higher 6-month mortality than the rest of the patients (44.5% vs. 17.6%; p <0.001)
Conclusion The prevalence of end-stage HF in patients admitted to hospitals is high. It is associated with advanced age and comorbidities. The use of therapeutic procedures should be carefully evaluated with the priority to improve the quality of life of patients. The management by a multidisciplinary team, following the recommendations of the Guidelines, is only sought in a small number of patients.

Heart failure and palliative care: an integrated service for patients across hospital and community settings

F Hodson[1]; M Al Barjas[2]; S Karwatowski[3]; R George[1]; J Ross[1]
[1]St Christopher's, Palliative Care, Kent, United Kingdom of Great Britain & Northern Ireland; *[2]Kings College Hospital, London, United Kingdom of Great Britain & Northern Ireland*; *[3]Princess Royal University Hospital, Orpington, United Kingdom of Great Britain & Northern Ireland*

Background: Effective integration of care across care settings and between clinical teams is essential to improve patient reported outcomes and resource use. We evaluate a new integrated clinical service for patients with end-stage heart failure (HF) palliative care (PC) needs.
Method: Six GP practices referred patients over 1 year. Patients were assessed and followed up by an Advanced Nurse Practitioner (ANP). The ANP worked closely with cardiology consultants and HF/PC hospital teams, the Community PC Team and primary care colleagues. Following initial assessment, patients were discussed at joint multidisciplinary team meetings (MDM) to assess both cardiac and palliative needs. Patient reported outcomes included the Integrated Palliative Care Outcome Scale (IPOS) and quality of life (QUAL).
Results: 102 patients, mean age 84.2 $\pm$ 10.2 years, were referred, 89 were accepted onto the pilot. 55 (61.8%) had left ventricular systolic dysfunction (LVSD), 14 (15.7%) patients had HF with preserved ejection fraction, 13 (14.6%) had predominately valvular dysfunction, 5 (5.6%) had right sided HF. This frail, elderly population had multiple co-morbidities.
44% of patients died during the 18 month pilot period; 69% at home/hospice versus 31% in hospital. For most patients, preferred place of care and death were home. Compared with the year pre-pilot, we demonstrated a 36% reduction in hospital admissions with 51% reduction in hospital bed days. There was a 9% increase in A&E attendances, but the proportion attending for cardiac reasons reduced (20% versus 13%). Actions from the MDM meetings included almost a half of patient's having cardiac medications titrated and a quarter had other medications titrated to aid symptom control. Joint decisions regarding switching or stopping anticoagulation were key. A small number of patients received hand held echocardiography and assessment at home by the cardiology consultant or were treated with subcutaneous Furosemide in the home setting, both to guide management and avoid hospital admissions where preferred place of care was home. The pilot supported integrated care across settings including referrals to hospice (inpatient admissions, breathlessness management service, living well at home), Community Services (District nurses, OT and Physio, Respiratory nurses). Ongoing carer support from the ANP was key.
IPOS improved over time in 55% of patients; declined in 40% and the remainder stayed the same. Views on Care showed that in 82% of assessments support from the palliative care service had made a benefit and patients reported a significant improvement in QUAL (p<0.001, 7 point Likert scale).

Conclusion: This model of care has had significant benefits in reducing hospital bed days and admissions, increasing patients dying outside of hospital, providing timely support and care to improve symptoms and wellbeing for palliative patients (and their carers) with end-stage heart failure.

Background/Introduction: Despite published guidelines emphasizing the importance of education in management of Heart Failure (HF), the most effective method of educating remains unknown.
Purpose: The purpose of this study was to test the efficacy of Constructivist Teaching Method (CTM) on the patients with HF.
Methods: This is a single-center, randomized controlled trial. Patients in the intervention group were educated using the CTM. For the study outcome measures five questionnaires were used: Atlanta Heart Failure Knowledge Test (AHFKT), Minnesota Living with Heart Failure (MLHFQ), Self-Efficacy for Appropriate Medication Use Scale (SEAMS), European Heart Failure Self-care Behaviour Scale (EHFScBS-9), Duke Activity Status Index (DASI).Repeated measurements analysis of variance (ANOVA) was used in order to investigate differences in study measures between the control and intervention group, during the six month follow up.
Results: A total of 122 adults (83.6% male, mean age ±SD 67.1±12.3 years) were enrolled in the study; 61 in the intervention group and 61 in the control group. The two groups were similar in terms of age, educational level and disease status. Concerning knowledge there was a significant improvement in both control and intervention group but the degree of improvement was greater in the intervention group ($p<0.001$). Minnesota dimensions for quality of life were also significantly improved in both study groups but at 6 months the intervention group reached better levels at both physical and emotional subscales ($p<0.001$). Furthermore, self-efficacy for medication adherence and the dimensions from EHFScBS-9 (adhering to recommendations, fluid and sodium management, physical activity and recognition of deteriorating symptoms) were improved in both groups but the degree of change was greater in the intervention group as indicated from the results of repeated measurements ANOVA ($p<0.001$). The functional capacity was improved only in the intervention group ($p<0.001$) and no significant change was found in the control group ($p=0.455$). Significantly lower proportion of readmission at hospital at one month (8.2% vs. 23%, $p=0.025$), and six months (13.1% vs. 36.1%, $p=0.003$) were found for the intervention group.
Conclusions: These data support the use of an intervention with CTM to improved clinical outcomes. This study will be an important step in creating an evidence base for the relative benefits of different educational strategies for management of HF.

Funding Acknowledgements: BIOSTAT-CHF was funded by a grant from the European Commission (FP7-242209-BIOSTAT-CHF; EudraCT 2010–020808–29).

Background: Heart Failure (HF) is associated with poor quality of life (QoL). Less is known about sex differences in QoL and their association with outcome in HF.
Aim:Our aim is to analyse sex differences in QoL and in the relationship between QoL and outcome in patients(pts) with HF and reduced ejection fraction (HFrEF).
Methods:We analysed 1216 HFrEF pts from BIOSTAT-CHF, all with Kansas City Cardiomyopathy Questionnaire overall score(KCCQos), EQ-5D visual analogue scale(VAS) and EQ-5D utility score(US). Higher scores reflect better health status. We used multivariable Cox regression to test the relationship between QoL with all-cause mortality and with all-cause mortality and/or HF hospitalization. 5-point change(pc) in KCCQos and EQ-5D VAS (range 0-100), and 0.1 pc in EQ-5D US(range -1 to 1) were considered because of clinical meaning and comparable magnitude.
Results: At baseline, mean±SD age was 66±12 years old, 81.9% pts were males, 62.4% had ischemic HF. Females had worse QoL when assessed with KCCQos and EQ-5D US, but not EQ-5D VAS (Figure). KCCQ and EQ-5D components showed more physical and social limitation in females. After adjustment for clinical confounders, all measures of QoL were independent predictors of both outcomes in the whole sample and in males. A non-significant trend was present for better outcomes in females with higher QoL scores(Table). For both outcomes, there was no interaction between QoL and sex (all $p>0.5$). KCCQos-based multivariable model was the best at predicting both outcomes in the entire sample and in males (all $p<0.001$).
Conclusions: In pts with HFrEF, QoL was worse in females than in males. Sex differences in QoL are better detected and characterized by KCCQ. QoL was an independent predictor of outcome in the whole sample and males, with a similar trend in females. KCCQos showed the best predictive value towards outcome.

Table. Association of QoL and outcome

Predictor	Population	Adjusted* HR (95% CI)for all-cause mortality	P value	Adjusted* HR (95% CI)for all-cause mortal-ityand/or HF hospitaliza-tion	P value

Exercise capacity is negatively associated with cerebral white matter hyperintensity in elderly patients with heart failure

A Akihiro Hirashiki[1]; K Kawashima[1]; K Nomoto[1]; M Kokubo[1]; A Shimizu[1]; H Arai[1]
[1]*National Center for Geriatrics and Gerontology, Obu, Japan*

Background: The extent of cerebral white matter hyperintensity (WMH) on magnetic resonance imaging (MRI) increases with age. Frailty associated with aging produces subclinical dysfunction across multiple organs and increases the risk of death. There is little information about the relationship among the extent of WMH, frailty status, and exercise capacity in patients with heart failure (HF).
Aims: To clarify the relationship among WMH, frailty, and exercise capacity in patients with HF.
Methods: Seventy-eight stable elderly patients with HF were subjected to cardiopulmonary exercise testing (CPX) and evaluated for WMH and with the Kihon Checklist (KCL), on which a score of ≥8 indicates frailty. WMH volume was quantified on brain MRI. Patients were classified into three groups (using tertiles of 0.52% and 1.05%) according to WMH as a percentage of intracranial volume, and their KCL scores and exercise capacities were compared.
Results: Mean age was 80.0 years, mean left ventricular ejection fraction was 56.7%, mean plasma brain natriuretic peptide content was 181 pg/mL, and mean KCL score was 8.7. The three WMH groups were mild (n = 26, 0.26% ± 0.14% of intracranial volume); moderate (n = 26, 0.70% ± 0.15%), and severe (n = 26, 1.75% ± 0.67%). Although there were no significant differences in Mini Mental State Examination scores, peak VO2 was 15.2 ± 3.7 mL/kg/min in the mild WMH group, 12.9 ± 3.5 mL/kg/min in the moderate group, and 11.4 ± 2.3 mL/kg/min in the severe group (mild vs. moderate, P = 0.049; mild vs. severe, P = 0.001). The KCL score was 6.6 ± 4.7 in the mild WMH group, 8.4 ± 6.0 in the moderate group, and 11.6 ± 5.6 in the severe group (mild vs. severe, P = 0.008). Linear regression analysis showed a positive association between WMH and peak VO2 (r = −0.344, P = 0.004) and between WMH and KCL score (r = 0.276, P = 0.021).
Conclusions: Frailty status was significantly positively associated, and exercise capacity was significantly negatively associated, with WMH percentage volume in stable elderly patients with HF. WMH volume may be useful for assessing the frailty of stable elderly patients with HF.

1338

Variation of exercise oscillatory ventilation characteristics is related to the severity of chronic heart failure

N Panagopoulou[1]; S Dimopoulos[1]; V Zarvalias[1]; P Ferentinos[1]; A Ntalianis[2]; C Kapelios[3]; D Delis[1]; A Sideris[4]; S Nanas[1]; E Karatzanos[1]
[1]*Clinical Ergospirometry, Exercise & Rehabilitation Laboratory, School of Medicine, NKUA, Athens, Greece*; [2]*University of Athens Medical School, Department of Therapeutics, Athens, Greece*; [3]*Laiko General Hospital of Athens, Cardiology Department, Athens, Greece*; [4]*Evaggelismos General Hospital of Athens, 2nd Cardiology Department, Athens, Greece*

Introduction: To date, presence of exercise oscillatory ventilation (EOV) is associated with increased severity and poor prognosis in chronic heart failure (CHF) patients, but the relationship between EOV characteristics with CHF severity has not been investigated.
Purpose: To investigate the relationship between EOV characteristics with indices of functional capacity and severity in CHF.
Methods: Three hundred eighty-seven consecutive patients with stable CHF (LVEF <50%, age: 55±12years) underwent a maximal cardiopulmonary exercise testing (CPET) and were evaluated for EOV presence according to EOV criteria (amplitude of exercise ventilatory cycles ≥15% of the average resting amplitude, lasting ≥60% of total exercise duration). Correlations were made in two hundred-eighteen patients presenting EOV between each EOV characteristic [duration (d), length (λ), amplitude (h or h%)] with parameters of CPET (VO2peak, VO2peak predicted, VE/VCO2 slope, VO2/t slope). The same patients were divided into groups according to the median value of each EOV characteristic [d:80%, λ:46.8sec, h%:12.9%] and expressed as mild (M) or severe (S) when their values were < or ≥ of the median value respectively. (M) and (S) groups for each EOV characteristic were compared for CPET parameters. Values are expressed as mean ± standard deviation.
Results: Length (λ) and amplitude (h%) ($p<0.05$) but not duration (d) ($p>0.05$) were correlated with cpet variables examined. Comparison between (M) and (S) groups for each EOV characteristic showed that dM did not differ from dS ($p>0.05$) as for parameters examined, while λM and h%M had higher values of functional capacity indices compared to λS and h%S respectively ($p\leq0.05$, Table 1).
Conclusions: Length and amplitude of EOV were found to relate to functional capacity and hence to severity in CHF. Specifically, increased values of them are associated to lower functional condition potentially reflecting greater haemodynamic and ventilatory abnormalities. More research is required to clarify clinical and prognostic significance of EOV characteristics in CHF.

	dM <80% (N=107)	dS≥80% (N=111)	λM <46.8sec (N=109)	λS ≥46.8sec (N=109)	h%M <12.9% (N=109)	h%S ≥12.9% (N=109)

Skeletal muscle dysfunction in patients with heart failure with preserved compared to reduced ejection fraction: association with an elevated level of pleiotropic cytokine (GDF-15)

T Bekfani[1]; S Derlien[2]; A Hamadanchi[1]; J Nisser[2]; E Froeb[1]; M Lichtenauer[3]; B Wernly[3]; G Dannberg[1]; UC Smolenski[2]; G Lehmann[4]; G Wolf[4]; S Moebius-Winkler[1]; PC Schulze[1]
[1]*University Hospital of Jena, Department of Cardiology, Jena, Germany*; [2]*University Hospital of Jena, Institute of Physiotherapy, Jena, Germany*; [3]*Paracelsus Private Medical University, Clinic of Internal Medicine II, Department of Cardiology, Salzburg, Austria*; [4]*University Hospital of Jena, Department of Endocrinology, Nephrology and Rheumatology, Jena, Germany*

Background: The main symptom of patients with HFpEF is exercise intolerance. The role of peripheral factors, such as skeletal muscle mass and function seems to play an important role in explaining the exercise intolerance in patients with HF.
Purpose: To compare skeletal muscle function, body composition and quality of life (QoL) among symptomatic and clinically stable outpatients with heart failure (HF) with preserved (HFpEF) and reduced ejection fraction (HFrEF) and age-matched healthy controls (HC).
Methods: 55 participants were recruited prospectively at our University Hospital. 17 HFpEF, 18 HFrEF, 20 non-diseased controls (HC): (Age: 71±6 vs. 68 ±9 vs. 66±7 years, p=0.1; sex (m/f): 8/9 vs. 3/15 vs. 7/13, p=0.0001; BMI: 28.7±4.6 vs. 27.9±5.3 vs. 26.4 ±4.2 kg/m2, p=0.2). All participants underwent standardized tests including echocardiography, cardiopulmonary exercise test (CPET), 6-minute walk test (6MWT), muscle function tests, blood tests, QoL assessment. Serum samples were analyzed for GDF-15 by means of ELISA.
Results: Patients with HFpEF compared to those with HFrEF showed reduced muscle mass in the trunk (muscle mass in the trunk/BMI 0.8 ±0.2 vs. 1.0 ±0.3, p=0.03) and worse muscle strength both in arms (Peak muscle strength in the internal rotation of the right shoulder 150°.sec 25.5 ±12.0 vs. 34.6 ±14.0 Nm, p<0.05) and legs (Peak torque knee extension 30°.sec/right leg lean mass: 13.3 ±5.0 vs. 18.0 ±5.9 Nm/kg, p=0.04, as well as worse bone mineral contents in both arms and legs (right arm bone/BMI: 6.2 ± 2.0 vs. 7.8 ± 2.0, p=0.03, left leg bone/BMI: 17.4 ± 5.0 vs. 21.5 ± 6.4, p=0.04). Patients with HFpEF scored worse in HADS- Questionnaire (Anxiety: 6.5 ±3.2 vs. 3.3 ±2.8, p=0.02). The above-mentioned alterations occurred in spite of the similarity of the reported and estimated physical activities among patients with HF (HFpEF: 93.0±52.3 vs. HFrEF: 74.2 ±42.7 MET, p=0.3). We found that GDF-15 - a pleiotropic cytokine- was significantly higher in patients with HF compared to HC: (HC: 590±152 vs. HFpEF: 870±246 vs. HFrEF: 1030±606 pg/ml, p=0.004). GDF-15 was associated with reduced muscle strength of both upper and lower extremities [internal rotation of the shoulders (r=-0.4, p=0.005) and muscle strength of quadriceps in all movements for example (knee extension with speed of 60° sec: r=-0.4, p=0.002)], increased BNP (r=0.7, p<0.0001), reduced 6MWT (r=-0.6, p<0.0001), reduced PVO2 (r=-0.5, p<0.0001), and elevated respiratory efficient slope (VE/VCO2): r=0.65, p<0.0001).
Peak torque internal rotation of the dominant shoulder 150°.sec correlated stronger with Peak VO2in HFrEF than HFpEF (p=0.001 r= 0.69 vs. p<0.05, r=0.47).
Conclusion: In spite of age-matching and similar physical activities, patients with HFpEF have worse muscle strength and quality of life compared to both HFrEF and HC. Elevated levels of inflammatory biomarkers seem to play an important role in explaining the reduced described muscle function.

1340

New approaches for the respiratory muscle trainings based on morphological features of the diaphragm

GP Arutyunov[1]; E A Kolesnikova[1]; KV Ilyina[1]; AK Rylova[1]; AG Arutyunov[1]; NV Scherbakova[1]
[1]*The Russian National Research Medical University named after N.I. Pirogov , Moscow, Russian Federation*

Background: Respiratory muscle trainings (RMT) is an essential part of physical rehabilitation in patients with severe heart failure. The studying of the morphological features of diaphragm and its role in ventilation disorders in patients with HF allowed proposing a new way of RMT prescription for severe HF pats.
The purpose: To study the effectiveness of RMT, prescribed based on morphological and functional status of diaphragm.
Materials: 1 Stage: 32 diaphragm autoptat (14 male, 16 female) with different lethal outcomes (8 myocardial infarction, 9 stroke, 5 pulmonary embolism, 10 pneumonia) were taken in 1 hour after death. Pats were selected from research data base of patients with NYHA I-IV class HF. The percentage composition of muscle, connective, adipose tissue was compared with the results of maximal inspiratory pressure (MIP)provided no longer then 90 days before the lethal outcome. Patients with 79-73% of muscle tissue had 43±9 mmH2O MIP, 58-55% - 21±4 mmH2O MIP. 2 Stage: 67 pats (35 men and 32 women) 64,6±7,2 years old with NYHA III-IV HF were divided into 3 groups: Group 1 with MIP ≤ 20mmH2O, Group 2 - 20 < MIP ≤ 40 mmH2O , Group 3 - MIP > 40 mmH2O. Pats in each group were randomized to either 1 of 4 ways of RMT: with gradual increase of inspire resistance (IRG)or with prolonged inspire at maximum resistance (MRG), their combination of IRMRG or to a control group (CG) with inspire without resistance. Trainings were held for 16 minutes twice a day for 12 months with Threshold IMT. VO2peak, MIP heath related quality of life by SF-36 and compliance in training participation by patients diary were measured at baseline and 3, 6, 12 months.
Results: In 12 months pats from Group 3 demonstrated better increase in physical capacity (PC) according to base line (VO256% vs 37 % in Group 2, no statistically significant change in VO2in Group 1). There was less hospitalization in period 6-12 month due to HF progression and pneumonia in pats from Group 3 (11,3 vs 17,9 vs 21,5%). There were less lethal outcomes in Group 3 (9,5 vs 14,7 vs 19,1). In Group 3 IRG and MRG and IRMRG patients demonstrated statistically significant increase in PC and less hospitalizations due to pneumonia over CG, with statistically better results in IRMRG. In Group 2 statistically significant best results showed IRG and IRMRG patients, with no big difference between them. In Group 3 no statistically significant difference in PC and pneumonia frequency was found. But CG patients showed better compliance and SF-36 results.
Conclusion: Morphological structure of diaphragm directly correlates with respiratory functional disorders and influence on the way of RMT with best benefits from combination of static and dynamic exercises with the over 70% of muscle tissue, dynamic exercises for 60-70% of muscle tissue and deep breathing without resistance for less than 60 % of muscle tissue.

Funding Acknowledgements: Greece and the European Union (European Social Fund-ESF) through the Operational Programme "Human Resources Development, Education, Lifelong Learning"

Introduction: Vascular endothelial dysfunction is an underlying pathophysiological feature of chronic heart failure (CHF). Exercise has been shown to stimulate the mobilization of endothelial progenitor cells (EPC) in healthy populations and populations with cardiovascular comorbidities. EPC, an index of vascular endothelial function, contribute to the regeneration of the inflammatory endothelium and promote neovascularization.
Purpose: The purpose of the present study was to evaluate the effect of a 36-session exercise training program on the EPC mobilization in patients with CHF.
Methods: Thirty eight patients (32♂, 6♀) with stable CHF [mean±SD, Age (years): 56±10, EF (%): 32±9, VO2peak (ml/kg/min): 18.1±4.1] enrolled a 36-session exercise training program including either high-intensity interval training (HIIT) or HIIT combined with resistance training (COM). All patients underwent a symptom limited maximal cardiopulmonary exercise testing (CPET) on a cycle ergometer before and after the training program. Venous blood was sampled before and after of each CPET. Five endothelial circulating populations were quantified by flow cytometry (table 1). EPC values are expressed as "cells/million enucleated cells" in median (25th, 75th percentiles).
Results: A significant intervention effect in CD34+/CD45-/CD133+, CD34+/CD45-/CD133+/VEGFR2, CD34+/CD45-/CD133- and CD34+/CD45-/CD133-/VEGFR2 populations and a significant time effect in CD34+/CD45-/CD133+ and CD34+/CD45-/CD133+/VEGFR2 populations were observed (table 1, p<0.001). An increase in 4 cellular populations was also observed during baseline after the 36-session training program (p<0.05). Finally, there were significant intervention by time differences in CD34+/CD45-/CD133+ /VEGFR2 and CD34+/CD45-/CD133-/VEGFR2 (p<0.001).
Conclusion: A 36-session training program stimulates both the acute and long term mobilization of different EPC populations in patients with CHF. The clinical relevance of these findings and the potential mechanisms need further investigation.

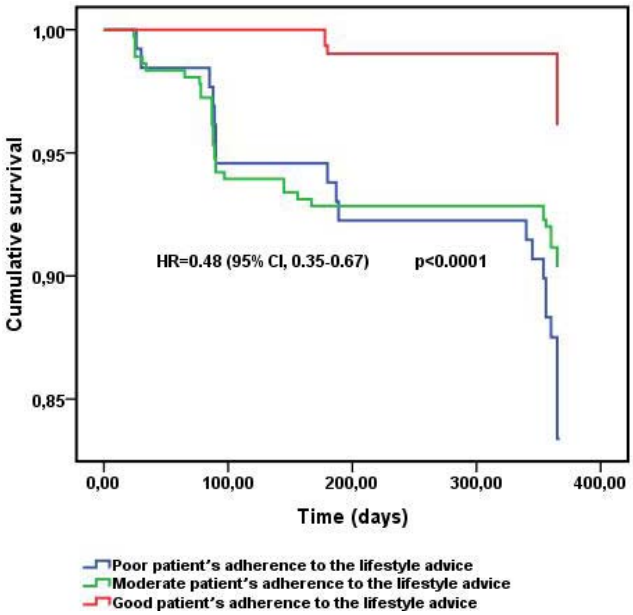
Background. Lifestyle advice is considered as a key component of education for self-care management in patients with heart failure (HF). However, little is known about the impact of specific lifestyle advice on prognosis in HF patients. The aim of our study was to analyze the impact of HF patients' adherence to lifestyle advice on all-cause mortality.
Methods. The analysis included data from the international prospective multicenter Optimize Heart Failure Care Program which was collected over 12 months from

801 patients (mean age 62.4 ± 11.9 years, 71% male, 76% with sinus rhythm) hospitalized with decompensated HF, NYHA II-IV (mean 2.7 ± 0.6), mean left ventricular ejection fraction 35.0 ± 10.0%, mean heart rate 87.0 ± 17.6 bpm, mean systolic/diastolic blood pressure 130 ± 23/81 ± 12 mm Hg. The underlying etiology of HF was ischemic in 66% of cases. Before discharge from the hospital all HF patients were provided with sufficient up-to-date information to make decisions on lifestyle adjustment and self-care. To assess patients' adherence to the lifestyle advice, an indirect method (patient-reported compliance, which was measured using a special questionnaire) was used. Three types of adherence were determined: good (patients always followed the lifestyle advice), moderate (patients sometimes followed the lifestyle advice) and poor adherence (patients did not follow the lifestyle advice).

Results. During 12 months of follow-up, 309 patients (38.6%) demonstrated good adherence to lifestyle advice, 363 patients (45.4%) had a moderate adherence to lifestyle advice and 129 patients (16%) did not follow lifestyle advice at all. After 12 months of follow-up, the rates of all-cause mortality were significantly lower in the group of good patients' adherence (5.8%, p<0.0001) in comparison with the groups of moderate and poor patients' adherence (8.8-16%, respectively, HR 0.48, 95% CI 0.35–0.67, p=0.0001) (Figure).

Conclusion. Less than half of HF patients demonstrated good adherence to the guideline-recommended lifestyle modification. The rates of all-cause mortality in the group of good patient's adherence were significantly lower compared with the groups of moderate and poor adherence to lifestyle advice. Greater efforts to promote lifestyle modification in HF patients are needed.



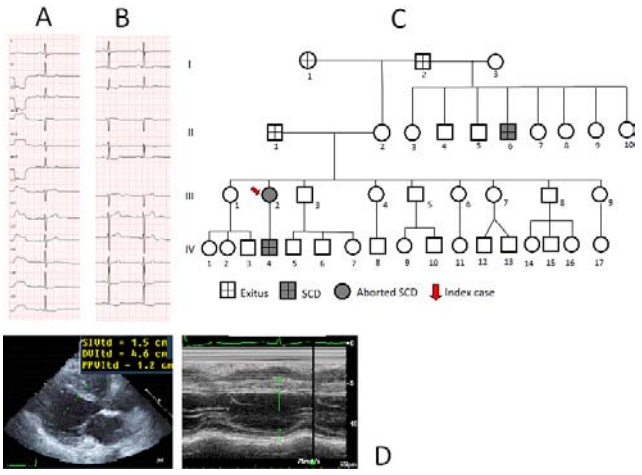
Clinical Case 2

1346

Challenges in preventing sudden cardiac death. The importance of familial background, genetic profiling and follow-up in specialised units.

P Jorda[1]; A Fernandez-Valledor[1]; O Campuzano[2]; S Prat[1]; A Garcia-Alvarez[1]; L Mont[1]; M Sitges[1]; R Brugada[3]; J Brugada[1]; E Arbelo[1]
[1]Hospital Clinic de Barcelona, Cardiology Department, Institut Clínic Cardiovascular, Universitat de Barcelona, Barcelona, Spain; *[2]University of Girona, Medical Science Department, Cardiovascular Genetics Center, IDIBGI, Girona, Spain*; *[3]University Hospital de Girona Dr. Josep Trueta, Cardiology Department, Cardiovascular Genetics Center, IDIBGI, CIBERCV, Universitat de Girona, Girona, Spain*

We present a case of a 50-year old woman diagnosed of idiopathic ventricular fibrillation (case III.2), following an episode of aborted cardiac sudden death (SCD) in her country (Colombia) at the age of 41 (2010). An implantable cardiac defibrillator (ICD) was placed for secondary prevention. Subsequent studies only showed mild septal hypertrophy on echocardiography. Right ventricle was normal. Single photon emission computed tomography (SPECT) showed no ischemia. Idiopathic ventricular fibrillation (VF) was the diagnosis suspicion.



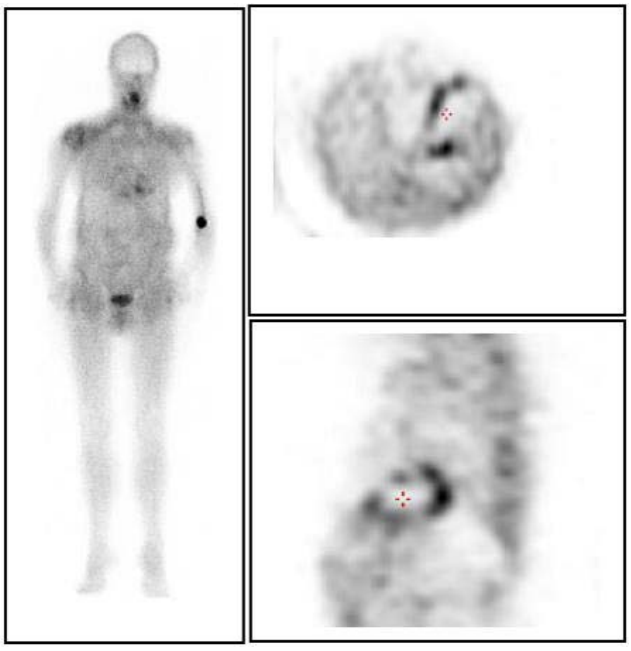
She was referred to our unit in 2013. ECG showed rectified ST and low voltage T waves on inferior and lateral leads (figure A), exacerbated during exercise test. She complained of occasional atypical chest pain so an SPECT was repeated resulting negative for ischemia again. Non-invasive CT coronary angiogram ruled out epicardial stenosis. Follow-up ecocardiography did not change.
Family background revealed another case of SCD: her uncle died at rest at the age of 35 (case II.6). Later, in 2017, her son suffered a SCD while walking on a sloping street at the age of 22 (IV.4); pathology did not show relevant findings (no report was available as it occurred in a foreign country).
In 2018, she presented an appropriate discharge due to VF. On the ECG, repolarization abnormalities progressed with greater ST rectification in the aforementioned leads (figure D). Echocardiography showed a hypertrophic septum of 15 mm (figure C). Hypertrophic cardiomyopathy (HCM) with a highly arrhythmogenic substrate was suspected. Next generation sequencing genetic panel found one pathogenic mutation TNNI3 p.Ala157Val and three other variants of uncertain significance in SCN1B p.(Val160Ile); DMD p.(Arg1728Cys); EMD p.(Gly156Ser).
Family screening with echocardiography, cardiac magnetic resonance (CMR), and 24-hours ECG recording and exercise test was only possible among individuals IV.1, II.4, IV.8, demonstrating a normal phenotype (genotype pending); the remainders are living in Colombia.
Malignant ventricular arrhythmias in spite of non-severe hypertrophy have been described among patients with TNNT2 and TNNI3 mutations. These phenotypes are characterized by the presence of myocyte disarray that contributes to the arrhythmogenic substrate.
Diagnosis might be challenging in mild HCM phenotypes that may not accomplish HCM diagnostic criteria in spite of an already established arrhythmogenic substrate. Even if the HCM is correctly identified the European Heart Society risk of SCD score has not a good predictive value in this sub-population with troponin mutations. According to that, high suspicion of this entity, the integrated family evaluation in specialised units and the support of diagnostic tools as the genetic study, contribute to an accurate diagnosis in the index case, which is crucial for the prevention in the other family members as early identification of genetic carriers can aid in SCD risk stratification.

1347

Early detection of hTTR cardiac amyloidosis with bone DPD scintigraphy in a patient with a rare transthyretin mutation

M Slama[1]; E Piekarski[2]; C Cauquil[3]; V Algalarrondo[1]; L Eliahou[4]; C Labeyrie[3]; D Adams[3]; F Rouzet[2]
[1]Hospital Bichat-Claude Bernard, Cardiology, Paris, France; *[2]Hospital Bichat-Claude Bernard, Nuclear Medicine Department, Bichat Hospital, Paris, France, Université Paris VII, Inserm U1148, Paris, France*; *[3]Bicetre University Hospital, Neurology, CRMR NNERF, Inserm U 1195 , Le Kremlin-Bicetre, France*; *[4]Hospital Antoine Beclere, Cardiology Department, Universite Paris Sud, CRMR NNERF, Clamart, France*

Hereditary transthyretin-mediated (hATTR) amyloidosis is an inherited, progressive, life-threatening disease caused by mutation of the transthyretin (TTR) gene, responsible for accumulation of amyloid fibrils in the heart and in the nerves. Recently specific disease modifying therapies have proven efficient to reduce mortality and major cardiac events, thus enhancing the interest of an early diagnosis.



DPD scintigraphy: cardiac uptake

A 78 years old female patient was referred to our institution in 2017 for assessment of her cardiac condition, after being diagnosed with a rare amyloidogenic genetic mutation of TTR (Glu61Lys) . She had a history of hypothyroidism, bilateral carpal tunnel surgery at the age of 60, and familial history of hTTR amyloidosis: one brother with symptomatic hTTR amyloidosis being the index case diagnosed at 68 years old and one asymptomatic carrier sister. Amyloid deposits were present in her accessory salivary glands biopsy.
Her clinical examination showed minor length dependent sensory neuropathy (PND grade 1). She was in NYHA class 1, her cardiac examination was normal, as well as ECG. During a 6min walk test she walked 531 m (expected distance 425 m). The BNP value was normal at 41ng/l (n<80), troponin value was normal. On echocardiography, interventricular septum thickness was measured at 8 mm, ejection fraction was 71%, global longitudinal strain was -19%, valves were normal. The cardiac MRI could not be performed because of claustrophobia. The 24h ECG Holter was normal. MIBG scintigraphy showed a normal uptake with a heart to mediastinum ratio of 2.4 (normal value >1.85). DPD "bone" scintigraphy showed a cardiac uptake with a Perugini grade 3 with a heart to lung ratio of 4, and attenuation of bone uptake.
A treatment with Tafamidis was initiated in June 2017, because of stage 1 hTTR neuropathy. Repeat assessment in October 2018 showed a stable disease: the patient had no cardiac symptoms, normal examination, normal BNP and troponin, normal ECG; interventricular myocardial thickness was measured 9 mm.
In this patient with biopsy proven hTTR amyloidosis, DPD "bone" scintigraphy was the only proof of cardiac involvement, while there was no myocardial wall thickening by echo and no cardiac denervation by MIBG scintigraphy. This pattern is unusual as MIBG reuptake is altered early in the course of hTTR cardiac amyloidosis, while DPD "bone" scintigraphy is usually positive when cardiac amyloid deposits produces wall thickening >12 mm.
Conclusion: positive "bone" DPD scintigraphy can be the first sign of cardiac hTTR amyloidosis in asymptomatic patients with some rare mutations; this prompts complete assessment of cardiac condition with multimodality imaging, even when echocardiography is normal.

1348

Alcohol septal ablation in a patient with hypertrophic obstructive cardiomyopathy due to Anderson-Fabry disease

N Nicolas Verheyen[1]; H Seggewiss[2]; K Ablasser[1]; E Kolesnik[1]; D Zach[1]; J Binder[1]; A Zirlik[1]; GG Toth[1]
[1]Medical University of Graz, Clinical Department of Cardiology, Graz, Austria; *[2]Klinikum Wuerzburg Mitte, Standort Juliusspital, Department of Cardiology, Wuerzburg, Germany*

Introduction A 63 year-old male patient with known Anderson-Fabry disease (AFD) presented with progressive deterioration of functional capacity (NYHA III). In the medical history, he had coronary artery disease (CAD) treated with PCI, ICD-implantation due to malignant ventricular arrhythmia, chronic kidney disease stage IV and depression. Besides enzyme replacement therapy he was treated with AT-II antagonist, beta-blocker, calcium antagonist, low-dose aspirin, statin and ezetimibe.
Methods Echocardiography showed severe global cardiac hypertrophy with pronounced interventricular septum thickening (maximal end-diastolic thickness of 31 mm). Left ventricular ejection fraction was preserved with grade II diastolic dysfunction and evidence of increased filling pressures, supporting the diagnosis of HFpEF. Maximal LVOT gradient was 52 mmHg at rest and 86 mmHg at post-extrasystolic beat. Mitral valve showed incomplete systolic anterior motion (SAM). At the time of presentation NT-proBNP levels were 1.108 pg/ml.
After treatment with verapamil at maximally tolerated doses NT-proBNP was lowered to 426 pg/ml and peak LVOT gradient declined to 26 mmHg at rest. However, during bicycle echocardiography the gradient increased to 76 mmHg after maximal workload. Also, the patient did not report relevant improvement in symptoms indicating septal reduction therapy. In face of comorbidities and high perioperative risk, percutaneous transluminal septal myocardial ablation (PTSMA) was preferred.
By PTSMA of the first septal branch provoked peak LVOT gradient dropped from 80 mmHg to 30 mmHg as measured invasively. Peak post-procedural levels of CK and high-sensitive Troponin T were 1.766 U/l and 6.600 pg/ml, respectively. Pre-discharge echocardiography showed a peak LVOT gradient of 16 mmHg without relevant increase during provocation and no evidence of SAM.
Conclusion Cardiac manifestation of AFB can mimic the phenotype of hypertrophic obstructive cardiomyopathy (HOCM). Therefore, AFB patients with signs or symptoms of heart failure should undergo a comprehensive diagnostic HOCM assessment. In case LVOT obstruction is confirmed, PTSMA in experienced hands can be a safe and effective treatment option for these patients.

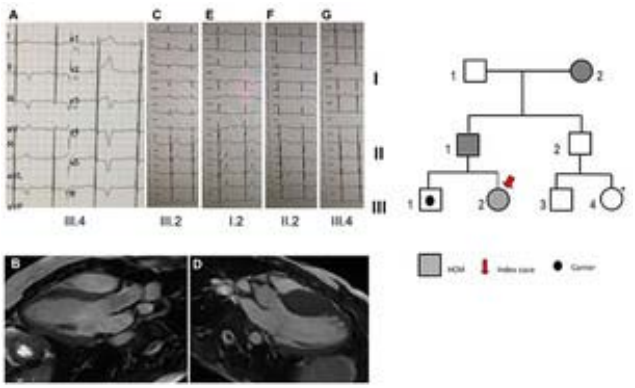
1349

Ventricular hypertrophy in a family with sarcomeric hypertrophic cardiomyopathy: always of genetic origin?

P Jorda[1]; A Fernandez-Valledor[1]; E Torrecilla[1]; E Arbelo[1]; O Campuzano[2]; F Perez-Villa[1]; L Mont[1]; J Brugada[1]; R Brugada[3]; M Sitges[1]; A Garcia-Alvarez[1]
[1]Hospital Clinic de Barcelona, Cardiology Department, Institut Clínic Cardiovascular, Universitat de Barcelona, Barcelona, Spain; *[2]University of Girona, Medical Science Department, Cardiovascular Genetics Center, IDIBGI, Girona, Spain*; *[3]University Hospital de Girona Dr. Josep Trueta, Cardiology Department, Cardiovascular Genetics Center, IDIBGI, Universitat de Girona, Girona, Spain*

A case of a young girl (III.4)* initially diagnosed of hypertrophic cardiomyopathy (HCM) during routine sports medical exam is presented.
In 2012, at 13 years old, suspicion of HCM raised after an ECG showing negative T-waves in inferior and lateral leads (A). Echocardiography showed anterolateral and anteroseptal apical hypertrophy of 13-14mm confirmed by cardiac magnetic resonance (CMR), without fibrosis (B). She was competing at basketball at that time; thus, competition sport cessation was recommended.Previously, her cousin (III.2) had been diagnosed of severe HCM at the very early infancy (<1 year old) and MYH7_p.Arg723Cys pathogenic mutation was identified. ECG showed Q-wave in inferior leads (C). In the last follow-up (24 years old), non-obstructive anteroseptal hypertrophy (30mm) was present with patched fibrosis in anteroseptal segments on CMR (D).
One year before, in 2011, also her grand-mother (I.1) had been diagnosed of obstructive HCM (20mm thickness) after admission for a stroke at the age of 76. ECG showed inferior Q-waves (E). No genotype was performed.
During the family screening, her uncle (II.1) showed as well hypertrophy of 14-15mm on echocardiography but he refused any further studies.
Her father (II.2), also a previous athlete, has an abnormal ECG showing negative T-waves in inferior and lateral leads similarly to the patient (F). Mild hypertrophy in CMR (13mm) has also been observed. Genetic study is pending at this time.The 17 year old brother of her cousin (III.1), carrier of MYH7 pathogenic mutation, has non-pathologic Q-wave on V3 to V6 ECG-leads but no hypertrophy in echocardiography or in CMR has been detected. After reduction of sport activity, the last CMR

of the discussed patient (III.4) demonstrated complete reversal of the aforementioned hypertrophy and absence of fibrosis. The genetic study of 34 genes by Next Generation Sequencing did not detect any mutation in either MYH7 nor in other genes related to structural cardiomyopathies. The last ECG showed isolated negative T-wave in lead III with normalization of all other parameters (G).We want to focus on the utility of genetic analysis to recognize phenocopies of hypertrophic cardiomyopathy identified during family screening. However, it is not always easy to completely exclude myocardiopathy. Particularly, in this family, it seems probable that the abnormalities observed in members II.2 and III.4 are secondary to left ventricle overload in response to exercise but also, an undiscovered sarcomeric mutation could be involved. Due to the severity of the observed abnormalities in repolarization, it has been recommended to maintain exercise restriction and continue clinical follow-up. Of note, a differential ECG expression (inferior Q-waves versus inferolateral negative T-waves) correlated with a clear phenotype of sarcomeric HCM in this family.



1351

Restrictive cardiomyopathy and anomalous origin of the right coronary artery in a patient with desmin- and myotilin-gene variants: a deleterious combination.

P Petros Athanassopoulos[1]; C Da Silva[1]; M Mannila[1]; A Manouras[1]
[1]*Karolinska University Hospital, Stockholm, Sweden*

Introduction A previously healthy 22-year-old Caucasian woman with a history of fatigue and unexplained exertional dyspnea was admitted to our clinic due to palpitations and chest pain. On admission, blood pressure was 110/70 mmHg, ECG showed sinus rhythm 60 bpm with incomplete left bundle branch block configuration. Blood tests showed slightly increased troponin-T 23 ng/L and NT-proBNP 2100 pg/mL.ProceduresTrans-thoracic echocardiography (TTE) revealed severely enlarged atria, decreased right ventricle function (TAPSE 10mm), restrictive filling pattern and hypertrophy (posterior left ventricular wall thickness 13mm). No wall motion abnormalities were observed and left ventricular systolic function was normal (LVEF 55%). Subsequent cardiac magnetic resonance imaging depicted myocardial oedema on the lateral wall and minor pericardial effusion. Positron emission tomography showed no inflammatory activity. Renewed TTE revealed diastolic flow between the aorta and the pulmonary valve (Figure 1). Multi-detector computed tomography for coronary anatomy analysis showed anomalous origin of the right coronary artery (ARCA) from the left coronary sinus with inter-arterial course between the aorta and pulmonary trunk (Figure 2a & 2b).

Patient management

The patient experienced recurrent chest pain while at hospital with troponin-T peaking at 520 ng/L. Subacute coronary angiography confirmed significant ARCA ostium narrowing (FFR 0.76) while IVUS revealed ARCA compression during systole, suggesting restricted ARCA blood flow. The patient underwent CABG with revascularization of the ARCA territory using right internal mammary artery and after uncomplicated post-operative clinical course was dismissed from the hospital. Comprehensive cardiology panel gene analysis at follow-up revealed simultaneous heterozygosity for desmin- [DES, c.1360C>T; p.Arg 454Trp] and myotilin-[MYOT, c.1423C>T; p.(Gln475*)] gene variants. Differential diagnosis

Desmin mutations have been associated with ventricular arrhythmias, atrioventricular conduction disturbances, progressive cardiomyopathy and sudden death. Myotilin mutations are associated with myofibrilar myopathy and peripheral neuropathy with uncertain significance for cardiac disease. In this heterozygous patient for DES- and MYOT- mutations we describe a novel cardiac phenotype of restrictive hypertrophic cardiomyopathy and malignant course ARCA.

Conclusions Multi-modality imaging and serial clinical assessment may lead to the discovery of rare cardiomyopathy. Genetic testing can offer insight into relations between unique gene profiles and specific cardiac phenotypes and facilitate improved outcomes in such patients. The patient in this case is considered for early ICD- referral due to high risk for sudden death while heart failure follow-up is ongoing due to progressive cardiomyopathy. In such patients genetic counselling and family member screening should be encouraged.

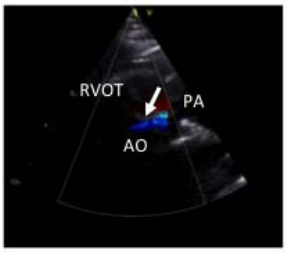


Figure 1. Echocardiography shows a short axis view at the aortic level where a diastolic flow (arrow) can be seen between the aortic valve (AO) and the pulmonary artery (PA).

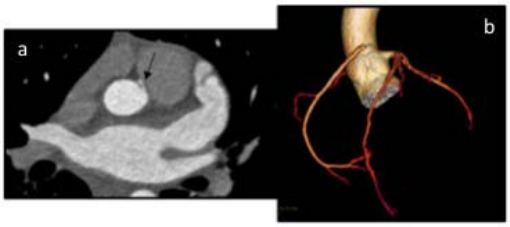

Figure 2. Computed tomography with a) contrast and b) volume reconstruction showing anomalous origin of the right coronary artery from the left coronary sinus with inter-arterial course between the aorta and the pulmonary trunk (arrow).

Rapid Fire 5 - Non-pharmacological treatments: beyond conventional

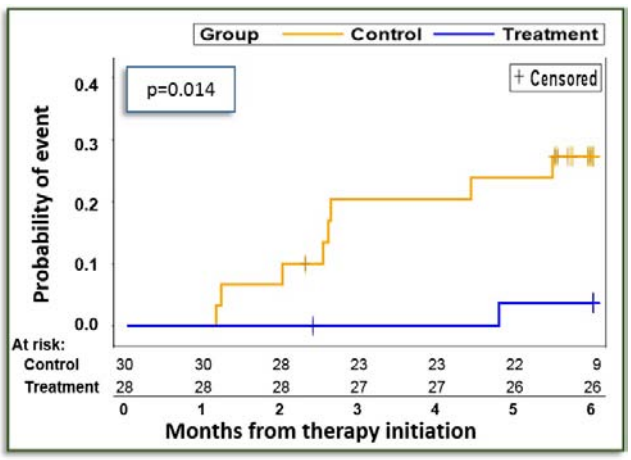
1417

Treatment of central sleep apnoea with phrenic nerve stimulation is associated with reduction in heart failure-related hospitalizations

P Ponikowski[1]; O Oldenburg[2]; S Javaheri[3]; L Goldberg[4]; C Stellbrink[5]; AC Kao[6]; R Augostini[7]; REG Robin Germany[8]; WT Abraham[7]; MR Costanzo[9]
[1]Wroclaw Medical University, Cardiology, Wroclaw, Poland; *[2]Clemens Hospital Munster, Munster, Germany*; *[3]Bethesda Medical Center, Cincinnati, United States of America*; *[4]University of Pennsylvania, Medicine, Philadelphia, United States of America*; *[5]Bielefeld Hospital, Bielefeld, Germany*; *[6]University of Missouri - Kansas City, Kansas City, United States of America*; *[7]Davis Heart & Lung Research Institute, Columbus, United States of America*; *[8]University of Oklahoma, Oklahoma City, United States of America*; *[9]Advocate Heart Institute, Naperville, United States of America*

Funding Acknowledgements: Respicardia, Inc.

Background: Patients with heart failure and reduced ejection fraction (HFrEF) often have central sleep apnoea (CSA), which increases the risk for HF exacerbation and hospitalization.
Purpose: Investigate the effects of phrenic nerve stimulation (PNS) on sleep metrics, quality of life (QoL), safety and HF hospitalization rate in symptomatic HFrEF patients.



Heart Failure Hospitalization by Group

Methods: We analysed data of HFrEF subjects (NYHA Class II-III, ejection fraction ≤ 45%) who participated in the remedē System Pivotal Trial. They were randomized to 6-month nightly treatment with PNS (remedē System, Respicardia, Inc.; n=28) or to control group (device implanted, no therapy; n=30). All subjects underwent full night attended polysomnography, blindly scored centrally. A Kaplan-Meier analysis estimated HF hospitalization rates.
Results: The cohort had mean age of 68 years, was primarily male (95%), with 52% in NYHA III, median LVEF of 27%, with severe CSA (median treatment arm [Tx] apnoea-hypopnoea index [AHI] was 47 events/hour vs 39/hour in the control arm [Ctrl]). Concomitant cardiovascular diseases included hypertension (79% Tx, 90% Ctrl), CAD (79% Tx, 80% Ctrl), and atrial fibrillation (57% Tx, 60% Ctrl). In the year prior to randomisation, 21% of Tx and 33% of Ctrl had a documented HF hospitalization.
With therapy, 52% of patients achieved a ≥50% reduction in AHI while compared to 7% of controls ($p < .001$). The median AHI decrease was 23 events/hour on therapy compared to an increase of 2 events/hour for Ctrl (between group difference $p < .001$). The AHI improvement was driven by a reduction in the central apneoa index, which decreased a median of 23 events/hour in the Tx group compared vs. 2 events/hour in controls ($p<.001$).
Patient global assessment was markedly or moderately improved in 48% of Tx subjects compared to 15% of Ctrl (p=0.010). Additionally, the Epworth Sleepiness Scale improved by 2 points in the Tx group and worsened 1 point in the Ctrl group (p=0.058).
Over a 6-month follow up period, heart failure-related hospitalizations were significantly fewer in patients receiving active PNS than the Ctrl group (3.7% versus 27.3%). The time to first heart failure-related hospitalization was significantly shorter in the treated group (log-rank test p-value 0.014) (Figure).
During the same period, 3 patients died: 1 in the Tx group (cause of death intracranial bleed subsequent to fall but conservatively called cardiac sudden death by clinical events committee) and 2 in the Ctrl group (both cardiac pump failures).
Conclusions: According to this exploratory analysis, treatment of CSA with PNS was associated with improved sleep indices, QoL, and fewer heart failure-related hospitalizations in symptomatic HFrEF subjects. The results of this subgroup analysis of a randomized controlled trial should be confirmed by larger studies.

1418

Bacterial infections as a mediator of ventricular assist device-induced HLA allosensitization

I Iakovos Armenis[1]; A Chaidaroglou[1]; MJ Bonios[1]; N Kogerakis[1]; A Gkouziouta[1]; E Leontiadis[1]; S Chatzianastasiou[1]; D Chilidou[1]; D Degiannis[1]; S Adamopoulos[1]
[1]Onassis Cardiac Surgery Center, Athens, Greece

Introduction: Induction of anti-Human Leukocyte Antigen (anti-HLA) antibodies after Ventricular Assist Device (VAD) implantation, a process called allosensitization, is insidious but potentially catastrophic, as it may impede the perspective of successful transplantation. The effect of VAD-related bacterial infections on allosensitization remains unknown.
Purpose: Aim was to describe the time-course of allosensitization during the first year after VAD implantation and to examine the potential effect of bacterial infections on allosensitization.
Methods: Fifty five VAD recipients were retrospectively studied with regard to anti-HLA allosensitization during the first year after VAD implantation. Anti-HLA antibodies were assessed with Panel Reactive Antibody (PRA) method till 2003, with ELISA (2003-2005) and with Single-Antigen method (2005-today). Allosensitization was defined as PRA>10% or as Mean Fluorescence Intensity (MFI)>1000 units. It was assessed at baseline, at 3,6 and 12 months post-implantation, as well as before and after the first documented bacterial infection. Bacterial infections studied comprised bloodstream infections (BSI) and VAD-specific infections. BSI was defined as >1 blood cultures positive for the same microorganism in a clinical context of infection. VAD-specific infection was defined as >1 cultures from VAD per-cutaneous drive-line/pocket with the same microorganism in a clinical context of infection with negative blood cultures. Comparisons were made using Pearson's Chi square test/Fischer Exact test.
Results: Twenty patients receiving left-sided VAD (LVAD) and 35 biventricular VAD (BiVAD) as bridge to transplant, (12 ischemic, 43 non-ischemic cardiomyopathy) were studied. Allosensitization time-course is shown on table 1. BSI was documented in 12 patients, 3 of them sensitized before BSI and 8/12 after (p 0.056). VAD-specific infections were documented in 30 patients, 6 of which sensitized before infection and 13/30 after (p 0.052).
Conclusions: VAD implantation induces allosensitization, potentially reducing the likelihood of successful heart transplantation. Bacterial infections, both BSI and VAD-specific infections seem to contribute to VAD-induced allosensitization.

Table 1

Timepoint	Sensitized patients	p (vs baseline)
Baseline	1/54 (1.9%)	-
3 months	14/45 (31.1%)	0.000
6 months	14/44 (31.8%)	0.000
12 months	11/31 (35.5%)	0.000

Improvement of right ventricular function with intraaortic balloon pump counterpulsation

MJ Bonios[1]; I Iakovos Armenis[1]; N Kogerakis[1]; A Gkouziouta[1]; E Leontiadis[1]; P Georgiadou[1]; S Fragkoulis[1]; S Dimopoulos[1]; D Tsiapras[1]; P Vlachos[1]; S Adamopoulos[1]

[1]*Onassis Cardiac Surgery Center, Athens, Greece*

Introduction: Right Ventricular (RV) Failure occurrence after Left Ventricular Assist Device (LVAD) implantation is a major contributor to morbidity and mortality among patients with end-stage bi-ventricular heart failure. On the other hand, patients who require bi-ventricular support (BiVAD) consistently show worse outcome compared to LVAD recipients.

Purpose: Purpose of this study was to investigate the effect of Intraaortic Balloon Pump counter-pulsation (IABP) on RV function in candidates for mechanical circulatory support due to end-stage bi-ventricular heart failure.

Methods: Patients with end-stage heart failure who required IABP support due to haemodynamic compromise were studied. RV function before and after IABP placement was studied echocardiographically (legacy methods and free wall RV strain analysis) and haemodynamically (invasive right heart catheterization). Specific laboratory parameters were also obtained. Paired-samples Student T-test was applied to compare values before and after IABP placement.

Results: Twelve patients with end-stage heart failure aged 35±13 years were supported with IABP for 73±58 (3-180) days. Haemodynamic compromise was the indication for IABP placement in 11/12 patients and further analysis refers to this population. Two out of 11 patients presented further clinical deterioration on IABP and required temporary/long-term BiVAD support, while 2 patients got stabilized on IABP but without significant amelioration, one of them receiving BiVAD on a non-urgent basis and the other dying on IABP due to infection. RV function significantly recovered in 7 patients. In the cohort of 11 patients, Central Venous Pressure (CVP) decreased from 18±6 to 11±9 mmHg (p=0.014), CVP/Pulmonary Capillary Wedge pressure decreased from 0.61±0.19 to 0.42±0.20 (p=0.022) and Pulmonary Artery Pulsatility index (PAPi) increased from 1.32±0.56 to 2.76±1.30 (p=0.009). RV free wall strain also improved from -12.6±4.4% to -17.5±3.0% (p=0.013). The above parameter optimization rendered the patients suitable for LVAD implantation, despite initial bi-ventricular compromise.

Conclusion: In patients with end-stage bi-ventricular heart failure, IABP placement might improve RV function and alter mechanical support type (LVAD instead of BiVAD), with potential morbidity and mortality benefits.

1420

Response to cardiac resynchronization therapy is present across all stages of chronic kidney disease

J M Jozine Ter Maaten[1]; P Martens[2]; AH Maass[1]; K Damman[1]; M Dupont[2]; W Mullens[2]

[1]*University Medical Center Groningen, Groningen, Netherlands (The)*; [2]*Hospital Oost-Limburg (ZOL), Department of Cardiology, Genk, Belgium*

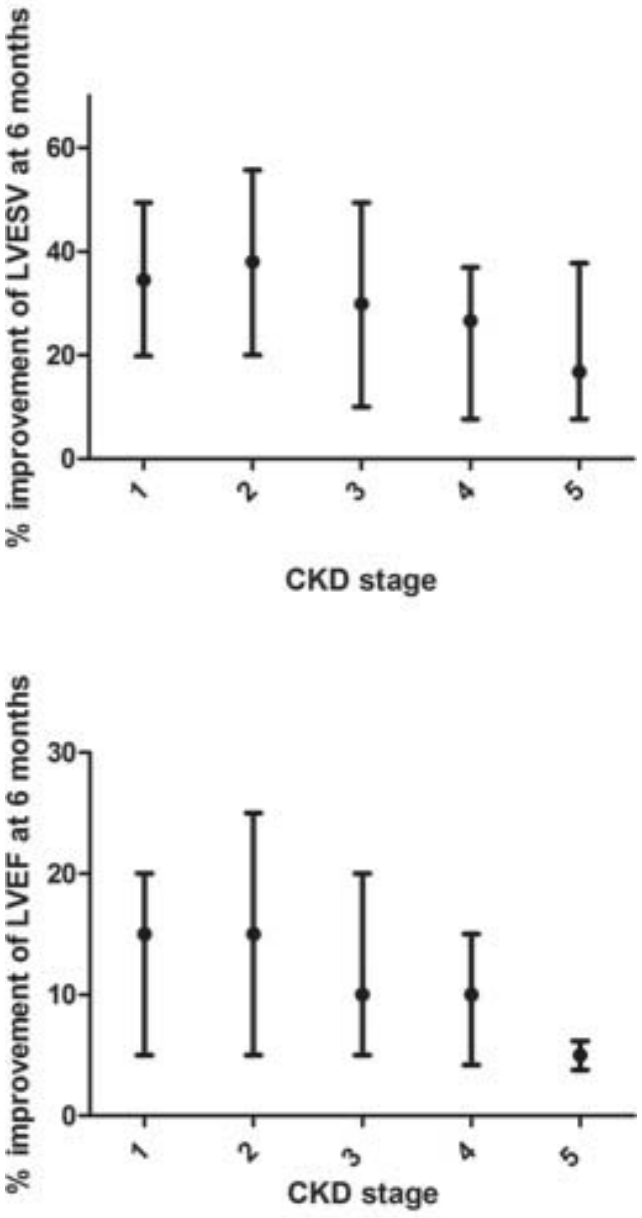
Introduction Limited data is available on the effect of chronic kidney disease (CKD) on the response to cardiac resynchronization therapy (CRT) as these patients are often excluded from trials.

Purpose We therefore aimed to assess the effect of CRT on renal function, reverse remodeling and outcome across all stages of CKD in a large patient population of CRT recipients.

Methods 798 consecutive heart failure (HF) patients undergoing CRT implantation between October 2008 and September 2016 were retrospectively evaluated. Renal function was available at baseline and 6 months following CRT. Remodeling based on left ventricular end systolic volume (LVESV)/left ventricular ejection fraction (LVEF) and clinical outcome was assessed using a combined endpoint of all-cause mortality and HF hospitalization.

Results Median baseline eGFR was 62.8 [43.6-77.8] ml/min/1.73m2. 33.6% of patients were in CKD stage 3, 11.0% in stage 4, and 1.1% in stage 5. At 6 months, compared with CKD stage 1-2, renal function improved among CKD stage 3-5 patients (P<0.001). LVEF and LEVSV improved across all CKD stages, however patients with CKD stage 1-2 exhibited a greater degree of improvement in LVEF (median 15% vs. 10%, P<0.001) and LVESV (median -37.2% vs. -29.9%, P<0.001) compared to patients with CKD stage 3-5. Despite a greater degree of reverse remodeling in CKD stage 1-2, the most accurate cutoff of remodeling predicting good clinical outcome was lower for patients with CKD stage 3-5, respectively 5.5% vs. 9.5% (LVEF), and -6.67% vs. -12.41% (LVESV).

Conclusions CRT results in reverse remodeling across all stages of CKD, although to a lesser extent in patients with renal dysfunction. However, patients with CKD derive benefit on outcome at a lesser degree of remodeling. Secondly, CRT results in stabilization of renal function in patients with CKD stage 3-5.



LV remodeling to CRT over CKD stages

1421

Transcatheter Mitral-Valve Repair in patients with heart failure and severe dysfunction.

P Paula Fluvia[1]; X Millan Alvarez[2]; S Mirabet Perez[2]; D Arzamendi Aizpurua[2]; CH Li Li[2]; J Alvarez Garcia[2]; L Lopez Lopez[2]; M Rivas Lasarte[2]; V Brossa Loidi[2]; A Serra Penaranda[2]; E Roig Minguell[2]

[1]*University Hospital de Girona Dr. Josep Trueta, Cardiology, Girona, Spain*; [2]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Significant functional mitral regurgitation (FMR) is associated with a worse prognosis in patients with dilated cardiomyopathy and severe systolic dysfunction.

Surgical indication is not clear in these patients, and there is still not enough data on the benefit of transcatheter mitral-valve repair (TMVR)in this setting. Besides symptomatic benefit, TMVR could contribute to left ventricular reverse remodeling and improvement of hemodynamic parameters.

Purpose: Analyze the clinical benefits of TMVR and echocardiographic changes.

Methods: Prospective and unicentric observational registry of patients with significant FMR and symptomatic heart failure with severe systolic dysfunction under optimal medical treatment. Functional NYHA class and heart failure (HF) hospitalizations before and after the procedure were assessed; as well as the need of heart transplantation and mortality during follow-up. Echocardiographic characteristics were also analyzed.
Results: From December-2012 to July-2017, 38 patients were included. Age 71±9; 84% were men, 73.7% with ischemic heart disease, 15.8% under resynchronization therapy and 57.9% with an implantable cardioverter-defibrillator. Logistic Euroscore II 9.7±10. Average EF 32,4±5%. TMVR was associated with an improvement in NYHA class (p <0.005, Figure 1) and lower HF hospitalizations (46.9% before vs 13% after, p <0.005). Two patients left the elective cardiac transplant list due to functional improvement. Regarding echocardiography data, there were no differences in left ventricular end-diastolic diameter (LVEDd; pre 63 ± 9 mm vs post 62 ± 11 mm, p = 0.5) or in left ventricular ejection fraction (LVEF; pre 32%±5 vs post 31%±10, p = 0.63). Systolic pulmonary pressure (PAPs) decreased post procedure (PAPs pre 54±14mmHg vs post 49±14 mmHg p=0.05). With a minimum follow-up of 6 months, 8 patients (21.1%) have died and two have undergone cardiac transplant.
Conclusions: In our population,TMVR resulted in an improvement of the NYHA class and a lower rate of HF hospitalizations; which could be related to the decrease in systolic pulmonary pressure.

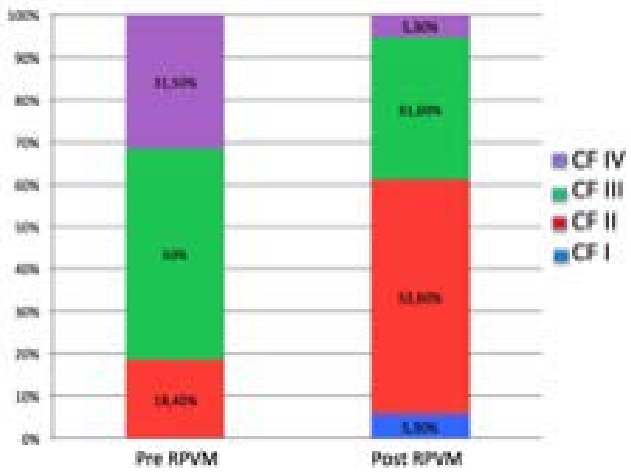


Figure 1; NYHA Class

1422
A novel rotary blood pump for HFpEF

E Gude[1]; DR Fiane[1]
[1]*Oslo University Hospital, Department of Cardiology, Oslo, Norway*

Heart Failure with preserved ejection fraction (HFpEF) has no treatment options to improve survival. We have developed a novel assist pulsed device for treatment of HFpEF.
The system consists of a small diagonal centrifugal rotary blood pump using hydrodynamic suspension of a four bladed impeller with partial unloading from the left atrium (LA) to the descending aorta. The pump is adaptive to patient physiological needs and is adjusted by feedback from the ECG and sensors. Pulsed rpm maintains pulse pressure. Implantation is by a small left side thoracotomy and minimally invasive procedure.
Animal studies in sheeps 50-80 kg have tested a spectrum of unloading and demonstrated adequate pulsed pump unloading between 1.5-3.0 l/min. ECG gated rpm increase in systole avoided LA suction and arrhythmia, interference with mitral valve opening and ventricular underfilling. Blood pulsepressure was maintained at 95-70 mmHg, CVP 10 mmHg and native cardiac output of 3.0-5.0 l/m. Human whole blood without added anticoagulation for 8 hours and 6 consecutive days have demonstrated no hemolysis, increase in energy consumption, heat increase or clotting inside the pump. Long-term animal studies will be performed.
Partial systolic pulsed unloading of LA demonstrated adequate hemodynamics and maintained pulse pressure. This novel pump may be the first effective treatment for HFpEF.

Temporal improvement in CRT response and survival: a review of multicenter trials

C Cecilia Linde[1]; S Liu[2]; DH Fagan[2]; V Laager[2]; E Chung[3]
[1]*Karolinska Institute, Danderyd Hospital , Stockholm, Sweden*; [2]*Medtronic, plc, Mounds View, United States of America*; [3]*The Christ Hospital, Cincinnati, United States of America*

Funding Acknowledgements: Medtronic, plc

Background: Despite new features and algorithms designed to promote the optimal delivery of CRT, the non-responder rate is often perceived to remain at 30%. The collective improvement in CRT response rates over time and correlation with survival remains unknown.
Purpose: We aimed to characterize contemporary versus historical CRT response rates and correlation of CRT response with survival at one year.
Methods: CCS at 6 months and 12-month survival values were evaluated for the CRT treatment arms 7 Medtronic CRT studies of 2413 patients, with starting dates ranging from 1999-2017. Analysis was limited to patients with NYHA III symptoms at baseline.
Results: Earlier CRT studies from 1999-2004 reported 6-month CCS improved rates from 52.7%-69.3% (see Table). More contemporaneous CRT studies from 2009-2017 have reported 6-month CCS improved rates from 74.2%-79.9%. 12-month survival rates correlated with CCS scores, with higher survival in CCS improved/unchanged patients and greater mortality risk in patients with worsened CCS scores.
Conclusion: CRT response rates appear to improve over time in correlation with improvements in device technology aimed at promoting effective, synchronized CRT. Overall, patients with a CCS of improved or unchanged at 6 months appeared to have greater survival at 12 months compared to patients with a worsened CCS, suggesting that unchanged CCS may also indicate CRT response.

Funding Acknowledgements: No funding

Introduction: As a consequence of the shortage of donor hearts and implantation as destination therapy, duration of mechanical circulatory support (MCS) is extended. Especially in longer term support, quality of life is important, which is promoted by a good exercise capacity. However, little is known about factors associated to exercise capacity in MCS patients, in whom hemodynamics are totally different from the normal heart function.

Purpose: The purpose of this study was to determine predictors of exercise capacity in terms of peak VO2 per kilogram (pVO2/kg), assessed by cardiopulmonary exercise test (CPET).
Methods: Data of all adult patients, who received a MCS in the University Medical Center Utrecht (UMCU, The Netherlands) between 2006-2018 and underwent CPET 6 months postoperatively were included. Data consisted of baseline characteristics, CPET and echocardiographic results at 6 months. IBM SPSS Statics 25 was used for linear regression analysis to search for predictive factors for pVO2/kg.
Results: 147 patients (102 (69%) male, mean age 50.6±11.9 years) underwent a CPET at 6 months after MCS implantation (table 1). Factors most associated with pVO2/kg were age and percentage of maximal predicted heart rate (=220-age); $F(2,43)=17$, $p<0.001$, $R2=0.664$. Both factors added significantly to the prediction ($p<0.001$). All other variables, including echocardiographic RV-function and left ventricular dimensions, were not associated with pVO2/kg.
Conclusion: Age and percentage of maximal predicted heart rate are significant predictors for pVO2/kg. This supports the importance of maximal heart rate with regard to maximal exercise capacity in MCS support.

1425
Continuous-flow ventricular assist device to small left ventricle: Is it nightmare?

M Minoru Ono[1]; K Nawata[1]; O Kinoshita[1]; S Shimada[1]; M Ando[1]; T Inoue[1]; E Amiya[1]; M Hatano[1]; I Komuro[1]
[1]*University of Tokyo, Department of Cardiac Surgery and Cardiology, Tokyo, Japan*

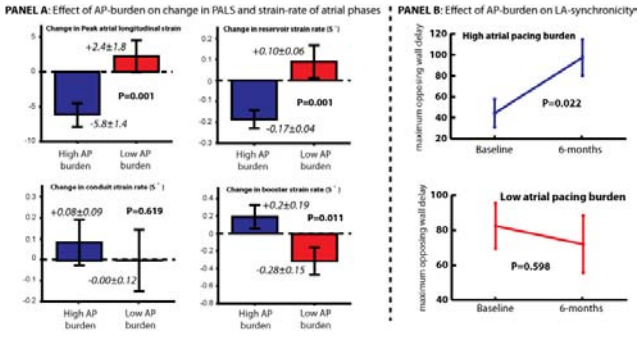
Objectives: Continuous-flow ventricular assist device (cf-VAD) implantation results have been improving. Small ventricle may pose serious problem. We sought to examine whether small LV is a hurdle for cf-VAD implantation using contemporary devices.
Patients and methods: Consecutive 146 patients were implanted with cf-VAD for bridge to transplantation, which is only an indication for use in Japan. Ninety-four axial-flow and 52 centrifugal-flow pumps were implanted. There were 38 females (26%) with an average age of 40.4 years. Follow-up rate was 100%. Small LV was defined as end-diastolic dimension (LVEDD) less than 55mm, and small indexed LVEDD (I-EDD: LVEDD divided by body surface area) was defined as < 35. Observed and event-free survivals were calculated and compared by Kaplan-Meier method with log-rank test.
Results: One, 2, 3 and 4-year survivals were 92.3%, 88.9%, 86.6% and 84.8%. Survival of small LV group (n = 24) or small I-EDD group (n = 28) was comparable to the counterpart. Cerebrovascular event-free survival in these small LV groups was also not significantly different from the counterparts. Pump thrombosis was only 4 cases (2.7%) in the whole cohort.
Conclusion: Small LV did not affect the long-term survival or adverse events of cf-VAD patients by using contemporary devises.

1426
The detrimental effect of right atrial pacing on left atrial function and clinical outcome in cardiac resynchronization therapy.

P Pieter Martens[1]; S Deferm[1]; M Dupont[1]; W Mullens[1]
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*

BACKGROUND: Data on the effects of right atrial (RA)-pacing on left atrial (LA) synchronicity, function and structure after cardiac resynchronization therapy (CRT) are scarce.

OBJECTIVE To assess the impact of RA-pacing on LA-physiology and clinical outcome.
METHODSThe effect of RA-pacing on LA-function, morphology and synchronicity was assessed in a prospective imaging cohort of HF-patients in sinus rhythm with guideline indication for CRT. Additionally in a retrospective outcome cohort of consecutive HF-patients undergoing CRT-implantation the relation of RA-pacing was assessed with various outcome endpoints. High versus low atrial pacing burden was defined as atrial pacing above or below 50% in both cohorts.
RESULTS Thirty-six patients were included in the imaging cohort (age=68±11years). Six-months after CRT, patients with high RA-pacing burden showed less improvement in LA-maximum volume, minimum volume and total emptying-fraction ($p<0.05$). Peak atrial longitudinal strain, reservoir and booster strain-rate but not conduit strain-rate improved after CRT in patients with low RA-pacing burden and worsened in patients with high RA-pacing burden ($p<0.05$ for all). A high RA-pacing burden induced significant intra-atrial dyssynchrony (maximum-opposing-wall-delay; 44±13msec vs 97±17msec, $p=0.022$) (see figure). A total of 569-patients were included in the outcome-cohort. After covariate adjustment, a high RA-pacing burden was associated with LV-reverse remodeling (β=0.146,95%CI= [3.101;14.374],p=0.002), and new-onset or recurrence of atrial fibrillation (AF; 41% vs. 22% at median 31 [22-44] months follow-up; $p<0.001$). There was no difference in time to first HF-hospitalization or all-cause mortality ($p=0.185$) after covariate adjustment. However in a recurrent event analysis, heart failure readmission were more common in patients exposed to a high RA-pacing burden ($p=0.002$).
CONCLUSIONSRA-pacing in CRT patients negatively influences LA-morphology, function and synchronicity, which is associated with worse clinical outcome including diminished LV- reverse remodeling, increased risk for new-onset or recurrent AF and heart failure readmission. Strategies reducing RA-pacing burden might be warranted.



effect of RA pacing on LA-function

1428
Consequences of a revised heart allocation system on the cost effectiveness of cardiac transplantation in the united states: game theory based insights

M Mitchell Saltzberg[1]
[1]*Medical College of Wisconsin, Comprehensive Heart Failure and Transplant Program, Milwaukee, United States of America*

Purpose: Heart transplantation (HT) is a cost-effective (CE) therapy for end stage Heart Failure. A new US organ allocation system expands the listing statuses

and favors short-term, mechanical circulatory support (MCS) therapies and greater regional organ sharing with longer ischemic times and reduced survival.
Methods: CE (Quality adjusted life year (QALY) and Cost for Year of Life Expectancy (LE)) of HT was evaluated using a decision-tree model populated with local and published clinical probability, LE and Cost data. Sensitivity analyses was performed to assess the impact of changing clinical practices. Data are expressed in inflation adjusted 2018 USD and costs are discounted at 3%. A Willingness to Pay (WTP) threshold of $50,000 was considered acceptable.
Results: CE of HT is $75,751.88/QALY and $61,914.18/LE based on 79 % MCS use pre-HT and 21% short-term (ST) MCS use assuming a procurement radius (PR) of 350-miles. Varying % ST MCS (Fixed PR) from 5-79% negatively impacted CE; $57,239.12 - $163,299.40/QALY and $46,717.69-$183,819.12/LE. Increasing PR (<100 miles, 100-350 miles, 351-500 miles and > 500 miles) adversely impacted CE; $75,751.88- $78,548.65/QALY and $61,914.18-$64,200.06/LE. Assuming longer ischemic times (< 3.49 hours, 3.5-4.9 hours and > 5.5 hours) reduce post-HT survival (-1.4 yrs for 3.5-4.9 hrs and - 2.8 yrs for > 5.5 hrs), CE was negatively impacted: $75,751.88 (<3.49 hrs), $97,604.57 (3.5-5.5 hrs) and $137,177.02/QALY (>5.5 hrs); $61,914.18/LE (<3.49 hrs), $80,971.59/LE (3.5-5.5 hrs); and $116,977.76/LE (>5.5 hrs). Varying % ST MCS use (5%-79%) with a "worst case" ischemic time (4.9 hrs) significantly worsened CE; $76,925.93 -$219,268.68/QALY and $63,680.29 - $183,819.12/LE. Sensitivity analysis (Monte Carlo) confirmed a WTP of >$70,000 to render HT more cost-effective.
Conclusion: HT is a cost-effective strategy. CE of HT will be adversely impacted with the revised allocation system due primarily to increased ST MCS use, increased PR, longer ischemic times and secondary reduced post HT survival. It will be increasingly important to monitor CE as HT programs adjust to the new allocation system.

Funding Acknowledgements: Supported by Ministry of Health of the Czech Republic, grant nr. 16-30537A.

Introduction: Heart failure (HF) represents one of the leading causes of death in the developed countries and heart transplantation (HT) is the only solution for patients with terminal refractory HF. Patients after HT are at risk of acute cellular rejection (ACR) potentially causing graft damage and failure. Diagnostics of ACR is based on histopathologic evaluation of endomyocardial biopsies (EMB) as no non-invasive biomarker has been found yet. microRNAs (miRNAs, miRs) are tiny non-coding RNA molecules involved in post-transcriptional regulation of gene expression. Extracellularly they are potentially involved in intercellular communication and because of their high stability they represent novel potential biomarkers.
Purpose: The purpose of the current study was to identify potential urinary miRNAs that would reflect ACR occurrence without the need of EMB and even blood sampling performance.
Methods: Prospective monocentric study. 26 consecutive patients after HT have been enrolled and followed-up for one-year. During the follow-up period, patients absolved 12 regular check-ups including EMB performance and urinary sampling. 8 patients experienced at least one episode of ACR of grade IB and higher (using ISHLT criteria) during the follow-up. Three distinct urinary samples were analyzed from each patient: prior to rejection, during the rejection and after the rejection (as correlated with the results of EMB). Total RNA enriched for small RNAs was isolated using Urine microRNA Purification Kit and next-generation sequencing was performed using Illumina instrument according to manufacturer´s instructions. Differentially expressed miRNAs were identified using multiple comparisons and appropriate statistical methods.
Results: We have identified 737 individual miRNAs in urinary samples. Levels of 8 miRNAs were statistically significantly decreased (hsa-miR-582-3p, hsa-miR-7a-3p, hsa-miR-139-5p, hsa-miR-3065-5p, hsa-miR-676-3p, hsa-miR-199b-5p, hsa-miR-504-5p and hsa-miR-7706) and levels of one miRNA (hsa-miR-6764-5p) was statistically significantly increased (p value < 0.05) during the rejection episode.
Conclusions: We have identified several candidate miRNAs whose levels are altered in urinary samples in patients with histologically proven ongoing ACR. Results need to be validated on the rest of the patient cohort using qRT-PCR. Identification of such a non-invasive marker of ACR could lead to a decrease in number of EMB and would increase patients´ safety.

1430

Exercise oscillatory ventilation improves the performance of prognosis scores currently used for heart failure

F Francisco Gama[1]; P Freitas[1]; C Aguiar[1]; A Ferreira[1]; A Tralhao[1]; C Strong[1]; A Ventosa[1]; J Ferreira[1]; M Mendes[1]
[1]Hospital de Santa Cruz, Lisbon, Portugal

Background and aim: Several prognostic risk scores are available for heart failure with reduced ejection fraction (HFrEF), and are used, together with other criteria, to help decide the ideal timing for listing candidates for a heart transplant. The detection of an oscillatory ventilatory pattern (OVP) during cardiopulmonary exercise testing (CPET) has been associated with more advanced HF and a worse prognosis, but was not considered in the development of all the current risk scores. We evaluated whether OVP adds significant prognostic information to four contemporary HF scores.
Methods: Single-centre retrospective cohort study of consecutive HFrEF patients undergoing CPET for functional and prognostic assessment from October 1996 till May 2018. The Heart Failure Survival Score (HFSS), Seattle Heart Failure Model (SHFM), Meta-analysis Global Group in Chronic Heart Failure (MAGGIC) and Metabolic Exercise Cardiac Kidney Index (MECKI) were obtained in each patient. Cox model was fit with time to death or urgent transplant (whichever came first within 2 years) as the dependent variable and OVP and respective HF score as the independent variables. We further assessed the added discriminative power by performing ROC curve comparisons.
Results: We studied 387 patients, median age 58 (IQR 49; 65) years, and 77% were male. The most common HFrEF aetiology was ischemic heart disease (54%). Median peak oxygen consumption was 15,7 mL/kg/min (IQR 12,8; 20,0). OVP was present in 150 (39%) patients. Over the 2-year follow-up period, 48 patients died, and 52 underwent heart transplantation (of which 25 were urgent). HFSS showed the weakest (c-statistic 0,625; 95% [CI] 0,54-0,71) and MECKI score the strongest (c-statistic 0,819; 95% [CI] 0,76-0,88) discriminatory ability. The presence of OVP predicted the study endpoint independently of the HF prognosis score used (see table). Adding the occurrence of OVP to the HFSS and the MAGGIC scores significantly improved their prognostic performance (see Table).
Conclusion: An OVP is a common finding in HFrEF patients undergoing CPET, and adds prognostic information to contemporary HF prognosis scores. Systematic evaluation of this easily available criterion may assist the decision on the appropriate timing for heart transplantation listing.

From transcatheter atrial septal defect closure to atrial left-to-right shunt as a novel application of heart failure with preserved ejection fraction (HFpEF)

X Jin[1]; YM Hummel[2]; WT Tay[1]; JF Nauta[2]; NS Bamadhaj[1]; CSP Lam[1]; AA Voors[2]; ES Hoendermis[2]
[1]National Heart Centre Singapore, Singapore, Singapore; *[2]University Meidical Center Groningen , Groningen, Netherlands (The)*

Background: Transcatheter atrial septal defect (ASD) closure is a well-accepted therapeutic approach for wide ASD populations. Conversely, iatrogenic inter-atrial shunt creation recently emerged as a potential treatment modality for patients with heart failure with preserved ejection fraction (HFpEF). Given the opposing approaches of ASD closure versus creation, we hypothesized that some patients undergoing ASD closure may be predisposed to develop HFpEF. Thus, we aimed to investigate the early and sustained cardiac functional changes following transcatheter ASD (T-ASD) closure and their clinical correlates.
Methods: A prospective study of all adult secundum type ASD patients undergoing transcatheter closure enrolled between 2013 and 2017 in the University Medical

Center Groningen, the Netheraldns. Each patient underwent 3 sequential transthoracic echocardiography (TTE), pre- (Echo 1), 1 day post- (Echo 2) and within 1 year post- (Echo 3) procedure to determine hemodynamic characteristics associated with ASD and T-ASD closure. The associations between risk factors of HFpEF and significant hemodynamic changes after T-ASD closure were also investigated.

Results: Thirty-nine patients (mean 48±16years, 61.5% women) were included. T-ASD closure resulted in early and sustained decrease of right ventricle (RV) systolic and diastolic function (Table 1), indicated as significant decrease of relative values of RV global longitudinal strain (RV GLS, mean -20.7, -18.5 at Echo 1 vs Echo 2), RV S' (mean 14.3, 12.7 cm/s at Echo 1 vs Echo 3) and right atrium GLS (RA GLS, mean 36.9, 31.4, and 30.4 at Echo1, Echo2, Echo3 respectively) post-procedure. Comparatively, T-ASD closure resulted in early and sustained increase of left ventricle (LV) systolic function and deterioration of LV diastolic function with increase of LV filing pressure (LVFP) estimated by echocardiography (Table 1), which overall were demonstrated as significant increase of LV ejection fraction (LVEF, 54.0, 56.7 at Echo 1 vs Echo 2), LV mass index (LVMi, mean 72.9, 81.7 g/m2, at Echo 1 vs Echo 3), mean E/e' (mean 6.3 vs 7.3 at Echo 1 vs Echo 2)and decrease of left atrium GLS (LA GLS, mean 32.8, 26.7 and 26.7 at Echo1, Echo2, Echo3 respectively) post-procedure. Age (β= 0.31, p=0.009) and atrial fibrillation (β=0.24, p=0.03) were associated with sustained increase of LVFP after T-ASD closure estimated by mean E/e', while ASD size, sex and hypertension were not.

Conclusion: Older ASD patients and those with atrial fibrillation predisposed to sustained increases in left-sided filling pressures and HFpEF following ASD closure. We argue that in particular elderly HFpEF patients with atrial fibrillation might benefit from the artificial creation of a atrial left-to-right shunt.

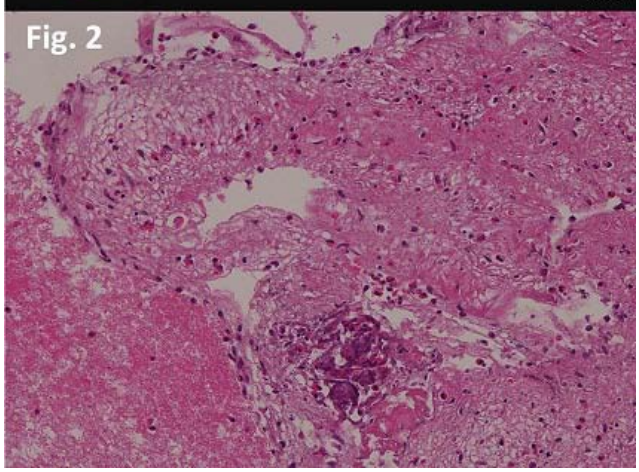
Refractory Pericardial Effusion associated with Churg-Strauss Syndrome

SK Lee[1]; MS Park[1]; SW Choi[1]; JC Youn[1]; SW Han[1]; KH Ryu[1]; EJ Kim[2]
[1]Hallym University, Cardiovascular center , Dongtan, Korea (Republic of); *[2]Korea University Guro Hospital, Cardiovascular Center, Korea University Guro Hospital, Seoul, Korea (Republic of)*

Case: A 46-year-old female with a history of allergic rhinitis visited for cardiomegaly on chest X-ray. She presented with intermittent mild fever, abdominal bloating, and worsening shortness of breath since 10 days ago. She had a history of eosinophilic pneumonia in 2012, and had never taken drugs which are known to induce eosinophilia. Immediate transthoracic echocardiogram (TTE) demonstrated moderate to large amount of pericardial effusion without hemodynamic significance. We decided to start acute pericarditis medications first, including NSAIDs, colchicine, and diuretics. After 7 days of medications, her symptoms and cardiomegaly on chest X-ray were improved, however, 3 months after treatment, her dyspnea and cardiomegaly were aggravated and repeat TTE showed large amount of pericardial effusion with fibrin-like material in pericardial space (Fig 1.). Pericardiocentesis was performed, and 300 ml of yellow-turbid fluid with many whitish crumb-like materials were aspirated. The fluid analysis revealed 9,825 WBC/mm3 with a differential count of 88% eosinophils, 1% neutrophils, and 2% monocytes. Bacterial and mycobacterial cultures were negative. Histopathologic examination of the pericardial fluid with needle biopsy revealed marked eosinophilic infiltrate with granulomatous lesion (Fig. 2) without malignant cells. Laboratory test revealed marked peripheral eosinophilia (38%, 4.4×103/μL) with mild leukocytosis (11.5×103/μL) and this finding was consistently noticed since her first visit. Furthermore, we could also detect nasal polyps on both sided of the nose by nasal endoscopy. The combination of clinical (allergic rhinitis, nasal polyposis, and a history of eosinophilic pneumonia) and laboratory (peripheral eosinophilia, eosinophilic tissue infiltrates) features, we could confirm the diagnosis as Churg-Strauss syndrome (CSS). After diagnosis, we started prednisolone at an initial dose of 1mg/kg/day, and her pericardial effusion with symptoms improved and peripheral eosinophilia declined rapidly.



Figures

Problems: There are numerous causes of pericardial effusion that includes viral and bacterial infection, neoplastic and metabolic diseases, and idiopathic pericarditis. In this situation, it is hard to doubt rare cause of pericardial effusion (such as CSS) as a first line. In addition, there are no commonly accepted diagnostic criteria for CSS, which makes more difficult to make proper diagnosis.

Discussion and conclusion: Pericardial effusion appears during CSS in 20-30% of cases, and it is generally mild and asymptomatic. But in our case, patient demonstrated refractory and symptomatic pericardial effusion with hemodynamic significance. This is rare, but may be a fatal complication. Hence, proper diagnosis with adequate treatment is essential. Based on our case, pericardial fluid analysis with biopsy was the key to differential diagnosis and therefore, timely therapy.

A case of chemotherapy-induced heart failure

M Hassan Abdelnabi[1]; A Almaghraby[2]; Y Saleh[2]
[1]Medical Research Institute, Alexandria University, Cardiology and Angiology Unit, Clinical and Experimental Internal Medicine Department, Alexandria, Egypt; *[2]Alexandria University, Department of Cardiology, Alexandria, Egypt*

Introduction: Chemotherapy-induced cardiotoxicity is one of the most common complications of cancer therapy that can significantly impact morbidity and mortality. With a high prevalence of cardiovascular disease in cancer patients, the risk of developing HF is significantly increased especially in patients with co-morbidities such as hypertension and diabetes.

Case report :

A 59-year-old female patient presented to our facility with rapidly progressive dyspnea that was diagnosed as acute pulmonary oedema. Patient had a history of hypertension, diabetes, smoking and she was receiving Adriamycin on top of an excised left breast cancer.

Patient was managed in the intensive care unit according to the guidelines of acute heart failure and a bed side transthoracic echocardiography was done and revealed dilated left ventricular (LV) dimensions and volumes with severely reduced systolic function, ejection fraction was 25% with severe global hypokinesia and evidence of a large LV apical thrombus.

Anti-failure measures were initiated immediately in the form of diuresis for her symptoms, Ramipril 2.5 mg once daily and bisoprolol 2.5 mg once daily in addition to warfarin for the LV apical thrombus.

On her second day in the intensive care the patient developed right lag and she was diagnosed as acute ischemic stroke with a cardioembolic cause.

After 1 month of discharge, follow-up echocardiography revealed marvelous improvement of the LV dimensions and ejection fraction which returned to normal (65%) and the LV apical thrombus disappeared completely.

Patient was advised to continue of her medications and the Cardio-Oncology team decided to stop giving Adriamycin to her.

Conclusion: Chemotherapy-induced left ventricular dysfunction and heart failure is a common complication in cancer patients and close follow-up for those patients is very important, and its management demands a multidisciplinary approach from cardiologists, oncologists and the interdisciplinary team involved in the management of these patients.

The role of levosimendan and ivabradine in cardio-oncology: acute doxorubicin toxicity

G Georges El-Khoury[1]; A Bazarbachi[2]; H Skouri[1]
[1]American University of Beirut Medical Center, Internal Medicine-Cardiology, Beirut, Lebanon; [2]American University of Beirut Medical Center, Internal Medicine-Hematology-Oncology, Beirut, Lebanon

Funding Acknowledgements: not applicable

A 31 year old male patient, known to have Adult onset Still's disease maintained on methotrexate and recently diagnosed with T-cell lymphoma, admitted initially for chemotherapy session and administered R-CHOP regimen.
Two hours after receiving his chemotherapy regimen, the patient developed severe acute chest pain radiating to the back, orthopnea.
His initial vital signs were BP of 120/75 mmHg and HR of 120 bpm, O2 saturation of 90% on room air.
ECG showed sinus tachycardia with early repolarization of the ST segment. Troponin level was elevated (0.086 ng/ml) and trended up to 0.247 ng/ml. CXR showed congested lungs.
Urgent TTE showed a severely impaired LV and RV systolic function with estimated LVEF of 15%, severe MR and TR.His condition rapidly deteriorated and became hypotensive, tachypneic with evidence of cardiogenic shock (BP=62/46 mmHg and HR=115 bpm).
Urgent coronary angiography done showed normal coronaries. LVEDP was 35 mmHg, RA pressure of 25 mmHg and cardiac index of 1.6 L/min/m2. An intra-aortic balloon pump and Swan-Ganz catheter were inserted. He was started on norepinephrine/Dobutamine with IV diuresis with no significant improvement of his condition in the next 6 hours.
Decision was to switch treatment to Levosimendan/Norepinephrine/ivabradine/furosemide.
Over the course of few days, patient's condition improved and was successfully weaned of IABP, pressors and ventilator while ivabradine was kept at maximal dose. He became hemodynamically stable with normal vitals. A repeat TTE at 10 and 26 days showed significant improvement of his cardiac function with normalization of right and left systolic function (refer to table).
Discussion: Here we describe a rare presentation of acute doxorubicin toxicity with cardiogenic shock and successful treatment with recovery using levosimendan, ivabradine along with mechanical support.

Introduction: Nonbacterial thrombotic endocarditis is a rare disease characterized by the deposition of thrombotic material in cardiac valves, in the absence of infectious cause. It has been described its association with neoplastic disease, with high risk for central or peripheral embolism and high mortality.

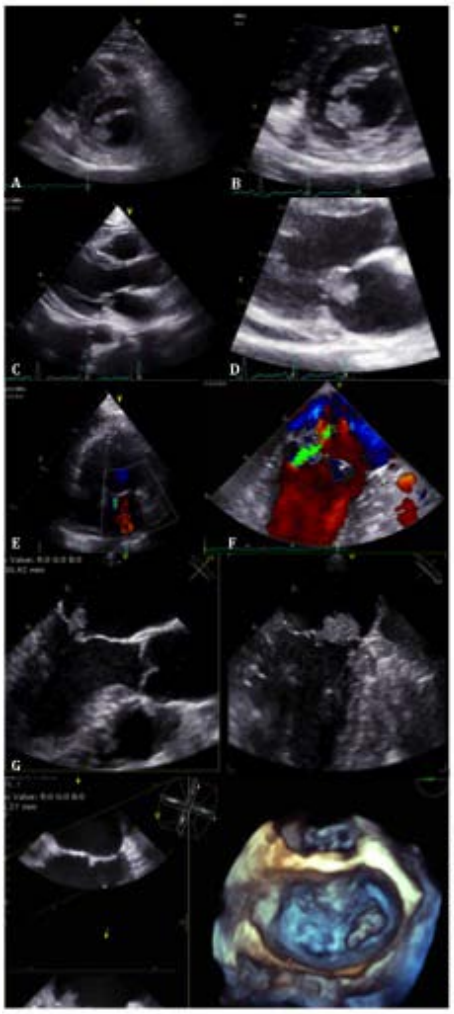

Figure 2.
Echocardiographic study of the mitral mass: A, B – Transtoracic small axix view; C, D Transthoracic longa xis view; E – Mild mitral regurgitation in transthoracic and (F) in transesophageal;
G – transesophageal view.

Echocardiograms

We report a case of a 63 yo female patient with no relevant medical history, presenting at the ED with insidious symptoms of dizziness and mnesic deficits for 1 month, lately associated with weakness of the right hemibody and speech abnormalities. At examination she was hypertensive, with right hemiplegia and aphafia of nomination. Head CT scan showed multiple non-recent bilateral parietal and occipital ischemic lesions, and a recent focal lesion in the left frontal lobe. Lab tests: Hb 13.0g/dL, WBC 11.9x10^3/uL, CRP 24mg/L, normal renal tests. Blood gas with hypoxemia and chest x-ray with evidence of left pleural effusion. Better characterization with MRI confirmed multiple subacute ischemic strokes and no vascular defects. Considering the multiples focal cerebral lesions, cardioembolic source was suspected. Transthoracic echocardiogram observed a hyperechogenic, non-mobile mass in the atrial face of posterior leaflet of the mitral valve, 9x10mm, with mild regurgitation; thin circumferential pericardial effusion and pleural effusion of moderate volume. Transesophageal echo confirmed preservation of the valve leaflets. Absence of infectious history and negative serial blood cultures led to investigation of alternative diagnosis to explain also polyserositis. Thoraco-abdominal CT showed multiple bilateral pulmonary and right axillary nodules. Pathology of the pleural effusion and excision

biopsy of the nodes were consistent with lung adenocarcinoma. Progressive clinical deterioration ultimately led to patient death.
Conclusion: This case reflects the importance of meticulous investigation of repeated embolic events, keeping high suspicion index for this rare and lethal entity, sometimes even masking other potential severe diseases.

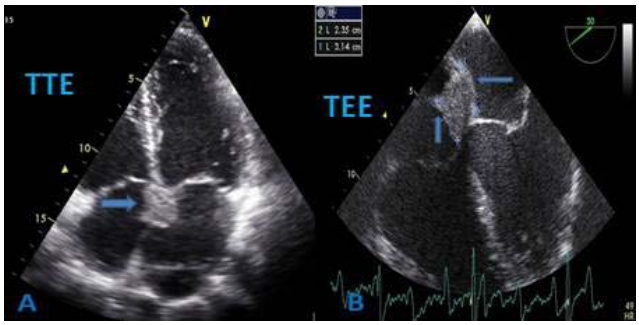
Complete atrioventricular block revealing cardiac metastasis of pulmonary adenocarcinoma

S Antit[1]; F Yangui[2]; M Ben Kilani[1]; I Boussabeh[1]; M Triki[2]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*;
[2]*Interior Security Forces Hospital, Department of pneumology, Marsa, Tunisia*

Background: Metastases in lung cancer are common; however the heart represents a rare metastatic site in which the diagnosis is often made in post-mortem. We report a case of complete atrioventricular block resulting from a bronchopulmonary tumor's secondary site at the atrial septum.
Case report : It was a 57-year-old patient, with no particular medical history, smoking at 35 packs a year, who for four months had chronic bronchitis with deterioration of health condition and dyspnea. This symptomatology was related to a pulmonary adenocarcioma with multiple metastatic sites: lymph node, adrenal and peritoneal metastases. The patient was hospitalized in the emergency room because of a worsening of his dyspnea. The clinical examination found an apyretic and eupneic patient at rest. The blood pressure was 130/80 mmHg with a heart rate of 40 cpm and oxygen saturation of 95% on room air. The electrocardiogram showed complete atrioventricular block at 37 cpm with narrow QRS complex (Figure 1). Transthoracic echocardiography (TTE) revealed an echogenic ovarian mass infiltrating the lower half of the interatrial septum (IAS) (measuring 26 x 17 mm), which did not interfere with the mitral valve function except for a grade 1 mitral regurgitation. Ventricular contractility was preserved and pulmonary arterial hypertension at 55mmHg with a minimal pericardial effusion was also observed. Transesophageal echocardiography confirmed the results of the TTE (Figure 2). The patient was implanted by a dual-chamber pacemaker without incident and then transferred to the pneumology department for further treatment by chemotherapy.
Conclusion: which have metastasized to the heart are found in six to 20% of patients with malignant neoplasms. In case of a conduction disorder in a patient with a neoplasia, it is necessary to evoke a secondary cardiac location. TTE is the key exam that has to be conducted systematically.



TTE A/TEE B: mass infiltrating the IAS

Cardiogenic shock in a postoperative patient with neoplasia: what went wrong?

M L Mariana Loredana Barbu[1]; C Humulescu[1]; A Trandafir[1]; D Pasoiu[1]; R Ciomag[1]; C Homentcovschi[1]; A Gurghean[1]; D Spataru[1]; R Siliste[1]
[1]*Coltea Clinical Hospital, Bucharest, Romania*

Takotsubo cardiomyopathy is a rare stress-induced acute heart disease, which can manifest as severe left ventricle (LV) dysfunction. Data suggests that the underlying mechanism might be coronary spasm, induced by either the perioperative catecholamine storm, or by the anesthetics used in surgery, sometimes with a delay of a few days. Recent studies also show possible molecular correlations between neoplasia and this type of cardiomyopathy.
We present the case of a 48-year-old female patient, with a history of uterine cervical cancer for which she received surgical and radiotherapy treatment. One year later, a second intervention was performed, for occlusive syndrome in the setting of post-irradiation enteritis. While in the ICU, in the 48 hours after surgery, the patient developed dyspnea with orthopnea and anterior thoracic pain. The clinical exam shows tachycardia, LV gallop, pulmonary crackles, systemic congestion and hypotension, despite vasopressor support. Blood tests showed positive troponin levels and a high NT-proBNP. The ECG revealed ST-segment elevation, while the echocardiography showed circumferential apical akinesia and severe LV systolic dysfunction with an ejection fraction of 25%. An emergency angiography was performed, which did not find any coronary lesions. For the next 10 days, the patient's condition improved constantly, with significant improvement of systolic function. As such, the final diagnosis was Takotsubo cardiomyopathy, triggered by the surgical intervention.
Our case had an association of all of the possible trigger factors (neoplasia, anesthesia, major surgery), which perhaps explains the severity of the disease in a patient with no previous cardiovascular disease.

1463
Early onset of coronary artery disease in young survivor after combined treatment of non-Hodgkin lymphoma

EK Shavarova[1]; IA Chomova[1]; VV Maiskov[1]; ZD Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Introduction: the success and continued progress of cancer control strategies have resulted in a rise in the number of long-term cancer survivors. Cardiovascular diseases are increasingly observed as late effects of B-cell Non-Hodgkin lymphoma treatment.
Case report : a thirty five-years-old female without previous cardiovascular risk factors and established diseases was diagnosed with B-cell Non-Hodgkin lymphoma (CD20+, CD3-, CD79a, CD15-, LCA+), II BE stage in March of 2012. After six courses of R-CHOP the radiation therapy was done (total dose 40 Gy). In January of 2013 complete disappearance of all detectable clinical evidence of disease and disease-related symptoms presented before therapy (fever, lymphadenopathy, cough, dyspnea) were observed. Complete remission was confirmed by CT-scan and Immunohistochemistry assay. All clinical exams and CT-scan were repeated every 6 month, no relapse symptoms were identified. Arterial hypertension grade II (transient), obesity class I, dyslipidemia (LDL-cholesterol 3.44 mmol/l) were observed without intake of any medications. In October of 2018 new onset angina (Canadian Cardiovascular Society class I – during intensive aerobic exercises in fitness club) occurred. Two weeks later the patient was hospitalized with acute coronary syndrome (Class III angina). Negative T-wave were registered on ECG in I, avL, V2-V6. Troponin I was 0.02 ng/ml at admission and 0.05 ng/ml after 6 h. Two-vessels disease (critical stenoss of left main disease and proximal left arterial descending artery) were observed on coronary angiography. Stent was placed into left main stem with optimal results of PCI (TIMI III). No angina attack were registered in post-PCI period and during follow up. On echocardiography one month after PCI – pulmonary hypertension grade I, concentric remodeling, ejection fraction >50%, LV global longitudinal strain was -19% (-14% in septal segments). NT-proBNP level was 256 pg/ml.
Conclusion: anthracyclines therapy and exposure of the heart to ionizing radiation during non-Hodgkin lymphoma treatment increases the subsequent rate of ischemic heart disease. Echocardiography and functional stress tests should be recommended at long-term follow up of non-Hodgkin's lymphoma survivors, especially after combined anthracycline and radiation therapy.

1464
AV Block with unconventional cause

A Amr Abdin[1]; P Baldia[1]; M Frick[1]; N Marx[1]; K Schuett[1]
[1]*RWTH University Hospital Aachen, Aachen, Germany*

Complete atrioventricular (AV) block can occur due to many structural causes. Common structural etiologies include sclerodegenerative disease of the conduction system, ischemic heart disease and following cardiac surgery. Rare structural causes could be infiltrative myocardial disease and congenital heart disease (1). Herein, we present a case of a 78-year-old male with primary cardiac sarcoma who was admitted to our institution with complete AV block.
A 78-year-old patient without known history of cardiovascular disease was referred to our institution for permanent pacemaker implantation due to complete AV block. The patient reported nonspecific symptoms of fatigue, anorexia, weight loss and progressive dyspnea (NYHA class II) over a period of 2 months. There were no symptoms of dizziness, chest discomfort, or syncope. His electrocardiogram revealed a complete AV block with a junctional escape rhythm (40 bpm). Transthoracic echocardiography revealed normal LV function with a mass located in the right atrium (RA) and protruding into in the right ventricle (RV) through the tricuspid valve. For further differentiation cardiac magnetic resonance (CMR) imaging was performed. CMR showed a mass in the inferior RA and basal RV wall (60 x 40 x 49 mm; Figure 1), involving the atrioventricular node and the posterior leaflet of the tricuspid valve

with inhomogeneous gadolinium enhancement. The patient was transferred to the operation theater. A jelly-like mass was detected, which was diffusely infiltrating the RA and RV wall. A curative resection was impossible and biopsies were performed. Additionally, a permanent epicardial pacemaker was implanted. In the pathological examination, a malignant spindle cell tumour was seen. Moreover, morphological and immunohistochemical findings were compatible with a synovial sarcoma. A metastatic workup revealed one pulmonary metastasis. After an interdisciplinary team discussion, chemotherapy with Olaratumab and Doxorubicin was initiated.
Primary cardiac tumours are extremely rare entities with an incidence of 0.001% to 0.03%. In adults, approximately one-fourth of primary cardiac tumours are malignant with sarcomas representing the most common histology (2). Data from patients with primary cardiac sarcomas show that median survival is approximately 6 months.
In summary, it is always important to investigate the cause of complete AV-Block.

Moderated Poster Session - Basic Science

1465

Serum uric acid levels and xanthine oxidase activity in chronic heart failure patients with chronic kidney disease

M Maryna Kolomiiets[1]; A Bilchenko[1]
[1]*Kharkiv National Academy of Postgraduate Education, Kharkiv, Ukraine*

Background. Recent experimental and clinical data suggest that there might be a direct pathophysiological role for increased xanthine oxidase (XO) activity and hyperuricemia in the progression of heart failure (HF).
Purpose. To evaluate the impact of hyperuricemia and XO activation in HF patients with chronic kidney disease (CKD).
Methods. Baseline characteristics were: 112 patients with chronic HF (among them 51 men and 61 women), mean age – 72.5±8.6 years. All patients were divided into 2 groups: within CKD (n=72) and non-CKD (n=40) participants. We used enzymatic colorimetric test, PAP – method with antilipid factor to evaluate serum uric acid (SUA) levels. Asymptomatic hyperuricemia was defined as SUA levels >7.0 mg/dl in men and >6.0 mg/dl in women. XO activity was determined by a coupled enzyme assay, which resulted in a colorimetric (570 nm)/fluorometric (lex= 535/lem=587 nm) product, proportional to the hydrogen peroxide generated. One unit of XO was defined as the amount of enzyme that catalyzed the oxidation of xanthine, yielding 1.0 mmole of uric acid and hydrogen peroxide per minute at 25 °C.
Results. In patients group 62,5% had asymptomatic hyperuricemia. The mean SUA levels for matched patients were (8,47±0,23) mg/dL, in the group without hyperuricemia – (5,38±0,19) mg/dL. SUA correlated negatively with left ventricular ejection fraction (LVEF) (r=-0,3, <0,05). Patients with functional class New York Heart Association (NYHA) III have significantly higher SUA levels compared to patients with NYHA II: (8,5±0,39) mg/dL and (6,88±0,25) mg/dL respectively (<0,01). The kidney function significance in the development of the xanthine metabolism violations proves the revealed inverse correlation between estimated glomerular filtration rate (eGFR) and XO activity (r=-0,7, p<0,05) as well as SUA levels in patients with chronic HF (r=-0,3, p<0.05). Patients with concomitant CKD had higher XO activity levels compared to non-CKD patients: (7,51±0,77) mU/ml vs (4,69±0,77) mU/ml respectively (=0,01). The mean SUA levels were not significantly different: (7,63±0,27) mg/dl vs (7,46±0,39) mg/dl respectively (=0,73). Comparison of mean GFR in patients with and without hyperuricemia revealed significantly lower GFR in patients with asymptomatic hyperuricemia: (59.9±2.95) ml/min/1.73m2 and (76.6±6.05)ml/min/1.73 m2 respectively (p<0.01). Data also showed that patients with eGFR≤60 ml/min/1.73 m2 have significantly higher SUA levels and XO activity compared to those with eGFR>60 ml/min/1.73 m2: (8,21±0,29) mg/dl vs (6,73±0,31) mg/dl (<0,001) and (8,72±0,8) mU/ml vs (4,15±0,56) mU/ml respectively (<0,001).
Conclusion. Uric acid itself rather than up-regulated XO activity in patients with chronic HF is associated with LVEF and the progression of HF functional class. But the presence of concomitant CKD in chronic HF patients can modify the xanthine metabolism towards oxidase pathway.

BACKGROUND: Limited knowledge exists of the extent of epigenetic alterations, such as DNA methylation, in Heart Failure (HF). We conducted targeted DNA methylation sequencing to identify DNA methylation alterations in coding and non-coding RNA across different etiological sub-types of HF.
METHODS AND RESULTS: A targeted bisulfite sequence capture sequencing platform was applied to DNA extracted from cardiac interventricular septal tissue of 30 male HF patients encompassing etiologies including Hypertrophic Obstructive Cardiomyopathy (HOCM, n=12), Ischemic Cardiomyopathy (ISCM, n=9), Dilated Cardiomyopathy (DCM, n=9), and 9 control patients with non-failing hearts (NF). We detected 62,678 differentially methylated regions (DMR) in the studied HF cohort. By comparing each HF sub-group to the NF control group we identified 195 unique DMRs: 5 in HOCM, 151 in DCM, and 55 in ISCM. These translated to 4 genes/1 non-coding RNA (ncRNA) in HOCM, 131 genes/17 ncRNA in DCM, and 51 genes/5 ncRNA in ISCM. Subsequent gene/ncRNA expression analysis was assessed using qRT-PCR and revealed 6 genes: 4 hypermethylated (HEY2, MSR1, MYOM3, COX17), 2 hypomethylated (CTGF, MMP2); and 2 microRNA: 1 hypermethylated (miR-24-1), 1 hypomethylated (miR-155) with significantly up- or down-regulated expression levels consistent with the direction of methylation in the particular HF sub-group.
CONCLUSIONS: For the first time DNA methylation alterations and associated gene expression changes were identified in etiologically-variant pathological heart failure tissue. The methylation-sensitive and disease-associated genes/non-coding RNA identified from this study represent a unique cohort of loci that demonstrate a plausible potential as a novel diagnostic and/or therapeutic target in HF and warrant further investigation.

Sodium-glucose co-transporter 2 inhibition with empagliflozin improves cardiac function in non-diabetic rats with heart failure after myocardial infarction

SR Yurista[1]; HHW Sillje[1]; SU Oberdorf-Maass[1]; EM Schouten[1]; MG Pavez-Giani[1]; JL Hillebrands[2]; H Van Goor[2]; DJ Van Veldhuisen[1]; RA De Boer[1]; BD Westenbrink[1]

Purpose: Sodium glucose co-transporter-2 (SGLT-2) inhibition reduces heart failure (HF) hospitalizations in patients with diabetes, irrespective of glycemic control. We examined the effect of SGLT-2 inhibition with Empagliflozin (EMPA) on cardiac function in non-diabetic rats with HF after myocardial infarction (MI).
Methods: Male non-diabetic Sprague-Dawley rats underwent permanent coronary artery ligation to induce MI, or sham surgery. Rats received chow containing EMPA (30 mg/kg/day) or control chow, starting before surgery (EMPA-early) or 2 weeks after surgery (EMPA-late). Cardiac function was assessed using echocardiography and histological and molecular markers of cardiac remodelling and metabolism were assessed in the left ventricle. Renal function was assessed in metabolic cages. The investigation conforms to the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health and in accordance with national regulations.
Results: EMPA increased urine production by 2-fold without affecting creatinine clearance and serum electrolytes. EMPA did not influence MI size, but left ventricular ejection fraction was significantly higher in the EMPA-early and EMPA-late treated MI-groups compared to MI-group treated with vehicle (LVEF 54%, 52% and 43% respectively, all $P < 0.05$; Figure 1). EMPA also attenuated cardiomyocyte hypertrophy and reduced interstitial fibrosis. Mitochondrial DNA damage and mitochondrial biogenesis were augmented by EMPA treatment, associated with restoration of the myocardial uptake and oxidation of glucose and fatty acids. EMPA also increased circulating ketone levels and enhanced the myocardial utilization of ketone bodies.
Conclusion: EMPA favourably affects cardiac function and remodelling in non-diabetic rats with HF after MI, associated with substantial improvements

in cardiac metabolism. Importantly, it did so without renal adverse effects. Our data suggest that EMPA might be of benefit in HF patients without diabetes.

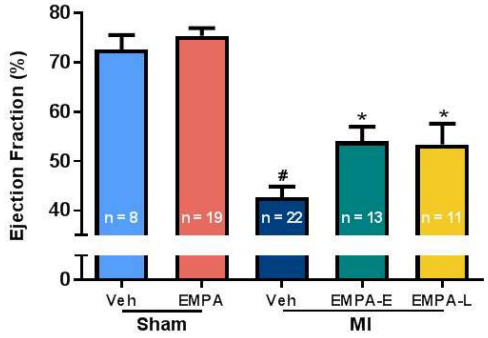

Figure 1. Ejection fraction of the left ventricle. Veh, Vehicle; EMPA, empagliflozin; EMPA-E, EMPA early; EMPA-L, EMPA late. Data are presented as means ± SEM. * $p < 0.05$ vs. MI-Veh; # $p < 0.05$ vs. Sham-Veh.

Rest myocardial perfusion defects are related to increased 99mTc-sestamibi washout and inflammation in CCC

L Oliveira[1]; JT Thackeray[2]; ML Delarisse[1]; DM Tanaka[1]; CG Fabricio[1]; ACL Barros-Filho[1]; D Hilfiker-Kleiner[2]; M Ricke-Hoch[2]; J Mejia[3]; BGA Schirmer[4]; C Malamut[4]; FM Bengel[2]; MV Simoes[1]

Funding Acknowledgements: São Paulo Research Foundation (FAPESP)

Background: Physiopathological mechanism of Chronic Chagas cardiomyopathy (CCC) includes myocardial inflammation and perfusion abnormalities resulting in interstitial fibrosis and cardiac dilation. 99mTc-Sestamibi (MIBI) is a myocardial perfusion tracer, whose uptake and retention depends on mitochondrial integrity, a process that can be altered by inflammation. Purpose: We tested the hypothesis that myocardial perfusion defects (MPD) are related to increased MIBI washout that is associated with inflammation in experimental CCC. Methods: Female Syrian hamsters infected with 3.5x104 trypomastigotes forms of T. cruzi Y-strain (n= 12) and their respective controls (n=5) were studied 8 months after infection. Planar scintigraphy imaging was acquired at 30min and 90min after MIBI injection to assess global washout rate followed by SPECT imaging for quantification of MPD extension. The left ventricular ejection fraction (LVEF) was assessed by using 2D-echocardiogram. The animals underwent PET imaging to assess myocardial inflammation. Neonatal rat cardiomyocytes (NRCM) and fibroblasts (NRFB) were isolated and stimulated by increasing concentrations of interferon-γ (5, 10 or 25 ng/mL) or vehicle for 24 or 48 hours. 99mTc-Sestamibi activity was measured at 30min, 90min, and 240min to determine tracer washout. Results: Compared to control infected animals displayed larger MPD at 30min (% of LV, 18.7±8.7 vs 2.4±2.4, p=0.0003), and at 90min (21.3±10.4 vs 3.3±2.7, p=0.001), higher MIBI washout (%, 13.3±7.1 vs 7.3±2.8, p=0.047) and more intense myocardial inflammation (cells/mm2, 555.1±128.7 vs 388.2±106.81, p=0.01). The MPD in infected animals increased from 30min to 90min (p= 0.02). The washout rate correlated positively with MPD area (r=0.55, p=0.03), negatively with LVEF (r=-0.6, p=0.016) and positively with myocardial inflammation (r= 0.75; p=0.0005). There was no correlation between the washout rate and fibrosis extension (p> 0.05). Areas of MPD presented visual topographic correlation with increased 18F-FDG uptake assessing myocardial inflammation. Compared to control, NRCM stimulated with 25ng/ml of IFN-γ over 24h resulted in accelerated MIBI washout (%, 90min: 55±3,5 vs 50,4±2,9, p=0.016; 240min 86,1±1,1 vs 83,6±1,7, p=0.001). Longer pro-inflammatory stimulation resulted in higher MIBI washout compared to matched control NRCM (%, 90min: 62.6±2.8 vs 56±5.6, p=0.013; 240min: 91.3±3 vs 86.6±4.8, p=0.024)band modest NRCM hypertrophy. By contrast, inflammatory cytokines did not affect washout in NRFB. Conclusion: Rest MPD extent is related to increased MIBI washout, and is topographically associated with myocardial inflammation in experimental CCC. In vitro data show that IFN-γ lowers uptake and enhances MIBI washout in isolated cardiomyocytes, reinforcing the correlation between inflammation and altered MIBI kinetic. Delayed MIBI imaging, with assessment of MIBI washout and rest MPD, is a potential tool to detect inflammation in CCC.

Different pathophysiological pathways between ischaemic and non-ischaemic heart failure

RJ Woolley[1]; AA Voors[1]; J Tromp[1]; JF Nauta[1]; IE Sama[1]
[1]University of Groningen, Department of Cardiology , Groningen, Netherlands (The)

On behalf of: BIOSTAT-CHF consortium
Funding Acknowledgements: This work was funded by the European Union FP7 Project [FP7-242209-BIOSTAT-CHF; EudraCT 2010-020808-29]

BACKGROUND: Ischaemic heart failure (HF) and non-ischaemic cardiomyopathy are largely treated the same, despite important potential underlying differences in pathophysiology. However, the mechanisms underlying these different aetiologies of HF remain unclear.OBJECTIVES The purpose of this study was to establish biological pathways specifically related to ischaemic HF relative to non-ischaemic cardiomyopathy.
METHODS: A network analysis was performed to identify biological pathways up/down-regulated in ischaemic HF versus non-ischaemic cardiomyopathy using 92 biomarkers from different pathophysiological domains in a cohort of 1,160 HF patients. Patients with ischaemic HF were defined as those having HF with a history of documented myocardial infarction. Non-ischaemic cardiomyopathy patients were those with primary cardiomyopathy in the absence of documented coronary artery disease. Results were externally validated in an independent cohort of 867 patients with ischaemic HF and non-ischaemic cardiomyopathy according to the same definitions. Networks were built using the relative difference in expression profiles of the 92 biomarkers from the Olink platform. Networks were enriched using existing knowledge of protein-protein interactions and categorised into biological pathways up-regulated in ischaemic HF versus non-ischaemic cardiomyopathy.
RESULTS: In the index cohort 715 (62%) patients had ischaemic HF and 445 (38%) patients had non-ischaemic cardiomyopathy. The median age of the 715 ischaemic HF patients was 71 years with 82% being male. The non-ischaemic cardiomyopathy patients were younger, with a median age of 64 years and 73% were males. In the index cohort, 23 protein-biomarkers were differentially expressed and statistically significant between the two groups. When adjusted for age and sex 3 biomarkers remained statistically significant. Of these, Galectin-4 and Growth-Differentiation Factor-15 were up-regulated while Paraoxonase-3 was down-regulated in ischaemic HF relative to non-ischaemic cardiomyopathy. The former two are implicated in inflammation while paraoxonase-3 is linked to the inhibition of both LDL oxidation and monocyte activation. Validation of protein-protein interactions led to the identification of several biological pathways that were up-regulated in ischaemic HF. These pathways were related to bone resorption, proteins involved in invasion and metastasis of cancer, neuroinflammatory responses, regulation of superoxide free radicals and dissolution of fibrin clots.
CONCLUSIONS: Ischaemic HF exhibits different expression levels of several biomarkers when compared to those with non-ischaemic cardiomyopathy. These ischaemic HF proteins appear to be involved in inflammatory processes and atherosclerosis. Further analysis using transcriptomics may help to consolidate the place of these proteins in the context of their biological pathway, and therefore facilitate further interpretation of their role in ischaemic HF.

Generation and phenotyping of a novel knock-in mouse model of arrhythmogenic cardiomyopathy

A Di Bona[1]; A Scalco[1]; N Kuperwasser[2]; P David[3]; R Celeghin[4]; K Pilichou[4]; M Pende[2]; C Basso[4]; M Mongillo[5]; T Zaglia[1]
[1]Venetian Institute of Molecular Medicine, Department of Cardiac Thoracic Vascular and Public Health, Padua, Italy; *[2]Institut Necker-Enfants Malades (INEM), Inserm U1151, Université Paris Descartes, Paris, France*; *[3]Institut Imagine, Paris, France*; *[4]University of Padova, Department of Cardiac Thoracic and Vascular Sciences, Padova, Italy*; *[5]University of Padova and Venetian Institute of Molecular Medicine, Department of Biomedical Sciences, Padova, Italy*

Rationale and purpose: Arrhythmogenic Cardiomyopathy (AC) is a cardiac disease, mainly caused by mutations in genes encoding desmosomal proteins, accounting for most cases of sudden death in the young and athletes. AC hearts display cardiomyocyte (CM) death and fibro-fatty tissue replacement, which lead to contractile dysfunction and generate the substrate for arrhythmias, triggered by physical stresses. The AC pathogenesis is unknown and no therapies are available. Up to now, most AC models express disease-causing mutations selectively in CM and, likely because they do not replicate the human genetics, they fail to faithfully reproduce the disease phenotype. Considering that all cell types forming the myocardial network express desmosomal proteins, knock-in (KI) mice represent the preclinical model most appropriate for AC studies. We thus aimed to generate a KI mouse model, harbouring the point mutation Serine (S) 311 Arginine (R) in Desmoplakin (DSP), which corresponds in the mouse to the mutation identified in a large part of the Italian AC population.

Methods and Results. Crispr-Cas9 was used to precisely edit the DSP gene. The first step was to design the targeting guide which was built around the target locus. Secondly, the expression plasmid for the guide and Cas9 was constructed, transfected into 3T3 cells, which were screened and the positive clones singularly isolated, let grow and selected by sequencing. Once confirmed that the guide worked as expected, we created the exogenous donor in the form of dsDNA targeting constructs, with homology arms flanking the mutation. The following step was to use the Crispr-Cas9 system to generate the mouse. To this purpose, one-cell-staged embryos were microinjected with Crispr components and transferred into a pseudo-pregnant mouse. At the time being, five heterozygous DSP S311R/WT mice have been obtained.
Conclusions and Perspectives. We successfully generated the founders of a novel AC DSP S311R/WT KI mouse strain, which will be characterized, structurally by gross histology, immunofluorescence and electron microscopy, and functionally by echocardiography and telemetry-based ECG analyses.

Inhibition of complement-coagulation system cross talk attenuates cardiac tissue injury in an ARVC animal model

M Mavroidis[1]; K Tsilafakis[1]; A Varela[1]; F Pantouli[1]; C Davos[1]; I Kostavasili[1]
[1]Biomedical Research Foundation Academy of Athens, Greece, Athens, Greece

Funding Acknowledgements: hellenic cardiological society

Inflammatory processes may influence arrhythmogenic right ventricular cardiomyopathy (ARVC) onset, progression or flares in disease activity associated with periods of increased arrhythmia. We have previously found that inhibition of complement receptor C5aR ameliorates disease severity in the desmin null (Des-/-) ARVC animal model. In the present study, we investigated the role of initial steps of complement cascade activation in ARVC disease progression. By generating C3 and desmin double knock out animals (C3-/-Des-/-), a more severe cardiac pathology was unexpectedly found. An 18% increase in cardiac tissue injury was observed in 4 month-old C3-/-Des-/- mice compared to Des-/-; and the survival rate at the end of 12 months period was reduced in C3-/-Des-/- mice (83.8%) compared to wildtype (98.2%). Although in the conventional way of C5 activation no C5 cleavage is expected to occur, as activated C3 is part of the C5 convertase, we observed intense C5 staining by immunocytochemistry in the myocardium of C3-/-Des-/- mice, in areas of coagulative necrosis and dystrophic calcification. In addition, increased levels of the C5a anaphylatoxin were found in the serum of C3-/-Des-/- mice compared to wildtype, indicating C5 activation independently of conventional convertase, presumably via the coagulation system. Increased staining for fibrinogen and von Willebrand factor was observed by immunofluorescence in the myocardium of C3-/-Des-/- and Des-/- animals when compared to wildtype, in the same areas where C5 deposition was also observed. Moreover, inhibition of the coagulation system activation by treatment with lepirudin, (a specific thrombin inhibitor) resulted in a 25.5% reduction in cardiac tissue injury compared to vehicle-treated Des-/- animals. C5 deposition was also reduced indicating a causative role of coagulation cascade activation in complement activation.
In conclusion, our data indicate an interplay of coagulation and complement systems in the myocardium of the Des-/- ARVC model, which could exacerbate the observed pathology.

Pharmacological inhibition of GRK2 in experimental heart failure

M Michele Ciccarelli[1]; J Gambardella[1]; A Fiordelisi[2]; D Sorriento[2]; M Sala[1]; P Campiglia[1]; B Trimarco[2]; G Iaccarino[2]
[1]University of Salerno, Salerno, Italy; *[2]"Federico II" University of Naples - Dept of Advanced Biomedical Sciences, Naples, Italy*

Introduction: G protein-coupled receptor kinase 2 (GRK2) levels are upregulated in failing cardiomyocytes and contribute to desensitization and downregulation of the β adrenergic receptor (βAR), impaired adrenergic response, cardiac insulin resistance and reduced metabolic plasticity. Several therapeutic options for targeting GRK2 in HF have been developed, but none have reached the clinical scenario so far. We here propose a recently synthesized cyclic peptide, C7, that has been showed to inhibit potently and selectively GRK2 activity in vitro. Purpose: Evaluate the pharmacological effects of C7 in an animal model of HF. Methods: Isolated adult ventricle myocytes (AMVM) from 12 weeks old C57BL/6J (WT) and MHCcre/GRK2fl/fl mice, carrying selective deletion of GRK2 in heart, were challenged with C7 (1μM) to verify specific GRK2 inhibition. Intraperitoneal (i.p.) injection of C7 was performed in WT mice to evaluate its effects on cardiac functions. Post-MI HF mice were then treated for 4 weeks with either C7 (2 mg/Kg/day) or vehicle by miniosmotic pumps and effects on both geometry, function and hemodynamic were assessed by echocardiography and cardiac catheterization. Results: C7 induces cardiac cell contractility and significant increase of FS% in AMVM from WT but not MHCcre/GRK2fl/fl mice. Stimulation with isoprenaline (ISO) was performed as a control and it increases FS% in AMVMs from both WT and transgenic mice, which is significantly higher in MHCcre/GRK2 fl/fl. In mice, C7 acutely produces a significant and rapid increase in heart rate at 10 min post i.p. injection, accompanied by a reduction of left ventricle diastolic diameter, increase in ejection fraction and systemic blood pressure. These effects disappear within 90 min. C7–treated but not vehicle treated Post-MI HF mice show a significant reduction of left ventricle diameter, improvement of ejection fraction and amelioration of +dP/dT both at baseline and after stimulation with ISO. Finally, C7 improves substrates utilization and recovers ATP production as compared to vehicle in post-MI HF. Conclusions: Collectively, these results demonstrate that 1) GRK2 is confirmed a key molecule in the physiological regulation of cardiac function 2) C7 is able to increase cardiac cell contractility through specific inhibition of GRK2 2) GRK2 inhibition with C7 represents as a novel pharmacological approach to promote cardiac reverse remodeling, metabolic and functional recovery in an animal model of HF.

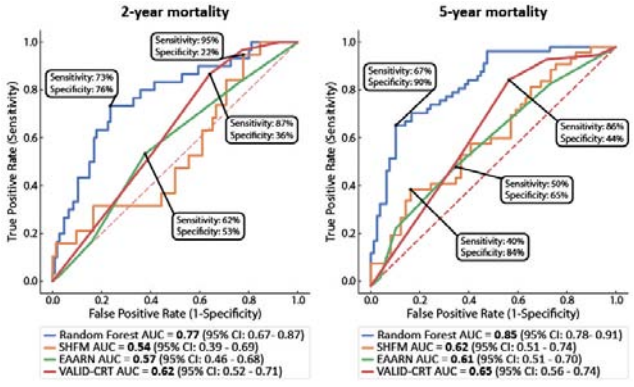
Rapid Fire 6 - Risk stratification and prognosis

1474

Machine learning based risk stratification of patients undergoing cardiac resynchronization therapy

M Marton Tokodi[1]; Z Toser[1]; AM Boros[1]; W Schwertner[1]; A Kovacs[1]; P Perge[1]; G Szeplaki[1]; L Geller[1]; A Kosztin[1]; B Merkely[1]
[1]*Semmelweis University Heart Center, Budapest, Hungary*

Background: Cardiac Resynchronization Therapy (CRT) is a cornerstone in the management of patients with advanced heart failure, reduced ejection fraction and wide QRS complex. Despite its well-known beneficial effects, mortality rates still remain high in this patient population. Therefore, accurate risk stratification of these patients would be essential, however, the currently available risk scores have several shortcomings which limit their utilization in the everyday clinical practice.
Purpose: Accordingly, our aim was to design and validate a machine learning based risk stratification system to predict 2-year and 5-year mortality from pre-implant parameters of patients undergoing CRT implantation.
Methods: We trained two models separately to predict 2-year (model 1) and 5-year mortality (model 2). As training cohort of model 1 we used 2098 patients (67±10 years, 1574 [75%] males, 1026 [49%] CRT-P, 1072 [51%] CRT-D) undergoing CRT implantation. Out of this population 1650 patients (66±10 years, 1258 [76%] males, 899 [54%] CRT-P, 751 [46%] CRT-D) also had 5-year follow-up data available and they served as the training cohort for model 2. At the time of implantation, demographics, cardiovascular risk factors, medication and laboratory test results were assessed. Forty-seven pre-implant parameters were used to train the models. Our models were designed in a way to tolerate missing values. Among non-linear classifiers, random forest (number of trees: 200) demonstrated the best performance. We validated our models, along with the Seattle Heart Failure Model (SHFM), VALID-CRT risk score and EAARN score on an independent cohort of 136 patients (66±10 years, 110 [81%] males, 114 [84%] CRT-P, 22 [16%] CRT-D).



ROC curves of the prediction models

Results: There were 458 (22%) deaths in the 2-year, 879 (53%) deaths in the 5-year training cohort. In the validation cohort, there were 30 (22%) deaths at 2 years and 58 (43%) deaths at 5 years after CRT implantation. For the prediction of 2-year mortality, the Area Under the Receiver-Operating Characteristic Curve (AUC) for model 1 was 0.77 (95% Confidence Interval [CI]: 0.67-0.87; p=0.002), for SHFM was 0.54 (95% CI: 0.39-0.69; p=0.006), for EAARN was 0.57 (95% CI: 0.46-0.68, p=0.002), and for VALID-CRT was 0.62 (95% CI: 0.52-0.71; p=0.002). To predict 5-year mortality the AUC for model 2 was 0.85 (95% CI: 0.78-0.91; p=0.001), for SHFM was 0.62 (95% CI: 0.51-0.74; p=0.003), for EAARN was 0.61 (95% CI: 0.51-0.70, p=0.002), for VALID-CRT was 0.65 (95% CI: 0.56-0.74; p=0.002). The AUCs of the machine learning based models were significantly higher than the AUCs of the pre-existing scores (DeLong test, all p<0.05).

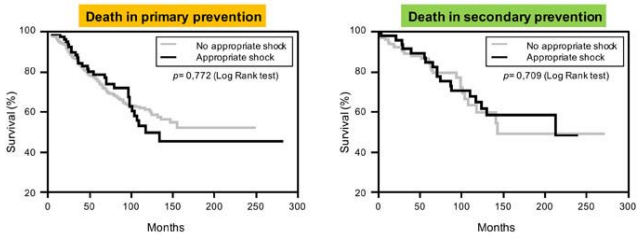
Conclusion: Our results indicate that machine learning algorithms can outperform the already existing linear model based scores. By capturing the non-linear association of predictors, the utilization of these state-of-the-art approaches may facilitate optimal candidate selection and prognostication of patients undergoing CRT implantation.

1475

Prognostic impact of ICD interventions in a real-world primary and secondary prevention population

E Elia[1]; L Baldi Caproriti[1]; G Bertero[1]; F Chiarella[2]; P Ameri[1]; C Brunelli[1]; P Sartori[2]; M Canepa[1]
[1]*University of Genoa, Genoa, Italy*; [2]*San Martino Hospital, Genoa, Italy*

Introduction and study aims: Implantable cardioverter-defibrillator (ICD) are recommended in primary (P1) and secondary (P2) prevention of sudden cardiac death (SCD). Recommendations in P1 patients rely primarily on reduced LVEF (i.e. ≤35%) and advanced NYHA functional class (i.e. II or III). The progressive reduction in SCD observed in the last 20 years and the non-superiority of ICD vs. optimal medical treatment in reducing overall mortality in a recent P1 trial have questioned these indications. Few surveys have analyzed the prognostic impact of ICD interventions in unselected real-world ICD recipients. The aim of this retrospective analysis was to compare the characteristics and mortality of P1 and P2 ICD recipients, and to investigate the association between appropriate ICD interventions and overall mortality.
Material and Methods: The study population was drawn from the ICD registry of a tertiary hospital. Patients with hypertrophic cardiomyopathy were excluded. The selected 611 patients underwent ICD implantation for P1 (=444, 72.7%) or P2 (=167, 27.3%) of SCD between January 2004 and February 2018. T test and $\chi 2$ test were performed for comparisons as appropriate. Cox analysis was performed to predict mortality, and Kaplan-Meier curves were plotted.



Figure

Results: The study population had a mean age of 66±10 years and a mean LVEF of 29±8%. P1 vs. P2 patients were significantly younger (65±10 vs. 69±10 years), with a lower LVEF (27±6 vs. 34±11%) and a longer follow-up (59±44 vs. 39±38 months, p<0.001 for all). 1-year appropriate shock rate was 3.32% in P1 and 6.06% in P2 group, whereas cumulative shock rate at a mean follow-up of about 4 years was 15.1% and 16.2%, respectively (both p=NS). 1-year death rate was 6.18% in P1 and 6.25% in P2 (p=NS), whereas overall mortality at final follow-up was 30.6% and 20.4%, respectively (p=0.01). Nonetheless, Kaplan-Meier curves did not show a statistically significant difference in mortality between P1 and P2 patients. In addition, Kaplan-Meier curves did not demonstrate a difference in mortality between patients who did or did not receive an appropriate shock during follow-up, both in P1 and P2 (Figure). In the overall cohort, older age and lower LVEF at ICD implantation were associated with increased mortality (HR 1.04; 95%CI 1.02-1.06; and HR 0.94; 95%CI 0.91-0.96; p<0.001 for both, respectively). These associations persisted in P1 patients (HR 1.04; 95%CI 1.02-1.06; p=0.002 and HR 0.95; 95%CI 0.91-0.98; p=0.003), but in P2 patients only lower LVEF remained associated with increased mortality (HR 0.92; 95%CI 0.87-0.96; p=0.001).

Conclusions: Appropriate ICD interventions were not independently associated with mortality in our cohort, both in P1 and P2 patients. Age and LVEF remain the primary determinants of mortality in these patients. These findings further support the need for more specific criteria in the selection of candidates to ICD implantation, especially in the setting of primary prevention.

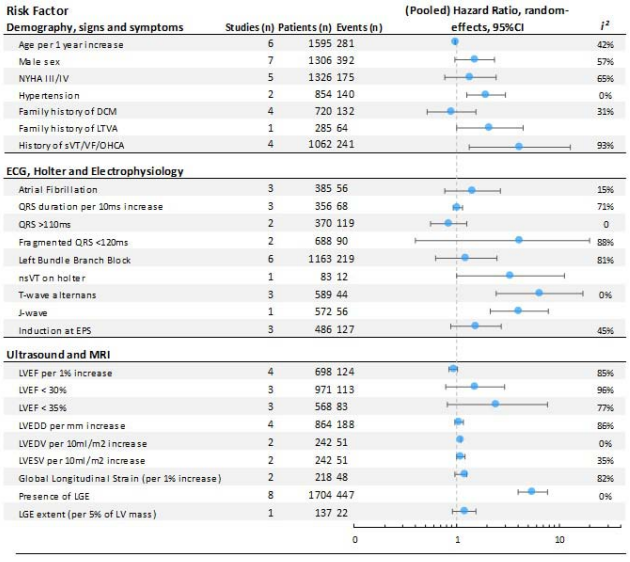
1476

Predicting arrhythmic risk in dilated cardiomyopathy: a meta-analysis of clinical parameter

A Arjan Sammani[1]; E Kayvanpour[2]; LP Bosman[1]; F Sedaghat-Hamedani[2]; T Proctor[3]; K Jensen[3]; HA Katus[2]; ASJM Te Riele[1]; B Meder[2]; FW Asselbergs[1]
[1]*University Medical Center Utrecht, Cardiology, Utrecht, Netherlands (The)*; [2]*University Hospital of Heidelberg, Cardiology, Heidelberg, Germany*; [3]*University of Heidelberg, Institute of Medical Biometry and Informatics, Heidelberg, Germany*

Funding Acknowledgements: ERA-CVD JTC2016: DETECTIN-HF

Background: Patients with non-ischemic dilated cardiomyopathy (NIDCM) are at increased risk of ventricular arrhythmias and sudden cardiac death (SCD). However, identifying patients at high risk for life-threatening ventricular arrhythmia (LTVA) who may benefit from an implantable cardioverter defibrillator (ICD) remains challenging.
Methods: We searched MEDLINE and EMBASE for prognostic studies describing predictors of LTVA (defined as sustained ventricular tachycardia (VT), haemodynamically unstable VT, ventricular fibrillation, (aborted) SCD or appropriate ICD intervention) in patients with NIDCM. We excluded articles with composite heart failure and arrhythmic endpoints but lacking (subgroup) analysis for LTVA. Study quality and risk of bias was assessed using the QUIPS-tool, and articles with high risk of bias in ≥2 areas were excluded from analysis. Univariable hazard ratios of reported predictors were pooled from the remaining studies in a meta-analysis using a random-effects model and presented with 95% confidence interval (CI).
Results: Out of 1402 unique citations, 28 studies were included comprising 5927 patients (mean age 55±4.1 years, 72% male) with a mean follow-up of 3.7±1.9 years. Crude event rate was 4.3% (95%CI 4.02-4.57) per year. Hypertension (HR 1.95;CI[1.26-3.00]), history of out of hospital cardiac arrest or sustained VT (HR 4.15;CI[1.32-13.02]), T-wave alternans (HR 6.50;CI[2.46-17.14]), LVEDV per 10ml/m2 increase (HR 1.10;CI[1.10-1.10]), LVESV per 10ml/m2 increase (HR 1.10;CI[1.00-1.22]) and delayed gadolinium enhancement (HR 5.55;CI[4.02-7.67]) were significantly associated with LTVA (figure). The quality of evidence was moderate and there was significant heterogeneity (median i2 57%;IQR 76%) among studies.
Conclusion: The risk of LTVA in NIDCM is 4.3% per year and is considerably higher in patients with hypertension, history of LTVA, high LVEDV, high LVESV, T-wave alternans, and delayed gadolinium enhancement. These results may help determine appropriate candidates for ICD implantation. The high heterogeneity in reported results indicate the need for future multicentre studies to further improve risk stratification in NIDCM.



Summary of meta-analysis results

1477

Serial change of Layer-specific myocardial functionby Chemotherapy in Breast cancer patients

MN Mi-Na Kim[1]; SM Park[1]; HD Kim[1]; DH Cho[1]; SP Jung[1]; KH Park[1]; WJ Shim[1]
[1]*Korea University Anam Hospital, Seoul, Korea (Republic of)*

Background As increasing prevalence of breast cancer and advance of treatment, chemotherapy induced cardiotoxicity (CIC) has emerged as one of major problem in breast cancer patient. Myocardium is composed with three layers of endocardial, mid myocardial and epicardial layer and recent advancements in echocardiography provide the capability to estimate function of each myocardial layer. It is not known which layers are vulnerable or more impaired by chemotherapy. The aim of this study was to evaluate layer-specific functional change in patients with CIC in breast cancer patients.
Methods Consecutive 45 patients with breast cancer (mean age=54.6±8.9 years) who undergone chemotherapy were included. Baseline echocardiography was performed within 1 day before chemotherapy and was followed up 3 and 6 month after start of chemotherapy. The function of myocardial layer was assessed by global longitudinal strain of endocardium (GLSendo), mid-myocardium (GLSmid) and epicardium (GLSepi). The definition of CIC was a decrease of LVEF by 5% or ≤55% in the presence of symptoms of heart failure or an asymptomatic decrease in LVEF by 10% or ≤55% at 3 month follow up (FU)
Results During 6 month FU, CIC occurred in 8 patients (18% of total patients). The prevalence of hypertension, diabetes, dyslipidemia, obesity and administrated chemo agents were not different between patient with and without CIC
The baseline LVEF, GLSendo, GLSmid and GLSepi were not different between patients with and without CIC. At 3 month FU, LVEF was significantly decreased and GLS of each layer were significantly decreased in patients with CIC. And these trends persisted at 6 month FU. In patients without CIC, GLSs of each layer were also decreased at 3 month FU and that persisted at 6month FU, although LVEF was not significantly decreased. The amount of decrement was larger in patients with CIC (figure 1). On the analysis of gradient of GLS from epicardium to endocardium, the decrement of strain gradient was larger in patients with CIC than in patients without CIC (figure 2).
Conclusion: In patients with CIC, myocardial function was decreased at 3 month FU and it persisted at 6 month FU. The decrement of endocardial function was greater than that of other layers. In addition, even in patients without CIC, LV function assessed by strain was also decreased by chemotherapy. Therefore, the close monitoring of LV function is needed to all patients with chemotherapy and endocardial layer might be most vulnerable to the chemotherapy in early period.

Figure 1. The comparison of changes of LVEF and GLSs of each layer between patients with and without CIC

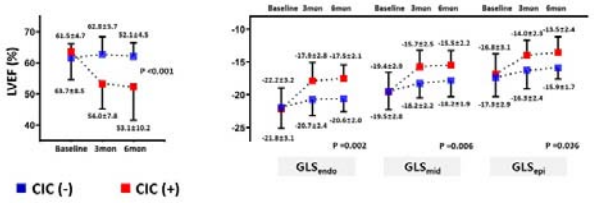


Figure 2. The comparison of changes of global longitudinal strain from epicardium to endocardium in patients with and without chemotherapy induced cardiotoxicity

Forecast of mOrtality Risk Early in the postCardiac Arrest Syndrome Therapy: pilot score for estimate early mortality in post cardiac arrest syndrome patient population

E Endre Zima[1]; B Kiss[1]; A Parkanyi[1]; E Kovacs[1]; P Nyeki[1]; ZS Jenei[1]; A Fekete-Gyor[1]; LA Geller[1]; B Merkely[1]
[1]*Semmelweis University Heart Center, Budapest, Hungary*

Intruduction: Sudden cardiac death (SCD) is one of the most significant cardiovascular causes of death. In the treatment of SCD – following a successful cardiopulmonary resuscitation (CPR) and return of spontaneous circulation (ROSC) - patients often require complex intensive care. Currently there are only a few validated risk-stratification score systems given to quickly and reliably estimate the

mortality risk of these patients at the time of admission to the intensive care unit (ICU).
Aim: In addition to cardiovascular risk factors that indicate instability, we also investigated factors, that potentially worsen the outcome of CPR, and examined them as predictors of mortality.
Methods: Medical records of 260 consecutive resuscitated patients, that received treatment between 2008-2014 at the Heart and Vascular Center of our University, were screened retrospectively. We were only able to include patients who's documentation contained all the data regarding the parameters in the FORECAST score at our disposal: initial rhythm, presence of an eyewitness at the event of SCD, time factors of CPR (time elapsed between SCD and administration of advanced life support (ALS) - TSCD-ALS, SCD and ROSC - TSDC-ROSC), catecholamine given pre- and in-hospital [first six hours in the ICU], age, any form of coronary disease (acute coronary syndrome [ACS]/ coronary artery bypass graft [CABG]/ myocardial infarction [MI]), left ventricular ejection fraction (LVEF), serum lactate levels and eGFR (estimated glomerular filtration rate). Due to missing data, 140 patients met our criteria and were included in the FORECAST study. The maximal FORECAST point that one could receive was 15, but due to the lower number of patients in certain groups we contracted the mortality data of groups that received 1-3, 4-6, 7-9 and 10+.
Results: The main characteristics of the examined population are as follows: 66%/34% shockable/ non-shockable rhythm, in 91% of cases there were eye-witnesses, TSCD-ALS=5,5±4,3min, TSDC-ROSC=19,4±19,6min, in 49% of cases patients were given prehospital adrenalin, 66,3±12,3 years, 1%/23% CABG/MI in the past, 81% of the cases ACS was responsible for the SCDs, 39,5±13,8% LVEF, 5,4±4,2mmol/L serum lactate, 53,3±17,2 ml/min eGFR. Number of patients by groups were: 26 (1-3), 40 (4-6), 61 (7-9) and 10 (10+). The 30-day mortality in group "1-3" turned out to be 4% (n=1), in group "4-6" 28% (n=11), in group "7-9" 59% (n=36) and in group "10+" 62% (n=8). The 180-day mortality was 4% (n=1), 35% (n=14), 70% (n=43) and 77% (n=10) by groups. The 360-day mortality was 8% (n=2), 38% (n=15), 72% (n=44) and 85% (n=11). Conclusion: The FORECAST pilot score shows increasing and distinct mortality tendencies in all four groups in the early and late CPR outcomes.

Early heart remodeling in type 1 diabetes patients: possible phenotypes

Y Mahamat[1]; A Safarova[1]; E Kokhan[1]; E Khasanova[1]; N Safarova[2]; V Efimova[3]; Z Kobalava[1]
[1]RUDN University, Moscow, Russian Federation; *[2]M.V. Lomonosov Moscow State University, Moscow, Russian Federation*; *[3]City Clinical Hospital No 64, Moscow, Russian Federation*

Background: Both epidemiologic and clinical studies confirm the close link between type 1 diabetes (T1DM) and cardiovascular disorders. Pathophysiology of this association is poorly understood, but changes appear to be caused by several factors, and occur even in the early stages of the disease. The degree of involvement of each of these factors in combination with individual patient features may lead to different types of heart remodeling. But the data concerning early heart remodeling in patients (pts) with T1DM is scarce.
We aimed to characterize early heart remodeling in T1DM pts without known cardiovascular disorders.
Methods: This cross-sectional study compared 90 T1DM pts (mean age of 29±8 years) without known heart disease with 20 healthy control subjects (mean age 28±8 years). All study participants underwent conventional and speckle tracking Echo (VIVID 7, GE). Subclinical systolic dysfunction is defined as global longitudinal strain (GLS)<20%. To assess ventricular-arterial coupling (VAC) arterial elastance (Ea), ventricular elastance (Ees) and the Ea/Ees ratio were calculated. Geometry of left ventricle (LV) remodeling was assessed using LV myocardial mass index (LVMI) and relative wall thickness (RWT). Normal values for RWT were <0.42 and for LVMI ≤ 95 g/m2 for women and ≤ 115 g/m2 for men. The level of NTproBNP (excluding pts with HF), glomerular filtration rate and albumin to creatinine ratio were measured for each patient.
Results: Compared to healthy subjects, pts with T1DM had significantly lower GLS (22±2 vs 18±5% p=0.001). Moreover, 95.6% of pts with diabetes had signs of early heart remodeling. Systolic dysfunction (GLS<20%) occurs in 67.7% of diabetes pts and dominates over diastolic, which occurs in 12.2% of them. The values of albumin to creatinine ratio > 14.5 mg/g (odds ratio (OR) 8.2; 95% confidence interval (CI) 1.3-13.2; p<0.05) and HbA1c≥9,6% (OR 3.6; 95% CI 1.2-10.9; p<0.05) were established as predictors of early systolic dysfunction (GLS<20%). Based on structural and functional characteristics of the LV, we distinguish 3 phenotypes of heart remodeling. The first – isolated systolic dysfunction (GLS<20%) – was observed in 33.3% pts, the second – structural remodeling (LV concentric remodeling) with preserved systolic function (GLS≥20%) and VAC imbalance (Ea/Ees <0.5) – in 29% of pts and the third – both structural (concentric remodeling) and systolic function alterations (GLS<20%) with VAC imbalance (Ea/Ees<0.5) – in 33.3% of the pts.
Conclusion: The vast majority of young pts with T1DM had structural or/and functional remodeling of the heart with the predominance of longitudinal systolic dysfunction over diastolic. Depending on the degree and type of these alterations, there are 3 distinct phenotypes of heart remodeling in this group of pts. Deep understanding of these phenotypes might be a key to personalized prevention of cardiac complications in T1DM pts.

Specific pattern of cardiopulmonary exercise testing in patients with right heart failure

I Zlobina[1]; A Berezina[1]; M Simakova[1]; O Moiseeva[1]
[1]Almazov National Medical Research Centre, Saint Petersburg, Russian Federation

Introduction ardiopulmonary exercise testing (CPET) is used to examine pts with right heart failure (RHF) mainly to assess the severity and prognosis. But it's role in RHF of different etiology is not yet completely defined.
Purpose
The purpose of the study was to detect the value of CPET in assessing the RHF etiology and prognosis.
Methods 84 pts with proven RHF I-III functional classes (fc) were examined: idiopathic pulmonary arterial hypertension (IPAH) – 60.7%, chronic thromboembolic pulmonary hypertension (CTEPH) – 39.3%. All pts underwent the right heart catheterization (RHC) and CPET with an assessment of peak oxygen uptake (VO2 peak), arterial oxygen saturation (SpO2), breathing reserve (BR), anaerobic threshold (VO2at AT), oxygen pulse (VO2/HR), oxygen delivery per power (dVO2/dW) , ventilation equivalent CO2 (VE/VCO2), end-tidal arterial carbon dioxide pressure (PET CO2). NT-proBNP level was assessed in all pts.
Results
VO2 peak, BR, VO2at AT were lower in pts with IPAH compared in pts with CTEPH (only II fc; p<0.05). Parameters of CPET related with traditional prognosis markers: high RA pressure and low cardiac index. Increased RA pressure was associated with higher PET CO2 (AUC= 0.661, p<0.05) and VE/VCO2(AUC= 0.351, p<0.05). Decreased cardiac index (<2.5 l/m2) was connected with increased VO2/ HR (AUC= 0.340, p<0.05) and decreased VO2AT (AUC= 0.358, p<0.05) Pts with NT-proBNP level>1400 pg/ml showed decreased VO2 peak (F=15.3; p<0.001), increased VO2/ HR (F=12.5; p<0.001), decreased dVO2/dW(F=20.5; p<0.001), VE/VCO2 (F=12.5; p<0.001) and decreased VO2AT (F=14.3; p<0.001).
Conclusions Specific patterns of CPET were reveled only in II fc pts with IPAH and CTEPH. Perspectively CPET could be used as non invasive method for risk assessment during follow-up.

Extent of late gadolinium enhancement was associated with re-worsening left ventricular ejection fraction in patients with non-ischemic dilated cardiomyopathy

T Nabeta[1]; T Naruke[1]; Y Ikeda[1]; T Ooki[1]; K Maemura[1]; M Yazaki[1]; T Fujita[1]; S Ishii[1]; J Ako[1]
[1]Kitasato University School of Medicine, Department of Cardiovascular Medicine, Sagamihara, Japan

Background: Re-worsening left ventricular ejection fraction (LVEF) after initial recovery is associated with cardiovascular events in patients with non-ischemic dilated cardiomyopathy (DCM). However, relationship between myocardial damage and re-worsening LVEF is unclear.
Purpose: To investigate relationship between late gadolinium enhancement (LGE) on cardiac magnetic resonance (CMR) and re-worsening LVEF in patients with DCM.
Methods: We included patients with recent onset DCM who had an LVEF 45% at diagnosis and LVEF 45% after medical therapy during 2007 to 2014. Patients divided

into two groups, Improved: defined as sustained recovery of LVEF 45% from initial improvement to final follow-up, Re-worsening: defined as LVEF 45% after initial improvement. LGE-CMR was performed in all patients at diagnosis. The extent of LGE defined as the location of LGE: only located at septum or free wall and located both septum and free wall (Figure). Cardiac events defined as hospitalization due to worsening heart failure, sustained ventricular arrhythmias, and sudden death.

Results: In the final cohort, 105 patients were included in this study. During 6.7 ± 2.7 year after diagnosis, Re-worsening LVEF was occurred in 27 (26%) patients. Median duration from initial improvement LVEF to Re-worsening LVEF was 3.7 ± 2.1 years. LVEF at diagnosis (31.4± 8.2% vs 30.6 ± 7.7%, p = 0.808) were not significantly different between the two groups. LVEF in the Re-worsening group was significantly lower than those in the Improvement group at initial improvement (52.8 ± 7.3% vs 56.7 ± 7.3%, p = 0.020) and final follow-up (40.2 ± 8.4% vs 60.0 ± 8.3%, p < 0.001). The type of medication regimen including beta-blockers was not significantly different among the two groups at baseline and initial improvement. The percentage of patients with LGE was higher in the Re-worsening group than those in the Improved group (17/27:63% vs 29/78:37%, p = 0.020). Particularly, the percentage of patients with LGE located both septum and free wall were significantly higher in the Re-worsening group than those in the Improved group (p = 0.005, Figure). Age and gender adjusted multivariate logistic analysis demonstrated that LGE located both septum and free wall was independently associated with re-worsening LVEF (odds ratio: 11.1, 95% confidence interval 1.82-67.38, p = 0.009). Cardiac events occurred in 15 patients during follow-up. Cardiovascular event rate in the Re-worsening group was higher compared with the Improved group (9/27:33% vs 6/72:8%, p = 0.001).

Conclusion: Re-worsening LVEF occurred in 27 patients after initial recovery. The extent of LGE was independently associated with Re-worsening LVEF.

Differences in circulating cardiac biomarkers between immunoglobulin light-chain and transthyretin cardiac amyloidosis

V Castiglione[1]; A Aimo[1]; N Ghionzoli[2]; C Prontera[2]; S Masotti[2]; C Grigoratos[2]; D Genovesi[2]; A Barison[2]; G Todiere[2]; GD Aquaro[2]; C Passino[1]; M Emdin[1]; G Vergaro[2]

[1]Sant'Anna School of Advanced Studies, Institute of Life Sciences, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*

Background: Cardiac amyloidosis is caused by progressive accumulation of a misfolded protein, mostly represented by immunoglobulin light chains (AL) or transthyretin (TTR). AL amyloidosis is characterized by a much more rapid progression and worse outcome, possibly due to a greater cytotoxic effect of AL fibrils. This mechanism may impact on circulating levels of biomarkers reflecting myocardial damage (natriuretic peptides and cardiac troponins), or inflammation and tissue remodeling (soluble suppression of tumorigenicity-2, sST2). This point has never been evaluated so far.

Purpose: We aimed to assess circulating levels of N-terminal fragment of proBNP (NT-proBNP), high-sensitivity cardiac troponin T (hs-cTnT), and sST2 in a cohort of patients with established diagnosis of cardiac AL or TTR amyloidosis.

Methods: 86 patients with cardiac AL (n=25, 29%) or TTR amyloidosis (n=61, 71%) underwent an echocardiographic and biohumoral characterization, including NT-proBNP, hs-cTnT and sST2 assays.

Results: Patients with AL amyloidosis were younger (70±9 vs. 80±7 years) and showed a lower left ventricular mass (302±83 vs. 349±88 g, p=0.028) and septal thickness (17±3 vs. 18±3 mm, p=0.029) compared to TTR, conversely there was no difference in terms of glomerular filtration rate between the two groups (59±34 vs. 56±23 mL/min/1.73 m2, p=0.622). Circulating levels of NT-proBNP (10,809 [interquartile interval 6,292-17,483] vs. 3,084 [1,841-7,624] ng/L, p=0.014) and hs-cTnT (30 [IQR 64-211] vs. 61 [48-95] ng/L, p=0.006) were higher in AL amyloidosis, while sST2 was not significantly higher in AL compared to TTR amyloidosis (33 [21-54] vs. 26 [19-33] ng/mL, p=0.086) (Figure). Prominent differences were found when biomarker levels were normalized for left ventricular mass: NT-proBNP 33.891 [20.409-53.803] vs. 9.966 [5.826-23.465] ng/L/g, p=0.002; hs-cTnT 0.476 ng/L/g [0.248-0.707] vs. 0.186 [0.141-0.258], p=0.001; sST2 0.102 [0.066-0.142] vs. 0.073 [0.057-0.106] ng/mL/g, p=0.029.

Conclusions: Despite a lower degree of pseudohypertrophy, circulating levels of cardiac biomarkers are higher in AL than TTR amyloidosis, especially when normalizing for cardiac mass. This may reflect a greater toxic effects of AL fibrils on the myocardium.

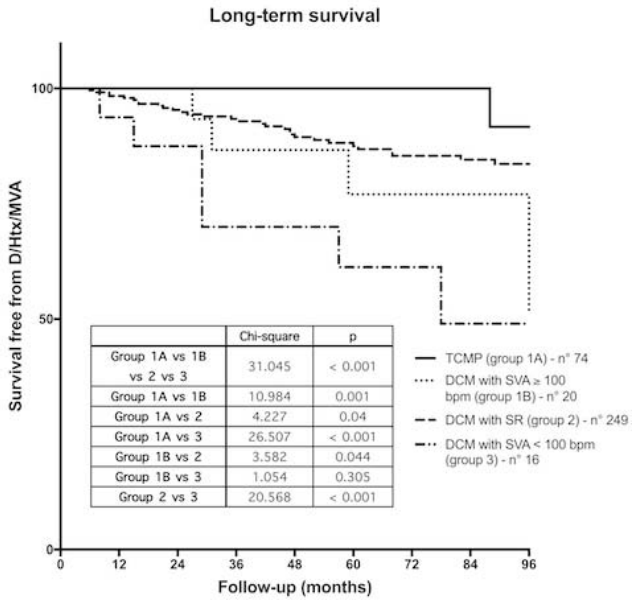
Early identification and prognosis of tachy-induced cardiomyopathy

M Merlo[1]; C Chiara Ruzzier[1]; D Zaffalon[1]; E Fabris[1]; M Gobbo[1]; M Bobbo[2]; G Barbati[3]; E Bianco[1]; M Zecchin[1]; G Sinagra[1]

[1]Ospedale Cattinara, Cardiothoracic Department, Trieste, Italy; *[2]Institute for Maternal and Child Health IRCCS "Burlo Garofolo", Trieste, Italy*; *[3]University of Trieste, Biostatistics Unit, Department of Medical Sciences, Trieste, Italy*

Background/Introduction: Diagnostic tools for early discrimination between tachyarrhythmia-induced cardiomyopathies (TCMP) and dilated cardiomyopathies



Kaplan-Meier curves: long-term survival

(DCM) and long-term prognosis of TCMP remain controversial. Aims were to assess baseline markers which may identify TCMP among a cohort of patients presenting with high-rate supraventricular arrhythmias (SVA) and reduced LVEF, and to compare the outcomes between TCMP and DCM.
Purpose: To assess baseline markers which may identify TCMP among a cohort of patients presenting with high-rate supraventricular arrhythmias (SVA) and reduced LVEF, and to compare the outcomes between TCMP and DCM.
Methods: 339 patients with non-ischemic LVEF<50% were enrolled and divided according to baseline rhythm and heart rate: group 1 (74 patients), SVA≥100 bpm; group 2 (249 patients), sinus rhythm; group 3 (16 patients), SVA<100 bpm. After 6-month follow up and re-evaluation of LVEF, group 1 was divided in TCMP (recovered LVEF ≥50%, group 1A) or DCM (persistent LVEF<50%, group 1B) patients. A survival-free from death, heart transplant or major ventricular arrhythmias comparison among the 4 groups (1A, 1B, 2, 3) was performed.
Results: Fifty-four patients (73%) of group 1 were re-classified as TCMP. At the multivariable analysis, a successful rhythm control strategy (Odds ratio [OR] 7.37, 95% confidence interval [CI] 1.46-37.27, p=0.016) was the only feature associated with 6-month LVEF recovery. During a median follow-up of 47 months, TCMP patients (group 1A) had the best prognosis (1 death); conversely, patients presenting with SVA and persistent dysfunction, regardless from baseline heart rate (group 1B and 3), showed the worst survival (p<0.001).
Conclusions: In non-ischemic patients presenting with LV dysfunction and high-rate SVA, a successful early rhythm control was associated with a higher likelihood of LVEF normalization. Conversely, patients who did not recover LVEF had a particularly poor prognosis.

1484

Screening of LAMP2 expression in peripheral white blood cells by flow cytometry effectively identifies Danon disease among young females with advanced heart failure.

M Milos Kubanek[1]; J Gurka[1]; F Majer[2]; L Piherova[2]; A Krebsova[1]; A Chaloupka[3]; J Krejci[3]; T Freiberger[4]; D Zakova[4]; T Kalina[5]; J Sikora[2]; V Melenovsky[1]

Funding Acknowledgements: Supported by the research grants of the Ministry of Health, Czech Republic [MZ 15-27682A] and No. 00023001 (IKEM, Prague, Czech Republic).

Introduction: Danon disease (DD) is a rare X-linked disorder associated with severe heart failure. DD is caused by mutations in the LAMP2 gene. As a result, LAMP2 protein is universally or mosaic absent in the tissues of male and female DD patients, respectively. Contrary to the noticeable phenotype in DD males, presentation in DD females is variable and includes isolated dilated (DCM) or hypertrophic cardiomyopathy (HCM) regularly progressing to advanced heart failure (AHF) between 20-40 years of age. In our study, we aimed to evaluate the prevalence of DD in young females (<40 years) with advanced heart failure due to non-ischemic cardiomyopathy.
Methods: The study cohort comprised of 60 female patients (pts), 47 pts (79%) were heart transplant recipients, 2 pts (3%) were treated by ventricular assist device and 11 pts (18%) were in pre-transplant phase. Median age of disease onset was 22 years, median age at surgery or pre-transplant assessment 28 years, and median age at screening 37 years. DCM was found in 77%, HCM in 15%, and other type of CM in 8% of pts. LAMP2 was detected by flow cytometry (FC) in peripheral leukocytes in 45 females with unexplained aetiology of cardiomyopathy and 2 females with previously diagnosed DD. The remaining 13 pts have already been diagnosed with a different disease at the time of FC screening. Whole exome sequencing and LAMP2 immunohistochemistry (IHC) in explanted myocardial samples were used as independent methods to confirm/exclude the diagnosis of DD.
Results: LAMP2 FC identified DD in 5 patients. In all of them, the diagnosis was confirmed by genetic analyses (and when possible also by IHC). The total DD prevalence in the cohort was 12%. FC detected DD with a sensitivity of 100% and specificity of 90% (p<0.001). Females with DD had more frequently HCM (57% vs. 9%; p=0.011) and delta waves in electrocardiogram (57% vs.0%, p=0.001).
Conclusion: Danon disease is an underdiagnosed cause of advanced heart failure in young females.
To facilitate timely diagnosis, treatment and family counselling in these specific patients. LAMP2. FC can be used as an effective screening method.

1485

Crude mortality risk in dilated cardiomyopathy. Comparison of the utility of general heart failure mortality scales derived from the Barcelona 2.0, MAGGIC and MUSIC studies in dilated cardiomyopathy.

E M Dziewiecka[1]; A Karabinowska[1]; M Glimak[2]; M Winiarczyk[2]; A Karapetyan[2]; S Wisniowska-Smialek[2]; P Podolec[1]; P Rubis[1]
[1]John Paul II Hospital, Department of Cardiac and Vascular Diseases, Krakow, Poland; [2]Jagiellonian University Medical College, Students' Scientific Group at the Department of Cardiac and Vascular Disease, Krakow, Poland

Introduction: Numerous survival scales exist in heart failure (HF). Yet, their applicability in dilated cardiomyopathy (DCM) is less certain. Purpose: Comparison of mortality between own DCM cohort and derivation cohorts from the Barcelona 2.0, MAGGIC and MUSIC studies.
Methods: Between January 2014 and October 2018 we analysed hospital records of 285 DCM patients (53 ± 13 years, 81% male, EF 26 ± 11%, NYHA 2.5 ± 0.9). Mortality risks were assessed based on survival scales: Barcelona 2.0 (clinical model) and MAGGIC. According to MUSIC scale patients were divided in 2 groups: high (>20points) and non-high (£20) mortality risk during 44 months.
Results: The 1-, 3- and 5-years mortality risks, obtained from Barcelona 2.0 calculator, were significantly higher in our DCM cohort compared to initial HF cohort. However, the 1- and 3-years mortality risks assessed by MAGGIC scale were significantly lower in our DCM cohort than in derivation HF cohort. As for the MUSIC scale, our patients were characterized with higher total HF mortality risk but lower sudden cardiac death (SCD) risk than derivation cohort.
Conclusions: The mortality risks of our homogenous DCM cohort, assessed with the Barcelona, MAGGIC and MUSIC calculators, significantly differed from the original general HF derivation cohorts. Further studies are needed in order to construct unique DCM-specific outcomes scales.

Comparison of mortality risks.

	DCM cohort	Derivation cohort	p-value
Barcelona 2.0 scale	(n=272)	Barcelona cohort	
1-year mortality risk [%]	9.7 ± 8.5	5.8	<0.001
3-years mortality risk [%]	29.4 ± 20.2	12.5	<0.001
5-years mortality risk [%]	46.27 ± 25.1	19.8	<0.001
MAGGIC scale	(n=247)	MAGGIC cohort	
1-year mortality risk [%]	10.9 ± 6.4	13.4	<0.001
3-years mortality risk [%]	25.5 ± 12.8	31.6	<0.001
MUSIC scale	(n=208)	MUSIC cohort	
High HF mortality risk [n (%)]	101 (48.6%)	374 (37.7%)	0.004
High SCD risk [n (%)]	41 (19.7%)	310 (31.3%)	<0.001

1486

Differences in clinical features of hypertrophic cardiomyopathy with or without left ventricular enlargement: a single-center and retrospective study

B Baiqing Ou[1]
[1]Hunan Provincial People's Hospital, Geriatric Medicine, Changsha, China

Background: Few studies have focused on the clinical features of hypertrophic cardiomyopathy (HCM) with enlarged left ventricle (ELV). Hypothesis: HCM patients with ELV exhibit unique clinical features. Methods: Study participants were patients with HCM (n = 170), divided into two groups, ELV and normal sized left ventricle (NLV). Patients were also divided according to diagnosis of obstructive (n = 40), septal (n = 88), and apical (n =42) HCM. Age at diagnosis, sex, complications, electrocardiogram, symptoms, drug treatment, and echocardiographic parameters were compared among the NLV (n = 153) and ELV groups (n = 17). Results: The incidence of end-stage HCM (ES-HCM) among all HCM patients was 5.29%, and 10% in those with ELV. For all patients with HCM and those with septal HCM, there were more males with ELV than NLV. Of patients with HCM and septal HCM, left ventricular ejection fraction was significantly lower in the ELV group than the NLV group; accordingly, rates of diuretic use were higher in the ELV group than the NLV group. Among apical HCM patients, the left atrial diameter, incidence of atrial fibrillation or ST-T change, and rate of angiotensin converting enzyme inhibitor/angiotensin receptor blocker use in the ELV group were all higher than those in the NLV group. Conclusions: HCM

patients with ELV are more likely to progress to ES-HCM than those with NLV. Additionally, ELV is more common in men than women and there are differences in the clinical features of different types of HCM with ELV.

Comparison of echocardiographic paramete			
Characteristics	ELVn=17	NLVn=153	p

Cardiovascular dysfunction associated with tyrosine kinase inhibitor use in patients with metastatic thyroid cancer

BM Dowsing[1]; K Bronis[1]; V Chambers[1]; K Newbold[2]; S Rosen[1]; A Lyon[1]
[1]Royal Brompton Hospital, Cardio-Oncology , London, United Kingdom of Great Britain & Northern Ireland; *[2]Royal Marsden Hospital, London, United Kingdom of Great Britain & Northern Ireland*

Introduction: Cardiovascular disease and cancer represent leading causes of morbidity and mortality in the developed world. The prevalence of cancer is increasing partly due to advancements in treatment, including targeted therapies such as tyrosine kinase inhibitors (TKIs). Despite improvements in oncological outcomes, associated cardiovascular disease remains a concern. Metastatic thyroid cancer is a rare condition with a poor prognosis; TKIs have improved survival but data regarding cardiotoxicity is limited.
Purpose: We investigated cardiovascular dysfunction associated with TKI use in metastatic thyroid cancer patients; specifically, the incidence of cardiovascular dysfunction, associated clinical outcomes and its risk factors.Method: A retrospective case series of 58 patients with metastatic thyroid cancer who received TKI therapy, with cardio-oncology review, between May 2013 and May 2018.
Results: The incidence of cardiovascular dysfunction in metastatic thyroid cancer patients receiving a TKI was 74%. Left ventricular dysfunction occurred in 59%, hypertension in 43% and QTc prolongation in 19%. Survival for greater than 12 months was significantly higher in patients with TKI associated cardiovascular dysfunction. There was no difference in 24-month survival or the proportion of patients completing 12 months of therapy. Age over 50, pre-existing hypertension and baseline cardiac MRI abnormalities were associated with TKI induced hypertension.
Conclusions: Most metastatic thyroid cancer patients experience TKI associated cardiovascular dysfunction, though not worse outcomes. Cardiovascular dysfunction is associated with improved 12-month survival, potentially demonstrating TKI efficacy. This has been described in other cancers as 'on-target' toxicity related to shared tyrosine kinase pathways, but not previously in thyroid cancer. Our results agree with studies of non-thyroid cancers regarding age and pre-existing hypertension as risks for TKI induced hypertension and demonstrates baseline cardiac MRI abnormalities as an additional risk. Our analysis is limited by a small cohort and its retrospective nature. Prospective studies with cardiovascular endpoints are needed.

Longitudinal Diastolic strain as predictor for systolic dysfunction among active breast cancer patients

LM Michal Laufer-Perl[1]; R Rosen[1]; L Mor[1]; M Derakhshesh[1]; N Amrami[1]; J Sherez[1]; G Keren[1]; Y Arbel[1]; Z Rozenbaum[1]; Y Topilsky[1]
[1]Tel Aviv Sourasky Medical Center, Cardiology, Tel Aviv, Israel

Background: Cardio-toxicity, defined as a left ventricular ejection fraction reduction, is a significant side effect of cancer therapy. Global longitudinal systolic strain (GLS) has been shown to identify early systolic dysfunction in patients with active cancer. Although diastolic dysfunction is common among cancer patients, no evidence has been shown that it predicts systolic dysfunction. Early diastolic strain rate is considered to be a predictor of cardiac events in the general population; however, longitudinal diastolic strain (Ds) was not evaluated among cancer patients.
Objectives: The aim of this study was to evaluate the correlation of Ds with echocardiography filling pressure and to estimate its role in the early detection of cardio-toxicity among breast cancer patients.
Methods: Data were collected as part of the International Cardio-Oncology Registry (ICOR), enrolling all cancer patients evaluated at the cardio-oncology clinic in our institution. All patients preformed serial echocardiography, including GLS and Ds, at baseline and following therapy. GLS relative reduction of ≥11% was considered to be clinically significant. Ds was assessed as the early lengthening rate=diastolic slope (cm/sec2) and measured in 6 segments in each of the 3 apical views.
Results: A total of 69 patients (97% women, mean age 54±13 years) with diagnosis of breast cancer were prospectively recruited. Significant GLS reduction was observed in 13% at 2nd echo and 29% at 3rd echo. Assessment of all Ds segments at 2nd echo showed that four chamber mid septum (p=0.003), two chamber mid inferior (p=0.017) and two chamber base inferior (p=0.024) segments were all a significant predictor of GLS reduction at 3rd echo. All of the mentioned segments had significant correlation with E/e' average (p=0.005, 0.009, 0.003) and E/A (p<0.001, <0.001, 0.005).
Conclusions: Among breast cancer patients, Ds showed high correlation to filling pressure parameters and emerged as significant early predictor for clinically significant systolic dysfunction.

Atrial Fibrillation

P1521

Worsening renal function in acute decompensated heart failure patients with atrial fibrillation

I Igor Gorda[1]; A Bezrodniy[2]
[1]Kiev Alexander Clinical Hospital, Kiev, Ukraine; *[2]O. O. Bogomolets National Medical University, Kiev, Ukraine*

Background. Our purpose was to determine the influence of worsening of the renal function (WRF) regard to its reversibility on clinical course of the hospital period in "wet and warm" patients with acute decompensated heart failure (ADHF) with atrial fibrillation (AF).
Methods. In to the prospective study were included 84 patients with ADHF and AF at the age from 38 to 85 years (mean age 67,1 ± 2,2). Transient WRF was defined as increase of creatinine ≥26.5 mmol/L after 48 hours with subsequent decrease to baseline at discharge. Patients with persistent WRF didn't have decrease of creatinine to baseline at discharge. Endpoints were CVP at day 4 (D4), ortho-oedema congestion index Lala, E/E' and NT-proBNP at discharge (Dsc).
Results. WRF occurred in 24 (29%) patients. The patients with persistent WRF comparing to patients transient WRF and with no WRF had significantly more increased values of ortho-oedema index Lala, E/E', NT-proBNP, CVP and worse results of decongestion treatment. In the same time the patients with transient WRF didn't have significant differences in main parameters and endpoints (see in table).
Conclusion: Only presence of persistent WRF is associated with significantly worse clinical course and outcome comparing to patients with transient WRF and with no WRF in the "wet and warm" patients with ADHF and AF.

	No WRF	WRF transient	WRF persistent	P1-2	P1-3	P2-3
Ortho-oedema index Lala D1	3,48 ± 0,11	3,59 ± 0,11	3,96 ± 0,12		p<0,01	p<0,01

Short and long-term outcomes after radiofrequency catheter ablation of the his bundle: the experience of a tertiary center

A Ana Manuel[1]; J Almeida[1]; P Fonseca[1]; C Guerreiro[1]; J Monteiro[1]; F Montenegro[1]; J Ribeiro[1]; F Rosas[1]; E Santos[1]; J Ribeiro[1]; M Oliveira[1]; H Goncalves[1]; J Primo[1]; P Braga[1]
[1]Hospital Center Vila Nova Gaia, Cardiology, Porto, Portugal

Background: In refractory supraventricular arrhythmias (SA) with rapid ventricular rates and in HFrEF with need of biventricular pacing and high burden of atrial fibrilation (AF) despite a rhythm control approach, catheter ablation of the His bundle (AHB) may be performed.
Purpose: To assess outcomes of AHB and pacing therapy in patients with refractory SA or patients with HFrEF under resynchronization therapy and with high burden of AF. Methods: Patients referred for AHB from 1997 to 2018 were retrospectively included. Baseline clinical data, procedural variables and outcomes of AHB were collected.
Results: 123 patients were included (69±9 years, 52% male). During a mean follow-up of 8.4 years, 28 patients died (23%). Patients presented advanced HF (NYHA class III- 42%, class IV – 3%), left ventricular dysfunction (mean LVEF 47% ± 13), AF (65%) and rapid ventricular rates (mean heart rate 114 ± 33 bpm). Most of the patients needed hospital admission due to decompensated HF: once 31%, twice 20%, three or more times 9%. Devices were implanted before the procedure: pacemaker 82%, CRT-P 6%, CRT-D 8% and ICD 4%. AHB was performed in 113 patients at right side (91%) and in 13 patients at left side (11%). There were no procedure complications. At follow-up patients were less symptomatic (HF NYHA class III 8%, class IV 2%) and had fewer hospitalizations: once 9%, twice 1%, three or more times 4%. After univariate logistic regression, multiple emergency department visits due to HF (OR 58.7, 95% CI, 16.2-116.7, p=0.004), hospitalizations due to HF and the use spironolactone (OR, 268, 95% CI, 26.7 – 969.8, p=0.017) before the procedure, were found to be independent predictors of the composite endpoint after the procedure (death, hospitalization or emergency department visit due to decompensated HF).
Conclusion: His bundle ablation and pacing therapy is a safe and effective method to control heart rate in patients with supraventricular arrhythmias and rapid ventricular rates who have failed medical therapy.

P1523

Conflicts of interest among authors of the ESC guidelines for the management of atrial fibrillation

B Schneider[1]; C Stoellberger[2]
[1]Sana Kliniken, Lübeck, Germany; *[2]Rudolfstiftung, Vienna, Austria*

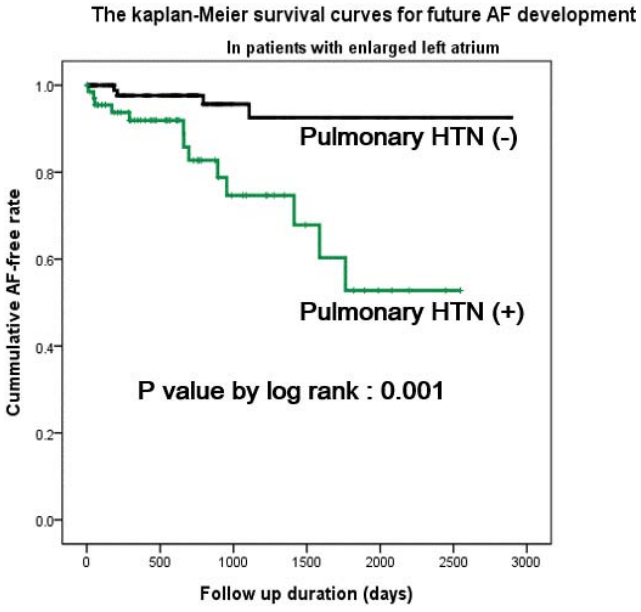
Background: In 2011, the Institute of Medicine (IOM) published standards for developing trustworthy clinical practice guidelines. It is recommended that "Whenever possible guideline development group members should not have conflicts of interest (COIs). In some circumstances, a guideline development group may not be able to perform its work without members who have COIs, such as relevant clinical specialists. Members with COIs should represent not more than a minority of the guideline development group members. The chair or cochairs should not be a person with COIs."
Aim of the present study was to assess if the ESC guidelines for the management of atrial fibrillation are in accordance with the standards proposed by the IOM.
Methods: The declaration of COIs from task force members (TFM) and reviewers of the 2010 and 2016 ESC atrial fibrillation guidelines were retrieved from the ESC homepage. The number and the type of COIs were assessed for each guideline and compared.
Results: Regarding the 2010 guidelines, 8 of the 25 TFM (32%) reported no COI. In the remaining 17 TFM, 148 COIs were reported (8.7±10.2 per member, range 1-44). The chairperson declared 11 COIs. Consulting and advising was reported by 15 and research contacts by 13 TFM. Among the guideline reviewers, 12/26 (46%) reported no COI, and 14 reviewers declared 72 COIs (5.1±3.3 per reviewer, range 2-14).
Regarding the 2016 guidelines, 3 of the 17 TFM (18%) reported no COI. The remaining 14 TFM declared 182 COIs (13.0±10.4 per member, range 1-32). The chairperson of the task force had the second most COIs (n=30). Direct personal payment was reported by 14 and research funding of the department by 10 TFM. Among the guideline reviewers, 16/79 (20%) reported no COI, and 63 reviewers declared 473 COIs (7.5±6.8 per reviewer, range 1-34).
Comparing the 2010 and the 2016 guidelines, there was an increase of TFM with COIs (from 68% to 82%), of the number of COIs per TFM (from 8.7±10.2 to 13.0±10.4) and the COIs of the chairperson (from 11 to 30). Moreover, the proportion of TFM receiving personal payment (60% vs 82%) and the number of COIs due to personal payment (5.9±7.3 vs 7.7±7.4) were higher in the 2016 guidelines. In addition, more guideline reviewers had COIs in 2016 (54% vs 80%).
Conclusion: The high and increasing rate of TFM and reviewers with COIs is not in accordance with the recommendations of the IOM. Since COIs can influence healthcare decision makers and may consciously or unconsciously influence choices made throughout the guideline development process, the ESC should follow the standards of the IOM.

P1524

Right ventricular systolic pressure predicts the future development of atrial fibrillation in end-stage renal disease patients with enlarged left atrium

H Chung[1]; JML Lee[1]; JSW Woo[1]; JBK Kim[1]; SJK Kim[1]; YSB Byun[2]; SKR Ryu[3]; WK Kim[1]; WSK Kim[1]
[1]Kyunghee University, Cardiology, Seoul, Korea (Republic of); [2]Inje University, Cardiology, Seoul, Korea (Republic of); [3]Eulji University School of Medicine, Cardiology, Seoul, Korea (Republic of)

Background: The outcome of patients with end-stage renal disease (ESRD) is associated with cardiac disease. Atrial fibrillation (AF) is a common cause which leads to adverse cardiovascular outcome. It is unclear the predictors of future AF in patients with ESRD.
Purpose: We investigated the predictors for future development of AF in patients with ESRD who had never documented AF.
Methods: We enrolled 226 patients with ESRD who has performed transthoracic echocardiography. We excluded the 16 patients who had been received a diagnosis of AF, and 210 patients (130 males, mean 62 ±13 years) were analyzed. The patients were classified into two groups according to size of left atrium (LA); anterior-posterior (AP) dimension>35.7mm or≤35.7mm. Cut-off value of LA AP dimension was measured using ROC curve for LA dimension.
Results: During a mean follow-up period of 911±725 days, AF occurred in 24 (11.4%) patients. The patients with AF development was older (68±12 vs. 61±14 years, p=0.038) and had a higher right ventricular systolic pressure (RVSP) (30±16 vs. 37±14mmHg, p=0.046). RVSP was a significant predictor of AF development in multivariate analysis (hazard ratio, 1.028; 95% confidence interval, 1.004-1.052; p=0.040). RVSP (hazard ratio: 1.027, 95% confidence interval: 1.003-1.052, p=0.027) predicted AF development, and LA dimension tended to predict AF development (hazard ratio: 1.057, 95% confidence interval: 0.990-1.129, p=0.097) in univariate Cox regression analysis. When we divided the patients into two groups according to LA AP dimension, RVSP predicted AF development (hazard ratio: 1.033, 95% confidence interval: 1.005-1.061, p=0.020) in patients with enlarged LA (LA dimension> 35.7mm). In group with enlarged LA, the area under the ROC curve of RVSP for newly developed AF was 0.677 (p=0.017), and optimal cut-off value was 26.4mmHg with 88% of sensitivity and 41% of specificity).
Conclusion: In patients with ESRD, elevated RVSP predicts an increased risk of future AF development, especially in patients with enlarged LA. This study supports the necessity of strict volume control or associated factors to increase RVSP for prevention of future AF and adverse cardiovascular outcome.



The Kaplan-Meier curve for future AF

P1525

Left atrial function and left atrial late gadolinium enhancement magnetic resonance in patients with atrial fibrillation.

L N Lucia Nelica Agoston Vas Coldea[1]; I Muresan[1]; B Cojan-Minzat[1]; T Mocan[1]
[1]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania

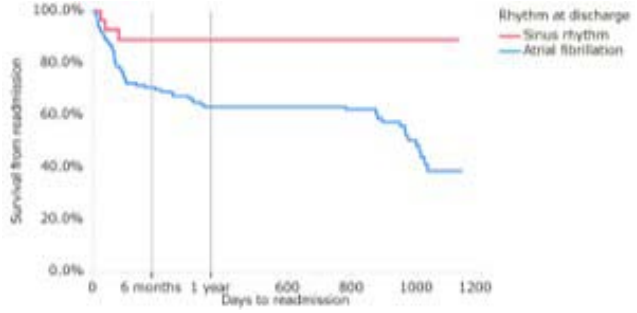
BACKGROUND: Left atrial (LA) remodelling is a physiological response in patients with atrial fibrillation (AF) due to pressure overload. AF is associated with LA structural and functional changes. Left atrial late gadolinium enhancement (LGE) and feature-tracking quantification by cardiac magnetic resonance are capable of noninvasive assessment of LA fibrosis and myocardial motion. The aim of this study is to determine the relationship between LA function and LA-LGE magnetic resonance in patients with AF.
METHODS: We conducted a prospective study on 98 patients with AF (48±7 years, 52 men) and 30 healthy volunteers (47±9 years, 19 men), which were all evaluated by cardiac magnetic resonance. To achieve our purpose, we measured LA volumes during reservoir, conduit and pump phases, peak global longitudinal LA strain, LA systolic strain rate; early and late diastolic strain rates were evaluated using cine-cardiac magnetic resonance imaging and LGE by quantification of LA fibrosis.
RESULTS: Medium LA volume indexed to body surface was significantly higher in patients with AF 48.8 ±6.3 ml/m2 compared to the healthy volunteers 36.3 ±4.5 ml/m2 with a p value of p<0.001. Compared to patients with paroxysmal AF (58% of cohort), those with persistent AF had a larger maximum LA volume index (51±10.1 versus 45±8.2 mL/m2; p<0.01), and an increased LGE (28±10% versus 33±11%; p<0.001). All LA parameters (LA active emptying fraction, passive emptying fraction, peak global longitudinal LA strain, systolic strain rate, early diastolic strain rate, and late diastolic strain rate) were lower in patients with persistent AF (p<0.05 for all). Compared to healthy volunteers, patients with AF and mild diastolic dysfunction had lower corrected passive emptying fractions (p<0.01) and higher corrected active emptying fractions (p<0.001), as result leading to a similar corrected total emptying fraction. However, in patients with AF and moderate diastolic dysfunction, passive, active and total emptying fractions were decresed. In multivariable analysis, increased LA-LGE was associated with lower LA passive emptying fraction, peak global longitudinal LA strain, systolic strain rate, early diastolic strain rate, and late diastolic strain rate (p<0.01).
CONCLUSIONS: LA indexed volumes evaluation during the reservoir, conduit and pump phases proved to be valid parameters for early diastolic dysfunction assessment in patients with AF. LA-LGE is associated with decreased LA reservoir, conduit, and booster pump functions. LA function using feature-tracking cardiac magnetic resonance may bring important information about the physiological importance of LA fibrosis

P1526

Heart failure patients discharged with atrial fibrillation showed significantly higher readmission rate.

K Kaoru Hirose[1]; MF Fukunaga[1]; SI Ito[1]; MY Yano[1]; TM Morinaga[1]; AI Isotani[1]; MH Hyodo[1]; SS Shirai[1]; KA Ando[1]
[1]Kokura Memorial Hospital, Cardiology, Fukuoka, Japan

Background: Relationship between atrial fibrillation (AF) and heart failure (HF) is often compared with proverbial question of which came first, the chicken or the egg. Some patients showing AF at the HF admission result in restoration of sinus rhythm (SR) at discharge. It is not well elucidated that the restoration into SR during hospitalization can render the preventive effect for rehospitalization.
Purpose: To investigate the impact of restoration into SR during hospitalization for readmission rate of the HF patients showing AF.



Methods: We enrolled consecutive 167 HF patients showing AF on admission in our hospital from January 2015 to December 2015. Patients data were retrospectively investigated from medical record. Patients were divided into 2 groups based on the rhythm at discharge, SR group and AF group. The endpoint was rehospitalization due to HF. Readmission related to HF was followed up until 2 years later.
Results: During mean follow up of 24 months, 29 patients were discharged with SR (17%) and 138 patients were discharged with AF (83%). Nineteen patients in SR group (66%) were performed pharmacology or electrical defibrillation. Only one patient in SR group (3%) and one patient in AF group (1%) underwent catheter

ablation. Baseline characteristics of gender, age, BMI, and history of HF hospitalization, hypertension, diabetes, dyslipidemia, stroke, and chronic kidney disease were similar between two groups. History of myocardial infarction was more frequent in AF group(p=0.04). Readmission rate due to HF was significantly lower in SR group compared with AF group (3% vs. 44%, p<0.01). To compare the risk factors related to readmission due to HF with the cox proportional-hazards model, discharge with AF was significantly associated [Hazard Ratio (HR)=1.86, p=0.01]. LVEF<40% (HR=1.79, p=0.02), beta blocker use (HR=1.62, p=0.02), CHADS2 score (HR=1.43, p=0.04) were also independently associated with HF readmission.
Conclusion: AF patients who restored to SR until discharge was a good marker to forecast future readmission due to HF.

P1527
High prevalence of sleep apnea in patients with paroxysmal atrial fibrillation

GM Traaen[1]; B Oeverland[2]; L Aakeroey[3]; T Hunt[1]; C H Bendz[1]; N Bredesen[3]; LO K Sande[4]; S Aakhus[5]; L Hansen[6]; K Ausen[6]; S Steinshamn[3]; OG Anfinsen[1]; JP Loennechen[5]; H Akre[7]; L Gullestad[1]

Background Recent studies have suggested an association between sleep apnea (SA) and different cardiovascular disorders. The prevalence, severity and type of SA in patients with paroxysmal atrial fibrillation (AF) are less known.
Purpose We aimed to examine the prevalence, severity and type of SA in patients with paroxysmal AF.
Methods We prospectively studied 578 patients with paroxysmal AF scheduled for catheter ablation at two centers. SA was diagnosed using portable respiratory polygraphy two nights at home. Sleep studies were analyzed by an experienced specialist, using standard American Academy of Sleep Medicine definitions. The degree of subjective daytime sleepiness was assessed by the Epworth Sleepiness Scale (ESS), with scores ranging from 0 to 24 (most sleepy). We calculated differences in variables between SA categories by Chi-Square Test or ANOVA as appropriate (Table).
Results 158 women (27 %) and 420 men (73 %) were enrolled. Mean age was 59.9 (9.6) years, with a mean BMI of 28.6 (4.4) kg/m^2. 477 (83 %) of the patients had an apnea-hypopnea index (AHI) ≥ 5/h, while moderate/severe SA (AHI ≥ 15/h) was diagnosed in 243 patients (42 %). Men had a higher prevalence of moderate/severe SA (47 %) than women (30 %). The type of SA was predominantly obstructive, with mean AHI 15.3/h (12.1) (range 0.4/h-85.8/h). Mean central apnea index was 0.8/h (2.1). AHI increased with age, BMI, weight, neck-and waist circumference. Mean ESS score was 7 (4.1), indicating normal daytime sleepiness. There was no association between ESS and AHI/h, Spearman rho = 0.08.
Conclusion In our AF population we found no correlation between the ESS and SA severity. The prevalence of moderate/severe SA was 42 %, which is several times higher than in the general population (8 %). The high prevalence of SA in this study may indicate that SA is under-recognized in patients with AF. More studies are needed to evaluate if treatment of SA can reduce the burden of AF.

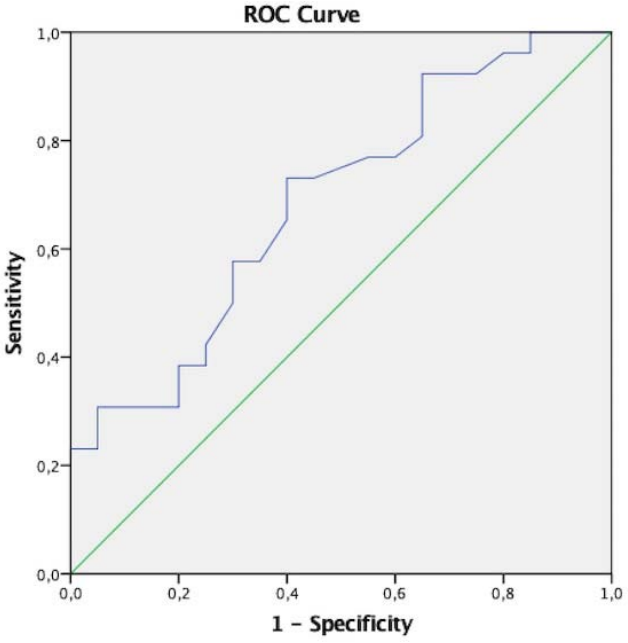
Assessment of diastolic function in patients with heart failure and atrial fibrillation

R Ventura Gomes[1]; J Pais[2]; A Pereira[3]; D Sebaiti[3]; B Rocha[4]; G Cunha[4]; A Marques[3]; M Quadrado[3]; I Cruz[3]; AR Almeida[3]; P Fazendas[3]; I Joao[3]; H Pereira[3]
[1]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal; *[2]Hospital Espirito Santo de Evora, Cardiology, Evora, Portugal*; *[3]Hospital Garcia de Orta, Cardiology, Almada, Portugal*; *[4]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal*

Introduction Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia and is associated with an increased risk of thromboembolic events (TE), all-cause mortality, heart failure (HF) and cardiovascular morbidity. In patients (pts) with HF, AF is also the most common arrhythmia and a marker of worse outcomes. Assessment of left ventricular (LV) diastolic function (DF) is paramount in echocardiographic evaluation of HF pts.



Average e' velocity ROC curve.

Purpose To investigate the impact of LV DF transthoracic echocardiographic parameters on the prognosis of pts with AF and HF.
Methods Retrospective case-control study of pts with permanent AF and HF, who were assessed in our echocardiography laboratory between January 2015 and December 2016 with a comprehensive evaluation of DF (mitral inflow E velocity, E wave deceleration timeand tissue Doppler septal and lateral mitral annulus velocities (e') and E/e' ratios). The follow-up (FU) duration was 2.6±0.8 years. Clinical and

echocardiographic data were collected. The outcome was a composite of TE, HF hospitalization (HHF) and all-cause mortality.
Results Of the 171 pts with AF, 113 were included (mean age 74.7±9.3years; 46.0% male; left ventricular ejection fraction 44.6±13.4%; CHA2DS2-VASc 4.4±1.4).During FU, 72 pts had at least one event of the composite outcome. Sixteen (14.2%) had at least one TE, 43 (38.1%) had a HHF and 42 (37.2%) died. Pts with events were older (76.3±8.8years vs 71.9±9.5years, p=0.015), had higher CHA2DS2-VASc score (4.6±1.2 vs 4.0±1.6, p=0.059), NT-proBNP levels (3351±4735pg/mL vs 1046±1162pg/mL, p<0.0001) and average E/e' ratio (15.5±6.8cm/s vs 11.8±5.5cm/s, p=0.044). Additionally, these pts were more likely to have had increased left atrium dimensions (73.1±23.6mL/m2 vs 71.2±64.6mL/m2, p=0.822) and lower estimated glomerular filtration rate (59.7±26.6mL/min/1.73m2 vs 68.6±24.6mL/min/1.73m2, p=0.094), E wave deceleration time (186.8±38.7ms vs 210.8±61.6ms, p=0.083) and average e' velocity (7.3±2.1cm/s vs 9.0±2.6cm/s, p=0.02).In multivariate analysis, only average e' velocity was the only independent predictor of the composite outcome (OR 0.296, CI 0.10-0.88, p=0.029). ROC curve showed a reasonable discriminative capacity for average e' velocity (AUC 0.687, p=0.032), with similar findings for pts with HF with preserved, mid-range and reduced ejection fraction.
Conclusion Average e' velocity was a predictor of adverse events in patients with HF and AF, independent of other clinical and echocardiographic data. Echocardiographic assessment of LV DF is a simple and fundamental step of any HF routine echocardiographic evaluation. If prospectively validated, this finding may may be useful in risk stratification of pts with HF and AF, either alone or potentially integrated in a model of risk prediction.

P1529
Clinical use of a atrial fibrillation detection device for screening in highrisk patients

JM Hartog[1]; MJM Hartog[2]; LM Hartog[3]
[1]Diakonessen Hospital Utrecht, Utrecht, Netherlands (The); [2]Leiden University Medical Center, Medical Faculty, Leiden, Netherlands (The); [3]Catholic University of Louvain (UCL), Medical Technology, Leuven, Belgium

On behalf of: General physicians

Purpose: Detection of atrial fibrillation in high risk patients. Atrial fibrillation is the most common arrhythmia. However atrial fibrillation frequently does not cause symtoms and is unrecognized. Atrial fibrillation can cause blood cloths leading to a cerebral vascular accident. This can be prevented by adequate anti coagulation.
Methods: During the inluenza vaccination campaign of the general practioners in 22 locations in the region of Utrecht 3198 patients were prior to the vaccination asked to hold the MyDiagnostick device for 60 seconds. The lamp on the device turns green indicating a normal rhythm or red in case of atrial fibrillation. The name of the positive patients, time of measurement and number of stick were noted in al logbook. Afterwards the stored ecg's of positive tests were separately analyzed by assistent and cardiologist.
Results: We had per session 10 devices at our disposal. In 247 of 3198 screened patients we had a positive result. However after analizing the stored ecg's the diagnosis atrial fibrillation stood in 95 patients (3,0%). Of these 20 patients (21%) were known with atrial fibrillation and 75 patients (79%) were newly diagnosed with atrial fibrillation. The results were communicated to their general physician who calculated their CHADSvasc score (mean 4) and started treatment for anticoagulation and rate control. In 152 patients there was a false positive result, which was corrected by analysis of the stored ecg's.
Conclusion: Screening for atrial fibrillation in high risk groups is fruitfull. In this flue vaccination group the incidence of newly diagnosed atrial fibrillation was 2,3% with an mean annual stroke risk of 4%. In these 75 patients adequate coagulation will yearly prevent 3 strokes. However we should realize that this is only a snapshot and paroxysmal atrial fibrillation can be missed. Although the MyDiagnostick device is proven to be highly sensitive it gave 153 false positieve results (specificity of 95%). It is an adequate screening tool for a quick search in large patient groups. The analysis of the stored ecg's was easy and lightly time consuming. In the daily practice of cardiovascular risk management this can be a very useful tool when there is a good back office for the analysis of the stored ecg's. The ecg-pdf's can easaly be sent digitally to the back office.

P1530
A meta-analysis of rhythm versus rate control for atrial fibrillation in chronic heart failure

AD Armin Dan Copoeru[1]; O Cristea[1]; VH Cristian[1]; RF Pop[1]
[1]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania

INTRODUCTION: Atrial fibrillation is a pathology with growing incidence and mortality; it is also beginning to be viewed and treated differently when in the context of chronic heart failure. There is still debate about whether rate or rhythm control is the preferred therapy, given their different benefits, adverse effects and possible impact on the underlying chronic heart failure. The purpose of this meta-analysis is to evaluate the effectiveness of rhythm control when compared to rate control in patients with both atrial fibrillation and chronic heart failure.
MATERIALS & METHODS: A PubMed and Cochrane Library search was conducted for randomized controlled trials (RCTs) and their sub-studies up until December 2018. Outcomes were all-cause mortality, cardiovascular mortality, stroke-related mortality and number of hospitalizations. Five studies and sub-studies were selected totaling 2640 patients.
RESULTS: The studies had a wide range of inclusion criteria for both chronic heart failure (varying degrees of severity) and atrial fibrillation (from paroxysmal to sustained). There was no statistical difference for all-cause mortality (p=0.25), cardiovascular mortality (p=0.28) or stroke-related mortality (p=0.94). However, patients in the rhythm control group suffered more hospitalizations (RR: 1.08, 95% CI: 1.01 to 1.16, p=0.01).
CONCLUSIONS: Rhythm control seems to offer no improved outcomes compared to rate control in patients with both atrial fibrillation and chronic heart failure. However, there was heterogeneity among the selected studies, which may be a confounding factor. More specific studies are needed for the treatment of atrial fibrillation in the context of chronic heart failure.

Device Therapy

P1531
Characteristics and predictors of super response to the Cardiac Resynchronisation Therapy(CRT). An Algerian single Center Experience.

R Rhiad Benkouar[1]; MS Ait Messaoudene[1]; Y Aoudia[1]; A Boudrifa[1]; O Kassoul[1]; Y Tir[1]; K Bouasria[1]; N Ali Tatar[1]; MT Chentir[1]; MT Chentir[1]; Y Bouhouita[1]
[1]CHU Mustapha, Algiers, Algeria

Introduction: In some patients with dilated cardiomyopathy (DCM) and left bundle branch block (LBBB), cardiac resynchronization therapy (CRT) has been shown to reverse almost completely left ventricular (LV) function.

predictors of super response

		univariate analysis		multivariate analysis	
Parameters	Odss ratio(95%)	p value	Odss ratio(95%)	p value	
female gender	0.33 (0.12,0.91)	0.03			
Hospitalisation for HF before CRT	0.3 (0.15,0.62)	0.001			
Renal Failure	0.52 (0.19,1.39)	0.03			
CRTP versus CRTD	5.47 (1.48,20.27)	0.01	5.47 (1.48,20.27)	0.007	
QRS duration post implantation	0.94 (0.9,0.99)	0.007			
Normal RV function		3.19 (1.25,8.15)	0.01		
LVEF		1.18 (1.04,1.33)	0.005		
LVEDD		0.92 (0.85,0.99)	0.01		
LVEDV		0.97 (0.95,0.99)	0.001	0.97 (0.95,0.99)	0.002
PAPS		0.92 (0.87,0.96)	0.001	0.92 (0.87,0.96)	0.001

RV: right ventricle, LVEDD: LV end diastolic diameter.

Purpose: Determine the proportion of super responders among patients with DCM and attempt to determine their profile in a tertiary implantation center of Algeria.
Methods: Consecutive patients with DCM (LV ejection fraction (LVEF) <35%, LV end-diastolic diameter>60mm) and LBBB implanted with a CRT were prospectively followed. Patients were considered super-responders if they fulfilled two criteria:class NYHA I/II and LVEF≥ 50%.
Results: Among the 98 DCM patients, 19 (19.5%) were found to be superresponders following CRT (LVEF increased from 29.89± 4.44 to 53.37± 3.76 %, p=0.001). in

the 79(81%) remaining patients, there was a significant increase in LVEF from 26.49± 4.67 to 37.27± 7.20, p=0.001). At baseline, there were no significant differences between super-responders and other patients, except that they were female, had no hospitalization for HF before CRT and no renal deficiency. Super responders had also less severe LVEF and lower pulmonary artery systolic pressure (PASP).CRT-P (OR, 5.47; 95% CI, 1.48–20.27; P= 0.007), lower left ventricular end-diastolic volume (LVEDV)(OR, 0.97; 95% CI, 0.95–0.0.99; P=0.002) and lower PASP (OR, 0.92; 95% CI, 0.87, 0.96; p<0.001) were independent predictors of super-response to CRT (see the table).
Conclusion: Among patients with DCM and LBBB, Patients in earlier phases of the CMD, with a less altered ventricular geometry, seem to have a greater probability of becoming super-responders.

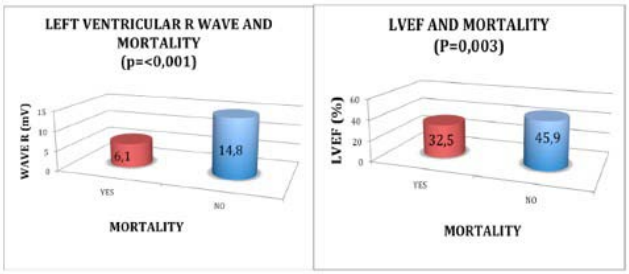
P1532

R wave sensed from the left ventricle as mortality predictor in patients with cardiac resynchronization therapy for primary prevention

N G Nancy Giovanna Uribe Heredia[1]; R Peinado Peinado[2]; JL Balaguer Recena[1]; LG Piccone Saponara[3]; S Moreno Reviriego[1]; C Solorzano Guillen[1]; JL Peyrat Benitez[1]; R Arroyo Espliguero[1]; ME Jimenez Martinez[1]; C Toran Martinez[1]; A Castillo Sandoval[1]; JL Garcia Gonzalez[1]; E Novo Garcia[1]; B Garcia Magallon[1]; ME Viana Llamas[1]
[1]University Hospital of Guadalajara, Guadalajara, Spain; *[2]University Hospital La Paz, Arrhythmia Unit, Madrid, Spain*; *[3]Hospital General de Ciudad Real, Nefrology, Ciudad Real, Spain*

BACKGROUND: A lower left ventricular R wave (LVRW) and a higher left ventricular threshold (LVT) could be related to a greater extent of myocardial scarring and lower myocardial vitality.

VARIABLE	MORTALITY	P	
YES	NO		
Paced QRSd (ms)	138,13+23,59	125,74+21,19	0,152
LVRW (mV)	6,09+3,05	14,81+7,6	< 0,001
LVT (V x 0,5ms)	1,83+0,85	1,17+0,65	0,021
LVEF postCRT%)	32,50+10,88	45,91+10,59	0,003
Absence of reverse remodelling (%)	62,5	22,9	0,028
NYHA III-IV postCRT (%)	62,5	0	< 0,001



PURPOSE: The purpose of this study was to analyze the value of left ventricular (LV) electrode measurements during the implant as predictors of mortality in patients with implantable cardioverter-defibrillator (ICD) with cardiac resynchronization therapy (CRT) in primary prevention.
METHODS: We retrospectively analyzed data of patients with implanted biventricular defibrillator between January 2010 and December 2013. CRT was indicated according to the guidelines of the ESC. During the implant, left ventricular sensing, impedance and threshold were measured. Clinical characteristics, left ventricular lead position and measurements, electrocardiography and echocardiography were evaluated before and after CRT. Statistical analysis SPSS 20. The variables were compared bye T-Student and Chi2. Multivariate analysis logistic regression. Statistical significance for p <0.05.
RESULTS: 43 patients were enrolled. Mean age was 72 y and 90% were men. Ischemic cardiomyopathy 49%. NYHA functional class III-IV 63%. LBBB was identified in 46,5% and permanent atrial fibrillation (AF) 35%. After the implant mean biventricular paced QRSd was 128±21ms. The mean duration of follow-up was 33.3±7.8 months. The mortality rate was 19% (N=8). The univariate analysis is detailed in table 1. With multivariate analysis, only a lower LVRW during the implant (6.1±3.1V vs 14.8±7.6V, OR 1.3, 95% CI 1.03-1.7, p=0.03) and a very low LVEF after the implant (32.5±10.9 Vs 45.9±10.6, OR 1.14, 95% CI 1.03-1.3, p=0,03) remained as independent predictors factors of mortality.
CONCLUSIONS: In our study, a lower left ventricular detection and a very low LVEF were independent predictors of mortality. However, a higher left ventricular threshold did not reach statistical significance. These variables could identify a subgroup of patients who would benefit from a closer follow-up.

P1533

Comprehensive approach to the outpatient management of patients with prosthetic heart valves

E Gorbunova[1]; N Trishkina[1]; V Rozhnev[1]; O Barbarash[1]
[1]Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation

Background: Patients with prosthetic heart valves require life-long anticoagulant therapy. The reduced length of in-hospital stay of patients after heart valve replacements determines the relevance of the outpatient management. Purpose: To develop an integrated approach to outpatient management of patients with prosthetic heart valves to increase the effectiveness and safety of anticoagulant therapy and improve the quality of life. Methods: Group 1 patients (n = 118) underwent simultaneous sequential restoration of the sinus rhythm, including (1) mitral valve replacement combined with maze procedure; (2) electropulse therapy; (3) catheter radiofrequency ablation. Group 2 patients (n = 144) received patient education in addition to the standard management. Group 3 patients (n = 216) had warfarin pharmacogenomic testing to guide anticoagulant therapy. Group 4 patients (n = 98) self-tested the INR using portable devices and were remotely monitored (1 in two weeks) by nurses using telephone and Skype calls in the anticoagulant center. Patients with mechanical and tissue heart valves were equally distributed in the study groups. The quality of life was assessed using the SF-36 questionnaire at the beginning of the outpatient monitoring and 12 months after it. Results. Sequential sinus rhythm restoration contributed to the 100% recovery of the sinus rhythm in patients with tissue heart valves, followed by the discontinuation of the anticoagulant therapy. Warfarin pharmacogenetic testing reduced 2-fold the selection of the warfarin dosing and resulted in an 25.2% increase of the therapeutic range (TTR) (p = 0.0056). Patient education reduced the risk of thrombotic and hemorrhagic complications by 1.8 and 2.6 times, respectively. Promising clinical outcomes were observed in the group of remote monitoring, whose TTR reached 82% (p = 0.014). The correlation between TTR and patients' quality of life have been deternibed. Conclusion. A comprehensive approach to the management of patients with prosthetic heart valves, including sinus rhythm restoration, warfarin pharmacogenetic testing, patient education ensures the effectiveness and safety of anticoagulant therapy and improved quality of life.

A decline in physical activity precedes sustained ventricular arrhythmias in women

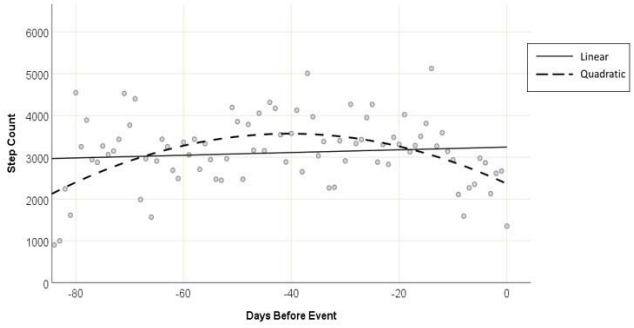
AE Ashley Burch[1]; V Kutyifa[2]; JW Erath[3]; B Assmus[3]; D Bondermann[4]; AM Russo[5]
[1]East Carolina Heart Institute, Psychology , Greenville, United States of America; *[2]University of Rochester, Medical Center, Rochester, United States of America*; *[3]JW Goethe University, Department of Cardiology, Frankfurt am Main, Germany*; *[4]Medical University of Vienna, Department of Internal Medicine, Vienna, Austria*; *[5]Cooper Medical School of Rowan University, Department of Medicine, Camden, United States of America*

Funding Acknowledgements: ZOLL, Medical

Background. Changes in physical activity before a ventricular arrhythmia event have not been described previously, especially in women. The wearable cardioverter defibrillator (WCD) provides continuous cardiac monitoring and delivers a shock if a sustained VT/VF occurs. Multiple accelerometers in the WCD provide information about patient activity. Understanding activity changes leading up to a VT/VF event may improve patient care and prevent sudden cardiac death.
Purpose. Describe the decline in physical activity in the days preceding a VT/VF event among female patients with reduced ejection fraction (EF).
Methods. Female adult patients prescribed a WCD after a diagnosis of either dilated cardiomyopathy or post myocardial infarction (n = 4972) with low EF were included. Step count was measured by the WCD. Curve estimation was used to evaluate the relationship between physical activity (defined as 24-hour step count) and number of days before a sustained ventricular arrhythmia. A linear model, suggesting a monotonic relationship between activity and time leading up to a ventricular arrhythmia, was compared to a quadratic model. Results. Sustained VT/VF was experienced by 27 patients. Mean age of all patients was 65 years (SD = 13), mean age of shocked patients was 64 years (SD = 10). On average, patients wore the WCD for 47 days (SD = 24) prior to receiving a shock for sustained VT/VF. The figure shows the median step count for 85 days preceding a sustained ventricular arrhythmia. The

solid line represents the non-significant linear equation (adjusted R^2 = -.003, p = .40). The dashed line represents the quadratic equation (adjusted R^2 = .206, p < .001). The significant quadratic equation suggests a non-linear relationship exists between activity and time leading up to a sustained ventricular arrhythmia. Using the quadratic equation, Step Count = 2370 - 59.52*(Day) - 0.74*(Day)^2, physical activity increased starting at the beginning of WCD use up until day -39 (39 days before the WCD shock) when activity begin to decline. Activity continues to decline up to day 0 (day of WCD shock).

Conclusions. Among women with cardiomyopathy or post myocardial infarction and a reduced EF a decline in physical activity began an average of 39 days before a VT/VF event. Activity monitoring for a sustained decline in activity may be useful to identify patients at near term risk of a cardiac arrest.



P1535

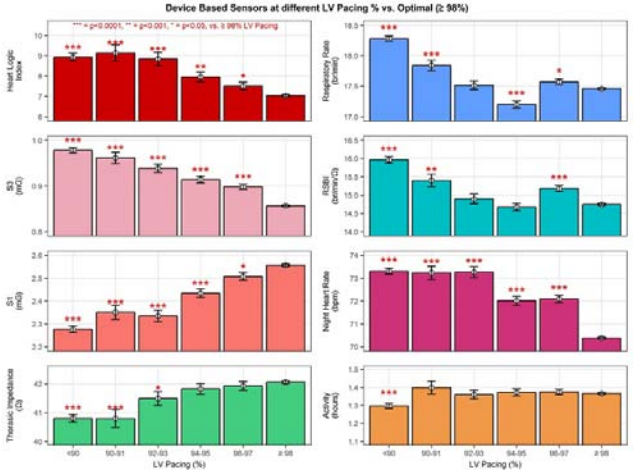
Progressive worsening in device-base failure sensors measurements are associated with sub-optimal BiV pacing percentages in CRT-D patients

N Varma[1]; M Cao[2]; EJ Schloss[3]; R Ahmed[4]; C Craig Stolen[4]; JP Boehmer[5]
[1]Cleveland Clinic Foundation, Cleveland, United States of America; *[2]Golden Heart Medical, Rosemead, United States of America*; *[3]The Christ Hospital, Cincinnati, United States of America*; *[4]Boston Scientific Corporation, St Paul, United States of America*; *[5]Penn State Hershey Medical Center, Hershey, United States of America*

Funding Acknowledgements: Boston Scientific

Background: Lower percentages of BiV pacing (<98%) have been associated with significantly worse survival in a cohort of >35000 remotely monitored CRT patients. HeartLogic (HL), a heart failure (HF) composite index and alert algorithm available in both CRT-D and ICD devices, aggregates physiologic trends associated with multiple aspects of HF status (e.g. heart sounds, heart rate, thoracic impedance, respiration rate, tidal volume, and activity). HL alerts were recently shown to detect HF events with 70% sensitivity, and identify patients with 10-fold increased risk of worsening HF.

Objective: We plan to investigate association between daily % BiV pacing and device measured individual heart failure sensors and HeartLogic.



Methods: The ALTITUDE database collects de-identified data recorded by the implanted devices from the LATITUDE remote monitoring system. Patients with HeartLogic enabled CRT-D devices and a minimum of 30 days of daily sensor data were included. All days with AF burden were excluded. Each patient day was grouped into 6 groups based on the daily % BiV pacing values (<90%, 90-91%, 92-93%, 94-95%, 96-97%, and ≥98%). For each pacing group, the mean of different device sensors, the HeartLogic index, and the proportion of days in HeartLogic alert were evaluated.

Results: Out of 2736 CRT-D patients, 594 met the selection criteria and had 248 alerts over 155.1 years. Sub-optimal BiV pacing percentages were associated with progressively worse device sensor values (see figure). HeartLogic index reflected significant worsening even for a small reduction in % BiV pacing. The proportion of days in HeartLogic alert was about 2x higher with <90% BiV pacing (19.08%; 95% CI 18.0-20.19) vs. ≥98% (11.29%; 95% CI 10.99-11.60; p<0.0001). Further, each individual sensor worsens with sub-optimal compared with optimal BiV pacing.

Conclusion: Lower %BiV pacing is associated with multiple worsening heart failure sensors. This analysis provides strong evidence that the poor survival associated lower %BiV pacing is likely caused by worsening heart failure.

P1536

Preliminary experience of remote management of heart failure patients with a multisensor ICD alert.

[1]Polyclinic Casilino of Rome, Rome, Italy; *[2]University Hospital Riuniti of Ancona, Ancona, Italy*; *[3]Cardiology division "G.B. GRASSI" Hospital, OSTIA (ROME), Italy*; *[4]Poliambulanza Foundation Hospital Institute of Brescia, Brescia, Italy*; *[5]University of Bari, Bari, Italy*; *[6]Sacred Heart Hospital of Negrar, Negrar-Verona, Italy*; *[7]Policlinic Foundation San Matteo IRCCS, Pavia, Italy*; *[8] AO dei Colli-Monaldi Hospital, Naples, Italy*; *[9]BOSTON SCIENTIFIC ITALIA, Milan, Italy*

Background: The HeartLogic index combines data from multiple implantable cardioverter-defibrillator (ICD)-based sensors and has proved to be a sensitive and timely predictor of impending heart failure (HF) decompensation.

Purpose: To describe a preliminary experience of remote HF management of patients who received a HeartLogic-enabled ICD or cardiac resynchronization therapy ICD (CRT-D) in clinical practice.

Methods: The HeartLogic feature was activated in 101 patients (74 male, 71±10 years, ejection fraction 30±7%). From implantation to activation (blinded phase), the HeartLogic index trend was not available, thus no clinical actions were taken in response to it. After activation (active phase), remote data reviews and patient phone contacts were performed monthly and at the time of HeartLogic alerts (when the index crossed the nominal alert threshold value of 16), to assess the patient decompensation status. In-office visits were performed when deemed necessary.

Results: During the blinded phase, the HeartLogic index crossed the threshold value 24 times (over 24 person-years, 0.99 alerts/pt-year) in 16 patients. HeartLogic alerts preceded all hospitalizations and unplanned in-office visits for HF (sensitivity: 100%, median early warning: 38 days for hospitalizations, 12 days for HF visits). No clinical events were detected during or within 30 days of recovery of 10 HeartLogic alerts (unexplained alert rate: 0.41 per patient-year). Thus, the positive predictive value was 58% (14/24). During the active phase, 44 HeartLogic alerts were reported (over 46 person-years, 0.95 alerts/pt-year) in 30 patients. 26 (59%) HeartLogic alerts were judged clinically meaningful (i.e. associated with worsening of HF and/or influenced the clinician's decision to make changes to the subject's management).

Conclusions: In this first description of the use of HeartLogic in clinical practice, the algorithm demonstrated its ability to detect gradual worsening of HF. The results of the blinded phase of our experience favorably compare with those reported in the validation study. In the active phase, the HeartLogic index provided clinically meaningful information for the remote management of HF patients.

AF.- Atrial fibrillation, SVT.- Supraventricular tachycardia, SVPB.- supraventricular premature beats, , VT.- ventricular tachycardia, VPB.- ventricular premature beats

parameters, including S3 and S3/S1, in a single index to predict impending HF decompensation.
Purpose: To evaluate the echocardiographic correlates of ICD-measured S3 and S3/S1 in patients with ICD and cardiac resynchronization therapy ICD.
Methods: The HeartLogic feature was activated in 104 patients (76 male, 71±10 years, left ventricular ejection fraction (LVEF) 29±7%). At in-office visit, 96 patients underwent echocardiographic evaluation and parameters of systolic and diastolic function were correlated with S3 amplitude and S3/S1 ratio measured on the same day of the visit.
Results: S3 amplitude significantly correlated with the deceleration time of E wave (DT) (r=-0.30, p=0.010). Patients with S3 >0.86mG (median value) showed significantly lower values of DT than patients with lower S3 (197±72ms vs. 242±85ms, p=0.022). Interestingly, S3 was detected at auscultation only in 8 patients who did not show lower DT values at echocardiography (201±70ms vs. 222±84ms, p=0.543). S3/S1 ratio significantly correlated with the LVEF (r=-0.34, p=0.002). Patients with S3/S1 >0.36 (median value) showed significantly lower values of LVEF than patients with lower S3/S1 (32±8% vs. 38±7%, p=0.0003).
Conclusions: The ICD-measured HS parameters are significantly correlated with echocardiographic indexes of systolic and diastolic function. This confirms their utility for remote HF patient monitoring when considered as single sensors, and their potential relevance when considered in combination with other physiological ICD sensors that evaluate different aspects of HF physiology.

P1538

Risk of arrhythmias in relation to hypoxia in patients with heart failure and chronic obstructive pulmonary disease

L Hernandez Urquieta[1]; A Orea Tejeda[1]; D Gonzalez[1]; A Jimenez Valentin[1]; AJ Flores Vargas[1]; A Ibarra Fernandez[1]; R Davila Ramos[1]; R Hernandez Zenteno[1]; R Perez Padilla[1]; R Sanchez Santillan[1]; K Balderas Munoz[1]; V Pelaez Hernandez[1]
[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico

Introduction: Arrhythmias are present in Heart Failure (HF) and Chronic Obstructive Pulmonary Disease (COPD) patients. Currently, the prevalence and risk of arrhythmias in subjects with HF and COPD concomitant and their relationship to hypoxia are unknow, which could explain the greater morbidity and mortality when they coexist.
Objective: To determine the prevalence and risk of arrhythmias in relation to hypoxia in patients HF and COPD concomitant.
Methods: In a cross-sectional study, patients with a confirmed diagnosis of HF and / or COPD were included, asthma and cancer subjects were excluded. Arrhythmias were determinate by 24-hour Holter electrocardiogram and hypoxia by 24-hour pulse oximetry.
Results: Were evaluated 98 patients, divided into three groups (HF + COPD, COPD and HF), predominantly women (60.47% vs 56.10% and 28.579%, p= 0.10). Subjects with COPD + HF had a higher prevalence of ventricular premature beats (VPB) > at 1% (of the total beats in the study) (35.15 vs 23.26 and 7.69, p = 0.15 respectively), R/T phenomenon (41.46 vs 23.08 and 20.93, p=0.10 respectively) compared to the other groups. The rest of the variables were not statistically significant. Subjects with a longer desaturation time (> 327 minutes/day) had major risk to arrhythimias: atrial fibrillation, OR: 4.04, CI 0.82-19.88, supraventricular tachycardia, OR: 2.83, CI95%: 0.92-8.64, paired extraheart beats OR: 3.31, CI95%: 1.1-9.91, sinus tachycardia OR: 3.58, CI95%: 1.02-12.59, and VPB > 1% OR: 2.51, CI95%: 0.08-7.82 compared with subjects with low desaturation time (<327 minutes/day) adjusting for age, sex, LVEF and oxygen use.
Conclusions: HF and COPD concomitant had higher prevalence of arrhythmias. The risk of arrhythmias increases in long desaturation time.

Introduction: Cardiac resynchronization therapy (CRT) has emerged as the predominant electrical treatment strategy for patients on pharmacological therapy who present chronic heart failure (CHF) with low ejection fraction. The objective of this study was to investigate whether cardiac resynchronization therapy improved morbidity among patients with heart failure.
Materials and methods: This follow-up study enrolled 70 adult patients undergoing CRT device implantation. Inclusion criteria was presence of heart failure (CHF New-York Heart Association functional class III, IV) and left bundle branch bloc. We performed measurements of cardiac contraction parameters by echocardiography (on the Vivid 7 GE) at the beginning of the study and 12 month after CRT device implantation. All patients received beta-blockers, angiotensin-converting enzyme inhibitors/angiotensin II receptor antagonist, diuretics (including aldosterone antagonists), antiplatelet agents, anticoagulants and HMG-GoA Reductase Inhibitors (up to indications).
Results: We observed significant increase in ejection fraction 12 months after CRT implantation (28.3 ± 0.9 % to 37.9 ± 0.9%, $p < 0.0001$ vs 0). There was no significant difference in left ventricle end diastolic dimension and mean pulmonary artery pressure. Intraventricular conduction delay significantly decreased in 12 month after CRT device implantation (238 ± 23.7 ms, $p < 0.05$). Interventricular conduction delay showed significant decrease after CRT device implantation (29.7 ± 5.6 ms for 12 month $p < 0.005$). We observed significant trend to increase in diastolic filling time (44.7 ± 0.98 for 12 month, at 0 point, $p < 0.05$). Positive changes in the parameters of central hemodynamics were accompanied by improvement of the clinical state of patients (reduction in dyspnea, increased tolerance to physical exercise).
Conclusion: Our results suggest that implantation of CRT device for patients with heart failure helps to improve contraction and relaxation of heart muscles, but has no positive effect on the end diastolic dimension of left ventricle and mean pulmonary artery pressure.

P1540

Super responders to cardiac resynchronization therapy- A terciary centre experience

A Briosa[1]; A Marques[1]; AR Pereira[1]; S Alegria[1]; D Sebaiti[1]; AC Gomes[1]; R Miranda[1]; S Almeida[1]; L Brandao[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Lisbon, Portugal

Introduction: Patients submitted to Cardiac Resynchronization Therapy (CRT) implantation may develop response patterns that are higher than expected with almost complete normalization of clinical and echocardiographic parameters (super-responders).
Purpose: To characterize patients (pts) who underwent CRT implantation and to evaluate clinical and echocardiographic characteristics of super-responders.
Methods: Restrospective study of a single center analysing patients submitted to CRT implantation in the last 6 years (2012-2018). Super-responders were classified as patients who normalized left ventricular ejection fraction (LVEF >= 50%) at 6 months after implantation.

Results: We analysed 103 pts, 65% males with mean age of 70± 10 years, with optimized medical treatment. Non ischemic etiology was present in 74,5% of pts. 68,1% pts had QRS > 150ms and 80,9% had left bundle brunch block (LBBB). Mean LVEF was 27,9±7,5%, mean left ventricular end-diastolic volume índex (LVEDVI) was 113± 38 ml/m2. By the time of CRT implantation, 67% of pts were in SR (n=69) and 33% had AF (13,6% with paroxystic AF and 19,4% with persistent AF), and NYHA class 3 was present in 56,3% of pts. Subsequent hospitalizations occurred in 18,4%, and 11 pts died. 76,7% of pts were considered responders. 21,4% of pts were considered super-responders (n=22).
Comparing both groups (super-responders vs global population), we found no differences between groups in respect to gender (p=0,990), presence of previous sinus rythm (SR) (p=0.156), etiology (p= 0,053) and previous QRS width (p=0,086). There were also no differences in long term outcomes (hospitalizations (p=0,371) or death (p=1)). However, super-responders had higher baseline ejection fraction (32 vs 26%, p= 0,002), lower left ventricular end-diastolic volume (167 vs 225 ml /m2, p=0,016) and lower left ventricular end-systolic volume (112 vs 156 ml/m2, p=0,016).
Conclusion: In this population, the super-responders appear to be pts with less advanced heart disease at baseline, with higher LVEF and lower left ventricular volumes. Surprisingly, we found no predictors of super-response in this population, not confirming previous studies that associated female sex, non-ischemic etiology and wider QRS duration with a super-response. This raises the question whether there are others non-recognized predictors of CRT response that would improve selection of patients for this therapy. Further studies are necessary to clarify this.

Bachmanns bundle pacing combined with his bundle pacing a new approach to reverse cardiac remodeling

P Peter Stephan Wolff[1]; P Strozik[1]; JM Zawadzki[1]; A Gajek[1]; D Zysko[2]; A Ciesliesłski[3]; A Slawuta[4]; J Gajek[5]
[1]Wroclaw Medical University, Students' Scientific Association, Wroclaw Medical University, Department of Clinical Nursing, Wrocl, Wroclaw, Poland; *[2]Wroclaw Medical University, Department of Emergency Medicine, Wroclaw, Poland*; *[3]Wroclaw Medical University, Department of Cardiology, Wroclaw, Poland*; *[4]Klodzko County Hospital, Department of Cardiology, Klodzko, Poland*; *[5]Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland*

On behalf of: Students' Scientific Association, Wroclaw Medical University

The treatment of patients with heart failure and concomitant atrioventricular conduction delay is difficult. The recommendations indicate the possibility to use the classic resynchronization but in the presence of narrow QRS-complex such approach could be even harmful. The therapeutic option for those patients to re-establish the physiological atrioventricular mechanical sequence is the permanent His-bundle pacing. The use of Bachmann's-bundle pacing can additionally correct the prolonged interatrial conduction thus further contribute to the echocardiographic and clinical improvement.
Aim of the study is to assess the influence of Bachmann's-bundle pacing and His-bundle pacing on the reversed remodeling of the heart in patients with heart failure and atrioventricular block.
The study group included 11 patients (5 women and 6 men), aged 73+/-9 years undergoing cardiac resynchronization using Bachmann's-bundle pacing and permanent His-bundle pacing from LV channel. All the patients had narrow QRS-complex which prevented us to use classic resynchronization. Five CRT-D and 6 CRT-P devices were implanted according to the ejection fraction and ventricular arrhythmia risk assessment. In all patients the direct His-bundle pacing was successfully achieved, selective in 10 and non-selective in 1 patient. The mean follow-up period was 8 months (1-18 months). The echocardiographic, clinical and ECG results are presented in the table:
Conclusions: 1. The correction of atrioventricular and interatrial conduction delay resulting in improvement of atrioventricular mechanical coupling can contribute to the reversed remodeling of the heart. 2. This also improves the patient's functional status. 3. In some patients this approach could lead to the normalization of echocardiographic parameters of the left ventricle.

	Before	After	P value
LVEDD (mm)	65.1+/-6.6	59.1+/-4.6	<0.05

P1542

Responders and non-responders after cardiac contractility modulation in patients with chronic heart failure and narrow QRS.

D Denis Losik[1]; V Shabanov[1]; U Verstuk[1]; E Fisher[1]; I Mikheenko[1]; I Peregudov[1]; E Morzhanaev[1]; N Elemesov[1]; A Filippenko[1]; E Pokushalov[1]; A Romanov[1]
[1]National Medical Research Center named after E.N.Meshalkin, Novosibirsk, Russian Federation

Background: Cardiac contractility modulation (CCM) is a novel method for treating patients with moderate-to-severe chronic heart failure (CHF) despite optimal medical therapy. Recent studies of CCM used left ventricle ejection fraction (LVEF) and peak O2 parameters for responders assessment, however data regarding brain natriuretic peptide (BNP) level as additional efficacy endpoint in patients with CCM are limited.
Purpose: To assess the number of responders after CCM therapy in moderate-to-severe CHF patients based on LVEF, end diastolic volume (EDV) and BNP.
Methods: The CCM device was implanted in 15 CHF patients (14 men, mean age 60±5 years). All patients had LVEF 35%, and QRS duration < 120 msec during sinus rhythm. The responder criteria was changing at least one of the following paraments on 10% (increasing LVEF, decreasing EDV and BNP). Patients were followed up during 12 months after CCM implantation with Echo and BNP level assessment each 3 month within observation period.
Results: There were no complications during implantation procedure. At the 12 months follow up 10 (67%) patients had achieved one or more responder criteria. One patient (6,7%) demonstrated increasing of LVEF and decreasing EDV, 3 (20%) patients had decreased BNP level and 6 (40%) patients developed improvement of all three parameters. In total study the was a tendency to improvement as compared to baseline, but without statistical significance (LVEF-31±5% vs 35±7%, p= 0,6; EDV - 148±44 ml vs 142±41 ml, p= 0,7; BNP-285±313 pg/ml vs 232±199 pg/ml, p=0,367, respectively). Two patients died due to heart failure progression within follow up.
Conclusion: The cardiac contractility modulation therapy can be acceptable method in moderate-to-severe chronic heart failure patients. More studies are needed to assess number of responders and clinical outcomes in larger patient's cohort.

P1543

Day-case implant of complex pacing devices is safe and preferred by patients; a 4 year experience.

R Chattopadhyay[1]; PA Chousou[1]; R Bellanti[1]; A Marinakis[1]; J Hayes[1]; K Sanders[1]; V Carpenter[1]; H Hewitt[1]; A Domingos[1]; M Virdee[1]; PJ Pugh[1]
[1]Addenbrooke's Hospital, Cardiology, Cambridge, United Kingdom of Great Britain & Northern Ireland

Background/Introduction: Across Europe, there is wide variation in length of stay of patients following pacemaker device procedures, requiring up to a two night hospital stay. We have previously reported the safety and acceptability of Day-Case pacing for bradycardia and our unit has operated a Day-Case Implant service for simple pacing for many years, but patients undergoing implant of complex devices; Cardiac Resynchronisation Therapy (CRT) or Implantable Cardioverter Defibrillator (ICD) stayed overnight. In August 2016 our institution introduced an extensive policy of Day-Case procedures, including implant of complex devices.

	Group A (overnight stay)n=50	Group B (Day-Case)n=60	p-value
Satisfied withdischarge strategy, n (%)	45(90)	57 (95)	0.46
Would have preferredthe alternative strategy, n (%)	17 (34)	9 (15)	0.024
Satisfactory pre-discharge information, n (%)	48 (96)	55 (93.2)	NS
Adequate analgesia, n (%)	49 (98)	50 (83.3)	0.021
Did the dischargestrategy cause inconvenience for family / friends? n (%)	5 (10)	8 (13.3)	NS
Long delay prior todischarge, n (%)	20 (40)	6 (10.1)	0.0003

NS - non-significant

Purpose To assess the feasibility, acceptability and safety of Day-Case implant of complex pacing devices.
Methods A single-centre retrospective study. Questionnaires were distributed to patients who had received elective complex device implant between August 2015

and August 2017, before (Group A- 50 patients) and after (Group B-60 patients) introduction of the Day-Case policy. In addition patients' electronic medical records were reviewed from August 2014 to August 2018 and the presence or absence of complications at first follow-up clinic (6 weeks) was recorded for Group A (105 patients) and Group B (120 patients).
Results Findings from the questionnaires are shown in Table 1. There were no adverse findings at 6 weeks that would have been avoided by or caused by overnight stay at implantation. Complications were recorded at 6 weeks in 11 subjects in Group A (10.5%) and 8 subjects (6.7%) in Group B. Between groups comparisons were made using Fisher's exact test.
Conclusions Day-Case implant of complex pacing devices appears safe and is preferred by most patients. Although most patients in both groups received appropriate analgesia, it is important to ensure that this is not compromised for day-case patients. While this approach may not be suitable for all patients, we suggest that overnight stay for elective complex device implantation should be the exception. As well as being better for patients, there is a significant economic advantage of this approach.

P1544

PR interval prolongation, still a marker of worse outcome in patients treated cardiac resynchronization therapy patients

A M W Antonius Martinus Wilhelmus Van Stipdonk[1]; M Dural[2]; F Salden[3]; IAH Ter Horst[4]; HJGM Crijns[1]; FW Prinzen[3]; M Meine[4]; AH Maass[5]; K Vernooy[1]
[1]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands (The); [2]Eskisehir Osmangazi University, Cardiology, Eskisehir, Turkey; [3]Cardiovascular Research Institute Maastricht (CARIM), Physiology, Maastricht, Netherlands (The); [4]University Medical Center Utrecht, Cardiology, Utrecht, Netherlands (The); [5]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The)

Background: Patients without left bundle branch block (non-LBBB) generally derive little benefit from CRT. Recently, CRT has been suggested to be beneficial in patients with prolonged PR interval. However, in the general HF population the presence of a prolonged PR interval is associated with worse outcome.
Purpose: To evaluate the association of a prolonged PR interval with clinical outcome in CRT-treated LBBB and non-LBBB patients.
Methods: Pre-implantation 12-lead ECGs from 1.245 consecutive CRT patients without atrial fibrillation from 3 implanting centres in the Netherlands, were evaluated for the presence of LBBB QRS morphology and PR interval prolongation (≥230ms). The primary endpoint was the combination of left ventricular assist device implantation, cardiac transplantation and all-cause mortality.
Results: Patients with LBBB (n=620) showed a significantly shorter mean PR interval than non-LBBB patients (n=625) (187ms vs 198ms, p<0.001). Prolonged PR interval was found in 12.6% of patients with LBBB and 19.2% of non-LBBB patients (p=0.001). In non-LBBB patients with PR prolongation event rate was significantly higher (54 vs 34%, p<0.001). In LBBB patients there was a non-significant difference (28 vs 20%, p=0.1). Regression analyses (figure 1) showed similar results, with a significantly higher odds of experiencing an event in non-LBBB patients with PR prolongation (2.24 [1.68, 2.99], p<0.001), and a trend to significantly higher odds in LBBB patients with PR prolongation (HR 1.61 [1.02, 2.56], p=0.04).
Conclusion: In HF patients treated with CRT, PR prolongation is negatively associated with long term clinical outcome. This association seems to be stronger in non-LBBB patients than in LBBB patients.

LV only fusion pacing CRT without RV lead: clinical and echocardiographic characteristics of super-response

C Vacarescu[1]; L Petrescu[1]; CT Luca[2]; C Mornos[2]; EV Goanta[3]; S Crisan[2]; D Cozma[2]
[1]University of Medicine Victor Babes, Cardiology Department, Timisoara, Romania; [2]Timisoara Institute of Cardiovascular Medicine, Timisoara, Romania; [3]Emergency County Hospital, Cardiology, Craiova, Romania

Background: LV only CRT pacing is an accepted option stated in the current guideline, however few data exist regarding fusion pacing super-response, even fewer for CRT without RV lead. Purpose: To identify predictors of super-responders (SRs) in this population.
Methods: LV only CRT patients (pts) with right atrium/left ventricle (RA/LV) DDD pacing system implanted in 3 CRT centers in Romania with nonischemic LBBB low EF cardiomyopathy were included. Device interrogation, exercise test, echocardiography and individualized drug optimization were performed each 6 months during close follow-up. SRs pts were defined those with left ventricular end-systolic volume (LVESV) improvement ≥30% and stable ejection fraction (LVEF) ≥45%.
Results: 16 pts (29%) were SRs out of 55 pts (29 male, 62±10y.o) initialy included. The mean follow-up was 37±18 months. Patients were divided in two groups: SRs and nonSRs (35 responders/4 hyporesponders). Four predictors were found in SRs group (males 56%): younger age (SRs 57±13y.o vs. non SRs 64±9y.o, p=0.0269), higher baseline LVEF (SRs 29±4% vs. nonSRs 26±5%, p=0.0382), lower pulmonary arterial systolic pressure (SRs 35±10mmHg vs. nonSRs 52±16mmHg, p=0.0003) and lower left atrium (LA) volumes (SRs 82±27ml vs. nonSRs 118±30ml, p=0.0001). Baseline severe MR was found in 19% of SRs vs. 50% in nonSRs group.
Conclusions: SRs in carefully selected pts in LV only CRT without RV lead is significative. Higher baseline LVEF, mild pulmonary arterial hypertension, lower atrial volumes and younger age were independently associated with super-response.

	LV only CRT SRs(N=16)	NonSRs(N=39)	p

P1546

Baseline characteristics determine long-term outcome to CRT, intermediate endpoints identify those at risk of adverse events.

A M W Antonius Martinus Wilhelmus Van Stipdonk[1]; M Ghossein[1]; M Kloosterman[2]; I A H Ter Horst[3]; F W Prinzen[4]; M Meine[3]; K Vernooy[1]; A H Maass[2]
[1]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands (The); *[2]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The)*; *[3]University Medical Center Utrecht, Cardiology, Utrecht, Netherlands (The)*; *[4]Cardiovascular Research Institute Maastricht (CARIM), Physiology, Maastricht, Netherlands (The)*

Background: cardiac resynchronization therapy (CRT) reverses cardiac remodelling, reduces heart failure complaints and heart failure (HF) hospitalizations, and finally reduces mortality in the long term. However it is not known whether intermediate endpoints are independently associated with long term outcomes in CRT patients.
Purpose: To evaluate the individual associations of endpoints with long term outcome in CRT patients.
Methods: 874 patients from a multicentre retrospective CRT database were included in this study. Intermediate endpoints were improvement in NYHA functional class and echocardiographic LVESV reduction (≥15%) at 6 months post-implantation, and HF hospitalization within the first year post-implantation. Long term outcome was the combined event of LVAD implantation, cardiac transplantation or all-cause mortality.
Results: The absence of NYHA class improvement (HR 1.36 [1.06, 1.75]) and LVESV reduction (HR 1.94 [1.53, 2.47]) are significantly associated to the occurrence of long term events. HF hospitalization (HR 5.00 [3.36, 7.44]) is also significantly associated to the occurrence of long term events. However, correcting for baseline parameters, intermediate endpoints occurring during follow-up are not independently associated to long term outcome in CRT patients.
Conclusion: Intermediate endpoints like functional improvement, echocardiographic remodelling and HF are all associated to long term outcome, and events during follow-up therefore identify those patients at increased risk of poor long term outcome. Though this association is not independent from baseline characteristics, which puts emphasis on the importance of patient selection for CRT.

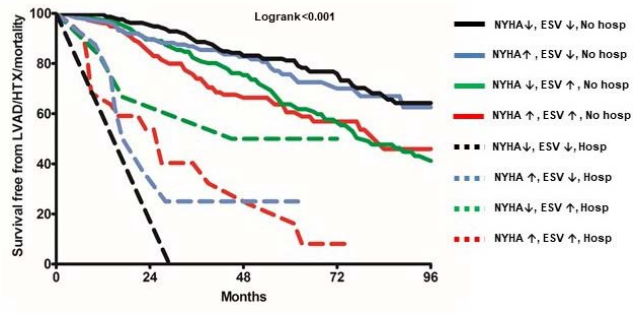

Figure 1.

P1547

Prognostic significance of cardiac sympathetic activity and dyssynchrony in response to cardiac resynchronization therapy

K Zavadovskiy[1]; A Mishkina[1]; M Gulya[1]; V Saushkin[1]; D Lebedev[2]; YU Lishmanov[1]
[1]Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Nuclear Medicine, Tomsk, Russian Federation; *[2]Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Science, Department of Surgical Arrhythmology and Cardiac Pacing, Tomsk, Russian Federation*

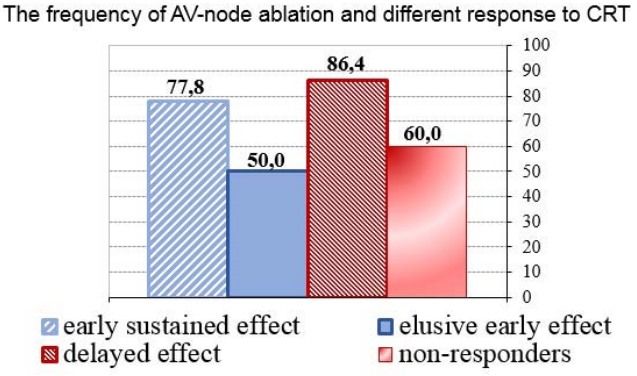
Purpose: The purpose of the study was to identify the scintigraphic predictors of the cardiac resynchronization therapy efficacy (CRT).
Methods: This study included 28 chronic heart failure patients (mean age of 56.5±10.2 years; 17 male; NYHA class III, mean QRS = 161.2±17.56 ms). Before CRT all patients underwent 123I-metaiodobenzylguanidine (123I-MIBG) scintigraphy as well as rest myocardial perfusion imaging (MPI) with 99mTc-MIBI for cardiac sympathetic activity and myocardial perfusion evaluation, respectively. Early and delayed heart to mediastinum ratio (eH/M and dH/M) as well as 123I-MIBG washout rate (WR) were calculated. According to the MPI we analyzed Summed Rest Score (SRS). Before CRT and six months after all patients underwent gated blood-pool SPECT (GBPS) for left and right ventricular end-systolic (ESV) and end-diastolic (EDV) volumes, ejection fraction (EF) and dyssynchrony (intra- and interventricular)evaluation. All scintigraphic images were acquired on the hybrid SPECT/CT unit with CZT detectors.
Results. Six months after CRT all patients were divided into two groups: (1) responders (n=15) – LV ESV decreased by ≥15% or LV EF increased by ≥5%; (2) non-responders (n=13) - LV ESV decreased by <15% and LV EF increased by <5%. Prior to CRT, significant differences in the following preoperative scintigraphic parameters between responders and non-responders were found: eH/M (2.42 and 1.87; $p<0.05$), dH/M (1.89 and 1.78; $p<0.05$), LV EDV (271 and 299; $p<0.05$); LV ESV (206 and 227; $p<0.05$) and interventricular dyssynchrony (109 and 62; $p<0.05$). Correlation analysis demonstrated the presence of significant association between baseline dH/M value and the LV volumes and EF 6 months after CRT: LV EDV ($r=-0.78$, $p < 0.5$), LV ESV ($r=-0.833$, $p < 0.5$) and LV EF ($r = 0.904$, $p < 0.5$) in (1) group. Moreover, only in responder group dH/M was significant association with baseline RV EF (-0.702, $p<0.05$). Univariate Cox proportional hazard analysis showed that dH/M and Interventricular dyssynchrony were strongly related to CRT response. In multivariate analysis, cardiac dH/M (hazard ratio=4.25; 95% confidence interval 1.4-12.92) and IVD (hazard ratio=1.01; 95% confidence interval 1.003-1.03) were the only independent predictors of response to CRT.
Conclusion: In multivariate analysis, both dH/M and IVD were independent predictors of CRT response. The results of 123I-MIBG scintigraphy with gated blood-pool SPECT may be used for prediction of the efficacy of CRT.

P1548

Connection of clinical indicators and various response to cardiac resynchronization therapy in patients with chronic heart failure and atrial fibrillation

T Tatyana Troyanova-Shchutskaia[1]; A Kurlianskaya[1]; T Denisevich[1]; D Goncharik[1]; A Chasnoyt[1]; O Shatova[1]
[1]Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

Background. Previously any form of atrial fibrillation (AF) was considered a contraindication to cardiac resynchronization therapy (CRT). The search for ideal responders remains relevant and is widely discussed.
Purpose: To assess the echocardiographic response to CRT depending on the etiology, severity of chronic heart failure (CHF) and comorbidities in persons with persistent AF.
Methods. The study included 101 patients with CHF NYHA II – III, left ventricular ejection fraction <35% and QRS≥130 ms. All patients underwent CRT. Then atrioventricular node ablation (AVNA) was performed to 83 patients, but 18 patients refused it. The criterion for the effectiveness of CRT was a decrease in the end-systolic volume ≥15%. The survey was conducted initially, after 3 and 12 months from the date of inclusion in the study.



Picture 1

Results. The study did not reveal statistically significant differences between patients with ischemic and non-ischemic etiology of CHF in terms of the duration and sustainability of a positive response to CRT. Patients with early and delayed response (3 and 12 months) were characterized by significantly higher median values of the 6-minute walk test. By the 12th month after CRT the proportion of respondents increased both in NYHA II and III patients, but a comparative analysis of the frequency of different responses to CRT revealed that in NYHA II there were significantly more patients with early response and preservation of effect by 12 month (61.0% compared with 30.0% in NYHA III, $p = 0.003$). Among those with NYHA III there were more non-responders (27.0% compared to 5% with NYHA II, $p = 0.008$). Type 2 diabetes mellitus with the same frequency was diagnosed both in responders and non-responders by the 12th month (23.8% and 20.0%, respectively, $p = 0.709$),

but more often it was detected in patients with an 'elusive' early CRT effect. Among delayed responders the proportion of individuals with AVNA was significantly higher than of non-responders (81.6% and 57.1%, p = 0.031), which confirms the need for ablation of the AV node. Picture 1 demonstrates the frequency of performed ablation among patients with CHF and different response to CRT.
Conclusions. The early sustained response to CRT was more commonly detected in NYHA II patients. There were more non-responders among those with NYHA III. Patients with an early and sustained response to CRT were characterized by higher median values of the 6-minute walk test. Diabetes mellitus was more often detected in individuals with the "escape" of the early CRT effect. A smaller proportion of AVNA was found in the subgroup with an elusive effect, which allows us to conclude that ablation of the AV node increases the effectiveness of CRT in patients with AF.

P1549
Normal cardiac autonomic control in good CRT responders is not reliable predictor of future major ventricular arrhythmias in patients with severe heart failure.

E Simeonidou[1]; C Pantsios[1]; G Giannakakis[1]; J Parissis[1]; G Filippatos[1]; E Iliodromitis[1]
[1]2nd University Cardiology Dept, Attikon Hospital, Athens, Greece

Purpose: Although cardiac resynchronization therapy (CRT) is expected to reduce the risk of arrhythmias in heart failure patients (pts) in long-term by the induction of reverse remodeling, its real impact in severe ventricular arrhythmias is not clear. Aim of the study was to analyze the ventricular arrhythmias ensuing in pts receiving CRTD and to combine it with a random assessment of cardiac autonomic control.
Methods: The study population consisted of 70 severe heart failure pts with CRTD, (13 ♀ and 57♂), mean age 61±15 years, with underlying disease ischemic cardiomyopathy in 36 and dilated cardiomyopathy in 34. Forty-six pts received CRTD as primary prevention (group A) and 20 pts as secondary prevention (group B). We analyzed the occurrence of ventricular tachycardia including appropriate VT therapies.Fifty-one pts underwent 24h Holter monitoring HRT analysis with calculation of 2 parameters, TO and TS. Abnormal values: TO>0, TS<2.5msec/RR. Pts were defined as HRT (+) when TO or/and TS were abnormal and as HRT (-) when both TO and TS were normal or when HRT could not be calculated because of none or too few suitablePVCs.
Results: Fifty-two pts were found as clinical responders, 8 super responders and 11 pts poor responders. Seven pts died of pump failure. After 10 years follow-up including at least one device replacement, we found almost similar incidence of sustained ventricular tachycardia (VT) (15%) in both groups, irrelevant to clinical improvement and underlying substrate. Pts who received CRTD as secondary prevention, although good responders, continued to experience VT and appropriate therapies. HRT was found abnormal in 51% of all pts, responders or not.
Conclusion: Due to electrical and mechanical heterogeneity among severe heart failure pts the antiarrhythmic effect of CRTD is unpredictable. The ventricular arrhythmia risk in CRT pts is independent to CRT-induced improvement of the failing heart and the cardiac autonomic status.

Chronic Heart Failure-Pathophysiology and Mechanisms

Endomyocardial injections of autologous mesenchymal stem cell for treatment the patients with non-ischemic cardiomyopathy

A Kurlianskaya[1]; O Polonetsky[1]; T Denisevich[1]; O Shatova[1]; T Osmolovskaya[1]; Y Isaikina[1]; D Dmitry Salauyou[1]
[1]Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

Background and purpose: The aim of our study was to determine the optimal areas of viable myocardium for the autologous mesenchymal stem cell (MSC) endomyocardial injections in treatment of Non-ischemic Cardiomyopathy (NICMP) patients with end-staged chronical heart failure (CHF).
Methods. The study included 30 patients (mean age 45.8 ± 3.4 years; 5 females, 15 males) with NICMP and end-staged CHF. All patients underwent echocardiography (EchoCG), heart magnetic resonance imaging (MRI), electromechanical myocardial mapping (EMM), endomyocardial injections of 0.2 ml autologous MSC culture (CD105+, CD90+, CD73+ cells) into akinetic and hypokinetic myocardial segments using endovascular method.
Results: After 12 months from MSC transplantation, an improvement of local contractility (LC) was found in 21.49% segments, 78% of which were akinetic (p = 0.018). We separated akinetic segments into two groups: A – segments with improvement of LC, B – segments with a lack of positive dynamics or worsening of LC. Significant differences were observed between groups A and B before MSC transplantation in median values of left ventricle (LV) myocardial systolic thickness (6 [5; 7] mm in group A vs. 4 [3; 6] mm in group B, p = 0.013), LV myocardial diastolic thickness (5 [3; 67] mm in group A vs. 3 [3; 5] mm in group B, p = 0.038) as confirmed by heart MRI; LV longitudinal strain (-8 [-10; -5]% in group A vs. - 5 [-9; -3]% in group B, p = 0.028) as confirmed by EchoCG; linear local contractility (5.8 [3.1; 7.5]% in group A vs. 3.9 [2.2; 5.0]% in group B, p = 0.049), unipolar voltage (9.0 [8.2; 10.8] mV in group A vs. 7.4 [6.8; 9.6] mV in group B, p = 0, 050) as confirmed by EMM. Characteristics of ROC-curves, optimal cut-off values for the mentioned parameters are presented in the table below.
Conclusions: Our study shows that the optimal areas of LV myocardium for MSC endomyocardial injections for NICMP patients with CHF are akinetic segments with longitudinal strain values ≤-7%, myocardial systolic thickness ≥6 mm, myocardial diastolic thickness ≥4 mm, linear local contractility of myocardium ≥5% and unipolar voltage ≥8.7 mV.

Parameter	Characteristics ofROC-curve	Cut-off value		
Area under curve	Standard error	95% Confidence interval		
LV longitudinal strain, %	0.61	0.13	0.50-0.71	≤-7
LV systolic myocardial thickness,mm	0.70	0.11	0.55-0.89	≥6
LV diastolic myocardial thickness,mm	0.77	0.10	0.58-1.0	≥4
Unipolar voltage, mV	0.63	0.15	0.52-0.94	≥8,7
Linear LC of myocardium, %	0.62	0.14	0.54-0.90	≥5

P1551
Altered number of apoptotic-modified endothelial cells originated micro vesicles predict phenotypes of heart failure

AE Alexander E Berezin[1]; AA Kremzer[1]; I Mozos[2]; AA Berezin[3]; D Petrovic[4]
[1]State Medical University, Zaporozhye, Ukraine; *[2]University of Medicine Victor Babes, Timisoara, Romania*; *[3]Medical Academy of Postgraduating Education, Internal Medicine, Zaporozhye, Ukraine*; *[4]University of Ljubljana, Institute of Histology and Embryology, Ljubljana, Slovenia*

Background: Heart failure (HF) remains a global health problem with increased risk of premature death and extremely high economic and social burden. Numerous factors corresponding to HF severity, such as some hormones (angiotensin-II, aldosterone, endothelial-1), pro-inflammatory cytokines, chemokines, components of oxidative stress may be triggers of an apoptosis of endothelial cells and thereby negatively influence on vascular function. Apoptotic-modified endothelial cells release micro vesicles (MVs) that are not just cargo of several active molecules, peptides, growth factors, and microRNAs participating in cell-to-cell cooperation, but they are able to directly injury endothelium and sub-intima layer inducing microvascular inflammation and extracellular matrix accumulation
The aim of the study was to evaluate the associations between signature of MVs and biomarkers of fibrosis, inflammation and cardiac remodeling in patients with different phenotypes of chronic HF.
Methods: The study cohort consisted of 388 prospectively involved subjects with established chronic HF. Phenotype of HF was determined according to left ventricular ejection fraction (LVEF) value per contemporary clinical guideline. HFrEF (LVEF ≤40%), HFmrEF (41-49%) and HFpEF (LVEF ≥50%) were determined. All biomarkers were measured at baseline.
Results: The number of circulating CD31+/annexin V+ MVs in HFpEF patients was significantly different from both HFrEF and HFmrEF individuals, but it was similar in HFrEF and HFmrEF patients. The number of circulating CD144+/annexin V+ MVs in HFrEF patients was significant higher to HFmrEF and HFpEF. We determined that a combination of number of circulating CD31+/annexin V+ MVs and galectin-3 (AUC=0.68; 95% CI = 0.61 - 0.77; P=0.001) was the best predictor of HFpEF. The predictive values of sST2 (AUC=0.65; 95% CI = 0.60 - 0.69), number of circulating CD31+/annexin V+ MVs (AUC=0.63; 95% CI = 0.58 - 0.69) alone and their combination (AUC=0.65; 95% CI = 0.59 - 0.70) for HFmrEF did not distinguished significantly (P=0.48). The double combinations of number of circulating CD144+/annexin V+ MVs and sST2 (AUC=0.70; 95% CI = 0.66 - 0.75) or number of circulating CD144+/annexin V+ MVs and galectin-3 (AUC=0.71; 95% CI = 0.65 - 0.76) were the best prognosticators for HFrEF.
Conclusion: we found that number of circulating CD31+/annexin V+ MVs may improve a prediction of galectin-3 for HFpEF, and that number of circulating

CD144+/annexin V+ MVs is able to increase predictive capabilities of sST2 and galectin-3 for HFrEF

P1552

The plastics of atrioventricular valve in patients with chronic heart failure and severe left ventricular dysfunction

O Olesya Shatova[1]; N Feaktsistava[1]; A Kurlianskaya[1]; T Denisevich[1]; T Troyanova-Shchutskaia[1]; T Dubovic[1]
[1]*Republican Scientific and Practical Centre of Cardiology, heart failure, Minsk, Belarus*

The patients with severe mitral regurgitation (MR) with severe left ventricular systolic dysfunction (LVHD) are potential applicants for orthotopic heart transplantation (OHT). However, the issue of atrioventricular valve repair in patients with severe LV dysfunction is currently debatable, in that the operative risk may exceed the expected benefit.
The purpose to estimate the efficiency of atrioventricular valve repair in patients with CHF and LVHD.
Methods we included patients with ischemic and non-ischemic cardiomyopathy (class III-IV of NYHA) underwent atrioventricular valve repair from 2012 to 2017 (n = 149). The men were 140 (94%), women - 9 (6%). The mitral insufficiency was corrected according to Carpentier. The tricuspid valve (TV) was operated according to DeVega. The isolated MR repair were performed in 33 (22%) patients, MV + TV repair in 116 (78%) patients. The end points were considered death, OHT. The intermediate points were recurrent regurgitation (RR) after surgical correction of MR. We performed echocardiography, MRI, 6-minute walk test before and 6 months after operation, NTproBNP, CRP. We were assessed the Minnesota Quality of Life Questionnaire (MQLQ).
Results and discussion RR (≥2 degrees) in early postoperative period was detected in 25 (17%) patients. Preoperative MR decreased from severe to moderate in 19 (13%) cases, to mild in 103 (69%). RR was absent in 21 (14%) patients. Patients with RR on the MV showed a significant increase LV volume sizes by 12 months after surgery: Dynamics indexes (DI) End diastolic volum – (Me(LQ;UQ)) befor 110 (98;117) and 12 months after surgery 88 (67; 90), respectively (=0,039); End systolic volum – 105 (93;113) and 88 (76; 105), respectively (p = 0.047). In patients with no RR, a significant decrease in LV size was recorded by 12 months after surgery: End diastolic dimension – befor 72 (67; 78) and 12 months after surgery 66 (62; 75) (=0,002). End systolic dimension : befor 62 (57; 67), after 57 (50; 60) (=0, 01). A statistically significant decrease in size LV, RV2, LVEF, Pap was observed during the observation period: Left ventricle befor 51 (47; 55) after 12 months 48 (46; 53) (=0,05); Right ventricle befor 80 (75; 86) after 77 (70; 80) (=0,038); Ejection Fraction, B mode befor 28 (25; 29) after 33(32; 35) (=0,05); Pulmonary artery pressure- befor 48 (40; 56) after 38 (30; 44) (<0,001).
There were no significant biomarker changes levels after surgery (p> 0.05). NT-proBNP levels was decreased (p = 0.087). 6-minute walk test distance increased in all patients (from 243 (188; 265) after 348 (205; 325), p <0.03) and the quality of life improved according to MQLQ (with 74 (55; 85) points to 38 (25; 48) points, p = 0.04).
Conclusions Thus, surgical valve repair of MR in patients with severe HF and severe LVHD improves cardiac hemodynamics, clinical status, quality of life and increases patient life expectancy free of heart transplantation

P1553

Population pharmacokinetics and pharmacodynamics of vericiguat in heart failure patients with reduced ejection fraction

M Meyer[1]; H Ruehs[1]; D Klein[1]; M Frei[1]; D Garmann[1]; J Grevel[2]; R Austin[2]; C Becker[3]; L Roessig[4]; B Pieske[5]

Funding Acknowledgements: Funding for this research was provided by Bayer and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA

Background: Vericiguat is a once-daily, novel oral stimulator of soluble guanylate cyclase (sGC) in development for chronic heart failure (HF).
Purpose: This analysis aimed to characterise the pharmacokinetics (PK) and PK/pharmacodynamic (PK/PD) relationship of vericiguat in HF patients with reduced ejection fraction (HFrEF).
Methods: Non-linear mixed-effects modelling was used to develop a population PK/PD model describing vericiguat PK and PK/PD relationships based on data from 454 patients with HFrEF from the Soluble Guanylate Cyclase Stimulator in Heart Failure with Reduced Ejection Fraction Study (SOCRATES-REDUCED; NCT01951625).
Results: Vericiguat PK was well-described by a one-compartment model parameterised by apparent clearance (CL/F), apparent volume of distribution (V/F) and an absorption rate constant (ka). The population mean estimates (inter-individual variability [%]) for CL/F, V/F and ka were 1.3 L/h (38.5), 38.9 L (28.2) and 1.5 1/h (103.0), respectively. Clearance and V/F were allometrically scaled by body weight. Body weight and albumin were identified as covariates for ka. Age, body weight, creatinine clearance standardised by body weight and bilirubin partially explained the variability in CL/F, and gender and body weight partially explained the variability in V/F. Acute haemodynamic response after vericiguat intake (post-dose measurement at 2 h ± 15 min) was investigated using linear regression analysis. This revealed a maximum observed concentration (Cmax)-dependent lowering of systolic blood pressure (SBP) on Day 1 (Visit 1; when dosing started at 1.25 mg), but not on Day 56 (Visit 4; when most patients had been up-titrated to 10 mg vericiguat). This finding suggests that the studied vericiguat dose range (up to 10 mg) caused no long-term decrease (Day 56) in SBP in patients with HFrEF. For heart rate, no changes from pre- to post-dose were observed at either Visit 1 or Visit 4. A PK/PD correlation analysis of change from baseline in N-terminal pro-B-type natriuretic peptide (NT-proBNP), did not show any significant relationship. In contrast, an exposure- and time-dependent turnover PK/PD model for NT-proBNP considering production rate as a surrogate for physiological release of natriuretic peptide levels in response to myocardial stress in HF and an elimination rate as a surrogate for urinary excretion, clearly demonstrated an exposure-dependent reduction of NT-proBNP by vericiguat on top of standard of care (SoC) compared to SoC alone. This vericiguat-dependent reduction of NT-proBNP was dependent on baseline NT-proBNP values and duration of treatment.
Conclusion(s): Vericiguat has predictable PK, minor haemodynamic effects with low clinical impact at initial co-administration with SoC but no long-term haemodynamic effects in patients with HFrEF. The NT-proBNP turnover model showed exposure-dependent reduction of NT-proBNP with vericiguat which was dependent on disease severity.

P1554

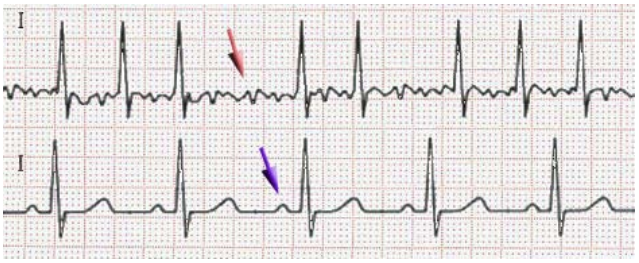
Slow and steady wins the race- the managment of tachycardia induced cardiomyopathy

C Farrell[1]; K Mcglynn[2]; S Quinn[2]; A Slevin[2]; K Ahmad[2]; J Mclaughlin[2]; L Rahmani[2]; B Jasinski[2]; S David[1]; G Aleong[1]
[1]*Letterkenny General Hospital, Heart Failure Unit, Letterkenny, Ireland*; [2]*Letterkenny General Hospital, Letterkenny, Ireland*

Aims & objectives: Heart Failure (HF) and Atrial Fibrillation (AF) coincide in many patients. They share common risk factors and can both cause and exacerbate each other. The aim of this study was to examine the management of patients presenting to a regional 440 bed hospital who had a tachycardia induced cardiomyopathy as a result of their AF.
Methods Included were patients known to the heart failure support service that had a diagnosis of tachycardia induced cardiomyopathy. In addition, a hospital information patient enquiry (HIPE) system search was undertaken for primary admission with AF and secondary diagnosis of HF and the medical chart reviewed. Patients with known ischaemic heart disease or preserved ejection fraction HF were excluded. Data was analysed using SPSS.
Results48 patients were identified, with a mean age of 67yrs (range 44-88). The majority had AF and HF diagnosed at the same hospital presentation. Hypertension was the most common comorbidity.
96% of patients had an ejection fraction (EF) of <40% at presentation. The majority of patients were appropriately anti coagulated and had good levels of HF medications (ACEi / Beta-blockers) although MRA use was low.
44% underwent direct current cardioversion with an additional 6% reverting to sinus rhythm chemically or spontaneously. While the whole group showed increased EF at one year, those who remained in SR had markedly better improvements with only 12% remaining at EF <40% compared to 46% of those who were in AF at follow up.
Conclusion Tachycardia induced cardiomyopathy is a potentially reversible cause of heart failure and when sinus rhythm is restored it resulted in substantial increases in EF. Further study is required to identify how this group of patients could be identified early for rhythm control strategy in order to improve outcomes.

Results

	Baseline	Follow up SR	Follow up AF		At follow up
EF <25	31%	0%	4%	ACEi	95%
EF 25-40	65%	0%	23%	BB	80%
EF 41-54	4%	65%	61%	MRA	20%
EF>55	0%	35%	12%	OAC	90%
LA normal	2%			SR	39%
LA mild dilated	19%			AF	61%
LA mod dilated	38%				
LA sev dilated	41%				



P1555

Higher levels of ferritin as a predictor of improvement of left ventricular ejection fraction in recent-onset idiopathic dilated cardiomyopathy

A Alberto Giraldez Valpuesta[1]; S Gamaza Chulian[2]; B Serrano Munoz[2]; F Zafra Cobos[2]; J Oneto Otero[2]
[1]Puerta del Mar University Hospital, Cardiology Service, Cadiz, Spain; *[2]General Hospital de Jerez, Jerez, Spain*

Background: Improvement in the left ventricular ejection fraction may occur in patients with dilated cardiomyopathy.
Purpose: This study was designed to determine the frequency and to identify predictors of improvement of left ventricular ejection fraction in a cohort of Spanish patients with recent-onset idiopathic cardiomyopathy receiving contemporary medication
Methods: A consecutive series of patients admitted from June 2014 to November 2018 with the clinical diagnosis of idiopathic dilated cardiomyopathy and left ventricular ejection fraction <40% by echocardiography at presentation were followed up 12 months to identify those with improvement of left ventricular ejection fraction, define as an increase in left ventricular ejection fraction >15% or to a final level of >50%.
Results: After a follow-up of 12 months, 52% of 85 patients had improved their left ventricular ejection fraction Multivariate analysis demonstrated that improvement of left ventricular ejection fraction was associated with a electrocardiographic QRS duration<120ms, lower left ventricular ejection fraction at baseline and a higher levels of ferritin and haemoglobin
Conclusion: In our study, the presence of higher levels of ferritin and haemoglobin was related with an improvement of left ventricular ejection fraction in recent-onset idiopathic dilated cardiomyopathy. This finding adds a new objective to the treatment of iron deficiency in patients with heart failure with reduced ejection fraction, apart from the improvement of functional capacity and quality of life

P1556

Importance of serum sodium in ischemic heart failure with systolic dysfunction

S Bansal[1]; M Chaudhary[1]
[1]Safdarjung Hospital, New Delhi, India

Funding Acknowledgements: TREATMENT IS FREE FOR ALL PATIENTS IN THIS GOVERNMENT OF INDIA HOSPITAL

We assessed the effects of addition of ivabradine to Optimal Medical Therapy (OMT) in patients of ischemic heart failure with systolic dysfunction on left ventricular function, exercise duration, serum Brain Natriuretic Peptide (BNP) levels. As a part of this study we studied the serum sodium levels in these patients.

Methods: In this open-label, randomized, a total number of 309 patients of stable, ischemic heart failure were included and were randomly assigned into Ivabradine (n=157) and control (n=152)Baseline assessments included assessment of Left ventricular dimension and Left ventricular ejection fraction (LVEF), Exercise duration (in seconds) by exercise test and Serum BNP level . Influence of serum Sodium levels at baseline were studied. Patients were divided into two groups, based on Serum Sodium <137 meq/l and > 137 meq/l .
Observations : The main observations are given in Table 1 .
Conclusions : Patients in low serum sodium levels at baseline had lower ejection fraction, exercise duration and higher BNP level and LV end-systolic and end-diastolic dimensions in both groups as compared to patients with higher serum Sodium values . Serum Sodium may serve as a simple clue to lower EF, higher BNP and poorer effort tolerance in stable patients of ischemic systolic heart failure.

Funding Acknowledgements: funded by Zoll Medical

Background: Outpatient management of heart failure (HF) is essential to reduce costs of care and improve patient quality of life. Many patient based factors have been analyzed in an attempt to identify 'at risk patients' and predict future episodes of decompensation.
Purpose: To assess the value of cardiac acoustic biomarkers (CABs - combination of heart sounds synchronized with ECG) in HF decompensation prediction.
Methods: A total of 304 patients with EF<35% and hospitalization for decompensated HF were enrolled in a prospective observational protocol. All wore a wearable cardioverter defibrillator, equipped with an accelerometer capable of recording heart sounds and ECG, as outpatients. Univariate followed by multivariate analyses were

used to determine the model that best predicted the occurrence of early HF readmission or emergency room (ER) visit for HF, which were collected for all patients.
Results: Patients were divided into 2 groups (HF patients/ non-HF patients) based on occurrence of HF events (HF hospitalization or ER visit). 69 HF events occurred in 49 (16%) HF group patients. The HF group had a lower BMI (26 +/- 5 vs 29 +/- 6, p<0.05) than the non-HF group, all other demographics were similar. A multi-parameter model using heart rate (HR), electromechanical activation time (EMAT, from onset of QRS to S1), and S3 strength (based on S3 timing, intensity, persistence, and frequency) produced the best predictive model (Table) for a decompensated HF event. All-cause readmissions prior to start of WCD wear (HF 62% vs nonHF 63%) and NYHA class (I+II, HF 68% vs nonHF 69%) were similar between the 2 groups. The ability of NYHA class to predict HF events was lower than the CAB predictor (sensitivity=30%, PPV=18%).
Conclusions: Cardiac acoustic biomarkers were superior to NYHA classification in predicting post discharge HF events. Our data suggest that use of CABs may be useful in early detection of decompensated HF after an episode of acute decompensated HF in at-risk patients.

	HF Event N = 40	No HF Event N = 224	
Prediction of increased risk for HF event	27	68	Positive Predictive Value (PPV) = 28%
Prediction of not at increased risk for HF event	13	156	Negative Predictive Value (NPV) = 92%

Funding Acknowledgements: National clinical program of Russian Federation Healthcare

Introduction: Perspective device treatment Cardiac Contractility Modulation (CCM) is proposed to become an addition to optimal medical therapy (OMT) in HFrEF and narrow QRS complex. Purpose: To analyze the influence of CCM stimulation on LV ventricular remordeling and HFFC in 2 years of follow-up (FU). Methods: During 2015-2017 ys 57 CCM devices (Optimizer IVs, Optimizer Smart) were implanted to the patients with HFrEF I-III FC after obtained informed consent. 47 patients were male,10 female, 55,0 ±10,6y.o,37- CAD, 20- DCM, sinus rhythm, QRS<120 ms. Patients were educated, FU visits provided in HF clinic include: device programming, QoL, 6-MWT, cardiopulmonary exercise test, ECG, Holter Monitoring, Echocardiography and NT-proBNP level. Results: In 2 years of FU 47 patients participated in the program, 8 were excluded (1- device deimplantation, 1- heart transplantation, 8- died due to sudden cardiac death or HF decompensation). Patients had good compliance and tolerated CCM stimulation well. 85% were clinically stable, 15% - had hospitalization with HF decompensation annually. 75% of patients had ICD. ECG did not show PQ, QRS, QT prolongation, significant rhythm or conduction disorders. In 21 patients (44%) stimulation of the CCM pocket was due to ventricular lead insulation failure, 1 lead was switched off in 14 patients (29%). 2 years FU visits were in 43 patients, positive trend in HF FC, LV reverse remodeling, VO2peak, physical capacity, NT-proBNP level were observed. During 2 years of FU in 50% of patients HF FC was unchanged, in 23%- increased on 1grade, in 27%- decreased on 1 grade. Baseline HF FC I/II/III - 2%/81%/16% vs 1 year - 25%/64%/14%- vs 2 years - 21%/69%/9%. Positive dynamics in LV indices, volumes, LV EF was observed compared to baseline: LV EDD 68.0±6.6 mm vs 64.0±8.6mm, p= 0,02, LV ESD 59.0±8.0 mm vs 55.0±9.0 mm,p=0,01, LVEDV 241.0±57.8 ml vs 209.0±62.2 ml, p=0,03, LVESV 164.0±56.2 ml vs 150.5±56.1 ml, p=0,02. In 76% of patients LV EF increased, in 18%-unchanged, in 6%- decreased: LVEF 26.0±6.3% vs 30.0±7.6% in 1 year p=0,003 and vs 32.0±6.2% in 2 years, p=0,01. NT-proBNP level – 1010 pg/ml vs 575 pg/ml, p=ns. CPET results in 30 patients (61% of patients) showed: VO2 peak 16.9±5.2 ml/kg/min vs 20.9±6.6 in 1 year, p=0,001 and vs 17.8±5.3 ml/kg/min in 2 years,p=0,02., VO2peak after 2 years improved in 54% of patients, worsened in 41%, unchanged in 5% in comparison with baseline. Conclusions: During 2 years of FU majority of patients with sinus rhythm and CCM devices showed positive trend in reverse cardiac remodeling, with most evident response in the second year. Tendency to improve functional capacity, decrease in CHF FC were obvious. Delayed response to CCM stimulation is possible and need to be studied further. Negative aspect of CCM devices was presented in pocket device stimulation due to ventricular lead insulation failure, situation that need to be resolved in technological process.

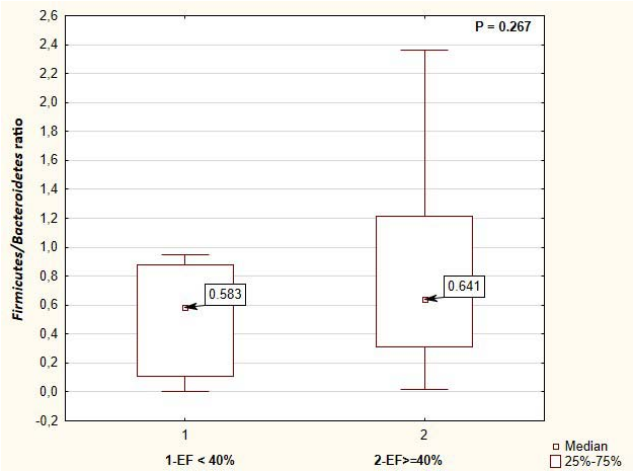
Background: Coronary artery disease (CAD) is one of the most common causes of hospitalization and death in Europe. It might leads to heart failure with reduced ejection fraction (HF-REF), which results in disability and decreases quality of life. As a consequence, new factors, like gut microbiome, that may lead to CAD, and then HF-REF are widely investigated.
Purpose: To evaluate gut microbiota composition in CAD population. To compare the composition of the intestinal microbiome of CAD patients with HF-REF and those who have ejection fraction (EF) at least of 40%.
Methods: The study included stool microbiome of 89 CAD patients, aged 64.3±7.4 years (72 males) who were hospitalized 12-18 months prior recruitment due to an acute coronary syndrome (n=57) or percutaneous coronary intervention (n=32). All patients underwent detailed assessment of health status, including echocardiography with biplane ejection fraction (EF) assessment. Based on EF, HF-REF subgroup was distinguished (n=12).
Stool samples were collected in Stool Tubes with DNA stabilizer. DNA was isolated with the use of the PSP-Spin Stool-DNA kit. Further analyses were based on the V3-V4 region of the 16S rRNA gene (Next Generation Sequencing method).
Results: We identified 8 clusters of bacteria (Table). The analysis revealed that the gut microbiome consists mostly of Bacteroidetes, Firmicutes and Actinobacteria, with the largest abundance of reads for Bacteroidetes (Table). HF-REF group was characterized with almost half of the operational taxonomic units reads in

Table

Cluster	Patients with HF-REF (n=12)	Patients without HF-REF (n=77)	All coronary artery disease patients (n=89)	P value
Bacteroidetes	11349.5 IQR: 4698 - 18406.5	9161 IQR: 5891 - 15058	9161 IQR: 5881 - 16069	0.815
Firmicutes	3210 IQR: 2327 - 5499.5	6040 IQR: 3484 - 9826	5815 IQR: 3334 - 9470	0.018
Actinobacteria	67.5 IQR: 25.5 - 447.5	223 IQR: 46 - 770	205 IQR: 46 - 679	0.264
Lentisphaera	0 IQR: 0 - 8	4 IQR: 0 - 16	2 IQR: 0 - 14	0.182
Proteobacteria	6IQR: 2 - 14.5	3 IQR: 1 - 8	3 IQR: 1 - 9	0.218
Cyanobacteria	0 IQR: 0 - 0	0 IQR: 0 - 0	0 IQR: 0 - 0	0.778
Verrucomicrobia	0 IQR: 0 - 0	0 IQR: 0 - 3	0 IQR: 0 - 2	0.192
Tenericutes	0 IQR: 0 - 0	0 IQR: 0 - 0	0 IQR: 0 - 0	0.475
Other	0 IQR: 0 - 48.5	1 IQR: 0 - 62	0 IQR: 0 - 62	0.505

Table. The distribution of operational taxonomic unit reads in study groups.

Firmicutes than group without HF-REF (Table). There was no difference in Firmicutes/Bacteroidetes ratio between study groups (Figure).
Conclusions: HF-REF among CAD patients was associated with altered microbiome composition. The analyses in larger subpopulations and in control group is required.



Firmicutes/Bacteroidetes ratio

P1560
Renal sympathetic denervation as a "mini-invasive bridge" to heart transplantation in patients with congestive heart failure and metabolic disorders

I Hrabianiuk[1]; A Kurlianskaya[1]; L Rachok[1]; O Shatova[1]; T Denisevich[1]; T Dubovik[1]
[1]Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus

On behalf of: Laboratory of Chronic Heart Failure

Background/Introduction: The gold standard treatment for patients with end-stage chronic heart failure (HF) is heart transplantation. The possibilities of heart transplantation (HT) and 'surgical bridge' (coronary revascularization, valvular correction) application are limited in this group of patients by carbohydrate and lipid metabolism disorders. The search of minimally invasive treatment methods in this group of patients is particularly relevant.
Purpose: effectiveness evaluation of renal sympathetic denervation in patients with congestive heart failure and metabolic disorders
Methods: Twenty patients underwent renal sympathetic catheter-based denervation (RSD), performed by unique operator. Data were performed before the denervation, and at 12 months of follow-up. All the patients were man in New York Health Association (NYHA) class III heart failure, left ventricular (LV) ejection fraction (EF) > 40% by Simpson, without indications for cardiac resynchronization therapy (CRT), with body mass index (BMS) > 30, blood level of HbA1 > 6.5%.
Results: According to echocardiography examinations in 12 months after RSD a significant increase of LV EF (p = 0.03) and significant decrease of pulmonary artery pressure (= 0,05) have been observed. Although there was an evident improvement in 6-minute walk test (p = 0.004). Contractility myocardial index (p = 0,06) and blood level of HbA1 (p = 0,55) showed a tendency to decrease in 1 year after RSD. We didn't find a significant increase of systolic or diastolic blood pressure levels associated with renal denervation (p = 0,36) and there were no local complications after RSD. In 12 months after RDS 1 patients undergo HT, 2 patients were removed from waiting list of HT due to improved condition.
Conclusions: RSD seems to be an effective and safe mini – invasive method for patients with chronic HF and metabolic disorders which can improve echocardiographic characteristics, reduce functional NYHA class of HF and give necessary time to recipients for chance to receive an optimal donor organ.

INTRODUCTION- In Canada, sacubitril/valsartan (SacVal) is indicated for the treatment of heart failure (HF) with reduced ejection fraction (HFrEF) in patients with NYHA Class II or III, to reduce the incidence of cardiovascular death and HF hospitalization. SacVal has been reimbursed by the Quebec public health insurance plan (RAMQ) since March 2017. As the second largest public payer in Canada, RAMQ covers over 3.6 million patients, including ≥65 y/o, beneficiaries of the social assistance program, and people without private drug insurance.
PURPOSE- The primary objective of this study was to describe the use of SacVal in a real-world setting, including patient characteristics, concomitant medications, treatment persistence, resource utilization as well as healthcare costs prior to SacVal treatment initiation.
METHODS- This was a retrospective database study based on RAMQ claims for drugs and medical services. The cohort consisted of patients whose first claim (index date) for SacVal was between June 2017 and April 2018. Patients had to be ≥18 y/o and covered by RAMQ for at least one year preceding the index date. Medical services and prescription drug claims were categorized into all-cause and HF related. All costs are reported in Canadian dollars and the mean monthly cost includes drug costs, physician fees, hospitalizations, as well as intensive care unit, emergency department and outpatient visits.
RESULTS- 1,483 patients were identified. The mean age was 70.0 years (SD=10.8) with 77% of patients ≥65 y/o. In the year prior to the index date, medication use included the following: 93% angiotensin-converting enzyme inhibitor or an angiotensin II receptor blocker, 98% beta-blocker (BB) and 67% mineralocorticoid receptor agonist (MRA). In the same period, 55% experienced at least one hospitalization due to any cause with an average length of stay (LoS) of 11.7 days (SD=15.1), and 21% had at least one HF hospitalization for whom the average LoS increased to 13.3 days (SD=16.1). The mean number of outpatient visits was 13.5 (SD=8.5), with an average of 3.1 (SD=2.2) for HF-specific outpatient visits. The mean monthly healthcare cost was estimated to be $3,688 (SD=$9,189), whereas that related to HF was $1,204 (SD=$5,478). Physicians prescribing SacVal were primarily cardiologists (71%), followed by general practitioners (15%). Following the index date, the majority of patients (91%) used a BB in concomitance with SacVal, and over half (57%) used a MRA. The mean duration of follow-up was 6.6 months (SD=2.9), and persistence with SacVal was 97% (95%CI=96;98) and 95% (95%CI=94;96) after 3 and 6 months, respectively.
CONCLUSION- This analysis describes real-world patient characteristics and prior healthcare resource utilization of HFrEF patients initiating SacVal in Quebec. Longer follow-up would be valuable to compare resource use and costs following initiation of SacVal to evaluate the impact of the drug on patients and the healthcare system.

P1562
Latino american experience with Sacubitril/Valsartan in a heart failure unit : Real insight

AL Rodriguez Pulido[1]; LG Gomez Escobar[2]; MP Morales Parra[1]; N Quijano Martinez[2]; AF Buitrago Sandoval[1]; G Gonzalez Robledo[1]
[1]Fundacion Santa Fe de Bogota , Cardiology Department, Bogota, Colombia; *[2]University of Los Andes, Bogota, Colombia*

Background: Sacubitril/Valsartan was included in the 2016 ESC guidelines as class IB recommendation for symptomatic heart failure patients with reduced ejection fraction. However, there is few information in the real world regarding its use in Latin America.
Purpose: To describe clinical characteristics and outcomes of patients that were prescribed with Sacubitril/Valsartan in a heart failure unit in Bogota, Colombia.
Methods: A cohort study of 59 patients with sacubitril/valsartan indication was conducted from January 2017 to December 2018. Baseline characteristics ,and changes in clinical outcomes were assessed at 3 months and 1-year.
Results: Overall 1-year mortality was 1.77%(n=3), one due to cardiovascular cause. At 3-months and 1 year, 2.9% and 8.7% of patients were hospitalized respectively. Patients improved ejection fraction in 6.8% (p<0.000), and functional status from NYHA III to NYHA II in 47% (p=0.005). Systolic blood pressure changes were statistically significant(p=0.026). Adverse side-effects were hyperkalemia (1.61%), renal failure (1.61%), and symptomatic hypotension (18%). Nonetheless, there was no withdrawal of treatment.
Conclusions: In our experience with real-life patients, sacubitril/valsartan is a safe and effective therapy. Patients have significant improvements in functional status

and ejection fraction, which suggest our results are similar to the PARADIGM-HF Latino American population.

High-risk percutaneous coronary intervention with mechanical support - Protected PCI. Initial experience

J Belohlavek[1]; T Kovarnik[1]; D Zemanek[1]; A Kral[1]; A Linhart[1]
[1]*Charles University Prague, 1st Faculty of Medicine, Prague, Czechia*

Introduction: Availability of mechanical support in cardiology enables its use both in acute and elective settings. Mainly, the high risk interventions including coronary, electrophysiological and surgical are being consider for mechanical assistance. Severe coronary artery disease is a frequent cause of advanced heart failure and revascularization playes an important role in the overall clinical management. In cases considered to bear unacceptable risk for surgery, percutaneous coronary intervention (PCI) with mechanical support (protected PCI) is being performed. The aim of the present work is to share our initial experience with protected PCI in pacients with advanced left ventricle (LV) dysfunction.
Methods: Percutaneous unloading device Impella CP (Abiomed, USA) has been used for protected PCI. We used preferentially femoral approach for pump cannulation and radial approach for PCI. Femoral puncture was performed using ultrasound guidance. We have evaluated periprocedural paramaters, hospitalization courses, survival and complications.
Results: During the study period from October 31, 2017 till December 2018, protected PCI has been performed in 15 patients, average age 70,2±10,4 years, 10 males. Average LV ejection fraction was 26% ±13%, Syntax score 31±10, 8 patients had over 35, 3 over 40.Twelve from 15 patients survived with average follow-up of 170 days, 30-day survival was 13 of 15 patients. Thus, hospitalization mortality was 13%.Following complications occured: 1 LV perforation (patient survived and was discharged), 1 unplanned groin surgical revision, 1 coronary artery rupture (patient survived) and 1 PCI was unsuccesful.
Conclusion: Protected PCI is an effective and safe method for high risk profile heart failure patients with severe coronary artery disease unsuitable for surgical revascularization.

P1564

Heart failure hospitalization in patients with reduced ejection fraction in a heart failure clinic

D Daniel Seabra[1]; I Oliveira[1]; A Neto[1]; A Andrade[1]; J Azevedo[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Cardiology Department, Penafiel, Portugal*

Introduction: Heart failure (HF) is a major clinical and public health concern. The high prevalence and clinical course of HF results in increased burden of hospitalizations and healthcare expenses. HF hospitalizations (HFhosp) remain a strong predictor of mortality and efforts should be made to recognize predictors that might help reduce HFhosp.
Purpose: Identify clinical and prognostic features in a cohort of pts with HF with reduced ejection fraction (HFrEF) in a HF Clinic (HFC) who had HFhosp in the previous year.
Methods: Unicentric and retrospective analysis of pts followed in a HFCsince 3/2011. Included pts with reduced ejection fraction (EF) (<50%) and previous diagnosis for at least 6 months; divided in two groups: pts with HFhosp (G1) and no HFhosp (G2) in the previous year.Clinical, demographic, analytical and echocardiographic characteristics and mortality (from cardiovascular (CV) cause (CVm) and non-CV cause (nCVm)) were appraised.
Results: Included 374 pts with a mean age of 60.6 ± 13.2 years. G1 consisting of 68 pts (18%) with male predominance (85 vs 73%, p=0.032); no differences were found between groups regarding age. Ischemic etiology was more prevalent in G1 (56 vs 37%, p=0.004) but there were no significant differences in CV risk factors prevalence, except for diabetes (50 vs 29%, p<0.001) and dyslipidaemia (78 vs 55%, p<0.001). G1 correlated positively with the presence of atrial fibrillation (AF) (50 vs 31%, p=0.003) and chronic kidney disease (CKD) (52 vs 26%, p<0.001). HFhosp group were associated to higher value of serum uric acid (p=0.005) and BNP (p<0.001). Left ventricle EF (LVEF) at admission (p=0.041) and during follow-up (FU) (p<0.001) were lower in G1, as well as right ventricle dysfunction (RVD) (p=0.005). On the other hand, G2 had more LVEF recovery (p<0.001). During the FU, G1 had higher mortality (53 vs 16%, p<0.001), mostly related to mCV (p<0.001). After multivariate analysis adjustment, ischemic etiology, CKD, AF and diabetes remained significantly associated with HFhosp.
Conclusion: In our cohort, HFhosp group showed a marked relationship with HFrEF severity surrogates, namely initial and FU LVEF and RVD. HFhosp had higher mortality rate, particularly related to mCV.

P1565

Correlation of nutritional status with chosen biochemical parameters in patients hospitalized due to heart failure with reduced ejection fraction.

H Krysztofiak[1]; J Migaj[1]; M Magdalena Dudek[1]; E Straburzynska-Migaj[1]; M Kaluzna-Oleksy[1]
[1]*Poznan University of Medical Sciences, 1st Cardiology Department, Poznan, Poland*

Background: Heart failure (HF) is a cardiovascular disease with still increasing morbidity. The fact that most European countries have a problem with aging society also contributes to raising a number of HF patients. HF is a clinical state which damages next to the heart, also other organs. Moreover, it can cause malnutrition and afterwards even cardiac cachexia. Cachexia is a medical condition when the balance between anabolic and catabolic processes is disturbed and it leads to a worse prognosis. That's why it is so important to diagnose HF patients with malnutrition and react as soon as possible by e.g. intensifying pharmacological therapy or adding non-pharmacological treatment like diet or supplements.
Purpose: To evaluate nutritional status of HF with reduced ejection fraction (HFrEF) patients and analyze the relationship between nutritional status and chosen biochemical parameters in this group of patients.
Methods: This study included 100 consecutive patients hospitalized due to HFrEF in Ist Cardiology Department, Poznan University of Medical Sciences. We assessed the clinical condition – NYHA class, decompensation of HF and chosen biochemical parameters eg.: blood cell morphology, natriuretic peptides, lipid panel, creatinine, fasting glucose, serum albumin, AST/ALT. We evaluated patient's nutritional status at the admission with use polish version of MNA form (Mini Nutritional Assessment), which consists of 2 parts: Screening and Assessment.
Results: Mean age of the study cohort was 55±11 years, 33% of patients were women. Mean left ventricular ejection fraction (LVEF) was 27±11% and mean NYHA class – 2,8±0,7. Among all patients just 40% had a normal nutritional status (group 1), 52% were at risk of malnutrition (group 2) and 7% were malnourished (group 3). Exacerbation of HF occurs significantly more frequently in group 3 than in group 1 (p=0,0016). In patients with diabetes mellitus and pre-existing stroke, malnutrition appeared more often. Higher NYHA class and lower body mass index (group 1 BMI-28,4 ± 4,1 kg/m2; group 3 BMI-23,6 ± 8,1 kg/m2) were significantly associated with malnutrition. Furthermore, there was much lower LDL-C (p=0,037) and total cholesterol (p=0,038) level in a group of malnourished patients as well as elevated

bilirubin level (p=0,028) and lower fasting glucose (p=0,039) in group 3. There were no significant changes in natriuretic peptides level observed.
Conclusions: In this study cohort the majority of patients has abnormal nutritional status. Mostly they are at risk of malnutrition, but some of them has already been malnourished Malnutrition was associated with the risk of HF exacerbation. There is correlation between decreased LDL-C and total cholesterol levels and nutritional status in patients with HF.

P1566
Insulin resistance as a predictor of mortality in patients with HFrEF in relation on follow-up duration.

N Nataliya Tkach[1]; L Voronkov[1]; L Voronkov[1]
[1]NSC Institute of Cardiology M.D. Strazhesko, Heart Failure department, Kiev, Ukraine

Background: Despite of knowledge about high predictive value of insulin resistance (IR) in chronic heart failure (CHF) the effect on the mortality of these patients in relation of patient's follow-up duration is still non-well investigated.
Aim: The purpose of the study was to identify the impact of IR on the mortality of patients with HFrEF depending on the duration of observation (12-, 24- and 36-month mortality).
Methods: 267 CHF patients with reduced LVEF < 40 % were analyzed. Survival analysis was performed using the "STATISTICA for Windows. Release 6.0" program (Non parametric and Survival Analysis sections) using the Kaplan-Meier method. The predictive value of the indicators was calculated as the odds ratio (OR) with a confidence interval of 95%.
Insulin sensitivity was assessed by the HOMA index, which was calculated using a standard formula based on fasting blood glucose and insulin levels. To assess the effect of IR on life expectancy in HFrEF, patients were separated "below vs above median HOMA index" (2.72 [2.07; 3.4]).
Results: The HOMA index above 2.77 was found in 47.1% of the examined patients. Cumulative 36-month survival was significantly lower in the patients with above median HOMA index (Fig. 1).
The NOMA index was one of the three strongest predictors of HFrEF patient's mortality irrespective of follow-up duration (Tabl.1)
Conclusions: HOMA index is the strong predictor of survival in HFrEF, irrespective of follow-up duration.

Predictors of mortality in HFrEF pts*

12 month	OR	24 month	OR	36 month	OR
HOMA>2,65	8.48	BMI<22kg/m^2	6.88	HOMA>2,65	6.67
HR>75 beats p.m.	7.9	HR>75 beats p.m.	6.23	BMI<22kg/m^2	5.99
SAP<100mmHg	5.4	HOMA>2,65	4.64	SAP<100mmHg	3.95

P1567
VO2 recovery delay is a useful predictor for impaired recovery of left ventricular function in heart failure with reduced ejection fraction

K Kyeong-Hyeon Chun[1]; BJ Kim[2]; JW Oh[1]; SM Kang[1]
[1]Yonsei University College of Medicine, Severance Cardiovascular Hospital, Seoul, Korea (Republic of); [2]Kosin University School of Medicine, Cardiology Division, Busan, Korea (Republic of)

Background: The pattern of VO2 recovery following exercise reflects cardiovascular response, related to the prognosis of heart failure (HF). We aimed to assess the VO2RD as a useful predictor for impaired recovery of left ventricular function (RLVF) in HFrEF.
Method: We investigated pts with HFrEF (EF ≤45%) who underwent cardiopulmonary exercise test (CPET). All CPET was performed VO2RD was defined as time until post-exercise VO2 falls permanently below peak VO2. We defined impaired RLVF as decreased EF or improvement in EF <10 %, RLVF as improvement in EF ≥10 % during follow-up period (median 16.5 months).
Result: Total 55 pts with HFrEF (mean 55.0 years old, 78.2% male, 20.0% ischemic) were included. We found 30 pts (54.5%) of impaired RLVF. In terms of baseline characteristics, there were no differences in age, sex, NT-proBNP level, NYHA class and baseline EF between 2 groups. There was significantly different in VO2RD between 2 groups (14.5±11.4 for RLVF group vs. 24.4±19.8 sec for impaired RLVF group, p=0.031). Multivariate regression analysis revealed VO2RD was an independent predictor for impaired RLVF (OR=1.055, p=0.021) when controlled for age, ischemic heart disease and EF. And the cut-off value of VO2RD > 30 sec was associated with impaired RLVF with sensitivity 30.0 % and specificity 96.0 % (ROC area under curve of 0.653, p=0.038).
Conclusion: Post-exercise VO2RD, reflecting impaired cardiac output augmentation may be a useful parameter to predict impaired RLVF in patients with HFrEF.

Heart failure with mid-range ejection fraction: a distinct entity or rather a transitional phase?

J Jan Stassen[1]; J Verwerft[1]; R Geukens[1]; P Dendale[1]; M Houbrechts[1]; H Goris[1]; M Scherrenberg[1]; P JR Timmermans[1]
[1]*Virga Jesse Hospital, Cardiology, Hasselt, Belgium*

Introduction Since 2016 the European Society of Cardiology has introduced a new category of heart failure (HF) with borderline reduced left ventricular ejection fraction (LVEF), called heart failure with mid-range ejection fraction (HFmrEF). However, the clinical features of HFmrEF, analysis of LVEF transition in time and predictive factors related to LVEF changes are still inadequately addressed.
Purpose This study aims to (1) assess the clinical characteristics of patients with HFmrEF, (2) examine their transition during follow up and (3) search for characteristics that predict a deterioration, improvement or stabilization of the LVEF.
Methods We retrospectively examined clinical characteristics and echocardiographic measurements in 374 patients with HFmrEF from a large referral teaching hospital heart failure database (n = 3040; 12,3%) dating from January 2006 till October 2018. We assessed the evolution of LVEF during a mean follow up of 967.98 ± 859.37 days and analyzed if there were any clinical or echocardiographic parameters that could predict their evolution to HFrEF, HFmrEF or HFpEF. To compare continuous variables between the three groups Kruskal-Wallis test was used and the Chi-Square test was used for the comparison of the categorical variables. Multinomial logistic regression was used to examine the predictors for transition of heart failure phenotype.
Results Mean age of our study population was 75.9 years, 46% were female, 62.6% had atrial fibrillation and 51. 6% had coronary artery disease of whom 89.1% underwent revascularization (42.4% CABG, 43.0% PCI, 14.5% PCI + CABG). Diabetes was present in 29.7%, hypertension in 79.4%, smoking in 41.2% and hypercholesterolemia in 70.1% of the patients.
After a mean follow-up of 967.98 ± 859.37 days, 41.7% entered the classification of HFpEF, 25.1% the classification of HFrEF and 33.2% stayed in the original category of HFmrEF. By multinomial logistic regression, left ventricle end diastolic diameter (LVEDD) > 50mm was a strong, independent predictor for deterioration of the LVEF and transition to the HFrEF classification (<0.0001, 95% CI, 0.159-0.514). Patients with coronary artery disease were more prone to stay in the HFmrEF - or entered the HFrEF classification (0.001, 95% CI 1.442-4.147).
Conclusions We found in our study population that most patients with HFmrEF made a transition to HFpEF and HFrEF, suggesting that HFmrEF represents a transitional phase between HFpEF and HFrEF, rather than a distinct mid position phenotype. Furthermore, there seems to be a strong association between LVEDD > 50mm and deterioration of the LVEF, whereas LVEF stabilizes or deteriorates in patients with coronary artery disease.
These results could advocate the early start of heart failure treatment in patients diagnosed with HFmrEF and a LVEDD > 50mm or coronary artery disease. Prospective, randomized trials are necessary to confirm these data.

P1569

Clinical and echocardiographic phenotypes of patients with postinfarction cardiosclerosis: focus on patients with heart failure with mid-range ejection fraction.

A Ailaana Kuular[1]; A Gamza[2]; V Tishkova[1]; E Lyasnikova[1]; A Vlasenko[1]; A Kozlenok[1]; M Sitnikova[1]
[1]*V.A. Almazov National Medical Research Center, Saint-Petersburg, Russian Federation*; [2]*Saint Petersburg Pavlov State Medical University, Saint Petersburg, Russian Federation*

Purpose. To investigate the clinical and echocardiographic characteristics and features of myocardial remodeling in patients with HFmrEF of ischemic etiology.
Materials and methods. 612 men aged 30-65 y.o., who had MI more than 3 months ago, were evaluated. The index group consisted of 74 patients with HFmrEF, with HF I-II NYHA and EF LV (Sim) 40-49% (gr.1). The diagnosis of HF was set according to the guidelines of ESC 2016. The reference groups included 276 patients with HF I-IV NYHA, EF LV (Sim) <40% (gr.2) and 262 patients without HF clinic with EF LV (Sim) >55% (gr.3). Exclution criteria in the study: primary and post-myocarditis DC, HCM, organic valvular diseases, dilatation of the heart chambers due to accumulation diseases, secondary hypertension, cardiac surgery/percutaneous coronary intervention /valvuloplasty within 3 months before. Standard clinical, laboratory and instrumental, including ECHO with defining signs of the LV hypertrophy and dilatation, diastolic function were performed.
Results. Patients of all groups were comparable in age. Duration of IHD was higher in gr. 1, 2 vs. gr. 3: 8 and 10 vs. 6.8 years. MI with Q wave (Q-MI) all groups developed more often. Q-MI of the anterior wall and Q-MI of the inferior wall of the LV were found in 39, 64, 30% and in 31, 29, 99% in the gr. 1, 2, 3, respectively. Myocardial revascularization (CABG/PCI) transferred 28/43; 30/36; 62/35% of respondents in gr. 1 ,2, 3, respectively. Significant differences in the groups related to the number of transferred MI. The groups were comparable in the duration of AH but different in the AH prevalence (86, 69, 83%) in the gr. 1, 2, 3 respectively. AF, COPD, CKD were more common in patients with HFpEF and HFrEF. Diabetes was detected predominantly in patients with HFrEF. ECHO data of gr. 2 and gr. 3 significantly differed from each other. In most cases, eccentric LV hypertrophy was observed among patients with HFrEF, concentric variants of LV remodeling prevailed in gr. 3. Phenotypic changes in the LV of patients with HFmrEF took an intermediate position. LV diastolic dysfunction (mainly type 1) was most often recorded in respondents with HFmrEF (65, 38, 26% in gr. 1, 2, 3, respectively).
Conclusion: The clinical and echocardiographic characteristics of patients with post-MI remodeling allow to consider HFmrEF of ischemic etiology as an intermediate phenotype that has similarities and, at the same time, differences with HFrEF. The echocardiography patterns of the studied groups require further study, including molecular genetic markers. New prospective studies are needed to improve the understanding of the pathophysiology of HFmrEF and to determine effective therapeutic strategies.

P1570

One year follow-up of clinical and mortality data of heart failure patients with mid-range ejection fraction

M Marta Szabo[1]; B Muk[1]; M Dekany[1]; D Vagany[1]; ZS Majoros[1]; T Borsanyi[1]; K Kosa[1]; E Szogi[1]; RG Kiss[1]; N Nyolczas[1]
[1]*Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary*

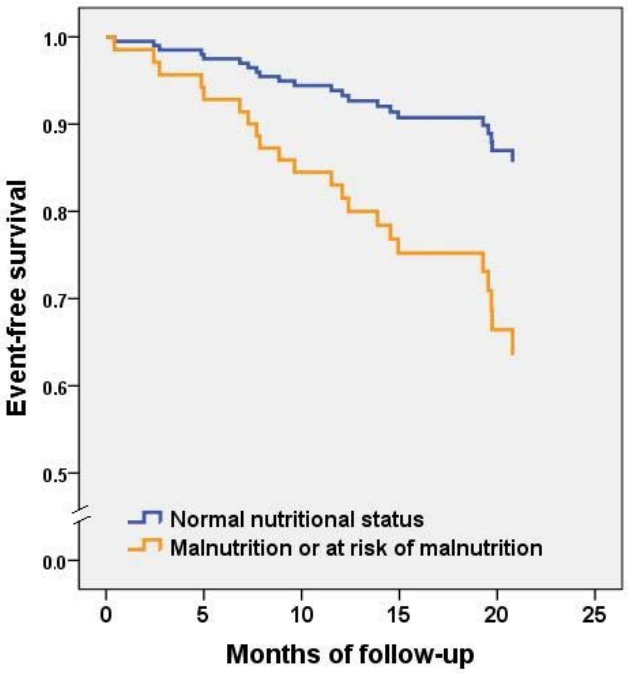
Background: The ESC guideline for the diagnosis and treatment of acute and chronic heart failure, published in 2016, introduced the terminology of heart failure with mid-range ejection fraction (HFmrEF) (40%≤LVEF<50%), besides heart failure with reduced (HFrEF) (LVEF<40%) and preserved (HFpEF) (LVEF≥50%) ejection fraction.
Aim: The aim of the study was to evaluate the one year clinical and mortality follow-up data of the patients diagnosed as HFmrEF based on the ESC criteria in our Heart Failure Outpatient Clinic. We assessed that one year after the diagnosis, how many of them stayed HFmrEF, and what proportion of them got into the HFrEF and HFpEF groups. We also analyzed the one-year mortality of this patient group and compared it to the one-year mortality of HFrEF and HFpEF patients, who were also diagnosed during the same period.
Patients and methods: In the study, we examined the data of 76 patients (age: 75.5 years, men: 73.7%, LVEF: 44.5 ±3.4%; NYHA: 2.69±0.84; NTproBNP: 3266.3±7456.3 pg/mL) managed at our Heart Failure Outpatient Clinic, between 1 December 2013 and 30 November 2018. The patients were newly diagnosed with HFmrEF and were not treated because of heart failure before.
Results: One year after the diagnosis, out of the 76 HFmrEF patients, the LVEF fell under 40% in 10 cases (13.2%), meaning they got into the HFrEF group. In 50 patients (65.8%) the LVEF stayed between 40 and 50%, making them stay in the HFmrEF group. In 16 cases (21.0%) the LVEF rose above 50%, therefore making them part of the HFpEF group.

The one year mortality was 7.7% in the HFmrEF group. During the same period, the one year mortality of the 392 newly diagnosed HFrEF patients was 11.0%, and 5.1 % for the 189 newly diagnosed HFpEF patients.
Conclusion: According to our study one year after the diagnosis, two thirds of the HFmrEF patients stayed in the group, approximately 10% became HFrEF, and about 20% became HFpEF. The one-year mortality of the HFmrEF patients lies between the mortality of the HFrEF and the HFpEF patients.

P1571
Prognosis value of the mini nutritional assessment short form tool in outpatients with heart failure with mid-range ejection fraction

E Zamora[1]; B Gonzalez[1]; V Diaz[1]; C Rivas[1]; P Velayos[1]; J Josep Lupon[1]; M De Antonio[1]; M Domingo[1]; P Moliner[1]; E Santiago-Vacas[1]; E Zamora[1]; C Joaquim[1]; N Alonso[1]; M Cachero[1]; A Bayes-Genis[1]
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*

Background: Nutritional status is an important prognostic factor in patients with heart failure (HF) beyond body mass index, although its prognostic value in patients with mid-range left ventricular ejection fraction (HFmrEF) is not completely elucidated. In a pilot study we observed that the Mini Nutritional Assessment Short Form tool (MNA-SF) was the best approach for the screening of nutritional status in HF outpatients over others screening tools.
Purpose: To assess the prognostic role of malnutrition or risk of malnutrition in HFmrEF outpatients after the implementation of the MNA-SF screening tool in a routine way in a multidisciplinary HF.
Methods: The MNA-SF screening tool was administered during the global nurse evaluation of patients. The scoring ranges from 0 to 14, being considered 0 to7 as malnutrition status, 8 to 11 as being at risk of malnutrition and 12 to 14 as normal nutritional status. For the present study those patients with malnutrition and at risk of malnutrition were merged and considered abnormal nutritional status. All-cause death was the primary end-point. Univariate and multivariate (backward conditional stepwise) Cox regression analyses were performed.
Results: Since October 2016 to November 2017, 153 HFmrEF patients were studied (mean age 68.8 ± 11.7 years, 72.5% men, body mass index 28.4 ± 4.4, LVEF 44% ± 3, NYHA class I 5.9%, II 86.3%, and III 7.8%). According to the MNA-SF 25 patients were (16.3%) fulfilled criteria of malnutrition (4) or where at risk of malnutrition (21). During a mean follow-up of 17.4 ± 6.1 months, 23 patients died (15%). In the univariate analysis, nutritional abnormal status was significantly associated with all-cause death (HR 2.93 [1.23-7], p=0.02). In the multivariate analysis which included age, sex, NYHA functional class, body mass index, ischemic aetiology of HF and years of duration of HF, abnormal nutritional status remained significantly associated with all-cause mortality (HR 3.64 [1.39-9.54], p=0.009), together with NYHA functional class (HR 7.93 [2.69-23.4], p<0.001) and years of HF duration (HR 1.10 [1.04-1.16], p=0.001).



Conclusions: Nutritional status assessed with the screening tool MNA-SF was an independent predictor of all-cause death in ambulatory patients with HFmrEF –beyond BMI– together with NYHA functional class and HF duration.

P1572
Determination of optimal energy needs, protein, fats and carbons in patients with obesity and chronic heart failure with mid- range ejection fraction (HFmrEF)

T Tatiana Zaletova[1]; AR Bogdanov[1]; SA Derbeneva[1]; YG Panova[1]
[1]*Research Institute of Nutrition of Russian Academy of Medical Sciences, Moscow, Russian Federation*

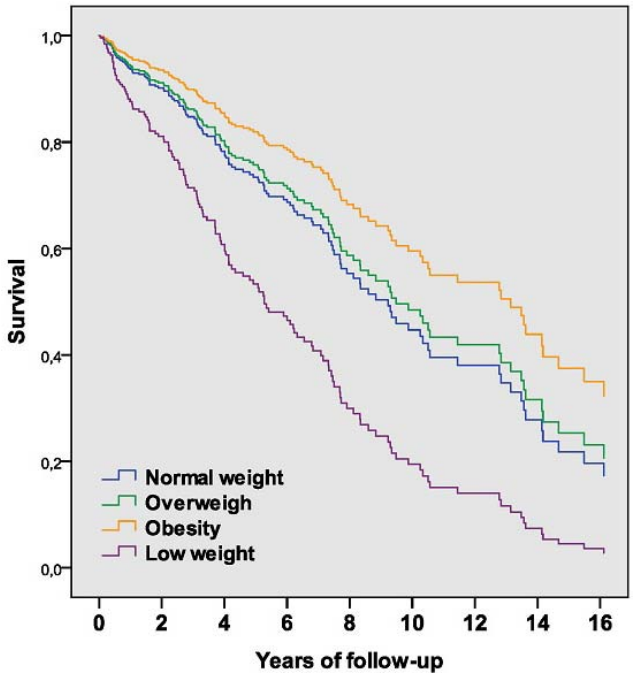
Research objective. Determination of resting energy in obese patients with HfmrEF.
Materials and methods. A total of 92 obese people were examined. According to echocardiography and cardiovascular functional assessment test systems (test with 6 minute walk) all patients had HFmrEF.
Analyses of basal metabolic rate was performed to all patients by indirect calorimetry with using a stationary metabolograph.
Results. We found lower rates of basal metabolism in patients with heart failure (HF) compared with patients without HF: with obesity I class (1687 ± 148kcal / day versus 1715.5 ± 63 kcal / day, p> 0.05), with obesity II class (1635 ± 164 kcal / day against 1843 ± 52 kcal / day, p> 0.05), with obesity III class (2072 ± 51 kcal / day versus 2334 ± 110 kcal / day - p <0.05).
Patients with HF also showed a significantly (p <0.01) more low rate of oxidation of carbohydrates compared with patients without HF. In studies have revealed an increase in the rate of protein oxidation in patients with HF by as obesity progresses; at the same time, in the group without HF, this pattern is not was observed.
So, in the group with obesity I class protein oxidation rate was 79 ± 11 g / day vs 55 ± 3.2 g / day, II class - 88 ± 6 g / day vs 69.4 ± 3.94 g / day, III class- 92 ± 4 g / day vs 73.75 ± 3.98 g / day for patients with HF and without HF, respectively.
Conclusion. Thus, obesity in combination with HFmrEF compared to obesity without HF accompanied by marked changes in nutritional status patients, in particular: lower basal metabolic rate, reduced speed oxidation of carbohydrates and an increase in the rate of oxidation of protein. It may be reflection of such pathogenetic processes as reduction of energy consumption of mitochondrial system, insulin resistance and catabolism of muscle tissue. The identified features justify the need to optimize diets in this category of patients.

P1573
Is the obesity paradox also present in heart failure with mid-range ejection fraction?

E Zamora[1]; J Josep Lupon[1]; M De Antonio[1]; M Domingo[1]; P Moliner[1]; E Santiago-Vacas[1]; J Santesmases[1]; M Boldo[1]; C Diez-Quevedo[1]; MI Troya[1]; C Rivas[1]; B Gonzalez[1]; V Diaz[1]; P Velayos[1]; A Bayes-Genis[1]
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*

Background: Obesity is identified as an independent risk factor for developing congestive heart failure (HF). Paradoxically it has been reported that obesity is associated with improved survival in different cohorts of HF patients. Nevertheless, the presence of obesity paradox in HF with mid-range ejection fraction (HFmrEF) is not completely elucidated.
Objective: To analyse the relationship between body mass index (BMI) and mortality in a HFmrEF ambulatory cohort of different aetiologies followed in a HF unit, with especial focus on the role of obesity in prognosis.
Methods: Baseline BMI was analysed as continuous variable and categorized in 4 groups based on 2009 WHO classification: low weight (BMI <20.5 kg/m2), normal weight (BMI 20.5 to <25.5 kg/m2), overweight (BMI 25.5 to <30 kg/m2) and obesity (BMI ≥30 kg/m2). All-cause mortality was the primary end-point of the study. Cox regression analyses adjusted by age, sex and NYHA functional class were performed and survival curves plotted.
Results: Three-hundred thirty patients were included in the study (age 65.9 ± 13.2 years, 68% men). The main aetiology was ischemic heart disease (52%, followed by dilated cardiomyopathy (11%) and hypertensive cardiomyopathy (11%). The majority of patients were in NYHA class II (65%) and III (26%). Mean ejection fraction was 43.2% ± 2.7. During a mean follow-up of 5.3 ± 4.6 years 142 patients (42%) died. BMI showed a protective effect on survival in Cox regression analysis (HR 0.96 [95%CI 0.92-0.99], p=0.01). When categorized groups of BMI were analysed, obese patients showed a trend towards lower mortality than normal weight patients (reference): HR 0.65 [95%CI 0.40-1.03], p=0.07. Adjusted survival curves according to BMI category are depicted in the figure. As a significant interaction (p=0.02) was found between BMI and ischemic aetiology of HF, separate analyses were performed for BMI categories for ischemic and non-ischemic patients, with remarkably different results: ischemic aetiology: HR 0.97 [95%CI 0.52-1.79], p=0.91; non-ischemic aetiology HR 0.28 [95%CI 0.13-0.64], p=0.003.

Conclusions: A greater BMI was associated with lower mortality rates in patients with HFmrEF during a mean follow-up of five years. Obesity showed a protective effect in HFmrEF patients, which remarkable in patients from non-ischemic aetiology and was absent in patients from ischemic aetiology.



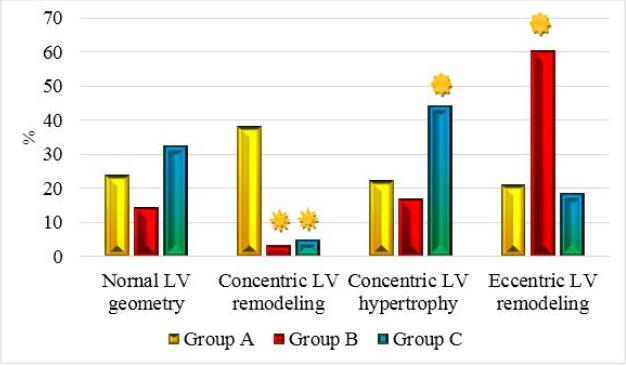
P1574

Characteristics of LV left ventricular myocardium remodeling in patients with acute decompensated heart failure and intermediate LV left ventricular ejection fraction

VA Kostenko[1]; EG Skorodumova[1]; EA Skorodumova[1]; AV Siverina[1]; VA Ilina[2]
[1]St. Petersburg I.I. Dzhanelidze Research Institute of Emergency Medicine, Cardiology and rheumatology, St. Petersburg, Russian Federation; *[2]St. Petersburg I.I. Dzhanelidze Research Institute of Emergency Medicine, Pathoanatomy, St.Petersburg, Russian Federation*

Background. One of key points in the acute decompensated heart failure (ADHF) pathogenesis is left ventricular (LV) myocardium remodeling which is considered a complex of structural and geometrical alterations occurred under the impact of pathogenic factors. Determination of remodeling type as well as its interaction with changes in extracellular matrix are important for assessment of cardiovascular events risk and selection of optimal therapeutic strategy in future.
Purpose. To determine types of myocardium remodeling in patients with mid-range left ventricular ejection fraction (LV EF) in comparison with reduced and preserved LVEF in the situation of ADHF.
Materials and methods. 195 patients with ADHF were examined, 141 were males , 54 - females. Their average age was 64,6+-14,8 years. Echocardiography was performed, LV EF by Simpson was measured, type of remodeling was established. General cohort was divided into 3 groups – A: LV EF = 40-49%, B: < 40%, C: >= 50%. Volume fraction of interstitial collagen (VFIC) was calculated indirectly. Results were statistically parsed.
Results. VFIC in group A was 6,6±0,6%, in group B - 10,4±1,0 % (p<0,001), in group C -3,31±0,2% (p<0,001). Distribution of remodeling types is showed on the Graph.1.
Normal LV geometry was observed more often in A and C cohorts, concentric LV remodeling – in A group. Eccentric LV remodeling was more typical for group B, concentric LV hypertrophy did notdominate in any group.
Dominant type of LV geometry in group A was concentric LV remodeling – 38,0%, against group – 3,2%, and – 4,9%, p<0,001.
Normal LV geometry in group occurred in 23,9% of all observations, 14.3% in and 32,5% in group, but those differences were proven statistically insignificant.
Rate of concentric LV hypertrophy had shown no significant differences between groups and : 22,2% vs 16,9%, p>0,05, but this type was significantly more often observed in cohort: 44,3%, p<0,001. Eccentric LV remodeling was significantly less common in persons of group as compared to cohort : 21,1% versus 60,3%, p<0,001; no significant differences observed between groups and (18,3%).

Conclusions: 1. VFIC in patients with intermediate LVEF is 6,6±0,6%, whichis significantly higher than in persons with intact LV EF -3,31±0,2%, but significantly lower than in patients with reduced LV EF, p<0,001.
2. In patients with ADHF and intermediate LV EF, signs of concentric LV remodeling were observed in 38% of all cases. Normal LV geometry was registered in 23,9% of cases without any statistical differences between the groups.



Note: ✹ - The differences are significant p<0,001

Heart failure with mid-range ejection fraction in southern Brazil: an eight year follow up cohort

L C Danzmann[1]; LC Petersen[1]; E Bartholomay[2]; EH Magedanz[1]; B Donay[1]; CP Moreira[2]; AP Tscheika[1]; PR Caramori[1]; LC Bodanese[1]; MH Miglioranza[3]
[1]Hospital São Lucas da PUCRS, Heart failure team, Porto Alegre, Brazil; *[2]Universidade Luterana do Brasil, Porto Alegre, Brazil*; *[3]Instituto de Cardiologia do RS, Porto Alegre, Brazil*

On behalf of: PUCRS Heart Failure Study Group

Background - Heart failure with mid-range ejection fraction (HFmEF), their epidemiological characteristics and particularly their clinical outcomes rates represent an important issue in developing countries due to the contingency of resources for health care.
Purpose - The study aimed to describe clinical characteristics, total mortality and cardiovascular mortality in an eignt-years follow up HFmEF population.
Methods - The study population was admitted in a period between January 2009 and December of 2011 with acute heart failure (HF) diagnosis by Boston Criteria and was followed up for a maximum period of 8 years (mean follow up: 4,7 years). The sample was divided in three groups according left ventricle ejection fraction (LVEF): HF with preserved ejection fraction (HFpEF), when LVEF was >50%, HF with reduced ejection fraction (HFrEF) when LVEF was < 40% and HFmEF when LVEF was ≥40% and <50%. In-hospital characteristics and outcomes were registered. A post-discharge follow up registered the incidence of total and cardiovascular mortality. The association between the categorical variables was performed using the Chi-square tests with adjusted residuals analysis and the comparison between the means of the continuous measures, through the analysis of variance - ANOVA with Bonferroni Post Hoc test. The Kaplan-Meier survival curve was used according to the ejection fraction categories. A P value <0.05 was considered statistically significant.
Results - A total of 380 pacientes were admited and followed up. The mean age was 68 (±13) years and the majority (53%) were female, 51% were HFpEF, 32% HFrEF and 17% were HFmEF. Patients considered HFmEF had a higher rate of myocardial ischemic disease than HFrEF and HFpEF (52,4% x 46,3%x 32,1%, P=0,004), respectively. The total in-hospital morality was 7,6% and was not different among the HF groups. The total cardiovascular mortality in the whole follow up was higher in the HFmEF group in comparison to the HFrEF and HFpEF (61,1% x 58,3% x 38,5%, P=0,38), respectively.
Conclusion - Our result demonstrated the HFmEF patients were associated to a higher myocardial ischemia rate, a non-different in-hospital mortality and had higher cardiovascular mortality in the whole period of follow-up.

P1576

Profile and differential management of patients with a mid-range ejection fraction compared to patients with depressed ejection fraction, long-term follow-up

D Daniel Enriquez Vazquez[1]; CN Perez Garcia[1]; M Ferrandez Escarabajal[1]; TS Luque Diaz[1]; A Travieso Gonzalez[1]; M Perez Serrano[1]; C Olmos Blanco[1]; D Vivas Balcones[1]; E Martinez Gomez[1]; J Higueras Nafria[1]; R Bover Freire[1]; J Goirigolzarri[1]; I Vilacosta[1]; C Macaya[1]
[1]*Hospital Clinic San Carlos, Cardiovascular Institute, Madrid, Spain*

Introduction Heart failure (HF) with midrange ejection fraction (EFmr) rises as a differential group.
The objective of this study is to characterize this type of patients and their comparison with the prototype of patients with heart failure with reduced EF (EFr).
Methods Patients with a diagnosis of HF admitted to a Cardiology Service of a tertiary hospital between July 2016 and March 2017 have been collected prospectively and consecutively, and their follow up.
Results Of the total of 341 patients collected, 49 patients had EFmr (40-49%) and 114 patients with EFr (<40%). The median follow-up was 403 days. The baseline characteristics are in Table 1. Patients with EFmr have a generally poorer cardiovascular risk profile, and more often have tachyarrhythmias or acute ischemic heart disease as triggers.
More beta-blockers were used at discharge in patients with EFr (83.8% vs 73.5%) without reaching statistical significance. The use of ACEi or ARA2 is similar (65% in both cases), but in the EFmr group, ARA2 was used in a higher percentage (20, 4% vs 8.1%, p 0.027). MRAs are used in both groups, with greater use in patients with EFr (65% vs 30% at discharge, p <0.001). The use of diuretics at discharge was higher in the group of patients with EFr than in the EFmr group (82% vs 69.4%), p 0.07).
In the long-term follow-up, patients with EFmr are admitted for different causes than the HF in a greater percentage, without reaching statistical significance (15.6% vs 8.6% at 6 months and 26.2% vs 18.6 % in more than one year, NS). No significant differences were found in terms of mortality due to HF or all causes.
Conclusions The patient with EFmr who is admitted for HF mainly due to tachyarrhythmias or acute ischemic heart disease. They also have less right ventricular dysfunction. Diuretics are used in smaller amounts, as well as ARMs. In long-term follow-up, a higher percentage of readmissions due to causes other than HF was observed in this subgroup.

Characteristic	Midrange EF	Reduced EF	p value
Mean age	77,0	71,7	0,002
Sex female	36,7%	23%	0,066
Hypertension	87,8%	75,2%	0,072
Smoker	6,1%	15%	0,117
Ischemic cardiopathy as trigger	20,4%	10,6%	0,095
Tachyarrythmia as trigger	26,5%	15,2%	0,089
Mean EF (%)	44,8%	27,6%	<0,001
Right ventricle disfunction	16,3%	43,2%	<0,001

P1577

On mid-term, had mid-range ejection fraction heart failure the same prognosis with reduced ejection fraction heart failure?

CM Goidescu[1]; LA Vida-Simiti[1]; E Muresan[2]; I Todor[3]; DL Mocan-Hognogi[1]; AD Farcas[1]
[1]*University of Medicine and Pharmacy of Cluj Napoca, Faculty of Medicine, Department of Internal Medicine, Cluj Napoca, Romania*; [2]*Cardiology Department of County Clinical Emergency Hospital, Cluj Napoca, Romania*; [3]*Oncology Institute "Prof. Dr. Ion Chiricuta" , Cluj Napoca, Romania*

Introduction: Heart failure (HF) is a progressive disease with an increasing incidence and a severe prognosis. Its mortality overpasses that of some malignancies and its evolution is marked by an altered quality of life and frequent hospitalizations. Few data are available from East European countries.
Objective: The aim of the study was to analyze the mid-term cardio-vascular events, (mortality, re-hospitalizations) of the patients with mid-range ejection fraction (HFmrEF) and to compare them with the events occurred in patients with heart failure with reduced (HFrEF) and preserved ejection fraction (HFpEF), respectively, in a county hospital from an East European country.
Method: 353 patients consecutively hospitalized for all cause acutely decompensated heart failure were included (age 70±11,2 years, 47% males; HF diagnosed < 1year in 63,7% of patients, more than 5 years in 11,6%) and followed up for 18 months. We noted the re-hospitalizations and all-cause of deaths.
Results: During the 18 months' follow-up, 19.3% patients died and 33.4% were re-hospitalized. The mortality was higher in the HFrEF group (27.1%) as compared with HFmrEF (20,6%) and HFpEF (14,2%) respectively, p= 0.03. Also, the mortality rate was significantly higher in the re-hospitalized group as compared with the group that did not require hospital readmission (25.4% vs 16.2%, p= 0.04). We found significantly more anemia (p<0.001) and atrial fibrillation at admission (p= 0,04) in the group of patients who died. The ischemic heart disease was the principal cardiopathy (65% of patients), in the surviving group we found significantly higher serum levels of lipids (p< 0.01). The body mass index was also significantly increased in the surviving group (p= 0.03), the obesity paradox? A cut-off value <46% for LVEF, a systolic blood pressure < 125 mm Hg and diastolic blood pressure <80 mmHg were associated with severe prognosis and increased mortality.
Conclusion: A cut-off value < 46% for LVEF, including patients with HFrEF and most of patients with HFmrEF, was associated with increased mortality suggesting that to a large extent, they have the same prognosis.

P1578

Influence of left ventricular ejection fraction category in patients with stenosis aortic undergoing with transcatheter aortic valve replacement

M Munoz-Garcia[1]; E Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; AJ Dominguez-Franco[1]; JM Garcia-Pinilla[1]; L Morcillo-Hidalgo[1]; JH Alonso-Briales[1]; F Carrasco-Chinchilla[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]
[1]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

European Society of Cardiology heart failure guidelines include a new patient category with mid-range (40%-49%) left ventricular ejection fraction (HFmrEF). HFmrEF patient characteristics and prognosis are poorly defined. The aim of this study was to analyze the clinical results in according to category of LVEF in a cohort of hospitalized heart failure patients

Methods: A prospective observational study was conducted with 667 patients undergoing TAVR with balloon-expandable or self-expanding valves were included. The patients were classified according to ejection fraction as follows: HFrEF, < 40%; HFmrEF, 40%-49%; and HFpEF ≥50%. Baseline patient characteristics were examined, and outcome measures were mortality and readmission for heart failure
Results: Among the study participants, 87 (13%) had HFrEF, 69 (10.3%) HFmrEF, and 511 (76.6%) HFpEF. The patients had a different clinical profile depending the category of EF (HFrEF, HFmrEF and HFpEF) in terms of age (76.4 ±10 vs. 78.8±6 vs. 79.2±6 years, p=0.001); gender (male) 60.9% vs. 55.1% vs. 35.6%, p< 0.001; ischemic etiology 64.4% vs. 50.7% vs. 39.9%, p<0.001) and use of blockers agents 65.5% vs. 55.1% vs. 47.2%, p 0.026). There was a good evolution of LVEF over time (baseline, post-TAVR and 1 year) on all categories, HFrEF: 32.09±4.9 to 42.7±11 to 50.02±12%; HFmrEF: 44.18 ±3.3 to 54.8±10 to 56.5±10%, HFpEF: 67.4±7 to 68.6±7 to 65.2±7%. There were no significant differences in three groups (HFrEF, HFmrEF and HFpEF) in all-cause in-hospital mortality (5.7% vs. 1.4% vs. 3.3%, p= 0.428); late mortality (35.4% vs. 44.1% vs. 40.9%, p= 0.448) or heart failure readmission (13.1% vs. 11.8% vs. 9.6%, p=0.289). The survival was similar among the 3 groups at 1-year and 3-years during follow-up (87.4% vs. 92.8% vs. 88.3% and 72.4% vs. 77.2% vs. 75.4%) respectively, log Rank=0.283, p= 0.808.

Conclusions: The HFmrEF patient group has characteristics between the HFrEF and HFpEF groups, with similarities to both groups. No between-group differences were observed in total mortality, or heart failure readmission.

P1579

Mid range ejection fraction: a continuum or a self clinical entity?

CL Gonzalez[1]; S Mettini[2]; NC Zareba[1]; CE Sandoval[1]; L Secco[2]; DA Fernandez[2]; S Garcia Zamora[1]; JJ Herrera Paz[1]; SM Pereiro Gonzalez[2]
[1]FLENI Institute, Cardiology, Buenos Aires, Argentina; [2]Hospital Center Churruca-Visca, Buenos Aires, Argentina

Background: From the use of the terms Heart failure (HF) with preserved ejection fraction (EF) and reduced ejection fraction, a group of undefined patients remains in the middle of these values (between 40 - 49 of EF), a true grey area. The European Guidelines incorporated this group as mid-range EF. Neither the behavior of this group nor the therapeutic strategy to be implemented are entirely clear.Objectives: To evaluate in a population hospitalized for HF if the patients with mid-range EF evolve as the reduced EF group or as the preserved ones. For this, we took death during hospitalization; CHF-related hospitalization and death during follow-up as end points.Materials and methods. We retrospectively evaluated 818 patients hospitalized for CHF in two centers in the city of Buenos Aires, Argentina, between 2008 and 2016. The hospitalizations were consecutive and for the first time. All the patients were followed up by telephone for at least one year. The population was divided in three groups, group A, n = 301 patients with preserved EF (> 50%), group B, n = 385 patients with reduced EF (<39%) and group C, n = 132 patients with mid-range EF (from 40 to 49%)The Wilcoxon test was performed for the analysis of the variables. For the comparison between EF groups, the chi2 test was carried out and later logistic regression was conducted.
Results. There was no statistically difference in mortality during hospitalization . (3.9% for group A, 6.4% for group B and 3.7% for group C.)
There was a statistically significant association between groups B and C in the end points of death and CHF-related hospitalization during follow-up of patients ($p < 0.05$) in comparison with A group.
During follow up, death was 29% for A, 31.4% for B and 34.8% for C. CHF-related hospitalization were 23.2 % for A, 30.3% for B and 22.7% for C.
In the logistic regression analysis we found a relation between groups B and C ($p < 0.005$) in terms of CHF-related hospitalization during follow-up in contrast with A group.
Between the baseline characteristics of each group, the presence of atrial fibrillation between groups A and B was statistically significant ($p = 0.004$).Conclusions- There was no difference in mortality during hospitalization among groups
- Patients with intermediate EF have a statistically significant association with the group of reduced EF in terms of death ($p = 0.03$) and CHF-related hospitalization ($p = 0.01$) in the follow-up. This could suggest that the mid-range EF group behaves, in this population, similarly to the reduced EF group. Considering this, we could propose a similar therapeutic strategy for this group

P1580

Sexual differences in heart failure with mid-range ejection fraction patients

JC Jeong Cheon Choe[1]; JH Choi[1]; JY Shin[1]; J Ahn[1]; JS Park[1]; HW Lee[1]; JH Oh[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]
[1]Pusan National University Hospital, Department of Cardiology, Pusan, Korea (Republic of)

Background: Little is known on the gender differences in patients with heart failure (HF) with mid-range ejection fraction (EF) (HFmrEF).
Objectives: We aimed to investigate the gender differences in patients with HFmrEF.
Methods: Among 252 consecutive patients with primary diagnosis of HFmrEF (EF 40-49%) and baseline and follow-up echocardiogram in an urban tertiary referral center from October 2013 to March 2017, 131 (52.0%) were in men and 121 (48.0%) were in women. We compared the characteristics and composite event (cardiovascular death and HF readmission).
Results: Compared with women, men had significantly higher rates of prior ischemic heart disease, chronic kidney disease, and peripheral arterial disease. No significant differences were found in other baseline characteristics between men and women. At baseline, LVEF was not significantly different between men and women. At follow-up, LVEF in women significantly improved from the baseline levels (48.9% vs. 45.3%, $p<0.001$), whereas no significant changes in LVEF were observed in men. In women, the use of inhibitor of the renin angiotensin system (odds ratio 0.386, 95% confidence interval [CI] 0.181-0.822, p=0.014) was contributed to the improvement of LVEF. Composite event occurred in 80 patients (31.7%). There were no significant differences in the composite event between men and women (32.1% vs. 31.4%, hazard ratio [HR] 1.155, 95% CI 0.738-1.807, p=0.529). Additionally, significant contributors for composite event were age (HR 1.035, 95% CI 1.012-1.058, p=0.002), the presence of atrial fibrillation (HR 1.781, 95% CI 1.148-2.764, p=0.010), spironolactone use (HR 0.556, 95% CI 0.358-0.865, p=0.009). Cardiac death occurred in 9 patients (3.6%). Men had a significantly higher rate of cardiac death than women (6.1% vs. 0.8%, HR 1.255, 95% CI 1.010-6.687, p=0.027). In men, age (HR 1.118, 95% CI 1.022-1.223, p=0.015) and chronic kidney disease (HR 3.142, 95% CI 1.034-6.581, p=0.042) were independently predictive for increased risk of cardiac death.
Conclusions: This study showed that in patients with HFmrEF, women might be associated with improved LVEF and lower risk of cardiac death compared with men. To establish the expected advantage of women, further prospective studies are needed.

Comparative study of patients with heart failure with ejection fraction in the mid range and patients with preserved ejection fraction: management and prognosis

D Daniel Enriquez Vazquez[1]; CN Perez Garcia[1]; M Ferrandez Escarabajal[1]; A Travieso Gonzalez[1]; TS Luque Diaz[1]; C Olmos Blanco[1]; D Vivas Balcones[1]; P Mahia Casado[1]; J Higueras Nafria[1]; J Goirigolzarri[1]; R Bover Freire[1]; I Vilacostai[1]; C Macaya[1]
[1]Hospital Clinic San Carlos, Cardiovascular Institute, Madrid, Spain

Introduction In recent years, the study of heart failure (HF) with ejection fraction in the middle range (EFmr) has been enhanced as a group with differential characteristics.
The aim of this study is to analyze the differences between patients with EFmr and preserved ejection fraction (EFp), as well as its long-term follow-up.
Methods Prospective and consecutive patients with HF admission in the Cardiology Service between July 2016 and March 2017 were collected, collecting the data referring to them, to the management, and to the follow-up performed until April 2018.
Results Of the total of 341 patients with HF, 49 had EFmr and 153 patients had EFp. The baseline characteristics of these are shown in Table 1. No significant differences were found regarding the main trigger. The patient with HF EFmr presents in general a profile of greater cardiovascular risk. The clinical presentation regarding the physical examination showed no differences.
The patients with EFmr received in a higher percentage treatment with beta-blockers (73.5% vs 64.7%, NS), ACEi or ARA2 (65.3% vs 55.6%, p 0.299) as well as ARM. No differences were found regarding the diuretic treatment at discharge. There were no significant differences in the patient's referral to the HF Unit after discharge.

Characteristic	Midrange EF	Preserved EF	p value
Mean age	77,0	78,24	0,459
Sex female	36,7%	68%	<0,001
Hypertension	87,7%	83%	0,428
Diabetes Mellitus	49%	50,4%	0,824
Mean EF	44,8%	61,2%	<0,001
Atrial fibrillation	53,1%	62,7%	0,228
COPD	18,4%	9,2%	0,077

Table 1

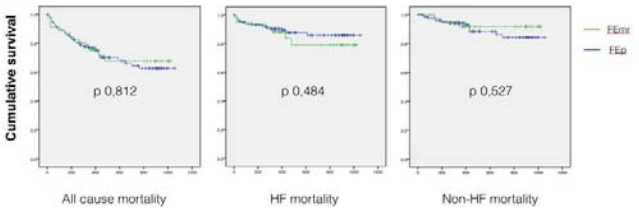

Figure 1

A median follow-up of 403 days was performed. No significant differences were found in terms of readmission due to HF or other causes. Regarding mortality, there were no differences (27.7% vs. 29.9%, p = 0.766), nor in their analysis due to causes.
Conclusions HF EFmr presents a phenotype similar to that of EFp in terms of presentation, patient profile and clinical management. It is similar in terms of readmissions and mortality due to heart failure and other causes.

P1582
The role of inflammation and fibrosis in the occurrence of atrial fibrillation in heart failure patients with mid-range ejection fraction

S Svetlana Grigoryan[1]; LG Hazarapetyan[2]; KG Adamyan[1]
[1]Institute of Cardiology, Yerevan, Armenia; *[2]Yerevan State Medical University after M. Heratsi, Yerevan, Armenia*

Heart failure (HF) is frequently accompanied by atrial fibrillation (AF). As HF is more severe, the prevalence of AF increases markedly. Such patients are at increased risk of both hospitalization due to HF decompensating and mortality. While HF with preserved and reduce ejection fraction (EF) are well described, determinants and outcome of HF with mid-range EF and AF remain unclear. The aim of this study is to examine clinical and biochemical predictors of AF incident in patients with HF mid-range EF (mrHF).
Methods: 56 patients (age 61± 6, 8) with mrHF and non-rheumatic AF after successful cardioversion were enrolled in this study. As a control group 42 patients with mrHF without AF were also enrolled. After the enrollment the echocardiography examination and 24-hour ambulatory Holter monitoring ECG were registered in each patient. We measured plasma indexes of inflammation such as highly sensitive C-reactive protein (hs-CRP) and interleukin-6 IL-6 (IL-6) as well as fibrosis marker (transforming growth factor TGF-β1) in all the observed patients. All of blood tests in plasma were determined by ELISA on the analyzer "Stat Fax 303 Plus" using commercial kits "Bio Source'. Studies were conducted on the basis of simple randomized protocols, using the universal statistical packages SPSS 13.0 and EXCEL-2007.
Results: The obtained results showed that mrHF patients with AF had higher levels of inflammation markers (hs-CRP p = 0.002, IL-6 p = 0.019) compared with mrHF patients without AF. There is the evidence linking inflammation to the initiation and perpetuation of AF. Plasma TGF-β1 level is also were higher among mrHF patients compared with controls group (p = 0.001). TGF-β1 is a key cytokine involved in the pathogenesis of fibrosis, whereas IL-6 plays an important role in the regulation of inflammation. Besides the levels of inflammation and fibrosis markers were markedly elevated in patients with dilated left atrium, poorly functioning left atrial appendage and longer duration of AF.
Conclusion: Increased inflammation and fibrosis markers in mrHF patients are related to the initiation and perpetuation of AF and may contribute to structural remodeling of left atrium in patients with mrHF and AF.

P1583
The significance of blood pressure control in heart failure with mid-range ejection fraction

M Maria Marketou[1]; S Maragkoudakis[1]; S Maragkoudakis[1]; A Kostaki[1]; A Kostaki[1]; K Fragiadakis[1]; K Fragiadakis[1]; A Patrianakos[1]; A Patrianakos[1]; S Kassotakis[1]; S Kassotakis[1]; A Alevizaki[1]; A Alevizaki[1]; O Theodosaki[1]; O Theodosaki[1]; P Vardas[1]; P Vardas[1]; F Parthenakis[1]; F Parthenakis[1]
[1]Heraklion University Hospital, Heraklion, Greece

Purpose: Heart failure (HF) with mid-range ejection fraction (HFmrEF) is a newly suggested entity in HF. Since it has been inadequately addressed, there is an urgent need to determine the profile of HFmrEF patients and the optimal approach to their management. The present study aimed to assess the long-term clinical outcomes of hypertensive patients with HFmrEF and the impact of blood pressure (BP) on their mortality and cardiovascular outcome.
Methods: We performed a retrospective observational study that included 121 hypertensive patients with HFmrEF and 149 hypertensives with heart failure and preserved ejection fraction (HFpEF). The median follow up was 84 months (22–122).
Results: Our analysis did not reveal any statistically significant difference between the two groups in total mortality (p=0.34) or cardiovascular mortality (p = 0.54). The total mean survival time was 102.9 months (100.5–110.1), while the mean survival time was 105.3 months (80.4–90.2) in HFpEF and 97.6 months (92.7–102.6) in HFmrEF. An office systolic BP > 138 mmHg and diastolic BP>89 mmHg were significantly associated with both all-cause mortality (p=0.02 and p=0.013, respectively) and cardiovascular mortality (p=0.02 for both) in HFmrEF. In HFpEF patients no significant association was found between outcome and office BP.
Conclusions: HFpEF and HFmrEF have similar long-term outcomes. Suboptimal BP levels are a significant risk factor for an adverse outcome in HFmrEF. Our results emphasize the importance of good BP control in order to achieve better outcomes in hypertensives with impaired EF and HF symptomatology.

P1584
Adherence to therapy in patients with heart failure with mid-range ejection fraction: a problem to solve

L Livia Popescu[1]; H Balan[1]
[1]University of Medicine and Pharmacy Carol Davila , Bucharest, Romania

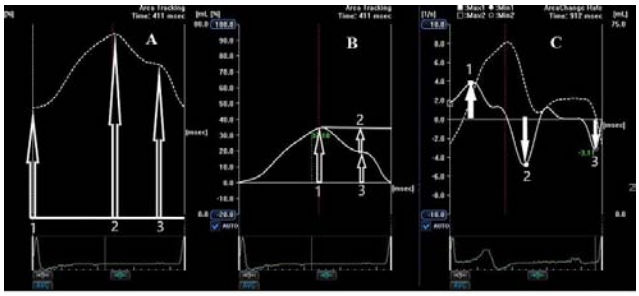
Background Heart failure with mid-range ejection fraction (HFmrEF) was for the first time described by Lam and Solomon in 2014 and, in 2016, the Task Force for the Diagnosis and Treatment of Acute and Chronic Heart Failure of the European Society of Cardiology introduced in guidelines HFmrEF as a distinct phenotype. In terms of left ventricular ejection fraction (LVEF) HFmrEF (LVEF 40-49%) occupies an intermediate position between HF with reduced ejection fraction (HFrEF) (LVEF<40%) and HF with preserved ejection fraction (HFpEF) (LVEF>50%) and the question is if patients with HFmrEF represents a distinct pathophysiological entity or a transitional phenotype. Suboptimal adherence to treatment is considered to be the main impediment in controlling chronic diseases and the most common precipitating factors for hospitalization among HF patients are respiratory infections, arrhythmias, myocardial ischaemia and medication noncompliance.
Purpose The aim of our study was to assess the adherence to treatment of patients with HFmrEF admitted in an Internal Medicine Department.
Methods We enrolled 84 consecutive patients with HFmrEF medium age 69±7 years old. We assessed demographic, clinical and laboratory features from the patient admission charts. All patients completed the Morisky questionnaire for adherence to treatment.
Results 51 patients (60.72%) were males and 33 (39.28%) females. 65.47% of the patients were active smoker. 35.71% were in NYHA III/IV class. When we assessed comorbidities, history of coronary artery disease was recorded in 57.14% of them, and ACS in 9.52%. Other comorbidities recorded were: hypertension 58.33%, diabetes mellitus 28.57%, atrial fibrillation 47.61%, COPD 26.19%, anaemia 27.38%, chronic kidney disease 44.04%. Maximum adherence (Morisky score 0) was recorded in only 10.71% of the patients, 65.47% had intermediate adherence and 23.82% low adherence. Patients with more comorbidities had the lower adherence to treatment.
Conclusions Patients with HFmrEF are mostly men, smokes, have coronary artery disease, atrial fibrillation, hypertension and chronic kidney disease in almost one half of them, and a very poor adherence to therapy. These patients need effective strategies to increase adherence to treatment, in order to reduce duration and frequencies of hospitalization and morbidity/mortality rates.

P1585
Left atrial remodeling in patients with mid-range ejection fraction heart failure with ischemic heart disease: the mirror image of systolic and diastolic dysfunction balance?

A Ailaana Kuular[1]; A Gamza[2]; A Vlasenko[1]; A Kozlenok[1]; E Lyasnikova[1]; M Sitnikova[1]
[1]V.A. Almazov National Medical Research Center, Saint-Petersburg, Russian Federation; *[2]Saint Petersburg Pavlov State Medical University, Saint Petersburg, Russian Federation*

Introduction . Diagnostic algorithms and therapeutic tactics of patients with HFmrEF are not fully defined, and the pathophysiological mechanisms underlying myocardial remodeling including atrial remodeling in HF are being actively studied. Studies assessing the atrial remodeling by three-dimensional speckle tracking echocardiography (3DSTE) in patients with HF are lacking.
Purpose of the study. To study the left atrial (LA) remodeling using new 3DSTE tools in patients with HFmrEF compared to patients with HFpEF and HFrEF ischemic etiology.

Material and methods. 3 groups of patients with IHD (mean age 59.0±10.3 yrs; 85% men, over 65% of patients had AH, most patients with HF II NYHA) were compared in a cross sectional study: HFpEF (n=23; EF 59.84±6.83%), HFmrEF (n=23; EF 44.20±2.69%) and HFrEF (n=20; EF 28.14±8.19%). The diagnosis of HF was set according to the recommendations of ESC 2016. All patients had sinus rhythm, were on the optimal drug therapy. Exclution criteria: valve prostheses, valve stenosis or regurgitation more than I degree, heart surgery/percutaneous coronary intervention/valvuloplasty within 3 months before the study. LA volumes parameters, strains, S(%): longitudinal (LALS), circumferential (LACS), area tracking (LAAT); strain rates SR(-): circumferential (LACSR), area change rate (LAACR) were estimated in reservoir, conduit and contractile phases (Figure).
Results. 3D STE of the LA mechanic showed significant differences in HFmrEF vs HFrEF patients. All volumetric parameters were lower in HFmrEF as compared to HFrEF: vol max 41.78 vs 56.05 ml/m2 (p<0.001); vol min 25.90 vs 42.67 ml/m2 (p<0.001); vol-p 34.76 vs 49.61 ml/m2 (p<0.001). LA S and LA SR were higher in HFmrEF group in comparison with HFrEF one during reservoir phase: LALS 18,10 vs 9,51 (p<0,001), LACS 20,52 vs 12,54 (p<0,01), LAAT 41,8 vs 23,18 (p<0,001), pLACSR 1,10 vs 0,61(p<0,01), pLAACR 1,92 vs 1,16 (p <0,01); conduit phase: LALS 8,36 vs 4,89 (p<0,001), LACS 9,42 vs 5,25 (p<0,01), LAAT 19,78 vs 10,30 (p<0,001), pLAACR -1,60 vs -0,90(p<0,05); contractile phase: LALS 10,03 vs 4,78 (p<0,001), LACS 12,95 vs 8,35 (p<0,05), LAAT 24,19 vs 13,83 (p<0,01), pLAACR -2,55 vs -1,42 (p<0.01). No volumetric, S and SR differences were found in groups between HFpEF and HFmrEF. Conclusion. The use of 3DSTE revealed geometric and functional differences in the remodeling of LA in patients with HFmrEF compared with patients with HFrEF and the absence of divergencies in the parameters studied compared with the group of patients with HFpEF of ischemic etiology. The severity of LV diastolic dysfunction in the HFmrEF group corresponded to the HFpEF group, significantly different from that in the HFrEF group. Patterns identified using 3DSTE require further study, including aspects of molecular genetic remodeling mechanisms and prognostic value in patients with HFmrEF.



A. Functional LA volumes: 1- Vol min, 2- Vol max, 3- Vol p

B. LA strain: 1 - LASr, 2- LASed, 3- LASct

C. Strain rate: 1- pLASRr, 2 - pLASRed, 3 - pLASRct

P1586

Characteristic of sympathetic nerve activity in two subgroups of patients with heart failure (heart failure with reduced ejection fraction and mid-range ejection fraction)

R Reka Urbancsek[1]; I Forgacs[1]; J Boczan[2]; J Barta[1]; I Edes[1]; Z Csanadi[1]; L Rudas[3]
[1]University of Debrecen, Institute of Cardiology, Debrecen, Hungary; [2]University of Debrecen, Department of Neurology, Debrecen, Hungary; [3]University of Szeged, Department of Anaesthesiology and Intensive Therapy, Szeged, Hungary

Introduction Sympathetic overactivity in severe heart failure (HF) is a well known feature. Muscle sympathetic nerve activity (MSNA) studies have been reported on subjects with reduced ejection fraction (HFrEF). The European Society of Cardiology has recently introduced a new HF category, i.e. HF with mid-range ejection fraction (HFmrEF), characterized by left ventricular EF of 40–49%. The autonomic regulation in this new category has not yet been thoroughly described.
Aims: Examination of the sympathetic and cardiovagal regulation in patients with HFmrEF compared with data obtained from HFrEF patients and healthy volunteers. Method: 7 patients in HFrEF group (3 females; age: 57±16), 18 patients in HFmrEF group (2 females; age: 62±10) and 9 healthy control subjects (3 females; age: 52±10) were enrolled. MSNA was recorded in the superficial peroneal nerve by microneurography. The signal was processed by the Nerve Traffic Analyzer System. Continuous ECG-, non-invasive blood pressure, and uncalibrated respiratory signals were also recorded. Data were digitized online (500 Hz/channel) with the Dataq/Windaq System. Offline analysis was performed with WinCPRS program. Sympathetic burst frequency (bursts/minute) and burst incidence (bursts/100 heartbeats) were determined. Cardio-vagal parameters, (HRV and BRS) were calculated by conventional methods.
Results: Burst frequency in rest was significantly different between the HFrEF and HFmrEF subgroups (50±12 bursts/min vs. 38±11 bursts/min; p=0,05). Burst frequency of the healthy control (HC) population (26±8 bursts/min) was significantly lower than in the HF subgroups, (HFrEF vs. HC: p <0,001; HFmrEF vs. HC: p=0,022). The differences were even more pronounced in the burst incidences (HFrEF: 80±16; HFmrEF: 64±15; HC: 36±11 bursts/100 heartbeats; HFrEF vs. HFmrEF p=0,035; HFrEF vs. HC: p <0,001; HFmrEF vs. HC: p <0,001). Cardio-vagal parameters were not significantly different in the three studied groups.
Conclusion: In the HFmrEF group, the sympathetic activity is abnormally increased but the elevation is less marked than in HFrEF group. Cardio-vagal parameters, on the other hand are unsuitable for similar sensitive differentiation. We have launched a follow-up study to determine the prognostic significance of our findings

P1587

Haemodynamic differences in response to physiological and pharmacological stress in heart failure with preserved ejection fraction

S Shantanu Sengupta[1]; GA Macgowan[2]; DG Jakovljevic[2]
[1]Sengupta Hospital and Research Institute, Cardiology, Nagpur, India; [2]Newcastle upon Tyne Hospitals NHS foundation trust, Newcastle upon Tyne, United Kingdom of Great Britain & Northern Ireland

Background: Heart failure with preserved ejection fraction (HFpEF) is associated with high prevalence, poor outcomes and quality of life for patients. Better understanding of the HFpEF pathophysiology is warranted. The aim of the present study was to assess differences in haemodynamic response to physiological and pharmacological stress in HFpEF.
Methods: Eighteen HFpEF patients (8 male; mean age 63±9 years of age and LVEF, 53±3), underwent blood sampling for natriuretic peptides and transthoracic echocardiography at rest and in response to different type of maximal tolerated stress testing i.e. i) physiological i.e. exercise stress test (ESS) using treadmill and modified Bruce protocol, and ii) pharmacological i.e. dobutamine stress test (DSS, with incremental dose of 5,10,15,20 ug/Kg/min in 3 minutes stages). DSS was performed within two weeks of the exercise test.
Results: The mean NTproBNP was 1821±1777 pg/ml. The duration of treadmill exercise test was 371±169 sec, and dobutamine 694±115 sec. Patients demonstrated a significant increase from baseline to peak physiological and pharmacological stress in heart rate (ESS, 42%, p<0.01; DSS, 35%, p<0.01), mean arterial pressure (ESS, 13%, p<0,01; DSS, 12%, p<0.01), stroke volume (ESS, 43%, p<0,01; DSS, 55%, p<0.01), cardiac output (ESS, 67%, p<0.01; DSS, 70%, p<0.01), cardiac power output (ESS, 76%, p<0.01; DSS, 74%, p<0.01), tricuspid regurgitation (ESS, 92%, p<0.01; DSS, 94%, p<0.01), early diastolic velocity (ESS, 21%, p<0.01; DSS, decreased by 3%%, p=0.34), left ventricular outflow tract velocity time integral(ESS, 10%, p=0.01; DSS, 20%, p=0.01), right ventricular tissue systolic wave (ESS, 20%, p<0.01; DSS, 40%, p<0.01), and global longitudinal strain (ESS, 9.5%, p=0.02, DSS, 8.75%, p=0.04). Systemic vascular resistance decreased from baseline to peak physiological and pharmacological stress (ESS, 63%, p<0,01; DSS, 69%, p<0.01). Further analysis revealed the following significant differences in cardiac response between the two stress modalities i.e. stroke volume was higher following DSS compared to ESS (127 ±24 vs 109 ±23 ml/beat, p=0.02) as was right ventricular tissue systolic wave (0.20±0.02 m/sec vs0.15 ±0.03 m/sec, p<0.01). The ESS however induced higher heart rate (128 ±12 vs 114 ±12 beats/min, p=0.08) and early diastolic velocity (1.06±0.26 vs 0.81 ±0.24 m/sec, p=0.01), whereas other echocardiography variables were not significantly different between the ESS and DSS.
Conclusions: The major findings of the present study suggest that there are differences in haemodynamic response to physiological and pharmacological stress in patients with HFpEF. Understanding differences in cardiac response to different stress modalities is important as it may improve understanding of the complex pathophysiology of HFpEF.

P1588

Hypovolemia and reduced hemoglobin mass in patients with heart failure and preserved ejection fraction

T Haider[1]; D Montero[1]; J Barthelmes[1]; JP Goetze[2]; S Cantatore[1]; I Sudano[1]; F Ruschitzka[1]; AJ Flammer[1]
[1]University Heart Center, Zurich, Switzerland; [2]Rigshospitalet, University of Copenhagen, Clinical Biochemistry, Copenhagen, Denmark

Background/Introduction: A fundamental tenet of heart failure pathophysiology hinges on a perpetual propensity for fluid retention leading to blood volume (BV) expansion and haemodilution. Whether this can be applied to heart failure patients with preserved ejection fraction (HFpEF) remains uncertain. Purpose: The present study sought to determine BV status and key hormones regulating fluid homeostasis and erythropoiesis in HFpEF patients. Methods: BV and haemoglobin mass (Hbmass) were determined with high-precision, automated carbon-monoxide rebreathing in 20 stable HFpEF patients (71.5±7.3 years, left ventricular ejection fraction = 55.7±4%) and 15 healthy age- and sex-matched control individuals.

Additional measurements comprised key circulating BV-regulating hormones such as pro-atrial natriuretic peptide (proANP), copeptin, aldosterone and erythropoietin (EPO), as well as central haemodynamics and arterial stiffness via carotid-femoral pulse wave velocity (PWV). Results: Carotid-femoral PWV was increased (+20%) in HFpEF patients versus control individuals. With respect to haematological variables, plasma volume did not differ between groups, whereas BV was decreased (-14%) in HFpEF patients. In consonance with the hypovolemic status, Hbmass was reduced (-27%) in HFpEF patients, despite they presented more than 2-fold elevation of circulating EPO (+119%). Plasma concentrations of BV-regulating hormones including proANP (+106%), copeptin (+99%) and aldosterone (+62%) were substantially augmented in HFpEF patients.
Conclusions: In contrast with the prevailing paradigm in heart failure, HFpEF patients may present with hypovolemia and markedly reduced Hbmass, underpinned by a generalised overactivation of endocrine systems regulating fluid homeostasis and erythropoiesis. These findings provide a novel perspective on the pathophysiological basis of HFpEF.

P1589
Peak VO2 as a main determinant of health related quality of life in symptomatic patients with heart failure with preserved ejection fraction

A Briatore[1]; JP Tormo[1]; B Ventura[1]; E Dominguez[1]; A Bellver[1]; FJ Chorro[2]; E Santas[2]; G Minana[2]; JM Ramon[2]; J Nunez[2]; P Palau Sampio[1]
[1]Hospital General de Castellón. Universitat Jaume I, Cardiology Department, Castellón, Spain; [2]Hospital Clínico Universitario, INCLIVA. Universitat de València, Cardiology Department, Valencia, Spain

Background: Heart failure with preserved ejection fraction (HFpEF) is a complex and multifactorial clinical syndrome characterized by poor health related quality of life (QoL). The determinants of poor QoL in HFpEF remains not fully elucidated.
Purpose: We sought to evaluate the contribution of predicted peak oxygen uptake (pp-VO2) in QoL in symptomatic patients with HFpEF.
Methods: A total of 74 stable symptomatic patients with HFpEF underwent a cardiopulmonary exercise test, echocardiography, physical examination, laboratory test, and assessment of QoL by Minnesota Living with Heart Failure Questionnaire (MLHFQ). Pearson correlation coefficient and multivariate linear regression analysis were performed to identify clinical covariates associated with MLHFQ.
Results: Mean age was 72.5±9.1 years, 53% were women and all patients displayed NYHA II-III. Mean MLHFQ and percent of predicted peak oxygen uptake (pp-VO2) were 42±19.8 and 57.3±13.8 %, respectively. MLHFQ showed negative and significant correlation with pp-VO2 ($r = -0.35$, $p < 0.01$). In a multivariate analysis, pp-VO2 was significantly associated with MLHFQ (β coefficient=-0.52, CI 95%: -0.87–0.18; p=0.004). Ranked in the order of importance (drop in R2), pp-VO2 (44%), ventilatory efficiency (26%), gender (20%) and systolic blood pressure at rest (10%) were the most important covariates predicting the MLHFQ (R-squared=28.3%). Interestingly, echocardiographic parameters of diastolic dysfunction and biomarkers surrogates of severity (NT-proBNP) were not associated with QoL.
Conclusions: In symptomatic patients with HFpEF, pp-VO2 emerges as a crucial determinant of QoL.

P1590
Characteristics and outcomes of HFpEF with declining ejection fraction

JJ Jin Joo Park[1]; CS Park[1]; A Mebazaa[2]; JH Lee[3]; DJ Choi[1]
[1]Seoul National University Bundang Hospital, Division of Cardiology,, Seongnam, Korea (Republic of); [2]University Paris Diderot , Paris, France; [3]Chunbuk National University Hospital, Department of Internal Medicine, Cheongju-Si, Korea (Republic of)

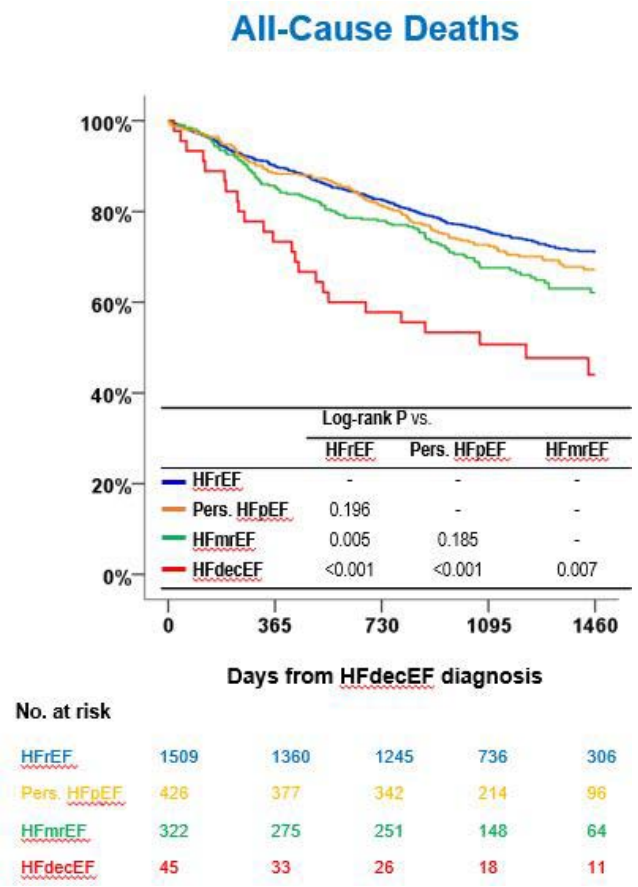
Background Some patients with heart failure with preserved ejection fraction (HFpEF) experience declining of left ventricular ejection fraction (LVEF) during follow-up.
Purpose We aim to investigate the characteristics and outcomes of patients with HF with declining ejection fraction (HFdEF).
Methods We analyzed a prospective, nationwide multicenter cohort with consecutive patients with acute HF enrolled from March 2011 to December 2014. HFpEF was defined as LVEF ≥ 50% at index admission. After 1 year, HFpEF patients were further classified as HFdEF (LVEF ≥ 50% at admission and <50% at 1 year), and persistent HFpEF (LVEF ≥ 50% both at admission and 1 year). Primary outcome was 4-year all-cause mortality according HF type from HFdEF diagnosis.
Results Of patients with HFpEF, 426 (90.4%) were diagnosed as having persistent HFpEF and 45 (9.6%) as having HFdEF. Natriuretic peptide level was an independent predictor of HFdEF (natriuretic peptide level > median: odds ratio: 3.20, 95% confidence interval [CI]: 1.42-7.25, P=0.005).
During 4-year follow-up, patients with HFdEF had higher mortality than those with persistent HFpEF (Log-rank P<0.001). After adjustment, HFdEF was associated with an almost 2-fold increased risk for mortality (hazard ratio 1.82, 95% CI 1.13-2.96, P=0.015). The use of beta-blockers, renin-angiotensin system inhibitors and mineralocorticoid receptor antagonists was not associated with improved prognosis of patients with HFdEF.
Conclusions HFdEF is a distinct HF type with grave outcomes. Further investigations that focus on HFdEF are warranted to better understand and develop treatment strategies for these high-risk patients.



Outcomes according to HF types

P1591
Incidence and probability of heart failure with preserved ejection fraction among high risk hypertensive patients.

K Gudieva[1]; M Islamova[1]; A Soloveva[1]; R Ammar[1]; L Babaeva[1]; A Safarova[1]; Y Karaulova[1]; Z Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), Department of Internal Medicine, Moscow, Russian Federation

Background: Diagnosis of heart failure with preserved ejection fraction (HFpEF) is still challenging in clinical practice. We aimed to assess HFpEF probability and incidence in high risk patients with hypertension using different diagnostic algorithms.
Methods: Study included 39 high risk hypertensive patients with at least one symptom or sign of HF and left ventricular ejection fraction (EF) ≥50% (71.4% female, 70±11 years (M±SD), obesity 48.6%, diabetes mellitus 40%, atrial fibrillation 28.6%, chronic kidney disease 43%, estimated glomerular filtration rate (eGFR) 65 [48.3;72.8] ml/min/1.73 m2, NT-proBNP level 120 [50; 195] pg/ml). Patients with significant valvular heart disease, acute coronary syndrome, acute infections, pulmonary embolism, neoplasm, eGFR <30 ml/min/1.73 m2, body mass index >40 kg/m2 were not included.HFpEF was assessed by 2016 ESC Heart Failure (HF) Guidelines and recently proposed ESC HFA-PEF2 and H2FPEF scores. Stress-echo

with passive leg raising was used to detect impaired LV diastolic function reserve and the increase in LV filling pressure.
Results: The most common HF symptoms and signs were: dyspnea at exertion 90%, fatigue 67.4%, tachycardia at rest 35%, peripheral edema 32%. 43% of patients had increased NT-proBNP ≥ 125 pg/ml.In 41% of cases that fulfilled criteria for HFpEF diagnosis according to 2016 ESC HF Guidelines, with median NT-proBNP level of 220 [150;562] pg/ml, only structural heart abnormalities, only diastolic dysfunction and both were identified in 31.2, 0 and 68.8% cases, respectively.
Low (<2 points), intermediate (2-5 points) and high probability (>5 points) of HFpEF was identified in 8.6, 65.7 and 25.7% of patients according to H2FPEF score.Using ESC HFA-PEF2 score HF was not detected in 8.6% of cases (<2 points), 57% of patients had intermediate risk of HF and required for stress echocardiography (2-4 points), and 34.4% of patients had confirmed HF (≥ 5 points). In intermediate risk patients echo-stress test additionally confirmed HFpEF in 25% cases. Thus, HFpEF was verified in 48.5 % of patients by HFA-PEF2 score. There was no agreement in verification of low HF probability between ESC HFA-PEF2 score and H2FPEF score in same patients, it was accounted for 37.1% and 15.4% of intermediate and high HF probability groups.Among patients with HFpEF diagnosed by 2016 ESC HF Guidelines, ESC HFA-PEF2 score identified 68.7% of patients with high HFpEF probability, H2FPEF score – 50% of patients. Results of 3 diagnostic algorithms were consistent in 22.8% patients.
Conclusion: HFpEF was diagnosed in 41% of patients using 2016 ESC HF Guidelines, in 48.5 % of cases by ESC HFA-PEF2 score and its high probability in 25.7 % by H2FPEF score. Disagreement between different HFpEF diagnostic algorithms was found with the consistency of the results only in 22.8% patients. According to this, additional analyses and future researches are needed to verify reasons of this heterogeneous data.

P1592
The prevalence of diastolic heart failure among patients with hypertension, suffering from atrial fibrillation and role of hypertension in the remodeling of left atrium after pulmonary vein isolation

A Azamat Baymukanov[1]; S Sovetova[1]; I Khamnagadaev[2]; S Termosesov[2]; I Ilich[3]; G Gendlin[1]; I Nikitin[1]
[1]Russian National Research Medical University, Moscow, Russian Federation; *[2]Research Clinical Institute of pediatrics, Moscow, Russian Federation*; *[3]Clinical Hospital name V.M. Buyanova, Cardiosurgery, Moscow, Russian Federation*

Introduction: It is known that an increase of systolic blood pressure leads to higher diastolic pressure in left ventricle and to growth of average pressure in left atrium (LA), which, in turn, leads to impairment left ventricular diastolic function (LVDF), remodeling of LA, fibrosis and the development of atrial fibrillation (AF). AF causes structural changes in LA, which plays an important role in the progression of arrhythmia. Pulmonary vein isolation (PVI) is one of the methods to treat AF. LA structural changes and the chance of LVDF recovery in group of patients with hypertension (HTN) remains unresolved after such procedures.
Purpose: To assess the effect of long-term maintenance of sinus rhythm after PVI on the LVDF and the size of the LA in patients with HTN.
Materials and Methods: The study included 108 patients aged 32-72 years (female patients - 53 (49,1%)). Median age was 59 years, interquartile range – 54-65 years. Patients were suffering from paroxysmal (n=90; 83%) and persistent (n=18; 17%) form of AF. All patients underwent PVI and were divided in two groups depending on the presence of HTN in history. Group I: patients with HTN (n=87; 80%), group II: patients without HTN (n=21; 20%). All patients had pre- and post-procedural (after 12 months) detailed echocardiographic measurements of LVDF and LA during sinus rhythm.
Results: Patients with HTN were older (p<0.001), with a higher body mass index (p<0.001). Within 12 months after surgery, 61 patients (56.5%) held sinus rhythm. In the group I before PVI, dysfunction of LVDF was detected in 47 patients (54%), after PVI - in 25 patients (28,7%) (OR 7,3; 95% CI 2,2 – 23,7; p<0,001); after PVI the following parameters characterizing LVDF were observed: increase of early diastolic velocity (E peak) (p<0,001); normalization E/A ratio (p<0,001); increase of early diastolic septal velocity (e') (p=0,009). In group II before PVI, dysfunction of LVDF was detected in 6 patients (28,6%), after PVI - in 2 patients (9,5%) (p=0,07); significant changes in the parameters characterizing LVDF were not detected. The dynamics of LA size changing was analyzed after 12 months in patients keeping sinus rhythm, with the presence and absence of HTN. It was revealed that the remodeling of LA continued in the background of sinus rhythm retention in patients with HTN in history (increase in indexed (p=0.026) and presystolic volume of LA (p=0.027)), while in patients without HTN an enlargement of LA was not recorded.
Conclusions: Diastolic heart failure occurs in more than half of hypertensive patients with AF. Patients with HTN, preserving sinus rhythm after PVI, have the chance of LVDF recovery. Enhancement of the left ventricular relaxation can be explained by early filling velocity improvement and the increase of early diastolic septal velocity. On the other hand, only in the group of patients with HTN in the history, continued remodeling of the LA was noted despite the long-term retention of sinus rhythm.

Chronic Heart Failure-Epidemiology, Prognosis, Outcome

P1594
High frequency of left ventricular recovery in a national cohort of patients with advanced heart failure

WH Teh[1]; MC Petrie[2]; AK Barton[2]; J Dalzell[2]; J Simpson[2]; RS Gardner[2]; SAS Beggs[2]
[1]Forth Valley Royal Hospital, Larbert, United Kingdom of Great Britain & Northern Ireland; *[2]Golden Jubilee National Hospital, Glasgow, United Kingdom of Great Britain & Northern Ireland*

Background Following an index presentation with heart failure and reduced ejection fraction (HFrEF), it is increasingly recognised that a subset of patients experience left ventricular (LV) recovery. However, the frequency of LV recovery (and the predictors of LV recovery) are uncertain.
Purpose To determine the rates of LV recovery in a consecutive cohort of patients assessed within a single, quaternary, national advanced HF service, and to describe the differentiating baseline characteristics and subsequent clinical trajectories of patients experiencing LV recovery.
Methods We analysed the medical records of consecutive new patients (inpatients and outpatients) referred to an advanced heart failure service unit between 01/12/2014 and 01/12/2016. This unit is the single, national cardiac transplant and left ventricular assist device centre serving a Western European nation with a population of 5.4 million people. Eligible patients were required to have HFrEF with an LVEF ≤40% at baseline and at least one further measurement of LVEF during study follow-up. All patients were followed until 31/01/2018 by electronic record linkage. LV recovery was defined as an increase in LVEF to >40% at any time during follow-up.
Results 153 patients were included. Mean age (± SD) was 47 (±11) years and 38 (25%) were female. Aetiology was ischaemic in 40 patients (26%), and non-ischaemic in the remainder. At baseline, mean LVEF (±SD) was 23% (±7); median NT-proBNP (IQR) was 1654 pg/ml (744-3253 pg/ml). 74 patients (48%) were inpatients and 52% were outpatients. LV recovery occurred in 69 patients (45%) during follow-up, with an increase in mean LVEF from 22±8% to 49±9%. LV recovery occurred within 12 months of index assessment in 76%, and within 13-24 months in 24%. Compared to patients without subsequent LV recovery, patients with LV recovery were more likely to be female (p=0.001), have non-ischaemic aetiology (p=0.001) and have a relatively shorter duration of HF (p<0.001). The incidence of all-cause mortality was significantly lower amongst patients who experienced LV recovery when compared to those without LV recovery (3% vs 14%; p=0.015) during a median follow-up period of 23 months.
Conclusion In this retrospective cohort study of young patients referred to an advanced HF service, LV recovery occurred in almost half of patients. LV recovery was more common in women, and in those with a non-ischaemic aetiology, and was associated with a lower all-cause mortality.

P1595
Significance of sST2 concentration last measurement in serial determination in patients risk stratification after acute heart failure decompensation

VN Protasov[1]; AA Skvortsov[1]; OY Narusov[1]; MD Muksinova[1]; DE Protasova[2]; VP Masenko[1]; SN Tereshchenko[1]
[1]Russian Cardiology Research and Production Complex, Moscow, Russian Federation; *[2]National Research Center for Preventive Medicine, Moscow, Russian Federation*

Background: sST2 concentrations are strong predictors for of adverse long-term prognosis in pts with ADHF.Purpose: to evaluate the significance of the last measurement of sST2 concentrations in risk stratification in patients (pts) with ADHF.Methods: In our study were included 159 pts with ADHF III-IV FC NYHA. Blood samples to determine NT-proBNP and sST2 concentrations were collected at the admission and at discharge from the hospital, and after 3, 6 and 12 months of follow-up. The primary end point was combined end point that included cardiovascular (CV) death and hospitalization due to HF.Results: During the 1-year of observation 56 (35.2%) pts reached the combined end point. 78 (49.1%) CV events were registered, of them 26 (16.4%) CVdeath, 47 (29.6%) episodes of hospitalization due to HF and 10 (6.2%) episodes of HF deterioration needed additional i/v diuretics. In high risk pts (with CV evets) sST2 and NT-proBNP concentrations at the last measurement before the CV episode were significantly higher than previous: 51.79 (41.32, 87.45) vs 34.50 (27.59, 48.40) ng/ml (%Δ = 35.65%, p = 0.02); and 3328.0 (1583.0, 5082.0) vs 2396.5 (1820.75, 4767.0) pg / ml, (% Δ = 21.0%, p = 0.01) respectively, and also compared with the low risk pts (without CV events): 30.36 (21.21, 39.98) ng / ml and 1165.75 (792.47, 1785.75), respectively, p <0.0001. In the ROC analysis sST2 and NT-proBNP concentrations had predictive significance, AUC = 0.814 (95% CI 0.736-0.893), Se 79.6%, Sp 70.8%, and AUC = 0.822 (95% CI 0.746-0.898) Se 78.2%, Sp 73.0%, respectively, p <0.0001. Pts

with sST2 concentration above the cut-off value of ≤37.8 ng / ml and NT-proBNP ≤1553.8 pg/ml in the last measurement before end point had higher risk of CV events [95CI] = 5.79 [2 , 97-11.28] and OR [95CI] = 4.81 [2.61-8.87], respectively, p <0.0001.Conclusion:Increase of sST2 concentration as the NT-proBNP value in serial determination is the strong predictor of CV events and hospitalization due to HF in pts after ADHF during long-term follow-up.

Investigation on patient knowledge about heart failure in China

R Ran Mo[1]; LITIAN Yu[1]
[1]*Fuwai Hospital- Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China*

On behalf of: emergency and critical care center, FuWai hospital

Purpose: to know about illness knowledge level of patients with heart failure(HF); to probe into factors influencing patients' illness knowledge levelso as to provide a theoretical foundation for carrying out appropriate clinical interventions. Methods: A total of 983 patients with HF from different regions in China were investigated using the knowledge scale questionnaire, which included awareness, lifestyle, drug adherence, convenience to medical treatment , economic burden and health education of HF. Results: The rates of awareness, drug adherence and disease education of HF in Chinese patients were 75.2%83.2% and 41.1% respectively. There was a significant difference in awareness rates between people with different levels of hospital classes, education, functional grading or marital status. Rural patients had lower rates of awareness, drug adherence and disease education than urban patients. Second and third level hospitals outperform first level hospitals both in drug adherence and disease education. Conclusion: In general, the cognition of HF in China is unsatisfactory, which is characterized by low rates of awareness, drug adherence, disease education and lack of self-management. Medical staff should fulfill informing obligation, in the meantime, enhance HF education by different strategies in order to improve patients' self-management. It's helpful to teach patients' relatives about HF knowledge too. As they can play a role as supervisors in reminding and changing lifestyles. It is beneficial to promote the hierarchical medical system especially the community health service institutions.

HF knowledge in different characteristic

variable	awareness rates	drug adherence		
	χ^2	P	χ^2	P

Long-term prognosis of dilated cardiomyopathy in women

AC Cannata[1]; E Fabris[1]; M Merlo[1]; J Artico[1]; P Gentile[1]; C Pio Loco[1]; A Ballaben[1]; F Ramani[1]; G Barbati[1]; GF Sinagra[1]
[1]*University of Trieste, Trieste, Italy*

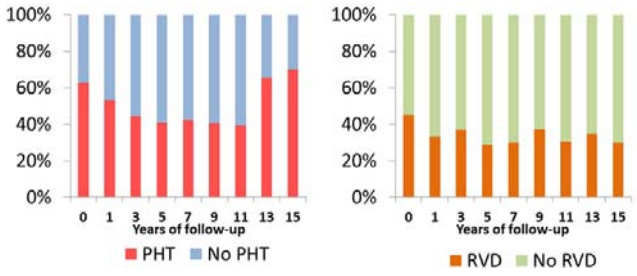
Background. Dilated Cardiomyopathy (DCM) represents a specific phenotype of heart failure (HF). The impact of gender on DCM patients is largely unknown.
Purpose. The aim of the study is to investigate the long-term prognosis in a large cohort DCM of patients.
Methods and Results. 1113 DCM patients (>90% on renin-angiotensin-aldosterone system inhibitors and beta-blockers) have been prospectively enrolled. To investigate the impact of gender, a propensity score matching analysis was performed on a sample of 586 patients. Moreover, univariable and multivariable Cox models were estimated both on the total and on the matched cohort for the following outcomes: all-cause mortality/heart transplantation (HTx)/ventricular assist device (VAD); cardiovascular mortality/HTx/VAD; sudden cardiac death (SCD) or malignant ventricular arrhythmias (MVA).Women were older than men (50±15 vs 47±15 years respectively, p=0.004) and presented more frequently moderate to severe left ventricular dilation (p<0.001) and left bundle branch block (p=0.019). Over a median follow-up of 126 months, in the matched population, 96 men (33%) vs. 66 women (22%) experienced all-cause mortality/HTx/VAD (p=0.03), 95 men (32%) vs. 57 women (20%) experienced cardiovascular mortality/HTx/VAD (p=0.025), 46 men (16%) vs. 28 women (10%) experienced SCD/MVA (p=0.07). At multivariable analyses, male gender turned out as independently associated to the three considered outcome measures in the total cohort and for cardiovascular death/HTx/VAD (hazard ratio 1.58, 95% confidence interval 1.06–2.36, p=0.025) in the matched cohort.
Conclusions. Long-term outcomes of women affected by DCM are more favourable than men and gender emerged as an important independent factor mostly for cardiovascular outcomes.

P1598

Prevalence and long-term evolution of pulmonary hypertension and right ventricular dysfunction in heart failure outpatients

E Santiago-Vacas[1]; J Josep Lupon[1]; G Gavidia-Bovadilla[2]; M De Antonio[1]; P Moliner[1]; M Domingo[1]; E Zamora[1]; F Gual-Capllonch[1]; A Teis[1]; J Santesmases[1]; J Nunez[3]; S Altimir[1]; P Martin[1]; A Ros[1]; A Bayes-Genis[1]
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*; [2]*Technological Center of Catalonia, Department of e-Health, Eurecat, Barcelona, Spain*; [3]*University Hospital Clinic of Valencia, Valencia, Spain*

Background: Heart failure (HF) patients with pulmonary hypertension (PHT) and/or right ventricular dysfunction (RVD) have a worse prognosis. How these two entities evolve in the long-term is not completely elucidated.
Purpose: 1) To assess long-term (up to 15 years) trajectories of systolic pulmonary artery pressure (SPAP) and right ventricular function based on tricuspid annular plane systolic excursion (TAPSE); 2) To describe the prevalence of PHT and RVD longitudinally through this long follow-up period; and 3) To analyse the relationship of these two later entities with mortality and number of HF admissions.
Methods: Retrospective analysis of a prospectively studied cohort of HF outpatients of different aetiologies attended in a multidisciplinary HF Unit. Prospectively scheduled echo-Doppler studies were performed at first visit (baseline), 1, 3, 5, 7, 9, 11, 13 and 15 years. PHT was defined as SPAP ≥40mmHg and RVD as TAPSE ≤16mm.
Results: Form August 2001 to July 2017, 1421 patients with SPAP (85%) and TAPSE (46%) data in the initial visit were included. Mean follow-up time was 4.6 ± 3.7 years. In survivors SPAP trajectories showedsignificant changes (p<0.001, both for the linear and for the quadratic term of time). An initial trend to decrease in the firsts years and to increase beyond 7 years observed, showing the global trajectory a clear U shape. Although trajectories of TAPSE showed statistically significant changes along follow-up (p- values also <0.001) no definite pattern was observed and changes seemed of clinically not relevant magnitude. The initial prevalence of PHT was 62.5% and of RVD 45.1%. Indeed the prevalence of PHT tended to decrease in the first 11 years and to increase later, while RVD initially decreased and remained stable thereafter (Figure). Both PHT and RVD were significantly associated with mortality at baseline: PHT (HR 1.7 [1.4-2], p<0.001), RVD (HR 1.6 [1.2-2.1]; p= 0.001). The combination of both entities (PHT + RVD) showed worse prognosis (HR 1.8 [1.3-2.3], p <0.001). When the analyses were repeated with 1 year SPAP and TAPSE values, the association with mortality was even higher: PHT (HR 2.7 [2.1-3.5]; p <0.001); RVD (HR 2 [1.3-2.8], p <0.001); PHT + RVD (HR 4.4 [2.9-6.6], p <0.001). Remarkably decedents always had higher SPAP in the immediately precedent study period. On the other hand, the presence of PHT (p=0.04) and RVD (p<0.001) at baseline were related to the number of recurrent HF admissions during follow-up.
Conclusions: SPAP showed a U shapetrajectory in the long-term follow-up in HF outpatients, while TAPSE improved mildly initially and remained stable afterwards. The presence of PHT and/or RVD was related to an increase in mortality and HF admissions.



P1599

Heart Failure in Internal Medicine and Cardiology: same entity, different patterns.

DR Perez Ramirez[1]; MF Davila Ramos[2]; DR Conde Martel[3]; DR Garcia Quintana[4]; DR Herrera Herrera[5]; DR Monereo Munoz[1]; DR Marfil Daza[5]; DR Garcia Vallejo[3]
[1]Hospital Universitario de Canarias, Internal Medicine Service, Santa Cruz de Tenerife, Spain; *[2]Hospital Nuestra Señora de Candelaria, Internal Medicine Service, Santa Cruz de Tenerife, Spain*; *[3]Hospital Universitario Dr Negrín, Internal Medicine Service, Las Palmas de Gran Canaria, Spain*; *[4]Hospital Universitario Dr Negrín, Cardiology Service, Las Palmas de Gran Canaria, Spain*; *[5]University Hospital Nuestra Señora de Candelaria, Internal Medicine Service , Santa Cruz de Tenerife, Spain*

On behalf of: Canary Registry of Heart Failure (RECANIC)

OBJECTIVE: To analyze the differences between patients hospitalized for heart failure in Internal Medicine (IM) and Cardiology (CAR) in terms of sociodemographic characteristics, comorbidity, type of heart disease, hospital stay and mortality.
MATERIAL AND METHODS: Observational and prospective study in which consecutively included patients admitted for heart failure in the IM and CAR Services from January 2017 to February 2018. Parameters recorded included demographic data, comorbidities, functional situation estimated by Barthel index, etiology of heart disease and triggers, analytical and echocardiographic parameters, treatment received and in-hospital evolution. A comparison was made between patients depending on the Admission Service (CAR or IM). The qualitative variables were analyzed by the chi-square test and the quantitative ones by t-Student test.
RESULTS: Data from 2115 patients were included, 48.7 % were females. The average age was 75.7 (range 24-103) years. Overall, 1214 (57.4%) were enrolled in IM Services. A higher percentage of women (57.3% vs. 37.1%, p <0.001) of older age (80 ± 9.3 years vs 69 ± 12.1, p <0.001) were admitted to IM compared to CAR. In general, the patients admitted to Internal Medicine presented a worse functional situation as measured by the Barthel index (75.8 vs 93.3, p <0.001). With the exception of myocardiopathy (11.2% vs 15.3%, p <0.001) and coronary disease (29.3% vs 33.5%, p = 0.08), the rest of comorbidities analyzed were significantly more prevalent in IM patients: HBP (92.8% vs 70.6%, p> 0.001), dyslipidemia, (67.1% vs 57.8, p <0.001), diabetes (57% vs 46.5%, p < 0.001), renal failure (68% vs 52%, p <0.001), anemia (56.1% vs 40.5%, p <0.001), peripheral arterial disease (11.8% vs 9.1%; p < 0.001), cerebrovascular disease (13.8% vs 10%, p <0.001), atrial fibrillation (54% vs 40.6%, p <0.001), cognitive impairment (18.6% vs 5.7%; p < 0.001) and COPD (39.1% vs 18.6%, p <0.001). In IM, heart failure with preserved ejection fraction predominated (49.2% vs 36.5%, p <0.001). In CAR, de novo heart failure was more prevalent (19.9% vs 67.1%; p <0.001). The presence of valvular heart disease was more frequent in IM (32.1% vs 27.1%, p <0.001). We did not find statistical differences in terms of average stay (15.0 days vs 15.4 days, p = 0.765) or in-hospital mortality (5.9% vs 4.6%, p = 0.16).
CONCLUSIONS: 1. In The Canary Islands , patients hospitalized for heart failure via Internal Medicine compared to entering via CAR are predominantly women, octagenarias and with preserved ejection fraction. 2.- They present greater comorbidity and worse functional deterioration. 3.- Despite this, there are no differences in terms of average hospital stay and mortality between services.

Introduction: Heart Failure (HF) is a prevalent condition that frequently leads to hospitalizations and has a negative impact on quality of life and prognosis. General public and patients' HF awareness may promote adherence to healthier lifestyle and to therapy, leading to lower HF incidence, hospitalizations and mortality.
Aim: To have an insight on general population's knowledge on HF manifestations and treatment.
Methods: in May 2018 we performed a general public survey to those attending HF Awareness Days activities in the country. This survey included epidemiological data (age, gender, living conditions, level of education), and questions on HF symptoms, comorbidities, exercise, and treatment.
Results: 732 participants answered the survey (50.3% female), age 58 ±18 y. 33% had only elementary school level of education, however 23% had a graduation. 438(59,8%) declared they were acquainted with HF symptoms. Fatigue was the most commonly recognized (66,4%) symptom, followed by dyspnea (52,4%) and peripheral edema (39,75%). However vomiting and chest pain were also symptoms participants frequently associated with HF (37,7% both). 221 (30%) of the participants were unable to recognize any of the most common listed HF signs and symptoms.
327(44,6%) believed that HF was normal at a higher age; 486 (66,4%) knew that HF can affect other organs. 153 (21%) answered that exercise should be avoided in HF.
Only 420 (57%) identified pharmacotherapy as relevant for HF treatment, followed by devices, surgery and diet (36%, 35% and 32%, respectively). For 24% of the participants none of the mentioned listed options was a valid HF treatment.
Putting these results in perspective, one can mention that in the UK´s "Cancer Awareness Measure 2017 "a prompted recognition of signs/symptoms was achieved in 75-95%.
Conclusion: Comparing to other conditions, HF is poorly known by the population. Additional to being conceived as normal at higher ages, other misconceptions are common such as exercise being detrimental and no form of treatment being valid. Education and awareness campaigns are an unmet need and can have a significant impact in the prevention and better treatment of HF. With a contribution of the Competence Network Heart Failure Germany and Comprehensive Heart Failure Center Würzburg.

Introduction and objectives: Patients with Diabetes Mellitus (DM) have an increased risk of developing acute heart failure (AHF) and it is considered a severe prognostic marker associated with mortality. We aim to review the prevalence of DM in patients with AHF in our environment and characterize AHF in diabetic patients.Method: A diabetic-non diabetic based analysis of the patients in the RECANIC registry was performed. This is an observational, prospective, multicenter, consecutive recruiting study that included patients admitted to the Cardiology and Internal Medicine wards with the primary diagnosis of AHF between JAN2017 and JAN2018.
Results: Of a total of 2200 patients included in the RECANIC study, 1154 patients (52%) were diabetics, 49,3% of them women, and mean HbA1c of 7,47±0,129%. Baseline characteristics are shown in table 1. Diabetics had a higher prevalence of HBP, dyslipidemia, IHD and PVD. Lower hemoglobin and creatinine levels and no differences in NT-proBNP levels were observed. HF with preserved ejection fraction

Basal characteristics				
	Total (N=2200)	Diabetic(n= 1154, 52%)	Non-Diabetic (n=1046, 48%)	p-value (diabetic Vs non diabetic)
Age (years)	75,97±12,0	76.178±0,59	75.74±0.83	0.389
Barthel Index	81,66	81.172	82.298	0.338
HBP / Dyslipidemia(%)	84/52	91/73	76/53	<0,001
IHD/PVD/AF (%)	31/10/49	39/14/47	22/6/50	<0,001/ <0,001/0.58
Decompensation/de Novo (%)	61/39	56/46	43/54	<0.001
FEVI:<40%, 40-50%, >50% (%), not determined (%)	27/11/43/19	24/12/44/20	29/10/42/19	p=ns
Hb g/dLCreatinine mg/dL	12.07±0.09 1.38±0.03	11.71±0.12/ 1.46±0.05	12.48±0.13 1.30±0.05	P<0,001 p<0.001
Nt-proBNP	7076±7548	6950±518.26	7250.61±569.47	P=0.44
Hospital Stay (days)	14.09	14.59	13.54	0.164
In-hospital mortality (%)	8,3	7,6	7.5	P=592

IHD: Ischemic heart disease; PVD: Peripheral vascular disease; High Blood Pressure

predominated in both groups (44,0 vs 41,9 %). Treatment in diabetic patients was: Metformine (34,7%), Insulin (32,1%), iDPP4 (13.8%), sulfonilurea (6,1%), iSGLT2 (2,6%), GLP1 (1%). No differences in average hospital stay or in in-hospital mortality rates for diabetic and non-diabetic patients. No differences in terms of HbA1c of patients exitus in-hospital vs discharged (7.62±0.61 vs 7.46±0.13, p=0.592).
Conclusion: DM is higly prevalent amonst patients with AHF (52%). Despite having DM and being more comorbid, in-hospital mortality rates did not vary in diabetic vs non-diabetic patients with AHF. The analysis of these data should serve to develop health management and planning strategies specifically tailored to patients with AHF and DM.

P1602

Predictors of mortality in patients with heart failure with mid-range ejection fraction (HFmrEF)

D Denes Vagany[1]; B Muk[1]; M Szabo[1]; K Kosa[1]; P Bogyi[1]; ZS Majoros[1]; M Dekany[1]; T Borsanyi[1]; RG Kiss[1]; N Nyolczas[1]
[1]*Medical Centre, Hungarian Defence Forces, Cardiology, Budapest, Hungary*

Background: The current ESC guideline for the diagnosis and treatment of acute and chronic heart failure (HF) introduced the terminology of HF with mid-range ejection fraction (40%≤LVEF<50%; HFmrEF) beyond HF with reduced EF (LVEF <40%; HFrEF) and HF with preserved EF (LVEF ≥50%; HFpEF). There are limited data on morbidity, mortality and prognostic factors for mortality in HFmrEF patients (pts).
Aim: The aim of our study was to investigate the predictors of all-cause mortality in a real-life HFmrEF patient cohort.
Methods: We analysed the data of 105 HFmrEF pts who had referred to our heart failure outpatient clinic (mean age: 64.2±11.7 years, male: 76.2%, NYHA: 2.7±1.0, LVEF: 42.5±2.6%). We assessed the prognostic value of age, sex, ischemic etiology, systolic blood pressure (SBP), heart rate, NYHA functional class (fc), PQ and QRS interval, LVEF, left atrial (LA) diameter, left ventricular hypertrophy (LVH), mitral regurgitation (MR), pulmonary artery systolic pressure (PASP), eGFR, hypertension and diabetes (DM). The possible prognostic factors were evaluated by univariate and multivariate Cox regression analysis. The average follow-up period was 93.4±53.0 months.
Results: During the follow-up period 55.3% of patients died (all-cause mortality at 5 years was 31.7% and at 10 years was 49.6%). With univariate Cox-regression analysis the NYHA fc, LA, PASP, MR, PQ, eGFR, DM and LVH were proved to be significant prognostic factors (p<0,05). With multivariate Cox-regression analysis NYHA fc (HR: 2.01; CI: 1.39-2.90; p<0.001), LA diameter over 57 mm (HR: 2.30; CI: 1.15-4.60; p<0.05) and LVH (HR: 2.39; CI: 1.23-4.63; p<0.05) were found significant, independent prognostic factors.
Conclusion: Based on our results, the predictors of all-cause mortality indicate a close relationship between mortality and diastolic left ventricular dysfunction as well as the clinical severity of HFmrEF patients.

P1603

Drug utilization patterns and its impact on health resource utilization and outcomes among patients with heart failure at a tertiary care hospital in southern india

On behalf of: Manipal Heart Failure Registry [MHFR]
Funding Acknowledgements: NIL

Background Drugs are the mainstay of heart failure (HF) therapy. Although several guidelines are available in this regard, optimal implementation of guideline-directed medical therapy (GDMT) still remains a challenge.
Purpose Assessment of drug prescription patterns and its effect on clinical outcomes among patients with heart failure enrolled in Manipal Heart Failure Registry (MHFR).
Methods MHFR is a prospective, observational cohort of patients with heart failure in a tertiary health centre in southern India. From this registry, we analysed drug utilization patterns over a period of one year from index admission. Clinical outcome was a composite of unscheduled visits, rehospitalization to intensive care unit or emergency wards, and all-cause mortality rate.
Results A total of 1354 patients with a mean age of 65 ± 13.6 years were enrolled in MHFR from September 2015 to September 2017. Average duration of index hospitalization was 5.3 days and 40.2% were females. Heart failure with reduced ejection fraction (<40%) was seen in 51.1% of patients. Ischemic heart disease was the most common underlying cause (38.9%).
Patients received disease-modifying drugs like beta-blockers (BBs), angiotensin converting enzyme inhibitors (ACEIs) or angiotensin receptor blockers (ARBs) and aldosterone receptor antagonists (ARAs) at rates of 43.6%, 49.3%, and 34.3% respectively. Isosorbide dinitrate/hydralazine, diuretics, and ivabradine were prescribed at rates of 54.3%, 74.2%, and 40.0% respectively. Dual therapy (BB and ACE or ARB) was used in 36.7 % and triple therapy (BB, ACE or ARB and ARA) in 31.2%.
Unscheduled visits and re-hospitalization rates were 34.8% and 11.2% respectively. Most of the rehospitalizations were to the emergency room (54%) followed by ICU (85%). All-cause mortality during index hospitalization and at one-year mortality was 8.8% and 16.5% respectively. The composite clinical outcome occurred in 32.1%. Patients who received monotherapy (BB or ACEI/ARB or ARA) had a better outcome compared to those who did not (p=0.021). Dual and triple therapy was associated with better outcomes compared to monotherapy (p=0.002).
Conclusion: GDMT improves outcomes in patients with HF but is underutilized in patients with HF. Steps to improve use of GDMT need to address the factors associated with underutilization.

P1604

HFpEF, HFmEF and HFrEF : clinical characteristics and prognosis: a retrospective cohort (cross sectional) study in a population from Colombia

C Gallego[1]; CI Saldarriaga[1]; LA Fajardo[1]; C Lema[1]; A Agudelo[1]
[1]*Cardiovascular Clinic Santa Maria, Medellin, Colombia*

Heart failure is a growing epidemic in the world, specially in developing countries like Colombia were there is a high burden of cardiovascular risk factors. There is huge need to generate data about this disease in our country in order to establish more effective health care policies.
Objective: The aim of this study is to identify the clinical characteristics and prognosis of patients with HFrEF , HFmEF and HFpEF in a population of patients that had been followed in a disease management heart failure program.
Methods: A retrospective cohort cross sectional study was performed.
Results: 1011 patients were included, 89.9% had HFrEF, 8.7% HFmEF and 1.3% HFpEF. The differences in clinical characteristics and prognosis are presented in table 1.
CONCLUSION: In this population of heart failure patients from Colombia, Patients with HFrEF and HFmREF were younger males, with more ischemic heart disease and presented more cardiovascular deaths. Patients with HFpEF were elderly women with less ischemic heart disease and presented more non cardiovascular deaths.

Clinical Characteristics and prognosis

	HFrEF	HFmEF	HFpEF
Age *	66.9 ±16.2	78.7 ±19.6	75.9 ±13.6
Male	65.7%	57.7%	35.7%
Female	34.3%	42.3%	64.3%
Ischemic heart disease	44.1%	39.8%	28.6%
Ejection fraction*	23.6%±8.7%	45.7 ±1.6%	55.2 ±5.0%.
Death	8.7%	9.1%	7.5%
Cardiovascular death	79.0%	85.7%	0.0
Non cardiovascular death	21.0%	14.3%	100.0%

Long-term survival in contemporary patients with dilated cardiomyopathy

K Kaspar Broch[1]; A Knutsen[2]; EC Sekne[2]; K Murbraech[3]; AK Andreassen[3]; S Aakhus[4]; L Gullestad[2]
[1]*University of Oslo, Rikshospitalet University Hospital, Department of Cardiology, Oslo, Norway*; [2]*University of Oslo, Faculty of medicine, Oslo, Norway*; [3]*Oslo University Hospital, Rikshospitalet, Department of cardiology, Oslo, Norway*; [4]*Norwegian University of Science and Technology, Trondheim, Norway*

Funding Acknowledgements: No grants were received for this work

Purpose: Historically, the prognosis in patients with dilated cardiomyopathy has been poor. Outcomes have improved substantially over the last decades due to advances in medical therapy and the development of implantable devices for the

treatment of heart failure. We report long-term survival data from a prospective cohort of contemporary patients with dilated cardiomyopathy.
Methods: Between October, 2008 and December, 2012, we recruited 102 patients referred to our tertiary care hospital with a left ventricular ejection fraction (LVEF) < 40 % and a diagnosis of idiopathic DCM based on patient history, echocardiography and coronary angiography. We performed an extensive baseline evaluation, and the patients were included in a prospective cohort study. During follow-up, vital status, device implantation and heart transplantations were recorded.
Results: Baseline characteristics are provided in the Table. After a median follow-up of 7.8 (IQR 6.3 – 9.0) years, 12 patients had received cardiac allografts. One of these patients later died from acute allograft rejection. In addition, 15 patients died. Transplant-free survival was 74 %, and over-all survival was 84 % (Figure). At follow-up after 7.8 years, the average LVEF in the long-term, transplant-free survivors was 41 ± 10 %. Baseline age and left ventricular size and ejection fraction did not differ between survivors and non-survivors. The longer the duration of symptomatic heart failure prior to inclusion, the higher the risk of heart transplantation or death (Cox regression p < 0.001), suggesting that late initiation of therapy or a lack of response to therapy for heart failure predicts a poor outcome.
Conclusion: In contemporary patients with dilated cardiomyopathy, survival is better than previously reported.

Baseline characteristics	
Age - years	51 ± 14
Male gender - no (%)	74 (73)
Duration of symptoms - months	7 (3 - 16)
NYHA class prior to inclusion - no I/II/III/IV	4/15/25/58
Systolic blood pressure - mm Hg	116 ± 20
Left ventricular ejection fraction - %	26 ± 10
Peak oxygen consumption - ml/kg/min	19.7 ± 7
N-terminal pro-B-type natriuretic peptide - pg/ml	1332 (584 - 2903)
Pulmonary capillary wedge pressure - mmHg	15 ± 8

The association of serum HbA1c level with heart failure severity in systolic heart failure patients with diabetes mellitus

MONIBA Bijari[1]; FARVEH Vakilian[2]; HODA Naseri[3]
[1]Mashhad University of Medical Sciences, Student Research Committee, Mashhad, Iran (Islamic Republic of); *[2]Cardiovascular Research Center, Mashhad, Iran (Islamic Republic of)*; *[3]Islamic Azad University, Mashhad, Iran (Islamic Republic of)*

Funding Acknowledgements: Mashhad University of Medical Sciences (MUMS)

Introduction Heart failure, a major public health problem, causes poor quality of life and increases hospitalization rate. The role of diabetes mellitus (DM) in both development and progression of heart failure has been well documented. However, the evidence for a benefit of HbA1c measurement in the severity of heart failure is understudied.
Purpose: In this study, we sought to determine the relationship between serum HbA1c level and severity of heart failure in diabetic patients with systolic heart failure.
Methods This cross-sectional study was performed on 203 patients with heart failure and DM. Demographic data, clinical symptoms and NYHA class were obtained using a questionnaire. Serum HbA1c level was measured and Echocardiography was performed for all the participants to record ejection fraction (EF).
Results: The mean age of the population was 62.33 ± 9.73 years and 55.7% of patients were men. The mean duration of diabetes and heart failure was 9.54 ± 9.25 and 7.82 ± 6.43 years, respectively. The patients had a mean EF of 30.15 ± 7.58 and a mean HbA1c level of 8.40 ± 1.93.
The HbA1c level was not associated with EF among all the participants and within subgroups based on age, sex, duration of heart failure, heart failure etiology, number and etiology of hospitalization; However, when patients were subdivided based on NYHA class, there was a significant association between HbA1c and EF in patients with NYHA class ≥ 2 ($p<0.05$) with the highest HbA1c level in patients with NYHA class 4 and EF<25%.
In patients with the duration of DM more than 10 years, HbA1c level was significantly associated with EF, with the maximum level among patients with EF<25% and the minimum level among patients with EF>35% ($p=0.002$). Moreover, HbA1c levels were higher in patients with EF 25-30% who did not have a history of insulin therapy ($p<0.05$).
Conclusion(s): In diabetic patients with more severe symptoms of heart failure there was an inverse association between HbA1c and severity of heart failure. In long standing DM, poor blood glucose control, as measured by HbA1c, is associated with severity of heart failure. Therefore, it is necessary to perform preventive measures in patients with heart failure and DM.

Funding Acknowledgements: Dutch Heart Foundation and ZonMw.

Background: There is limited data on referral patterns for heart failure (HF) despite increasing incidence of HF with preserved ejection fraction (HFpEF) in the population, mainly affecting women, and important developments in multidisciplinary HF care.
Purpose: To obtain an impression of referral patterns for HF and it's subtypes based on shifts in prevalence rates in three pre-hospital domains: high-risk community patients, routine primary care, and outpatient cardiology clinics.
Methods: Age and sex-specific prevalences of HF subtypes (with reduced ejection fraction (HFrEF) and HFpEF) were retrieved from studies in the three pre-clinical domains conducted in the Netherlands. Due to availability of information, we restricted our analyses to people aged 65 to 79 years.
Results: In community patients, 55% of 223 HF patients between 65 and 79 years detected by screening in a high risk older population were women. HFpEF was present in 70% of men and in 88% of women. In primary care, 43% of 167 confirmed HF cases between 65 and 79 years were women. HFpEF was present in 41% of men and in 55% of women. In outpatient cardiology clinics, 36% of 4742 HF patients between 65 and 79 years were women. HFpEF was present in 15% of men and in 28% of women.
Conclusion: The current study shows that prevalence of HF among men and women vary largely across the pre-hospital domains. Especially women are underdiagnosed with HF, particularly HFpEF at older age. From the changes in prevalence pattern from screening to diagnosis it becomes clear that women with HF are less likely to be referred to the cardiologist, notably those with HFpEF, as compared to men.

As known majority of patients with Heart Failure (HF) are admitted to internal medicine (M) units instead to cardiology units (C),but few studies have investigated the specific characteristics of these two populations.

The aim of our study was to compare the main characteristics of patients with HF at their admission in six M units vs. one C unit. Criteria inclusion were: I) symptoms/signs of HF, II) NTproBNP value>600 ng/L in hospital, III) i.v. diuretics and/or nitrates and/or inotropic therapy.

From April to July 2018 we enrolled 257 patients (M 202,C 55).M patients were older and more frequently female. The leading cause of admission in both groups was acute worsening of HF,most of patients had a known HF.Left ventricular ejection fraction (EF) available at admission was 96% in C, only 56% in M (25% unknown at discharge).

We obtained a "picture" in which M patients were frequently managed "blindly" .In this evolving epidemiological framework,M physicians could be more involved in diagnostic/therapeutic strategies developing.

Therapy at hospital admission

	Cardiology	Internal Medicine	p value
Oxygen therapy	25	57	< 0,001

Prognosis and completion of the advance directive survey among patients with chronic heart failure

MS Mi-Seung Shin[1]; J Kim[2]; SY Suh[1]; S Heo[3]

[1]Gachon University Gil Medical Center, Incheon, Korea (Republic of); *[2]Gachon University, College of Nursing, Incheon, Korea (Republic of)*; *[3]University of Arkansas for Medical Sciences, College of Nursing, Little Rock, United States of America*

Background: Early discussion with advance directive (AD) documentation is one approach to improve quality of heart failure (HF) management and reduce socioeconomic burden. However, ADs have been underutilized among patients with HF.
Purpose: To explore an advance directive (AD) of patients with HF and examine the association of the completion of an AD survey with HF prognosis.
Methods and Materials: In a descriptive, correlational study, data on the Korean-Advance Directive (K-AD) survey (values, treatment directives, and proxy) and HF prognosis were collected during the outpatient visit.
Results: Of 67 patients (age, 67 years; male, 61.2%), 52.2% provided all or part of the K-AD. "Comfortable death" was highly valued (n = 15), followed by avoiding family burden (n = 6). Preferences for hospice care, cardiopulmonary resuscitation, ventilation support, and hemodialysis were 68.6%, 42.9%, 28.6%, and 28.6%, respectively. Children (n = 12) and spouse (n = 10) were the most common proxies. Older age (odds ratio [OR] = 1.23) and more functional limitation (NYHA class III) (OR = 137.37) were associated with more likelihood of poor HF prognosis (SHFM score $\geq$ 1), while K-AD completion (OR = 0.06) was associated with better prognosis (SHFM score $\leq$ 0), after controlling for covariates. Conclusion: Independent of older age and worse functional limitation, K-AD completers had better HF prognosis, implying ADs be more likely acceptable in better prognostic state. Future research should investigate whether early prognostic discussion as part of the advance care planning with integration into the standard care of HF facilitates the documentation of ADs.

P1611

The role of NT-proBNP, MPO, HS troponin, sST2 in predicting systolic heart failure

LV Prokopova[1]; MYU Sitnikova[1]

[1]Almazov National Medical Research Centre, Department for Heart Failure, Saint Petersburg, Russian Federation

Prediction of systolic heart failure is necessary for the timely provision of high-tech medical care.
Objective: To evaluate the contribution of NT-proBNP, MPO, HS troponin, sST2 to one-year prediction of heart failure and compare their significance with other indicators.
Materials and methods: A prospective study of 212 II-IVF patients with "non-valvular etiology" of HF with an LV ejection fraction (Simpson) $\leq$ 35% at the age of 18-70 years. Of these, 176 men (83%) and 36 women (17%). Design work: hospitalization of patients in the treatment of heart failure; selection of therapy and stabilization of patients; assessment of status, performance of laboratory and instrumental studies; observation, telephone contacts, correction of therapy and hospitalization during decompensation; filling the database of 200 indicators. After 12 months, the endpoints were recorded.
Results: Within 12 months, 64% of patients (135 people) survived, 2% (5 people) had an implant system EXCOR, 10% (21 people) had cardiac transplantation, 24% of cases (51 people) were lethal. The end points reached 77 people. High prognostic MPO (p = 0.008), sST2 (p = 0.018), NT-proBNP (p <0.001) were significant.

The prognostic significance of the serum level of HS troponin in serum was not confirmed. (p = 0.338). With the traditional "gold standard" VO2 peak closest correlations were traced with NT-proBNP (r = | −0.44 |), sST2 (r = | −0.56 |), and% RDW (r = | −0.44 |); moderate correlation - with heart rate, urea and creatinine concentration, high troponin content, VE / VCO2, blood pressure level, relative lymphocyte content.
Conclusions: 1. NT-proBNP, myeloperoxidase, sST2.2 have high prognostic significance. With stabilized heart failure. 2. HS troponin in the blood has no prognostic value.

P1612
Do women with heart failure get the best treatment possible?

D Kosuta[1]; T Furlan[1]; K Vrbinc Vrtek[1]; B Leskovar[1]
[1]Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia

Introduction: Heart failure is a global pandemic with an increasing incidence and a great impact on the quality of patients life as well as public health. To improve treatment results it is mandatory to give patients optimal medical treatment with the use of disease modifying drugs and comorbidities management. There is a growing number of evidence about gender specific differences in heart diseases in general and heart failure in particular, with women being often times underdiagnosed and undertreated.
Purpose: We therefore aimed to investigate gender specific differences in our heart failure patients population.
Methods We retrospectively reviewed consecutive patients at the heart failure outpatient clinic at our Hospital from January 2017 to December 2018. We included all patients that had at least two consultations and excluded patients with lacking data. We performed a comparison analysis with student's t-test for normally distributed variables and chi-squared test for percentages using Microsoft Office Excel 2010 and SPSS Statistics v. 22.
Results: We enrolled a total of 215 patients, mean age was 76.5 ± 10.8 years; 84 (39.1%) had heart failure with reduced ejection fraction – HFrEF, 35 (16.3%) had heart failure with mid-range ejection fraction – HFmrEF, 96 (44.7%), had heart failure with preserved ejection fraction – HFpEF; 109 (50.7%) were women. Women were older (79.8 ± 9.3 vs 73.1 ± 11.1 years, p <0.001), had a lower BMI (28.9 ± 5.9 vs 30.5 ± 5.8 kg/m^2, p 0.027) and a lower median troponin level (23 (interquartile range 23) vs 30 (interquartile range 29) ng/L, p 0.004). They were more present in the HFpEF group (64.6%, p <0.001), had less comorbidities (p 0.010) and a lower prevalence of ischemic heart disease (24 (22.0%) vs 59 (55.7%), p <0.001). Women were less likely to receive optimal medical treatment with a lower percentage of disease modifying antihypertensive drugs (angiotensin-converting-enzyme inhibitors / angiotensin II receptor blockers / angiotensin receptor-neprilysin inhibitor) used in this group (88 (80.7%) vs 96 (90.6%), p 0.040), while there were no differences in the percentage of other heart failure medications.
Conclusion Our study show gender specific differences between women and men that are expected due to the different course of the disease and etiologic pathologies in those groups. According to our results women get less than optimal medical treatment compared to men. However since the prognosis of heart failure is similar in women and men, it is mandatory to improve and optimize the treatment for all patients regardless of their gender.

Introduction: Severe valvulopathy as aortic stenosis (AS) and mitral insufficiency (MI) usually worsen the prognosis of patients affected by Heart failure (HF), with higher rehospitalization and mortality rates. New transcatheter approaches have been introduced for patients with a very high surgical risk. To better classify HF patients in term of prognosis, we recently proposed the HLM staging system, analogous to TNM used in Oncology, which evaluates heart damage (H), lung involvement (L) and malfunction (M) of peripheral organs (JACC 2014;20;63(19):1959-60).
Purpose: The aim of this study is to compare HLM and NHYA classification in order to assess the most accurate prognosis of HF patients candidates for transcatheter valve implantation/repair in term of rehospitalization for major cardiovascular and cerebrovascular events (MACCE) and cardiovascular mortality.
Methods: We enrolled patients suffering from HF due to severe AS or MI candidates to transcatheter valve intervention according to guidelines. Each patient was classified according to NYHA and HLM, at the entrance and at the discharge. Clinical follow-up was performed at 6 and 12 months to verify re-hospitalization for MACCE and cardiovascular mortality.
Results: 152 patients with HF and severe valvulopathy were enrolled (50% male, mean age 79.6 ± 9.3 years). The percentage related to severe aortic stenosis were: 72,37%, severe mitral regurgitation: 27,63%. At 6 months of follow-up after transcatheter valve implantation/repair, the HLM showed a greater area under the ROC curve (AUC) than NYHA, in terms of rehospitalization (HLM = 0.799 vs NYHA = 0.518) and mortality (HLM = 0.808 vs NYHA = 0.522); similar results were observed at 12 months of follow-up, for rehospitalization (AUC for HLM = 0.846 vs NYHA = 0.509) and mortality (AUC for HLM = 0.866 vs NYHA = 0.517).
Conclusions: According to our preliminary results, HLM classification has a greater prognostic power compared to NYHA in terms of re-hospitalization and cardiovascular mortality in patients with HF undergone transcatheter valve intervention. HLM provides a more comprehensive assessment of cardiac, pulmonary and peripheral organs involvement, rather than only cardio-pulmonary symptoms evaluation. HLM might be extremely useful in patients with HF and severe valvopathy in order to better identify the right patient at the right moment to undergo intervention.

P1615
Profile of diabetic heart failure in a latin-american country. A national registry in Colombia

L E Luis Eduardo Echeverria[1]; CI Saldarriaga[2]; JE Gomez[3]
[1]Foundation Cardiovascular of Colombia, Heart failure and cardiac transplant, Floridablanca, Colombia; *[2]CardioVID, Heart Failure, medellin, Colombia*; *[3]Fundacion Valle del Lili, Heart Failure, Cali, Colombia*

On behalf of: RECOLFACA Investigators
Funding Acknowledgements: Novartis

Background: Heart failure (HF) and Diabetes mellitus (DM) are complex entities characterized by high morbi-mortality. Epidemiological and prospective studies have observed high frequency of co-existence among both conditions. Therefore, the aim of this study was to determine of prevalence of DM in patients with HF in the Colombian Registry and to characterize sociodemographically and clinically this population according to DM.
Methods: This a cross-sectional analysis of HF in the Colombian Registry. Continuous variables are expressed as mean (standard deviation) and categorical variables such as absolute values and proportions. T-student and Chi-square or Fisher test were used to identify differences between groups (HFDM vs. HF non-DM).
Results: A total 2087 patients were included from 2016 to 2018. Prevalence of DM was 29.18% (CI95%: 27.24% to 31.18%). Diabetic patients were older than non-DM (mean age 69.4±11.1 vs. 66.8±14.3 years; p=0.000); there was also a greater proportion of men diabetics than women (62.56% vs. 37.44%; p=0.003). Statistically significant difference was not found in the NYHA functional class between DM vs. non-DM: I: 12.42% vs. 11.00%, II: 54.80% vs. 53.04%, III: 28.15% vs. 31.24%, IV: 4.64% vs. 4.72%; p=0.500), but diabetic patients had a higher proportion of HFrEF and a lower HFpEF than non-DM (72.29% vs. 70.25% HFrEF; 19.18% vs. 16.79% HFmEF and 8.53% vs. 12.97% HFpEF; p=0.015). There was not difference in number of hospitalizations secondary to HF in the last year (p=0.879), however 73.15% DM vs. 72.73% non-DM patients was at least one hospitalization in the last year, with a mean length of stay of 11.4±12.8 days. Percentage of use of medications was similar in both groups: ACE inhibitors: 33.6% vs. 34.3%, p=0.753; ARB 43.02% vs. 41.27%: p=0.576; diuretics: 66.83% vs. 67.93%: p=0.505; MRA: 54.84% vs. 56.16%: p=0.412%; ARNI: 10.84% vs. 8.86: p=0.193. Except for beta blockers: 91.30% vs. 85.45%: p=0.001.
Conclusions: Diabetes is a common comorbidity in our population, this patients tend to be older, male and with HFrEF. Diabetic and non diabetic patients had a similar rate of hospitalizations due to heart failure but were less treated with beta-blockers.

P1616
Left ventricular functional recovery and prognosis in chronic heart failure

S Tavares[1]; A Monteiro[1]; J Pereira[1]; C Gomes[1]; I Albuquerque[1]; V Guiomar[1]; I Ferreira[1]; V Chaves[1]; P Lourenco[1]; P Bettencourt[2]
[1]Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal; *[2]Faculty of Medicine University of Porto, ;Internal Medicine Department,Hospital da CUF; Internal Medicine Department,Centro Hospitalar S.João, Porto, Portugal*

BACKGROUND: The prognostic impact of left ventricular functional recovery is still unclear. We aimed to study the prognostic impact of total and partial functional recovery in a cohort of chronic ambulatory heart failure (HF) patients.
METHODS: We analysed patients followed in our HF clinic from 2002 to 2015 who had 2 echocardiograms performed during the follow-up period. A total of 334 patients with initial left ventricular systolic dysfunction (left ventricular ejection fraction (LVEF) <50%) and an echocardiographic re-evaluation were included. Partial recovery was considered when patients presented ejection fraction recovery without attaining ejection fraction of at least 50% and total recovery was considered when patients reached a normal ejection fraction (LVEF ≥ 50%). Patients were

followed for a median follow up of 69 months from the first echocardiogram. A multivariate Cox-regression analysis was used to determine the independent association of total and partial recovery with survival benefit. Adjustments were made taking into consideration age, ischemic aetiology, severe dysfunction upon admission to the HF clinic, B- type natriuretic peptide, evidence-based therapy and surgical or percutaneous intervention between echocardiograms. Kaplan-Meier curves according to functional recovery are shown.

RESULTS: Mean patients' age was 66 years and 72.5% were male. HF was ischemic in almost 40% of the patients and 69.8% had severe systolic dysfunction upon admission. More than 95% of the patients were on beta-blockers and angiotensin converting enzyme inhibitors or angiotensin receptor antagonists and 54% of the patients were on mineralocorticoid receptor antagonists. During a median 34 months period between echocardiograms 111 patients (33.2%) showed total recovery, 58 (17.4%) partial recovery and 165 (49.4%) showed no recovery. During follow-up, 156 patients (46.7%) died. Patients with total recovery had a multivariate adjusted 52 (95% CI: 27-68) % lower risk of dying during follow-up when compared to non-recovered patients. Patients with partial functional recovery showed a non-significant multivariate adjusted mortality reduction of 12% when compared with non-recovered.Figure 1 shows the survival curves according to functional recovery.

CONCLUSIONS: Non-recovered and only partially recovered HF patients have approximately 2-fold higher all-cause mortality in long term follow-up when compared with those with full recovered left ventricular function. Mortality benefit of fully recovered was independent of age, ischemia, BNP and evidence based-therapy. Recovery should be a goal when treating HF patients.

Use of loop diuretics identifies patients with a poor prognosis regardless of a diagnostic label of heart failure

J Jocelyn Friday[1]; R Papworth[1]; S Kean[1]; P Pellicori[1]; D Mcallister[2]; S Barry[2]; P Jhund[2]; C Murphy[3]; K Hogg[3]; M Petrie[2]; P Forsyth[3]; N Lang[2]; JV Mcmurray[2]; M Wolters[4]; JGF Cleland[1]

[1]University of Glasgow, Robertson Centre for Biostatistics , Glasgow, United Kingdom of Great Britain & Northern Ireland; *[2]University of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland*; *[3]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom of Great Britain & Northern Ireland*; *[4]University of Edinburgh, Edinburgh, United Kingdom of Great Britain & Northern Ireland*

Background: Lack of a robust, practical definition of heart failure not only creates diagnostic uncertainty but limits the utility of epidemiological estimates of incidence, prevalence and prognosis on which health-care planning (both diagnosis and management) depends. Moreover, because of these uncertainties, heart failure research often focuses on patients in whom there is a high degree of certainty about the diagnosis, which may be a small fraction of the total disease-burden. One important feature of heart failure is congestion and one class of pharmacological agents is used almost exclusively (at least in the UK) for the treatment of congestion, namely loop diuretics.

Purpose We sought to describe the prevalence and three-year mortality of patients with a diagnosis of failure and/or prescribed loop diuretic therapy in a substantial regional population.

Methods The Greater Glasgow & Clyde Health Board provides healthcare for approximately one million people. We obtained and linked records for primary and secondary health-care, prescriptions and deaths between 2010 and 2017.

Results An initial search of all patients alive on January 1st 2010 identified approximately 360,000 who had a current or prior history of cardiovascular disease (including heart failure) or who had been prescribed angiotensin converting enzyme inhibitors, angiotensin receptor blockers, beta-blockers, mineralocorticoid receptor antagonists or loop diuretics between 2010-17. Within this population, 34,440 patients (55% women) with a record of heart failure were identified of whom 22,240 (57%) were treated with loop diuretics at some time during the study period. A further 41,442 patients (67% women) received repeat prescriptions of loop diuretics (or died within 90 days of first prescription) but never received a diagnosis of heart failure. Three-year mortality for patients with a diagnosis of heart failure and prescribed loop diuretics was 31%, for those with a diagnosis of heart failure but not prescribed a diuretic, it was 29% and for patients prescribed a loop diuretic but without a diagnosis of heart failure, it was 25%.

Conclusion Many more patients receive a prescription for loop diuretics than are diagnosed with heart failure. However, the prognosis of patients prescribed a loop diuretic is similar whether or not they receive a diagnosis of heart failure. In absolute terms, a similar number of deaths occur in those treated with loop diuretics with and without an associated diagnosis of heart failure.

P1618

Impact of geriatric nutritional risk index on mortality in patients with heart failure with preserved ejection fraction compared with HFmrEF and HFrEF

S Mori[1]; T Morinaga[1]; S Ito[1]; M Yano[1]; A Isotani[1]; K Ando[1]

[1]Kokura Memorial Hospital , Cardiology, Kitakyushu, Japan

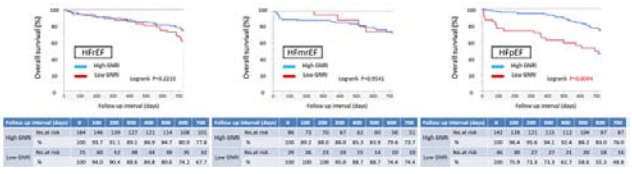
Background: It has been shown that malnutrition is a risk factor for the development of heart failure and risk factors for the occurrence of an event after the onset of heart failure. However, it is not clear that malnutrition can strongly influence which heart failure subset of 'heart failure with reduced ejection fraction (HFrEF)', 'heart failure with mid-range ejection fraction (HFmrEF)' and 'heart failure with preserved ejection fraction (HFpEF)'.

Purpose: Geriatric Nutritional Risk Index (GNRI) is a simple nutritional assessment tool for elderly subjects. We investigated the effect of GNRI on prognosis in HFrEF, HFmrEF, and HFpEF.

Methods: This study was a single center study. We retrospectively analyzed 538 patients hospitalized for heart failure at our Hospital in 2015. Among these patients, there were 235 patients (43.7%) with HFrEF, 115 patients (21.4%) with HFmrEF, and 188 patients (34.9%) with HFpEF. GNRI on admission was calculated as follows: 14.89 × serum albumin (g/dl) + 41.7 × body mass index/22. In each of HFrEF, HFmrEF, HFpEF, mortality of the low GNRI group (<92 : with moderate or severe nutritional risk) and the high GNRI group (≥92 : with no or low nutritional risk) were compared by the Kaplan Meier method and the log-rank test.

Results: At 2 years, there was no significant difference in the survival rate between the low GNRI group and the high GNRI group in the HFrEF (P=0.2215) and HFmrEF (P=0.9541), but in the HFpEF, the survival rate was remarkably low in the low GNRI group (P=0.0044).

Conclusion: GNRI may be more useful for predicting HFpEF prognosis rather than HFrEF.



GNRI:HFpEF/HFmrEF/HFrEF(Kaplan Meier)

Prognostic significance of left ventricular function alteration after acute myocardial infarction

SK Lee[1]; EJ Kim[2]; KH Ryu[1]
[1]*Hallym University, Cardiovascular center , Dongtan, Korea (Republic of)*; [2]*Korea University Guro Hospital, Cardiovascular Center, Korea University Guro Hospital, Seoul, Korea (Republic of)*

Background: The long-term clinical outcomes after acute myocardial infarction (AMI) according to baseline left ventricular ejection fraction (LVEF) is lacking, especially in large population. Also, little is known about the prognosis of LVEF alteration after AMI event in such patients.
Objective: We evaluated the prognostic impact of baseline left ventricular function on 3-year composite clinical outcomes after AMI. In addition, we compared baseline and 12 months LVEF after AMI to investigate the effect of LVEF change (recovered, deteriorated, and unchanged) on clinical outcomes.
Method: We analyzed the data from Korea Acute Myocardial Infarction Registry (KAMIR) between 2011 to 2015. A total of 11,782 AMI patients were grouped into preserved EF (LVEF ≥50%), mid-range (40 ≤ EF < 50%), and reduced EF (EF < 40%) at baseline and 12 months after AMI.
Result: Compared to patients with preserved and mid-range LV function, those with reduced LVEF at baseline had higher 3-year cumulative rates of major adverse cardiovascular events (MACE) (6.8 vs. 8.1 vs. 12.1%, p<0.0001), cardiac death (1.6 vs. 3.3 vs. 11.1%, p<0.0001), non-cardiac death (1.3 vs. 2.1 vs. 4.0%, p<0.0001), and re-hospitalization (1.6 vs. 2.3 vs. 5.5%, p<0.0001), differences which persisted after adjustment for baseline characteristics. However, there was no significant difference in the 3-year cerebrovascular event between the groups (0.9 vs. 0.9 vs. 1.1%, p=0.29). Intriguingly, patients who had shown deteriorated LVEF at 12 months showed poor clinical outcomes as compared to patients whose LVEF recovered or unchanged (MACE; 27.6 vs 10.9 vs 12.7%, p<0.0001).
Conclusion: Among patients with reduced LVEF (< 40%) at baseline after AMI, adverse events including MACE, cardiac death, non-cardiac death, and re-hospitalization were markedly increased. In patients whose follow-up LVEF deteriorated at 12 months after AMI had worse 3-year clinical outcomes.

P1620

Influence of gender on clinical results and predictor of long-term mortality after transcatheter aortic valve replacement

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; JM Garcia-Pinilla[1]; L Morcillo-Hidalgo[1]; JH Alonso-Briales[1]; AJ Dominguez-Franco[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; JJ Gomez-Doblas[1]
[1]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

Although it is well known, the differences between both sexes in cardiovascular disease, however, there is a lack of data in aortic valve, treated with Transcatheter Aortic Valve Replacement (TAVR). The purpose of our study was to analyze the long-term clinical results of patients treated with TAVR in the female and male population.
Material: Between April 2008 and December 2017, 647 patients with aortic stenosis and 20 patients with aortic prosthesis dysfunction, were treated with TAVR consecutively in our center. The primary objective was to analyze, by Cox regression, the predictors of long-term mortality in both sexes.
Results: 59.1% were women. Males had a higher number of comorbidities and after a mean follow-up of 2.87 ± 2.2 years (range between 0 and 9 years), mortality was higher for male patients 40.7% vs. 32% (HR = 1.447 [95% CI 1.057-2.009], p = 0.022) and there were no differences for the presence of threatening bleeding (HR = 1.654 [IC95% 0.719-3.808], p = 0.237), myocardial infarction (HR = 1,768 [IC95% 0.753-4.132], p = 0.191), stroke (HR = 0.992 [IC95% 0.564-1.743], p = 0.976) and hospitalizations for heart failure (HR = 1.388 [IC95% 0.811-2.376], p = 0.231). Among the predictors of long-term mortality, common to both sexes were: threatening bleeding, heart failure, Charlson index, Karnofsky, and STS score.

Conclusion: In our series, there was clinical differences between both sexes, which has an impact on survival, being worse for men due to comorbidities, however, in the population of patients with aortic stenosis treated with TAVI, we found predictors of late mortality similarities between in female and male.

P1621

Stress-induced growing prevalence of secondary aldosteronism among patients with coronary artery disease and chronic heart failure

VV Venzheha[1]; PO Shevelok[2]; AN Shevelok[3]; NT Vatutin[3]
[1]*M. Gorky Donetsk national medical University, Donetsk, Ukraine*; [2]*Donetsk district hospital #7, Donetsk, Ukraine*; [3]*M. Gorky Donetsk national medical University, V. K. Gusak Institute of urgent and recovery surgery, Donetsk, Ukraine*

Background/Introduction: Numerous studies have shown that aldosterone plasma level is an independent predictor of cardiovascular complications in patients with coronary artery disease (CAD) and chronic heart failure (CHF). It is well known that chronic stress unfavorably affects hormonal secretion and can lead to increase in cortisol one, but its effect on aldosterone level remain unclear.
Purpose: We evaluated the impact of chronic stress on the prevalence of hyperaldosteronism among CHF patients and assessed the relationship between aldosterone plasma level and the risk of major cardiovascular complications.
Methods: The study included 286 patients with stable CAD and CHF undergoing inpatient treatment in cardiology department at V. K. Gusak Institute of emergency and reconstructive surgery the from January 1, 2015 to December 31, 2017, in the period of military conflict in war-zone of Donbass region. Clinical characteristics and plasma aldosterone level of this group were compared with those of 218 CHF patients comparable for age and gender treated in the same hospital in previous peacetime 2012-2013 years. The primary endpoint consists of major cardiovascular events during 12 month after discharge.
Results: High plasma aldosterone level (>160 pg/ml) was found in 27.6 % of wartime patients and 15.6 % of peacetime patients (odds ratio (OR) = 2.1; 95% confidence interval (CI) 1.3 to 3.2). Primary aldosteronism was diagnosed in 2.6 % and 0.9 % of wartime and peacetime patients, respectively (OR = 2.7; 95% CI 0.6 to 13.2). The occurrence of major cardiovascular events (non-fatal myocardial infarction, percutaneous coronary intervention, stroke, new-onset or recurrence of atrial fibrillation, acute heart failure) during 12-months follow-up period was significantly higher during wartime compared to peacetime (OR = 2.6; 95% CI 1.7 to 4.3). The rate of fatal cardiovascular complications was comparable in both groups. High aldosterone plasma level was the independent risk factor of cardiovascular events in Cox regression models adjusted for covariates (OR = 3.2, 95 % CI 2.1 to 5.8 for aldosterone > 160 pg/ml).
Conclusions: Chronic stress leads to growing prevalence of secondary aldosteronism among patients with CAD and CHF. High plasma aldosterone level is associated with increased frequency of cardiovascular events independent of major established risk factors.

P1622

The utility of the MAGGIC heart failure risk score in predicting response to spironolactone: validation and results from the TOPCAT trial

D Daniel Silverman[1]; A Baldridge[2]; S Shah[2]
[1]*The University of Vermont Medical Center, Burlington, United States of America*; [2]*Northwestern University, Chicago, United States of America*

Background/Introduction: A primary challenge facing the implementation of heart failure with preserved ejection fraction (HFpEF) clinical trials is the optimal selection of patients with an appropriate risk profile from an otherwise heterogeneous population. Assessing those patients at sufficient risk of experiencing outcomes but who are not too ill to derive benefit from a therapy remains dependent on currently available risk models, though previously available heart failure risk models were primarily derived from heart failure with reduced ejection fraction (HFrEF) cohorts. The Meta-Analysis Global Group in Chronic (MAGGIC) Heart Failure Risk Score, however, is derived from a large and diverse cohort of patients equally representing heart failure with reduced and preserved ejection fractions and has been externally validated for its ability to predict time to mortality. We examined whether stratification of patient risk by MAGGIC risk score could predict response to Spironolactone in a contemporary HFpEF clinical trial population.
Purpose: To validate the MAGGIC risk score in a HFpEF clinical trial population for the first time and to test whether the MAGGIC risk score could be used to predict response to Spironolactone in the Spironolactone for Heart Failure with Preserved Ejection Fraction (TOPCAT) trial with regards to survival.
Methods: The MAGGIC risk score was calculated from input of its 13 variables in the 3,445 subjects enrolled in the multi-center, international, randomized, double blind placebo-controlled TOPCAT trial. Data for outcomes as well as a composite of time to the primary outcome were compared with the predicted MAGGIC risk in order to assess performance in the trial cohort. The odds of experiencing the primary outcome in TOPCAT were modeled through logistic regression of treatment alone, MAGGIC risk score alone, in a model of treatment adjusted for MAGGIC risk score, and through a model with an interaction term between treatment and MAGGIC risk score.
Results: The MAGGIC risk score was strongly associated (OR=1.06, 95% CI, 1.04-1.8) with incidence of the study's primary outcome. When stratified by MAGGIC risk score (increments of 10, from zero to 40), there was a statistically significant association between MAGGIC risk score quartile and survival (X2= 168.02, p<0.0001). Treatment effect on outcome when stratified by quartile increased with each quartile of increasing MAGGIC risk scores. There was a trend towards reduced incidence of the primary outcome in the treatment groups with lower MAGGIC risk scores.
Conclusion: The MAGGIC risk score performed well in predicting the incidence of the primary outcome in a large HFpEF clinical trial population and was further able to

stratify patients – those at lower calculated risk - more likely to experience treatment benefit. Use of such a risk score should be considered as part of patient selection for future HFpEF clinical trials.

heart failure awareness status of the general population in Korea: results from the KNOW-HF 2018 survey

M H Jung[1]; HL Kim[2]; JH Choi[3]; S Lee[4]; MG Kong[5]; JO Na[6]; YH Cho[7]; KI Cho[8]; EJ Kim[6]

[1]Chuncheon Sacred Heart Hospital, Cardiovascular center, Chuncheon, Korea (Republic of); *[2]Boramae Hospital, Cardiology, Seoul, Korea (Republic of)*; *[3]Hangang Sacred Hospital, Cardiology, Seoul, Korea (Republic of)*; *[4]Hallym University, Cardiology, Dongtan, Korea (Republic of)*; *[5]Soonchunhyang University Hospital, Cardiology, Bucheon, Korea (Republic of)*; *[6]Korea University Guro Hospital, Cardiology, Seoul, Korea (Republic of)*; *[7]Samsung Medical Center, Thoracic and Cardiovascular Surgery, Seoul, Korea (Republic of)*; *[8]Kosin University School of Medicine, Cardiology, Busan, Korea (Republic of)*

Background: For a better heart failure outcome, it is fundamental to improve the awareness of heart failure at the general population level.
Purpose: We conducted this study to identify the current status of awareness of heart failure in Korea.
Methods: A total of 1,032 participants were selected based on a stratification systematic sampling method to represent the Korean adult population (≥30 yrs old). Twenty-three question questionnaire were surveyed through a telephone interview.
Results: Although 80% of participants had heard of heart failure, only 21% accurately recognized the lifetime risk of developing heart failure and only 25% thought that heart failure has a higher mortality than other chronic diseases. Twenty-eight percent answered correctly about the cost of hospitalization. Regarding preferred treatment option, 71% chose a treatment that could improve the quality of life and 17.6% that allowed one to live longer. More participants believed that diabetes adversely affects the quality of life more than heart failure. Approximately two-thirds of participants agreed that recent medical treatment could reduce mortality and improve the quality of life, while the rest did not.
Conclusion: Despite the widely available sources, the current awareness status of heart failure is still low in Korea. Proactive educational efforts to improve public awareness are needed.

Chronic Heart Failure - Diagnostic Methods

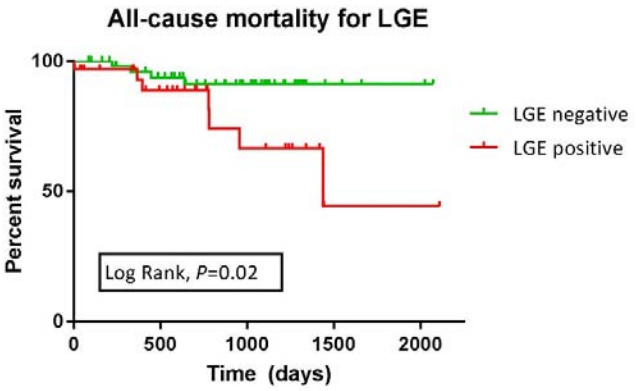
P1624

Myocardial fibrosis assessed with cardiac magnetic resonance imaging predicts mortality in heart failure with mid-range and preserved ejection fraction

G Van Woerden[1]; BD Westenbrink[1]; TM Gorter[1]; TP Willems[2]; M Rienstra[1]; DJ Van Veldhuisen[1]

[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The); *[2]University Medical Center Groningen, Radiology, Groningen, Netherlands (The)*

Introduction: Heart failure (HF) with mildly reduced or preserved ejection fraction (EF) (left ventricular ejection fraction; LVEF >40%) is a highly heterogenic disorder which limits therapeutic progress. There is an urgent need to identify subpopulations at increased risk. Myocardial fibrosis assessed by late gadolinium enhancement (LGE) imaging on cardiac magnetic resonance (CMR) may provide new insights.
Purpose: We sought to determine whether the presence of LGE on CMR could mark a distinct subpopulation in patients with HF with mid-range EF (HFmrEF) and HF with preserved EF (HFpEF).
Methods: Symptomatic HF patients with left ventricular ejection fraction >40% that complied with the 2016 European Society of Cardiology criteria for HFmrEF and HFpEF, who underwent CMR including LGE imaging were included. The frequency and pattern of LGE (i.e. ischaemic versus non-ischaemic) was assessed and we determined associations between clinical characteristics and all-cause mortality with logistic and cox-regression analysis.
Results: A total of 90 patients were included (mean age 70 years, 49% female). LGE was present in 32 out of 90 (36%) HF patients, of whom 14 (44%) had a non-ischemic LGE pattern. The presence of LGE was associated with previous myocardial infarction (Odds Ratio 7.8, 95% confidence interval (CI) 2.7 -22.4, P<0.001), higher left ventricular mass index (OR 1.04,95% CI 1.009 – 1.07 P=0.009), and male sex (OR 3.9, 95% CI 1.5 – 9.9, P=0.004). The presence of LGE was associated with all-cause mortality in multivariate analysis (independent from age, sex, NT-proBNP, left ventricular mass index and myocardial infarction, adjusted Hazard Ratio 8.9, 95% CI 1.86 – 43.0, p=0.006).
Conclusion: Focal fibrosis as measured by LGE on CMR is common in patients with HFpEF and HFmrEF, and approximately half of these patients have a non-ischemic LGE pattern. In addition, the presence of focal fibrosis is independently associated with all-cause mortality.



Survival LGE

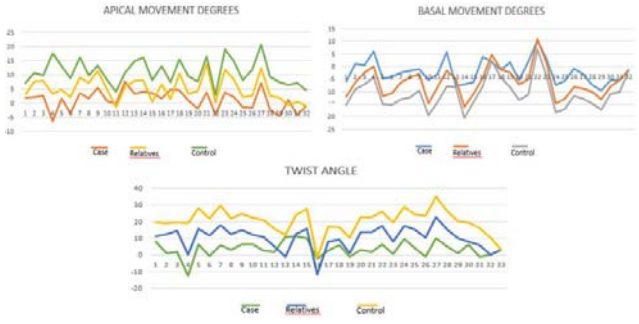
Evaluation of the predictive capabilites of LV wall motion pattern and other strain characteristics in LV noncompaction patients' first degree relatives for early diagnosis of cardiomyopathy

O Onur Akhan[1]; E Demir[1]; F Ozerkan Cakan[1]; S Nalbantgil[1]

[1]Ege University, Cardiology Department, Izmir, Turkey

BACKGROUND AND AIM: None of the diagnostic indices present in noncompaction cardiomyopathy involve left ventricular dysfunction. Left ventricular function and hemodynamics can be normal in these patients. For demonstrating regional deformation Tissue Doppler imaging studies, two and three dimensional 'speckle-tracking' and 'strain' echocardiography studies are available. The aim of this study is to evaluate 'Left ventricular noncompaction' patients and first degree relatives of these patients with respect to ventricular motion pattern and other strain characteristics, and demonstrate the predictive capabilities of these features for early diagnosis of cardiomyopathy.
METHODS: This cross-sectional, case-control study included 32 noncompaction cardiomyopathy patients, 30 first-degree relatives and 31 healthy volunteers. All patients were evaluated for baseline echocardiography, strain measurements, and ventricular wall motion pattern. Student t test, chi square test and ce fisher tests were used for statistical analysis. In all analyzes, p <0.05 was considered significant.
RESULTS: There was no difference between the case and control groups in terms of age, weight and body surface area. There was a statistically significant decrease in EF, FS, E / E ', GLS, GLSr, GCS, GCSr, GRS and GRSr values from the control group to the patient relatives and the patient group, respectively(patient relatives and control EF p = 0,023, for all other groups p <0.01). There was a significant correlation between EF and strain values in all groups (p <0.001). When the rotation values were examined, the decrease was observed from the control group to the patient relatives and the patient group, respectively, but significant difference was observed between the patient and the other groups and not between the patient relatives and control groups. In the case group, 'Rigid Body Rotation(RBR)' movement pattern was observed in 17 patients and the present pattern was observed in 9 patients in the patient relatives group. EF, GLS, GLSr and basal rotation values were significantly lower and GRS and GRSr values were higher in the group with RBR after comparison of patients with and without RBR pattern.



Rotation and twist parameters

CONCLUSIONS: It may be considered that the evaluation of the strain characteristics of all three study groups, observations of significant differences and findings in terms of RBR motion pattern contribute to reveal the genotype - phenotype relation of disease and to suggest that these features are predictive of early diagnosis of cardiomyopathy

P1626

Relationship between congestion by ultrasound, body mass index and cardiac rhythm in ambulatory patients with heart failure

P Pierpaolo Pellicori[1]; J Cuthbert[2]; P Shah[2]; A Urbinati[2]; A Kallvikbacka-Bennett[2]; JGF Cleland[1]; AL Clark[2]
[1]University of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland; *[2]University of Hull, Department of Academic Cardiology, Hull, United Kingdom of Great Britain & Northern Ireland*

Aims: Sub-clinical congestion is common in patients with chronic heart failure, associated with an adverse prognosis and a possible therapeutic target.
Methods: We measured ultrasound markers of congestion (including lung B-lines (interstitial oedema); inferior vena cava (IVC) diameter; and internal jugular vein diameter before and after Valsalva (JVD ratio)) in patients with heart failure during a routine out-patient clinic visit, and assessed their relationship with body mass index (BMI), cardiac rhythm, and outcome.
Results: Amongst 342 patients (mean age 73 years; mean left ventricular ejection fraction 45%, median (inter-quartile [IQR] range) NT-proBNP 1,275 (461-2,659) ng/l), the median number of B-lines was 7 (IQR: 2-17), median IVC diameter was 2.0 (1.6-2.4) cm and median JVD ratio 5.3 (3.1-7.1).
Compared to patients in sinus rhythm (SR; n=178, 52%), those in atrial fibrillation (AF; n=164, 48%) had higher NT-proBNP (median (IQR)) [AF: 1,915 (1,170-3,504) ng/l vs SR: 567 (256-1,614) ng/l; p <0.001], more B-lines [AF: 10 (3-25) vs SR: 4 (1-11); p<0.001)], larger IVC diameter [AF: 2.3 (2.0-2.6) cm vs SR: 1.7 (1.5-2.0) cm; p<0.001)] and smaller JVD ratio [AF: 4.0 (2.4-6.0) vs SR: 6.2 (4.6-7.9); p<0.001].
NT-proBNP was higher in patients with a normal BMI [(<25 kg/m2; n=76, 22%); 1,543 (618-3,783) ng/l], or overweight [(BMI 25-29.9 kg/m2; n=112, 33%); 1,579 (504-3,002) ng/L] compared to those who were obese [(BMI>30 kg/m2; n=154, 45%); 1,007 (363-1,884) ng/L, p<0.001]. There was no relation between BMI and either IVC diameter or JVD ratio, but obese patients had fewer B lines (4 (1-11)) than either those who were overweight (10 (3-21)) or with a normal BMI (9 (3-27)).
During a median follow-up of 600 (IQR: 363-749) days, 127 patients (37%) died or were hospitalized for heart failure. AF (HR: 1.44 (95% CI: 1.01-2.04), p=0.041), but not BMI either as a continuous or a categorical variable, was associated with outcome. Each ultrasound measure of congestion was associated with increased risk. The strength of the relations between NT-proBNP, IVC, JVD ratio and prognosis was unaffected by the presence of AF or obesity. However, the relation between B-lines and prognosis was lost for patients with a BMI<25 kg/m2 or > BMI>30 kg/m2.
Conclusions: In patients with chronic heart failure, AF is associated with a higher NTproBNP, more evidence of congestion on ultrasound and a worse prognosis. Obesity is associated with lower NT-proBNP, fewer B-lines but not with a better outcome. B-lines might be influenced by BMI and may be a less reliable ultrasound measure of congestion than IVC or JVD ratio.

Value of combined cardiopulmonary and echocardiography stress test to characterize the hemodynamic and metabolic responses of patients with heart failure and mid-range ejection fraction

N Nicola Riccardo Pugliese[1]; I Fabiani[1]; R Pedrinelli[1]; A Natali[1]; FL Dini[1]
[1]Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy

Funding Acknowledgements: No fundings

AIMS. To characterise heart failure with mid-range ejection fraction (HFmrEF), combining cardiopulmonary exercise test (CPET) and exercise stress echocardiography (ESE).
METHODS. We studied 169 consecutive subjects (age 62.3±11 years; 74% male): 30 healthy controls, 45 patients with HF and preserved EF (HFpEF), 40 HFmrEF and 54 with HF and reduced EF (HFrEF). Left ventricular (LV) stroke volume (SV), ejection fraction (EF), elastance, global longitudinal strain (GLS), E/E', oxygen consumption (VO2), and arterial-venous oxygen content difference (AVO2diff) were measured in all exercise stages.
RESULTS. HFmrEF revealed baseline features intermediate between HFrEF and HFpEF, except for B-type natriuretic peptide levels, which was similar to HFpEF and significantly lower than HFrEF. Peak VO2 was not significantly different between HF groups. HFrEF exhibited a significantly lower peak SV as compared to either HFpEF or HFmrEF (74.3±21.8 ml vs 88.0±17.4 ml and 96.5±25.1 ml; p<0.01), while peak heart rate (HR) was not significantly different between HF groups. A significantly reduced AVO2diff at peak exercise was apparent in HFpEF and HFmrEF (15.2±3.3 mL/dL and 13.3±4.2 mL/dL) vs HFrEF (17.±6.6 mL/dL; p<0.01), whereas no significant difference was reported between HFpEF and HFmrEF. Peak SVR was significantly higher in HFrEF (1288±648 dynes/cm) than in HFpEF (977±303 dynes/cm), HFmrEF (929±234 dynes/cm) and controls (1016±300 dynes/cm; p=0.009). HFmrEF demonstrated peak values of LV GLS (13.7±4.6%) and elastance (2.52±0.82 mmHg/mL) higher than HFrEF (8.3±3.1% and 1.25±0.56 mmHg/mL, respectively) and lower than HFpEF (17.1±4.6% and 4.40±2.32 mmHg/mL, respectively), with the highest values observed in controls (22.0±3.5% and 6.25±1.96 mmHg/mL, respectively; p<0.0001) (Figure 1). Multivariate analysis in the overall population and all groups revealed peak parameters as independent predictors of peak VO2 (R2=0.90, p<0.0001); AVO2diff showed the largest standardised regression coefficient.
CONCLUSIONS. In HFpEF and HFmrEF, effort intolerance is predominantly due to peripheral factors (AVO2diff), while in HFrEF peak VO2 is restricted by low increases in SV. Individual therapy according to which component of VO2 is more impaired is advisable.

Clinical and prognostic correlates of volume/time curve at cardiac magnetic resonance in patients with non-ischaemic dilated cardiomyopathy and left bundle branch block

A Aimo[1]; GD Aquaro[2]; A Valleggi[2]; A Barison[2]; S Salerni[3]; R De Caterina[4]; M Emdin[5]
[1]Azienda Ospedaliero-Universitaria Pisana, Scuola di Specializzazione Malattie dell'Apparato Cardiovascolare, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*; *[3]G. dAnnunzio University, Chieti, Italy*; *[4]Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*; *[5]Sant'Anna School of Advanced Studies, Pisa, Italy*

Background: In patients with non-ischaemic dilated cardiomyopathy (NIDCM) and left bundle branch block (LBBB), the systolic phase of the left ventricular (LV) volume/time (V/t) curve at cardiac magnetic resonance (CMR) can display a wide pattern (WP) and a narrow pattern (NP). Their clinical and prognostic correlates are currently unknown.
Methods: Consecutive patients with NIDCM (LV ejection fraction <50%) and LBBB were enrolled. They underwent a baseline evaluation including CMR, and were periodically re-evaluated during follow-up. The endpoint was a composite of cardiovascular death, heart failure (HF)-related event, and ventricular arrhythmias requiring defibrillator shock.
Results: Out of 101 patients (mean age 64±11 years, males 50%), NP was found in 29 and WP in 72, with no difference in QRS duration. Patients with WP had worse clinical presentation, and greater LV volumes, but similar LGE prevalence, extent or distribution. The WP subgroup displayed a greater maximal dyssynchrony time, expressed both as absolute duration (192±80 vs. 143±65 ms, P<0.001), and as percentage of the RR interval (25±11% vs. 8±4%, P<0.001). Even the systolic dyssynchrony index was higher in patients with WP (13±4 vs. 7±3%, P <0.001). The contractility index was lower in patients with the WP (2.6±1.2 vs 3.2±1.7, P<0.05). Over a median follow-up duration of 44 months (interquartile range 23-59), only WP (P=0.029) and NT-proBNP (P=0.004) demonstrated an independent prognostic value for cardiac events.
Conclusions: In patients with NIDCM and LBBB, the WP of V/t curves identifies a subgroup of patients with greater LV dyssynchrony, worse clinical conditions and prognosis.

Using cardiovascular magnetic resonance imaging to improve classification of ejection fraction

D Bromage[1]; MF Barakat[2]; L Pearce[1]; P Bhatti[1]; R Simpson[1]; L Dancy[1]; A Mcdiarmid[3]; M Monaghan[1]; D Okonko[1]; T Mcdonagh[1]; D Sado[1]
[1]Kings College Hospital, London, United Kingdom of Great Britain & Northern Ireland; *[2]Kings College London, London, United Kingdom of Great Britain & Northern Ireland*; *[3]St Thomas' Hospital, London, United Kingdom of Great Britain & Northern Ireland*

Background: Patients with heart failure (HF) with mid-range ejection fraction (HFmrEF) have poor clinical outcomes but no treatment convincingly reduces morbidity or mortality in this cohort. Studies of HF therapy are typically based on LVEF on transthoracic 2D echocardiography (echo). Echo has been shown to consistently underestimate LVEF when compared to CMR, which is the gold standard for calculating LVEF.
Purpose: We aimed to quantify the degree of reclassification achieved with CMR over echo, with respect to a preserved, mid-range or reduced LVEF status, and to investigate whether this reclassification associated with outcomes.
Methods: This was an observational study of consecutive patients with both CMR and echo studies performed within 90 days of each other from May 2017 to October 2017. EF categories were preserved (≥50%), mid-range (40-49%), or impaired (<40%). CMR and echo LVEF were compared with respect to their ability to discriminate a composite endpoint of all-cause mortality, HF admission or stroke after adjustment for age and gender.
Results: 141 cases were included. Echo underestimated LVEF compared to CMR (CMR: 42.0 [30.0-59.5%] vs. echo 34.0 [25.0-48.5%], P<0.0001). Subgroup analyses according to echo technique (Simpson's vs. 3D) and underlying diagnosis did not alter this trend. Importantly, echo underestimated LVEF compared to CMR for all categories of LVEF (preserved, mid-range and reduced). Overall, if a patient's LVEF was mid-range on echo, there was a 78% chance of being normal on CMR. In contrast, 87% of patients with reduced LVEF on echo had systolic impairment on CMR. On regression analysis, an echo LVEF<40%, which is relevant for treatment, corresponded to a CMR EF<47%, after adjustment for systematic differences in the two modalities and the interval between scans. On Cox analysis, an echo LVEF<40% was not associated with an increased hazard of the composite endpoint, whereas a CMR LVEF<47% was (Fig 1). Compared to an echo LVEF<40%, a CMR LVEF<47% enabled 3% of patients who had an event to be correctly reclassified as higher risk, and 18% of patients without an event to be reclassified as lower risk.
Conclusion: Echo underestimates LVEF compared to CMR across all LVEF subgroups. Misclassification may explain some of the lack of evidence for treatment benefit in mid-range patients. Large cohort studies are necessary to define cut-points for different, more reproducible imaging modalities. This may facilitate more targeted research and therapy in mid-range patients.

[1]Azerbaijan Medical University, Internal Medicine, Baku, Azerbaijan; *[2]RUDN University, Moscow, Russian Federation*

Funding Acknowledgements: Russian Academic Excellence Project 5-100

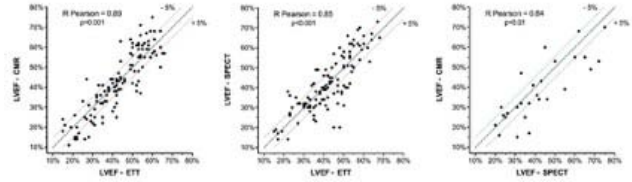
Aim: to evaluate the effectiveness of cardiac magnetic resonance (CMR) and stress-echocardiography in the assessment of long-term results of percutaneous coronary interventions (PCI) in post-MI patients with dysfunctional myocardium.
Methods: 112 patients were participated in the study. Inclusion criteria: myocardial infarction in previously; angina II-III functional class (CCS); multivessel coronary disease (SYNTAXscore I <32); the presence of segments with abnormality left ventricular local contractility; chronic heart failure I-III functional class (NYHA); left ventricular ejection fraction (LVEF) is less than 45%. All patients underwent stenting of the coronary arteries in the zone of viable myocardium. Only drug-eluting stents were implanted in coronary arteries. Long-term results were followed up 18 months after PCI in all patients. All patients underwent stress-echocardiography and CMR for visualization of myocardium after PCI.
Results: on average, initially accounted for 2.12 ± 0.74 segments with abnormality kinetic per patient according CMR, whereas, according to stress echocardiography, the average number of segments was 1.96±0.42. The average difference was 0.16 segment [0.11-0.18; 95% CI, p=0.003]. In the postoperative period, after 18 months, there was a significant decrease a segments with abnormality kinetics in the zone of hibernated myocardium, from 2.12 to 1.08, according to CMR (the average difference was 1.04 segment) [0.98-1.1; 95% CI, p <0.01], and from 1.96 to 0.98 according to stress-echocardiography (the average difference was 0.98 segments) [0.94–0.99; 95% CI, p = 0.023]. There is a significant discrepancy between the number of identified segments with abnormality kinetics using CMR and stress-echocardiography. There was a significant decrease in the transmurality index from 0.42 to 0.31 (according to CMR). The difference was 0.11 [0.09-0.14; 95% CI, p <0.05]. At the same time, recovery of myocardial function was clearly manifested in patients with a trasmurality index of 0.3–0.5, whereas with a transmurality index of more than 0.5, reliable recovery of myocardial function was not observed.
Conclusion: CMR allows a more objective analysis of the results of PCI in patients with dysfunctional myocardium, as compared with the stress-echocardiography method.

P1632

Variability in LVEF measured by echocardiography, gated SPECT and cardiac magnetic resonance: a real world analysis

CMF Strong[1]; A Ferreira[1]; B Rocha[1]; J Abecasis[1]; S Guerreiro[1]; P Freitas[1]; C Saraiva[2]; MJ Andrade[1]; R Ribeiras[1]; M Canada[1]; A Ventosa[1]; J Calqueiro[1]; M Mendes[1]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; *[2]Hospital de Santa Cruz, Radiology, Lisbon, Portugal*

Introduction Left ventricular ejection fraction (LVEF) plays a decisive role in many important clinical decisions. The purpose of this study was to assess the variability in LVEF measured by commonly used imaging modalities in a real-world setting.
Methods Single-center retrospective study including patients, with or without known coronary artery disease, undergoing any two of the following imaging modalities where LVEF was measured: non-contrast enhanced transthoracic echocardiography (TTE), gated single-photon emission computed tomography (SPECT), and cardiac magnetic resonance (CMR). Exclusion criteria were: difference between tests >90 days, performance of an exam within the 1st month of an acute cardiac event, and the occurrence of any cardiac event between tests. A separate analysis was conducted excluding patients with LVEF >55% by all modalities and those with >30 days between tests.
Results A total of 260 patients were assessed: 117 patients underwent both TTE and CMR, 115 TTE and SPECT, and 28 SPECT and CMR, with a median time interval between exams of 20 days (IQR 5-50). The mean absolute difference of LVEF between tests was 6±5%. Bland-Altman analysis showed no systematic overestimation or underestimation of LVEF by any of the modalities. Overall, the correlation between different methods was good (Pearson's r >0.8) - Figure. Nevertheless, the proportion of cases where the absolute LVEF difference was >10% ranged from 15-30%. Among patients with LVEF < 55% by one or more of the modalities, there was disagreement in the categorization LVEF ≤35% vs. >35% in 13% of the cases (n=34). Subgroup analyses including only those patients with <30 days between tests and those with LVEF <55% yielded similar results.
Conclusions Among patients with all types of cardiac disease assessed in a "real world" setting, the agreement between LVEF measurements using different imaging modalities was relatively good. Nevertheless, clinically meaningful discordance subsists in a small but significant proportion of patients.



P1633

Classifying heart failure patients based on objective Fast-SENC cardiac MRI measurements instead of subjective NYHA symptomatic criteria

H Henning Steen[1]; M Montenbruck[1]; S Kelle[2]; S Esch[1]; B Gersak[3]; F Andre[4]; G Korosoglou[5]

[1]Marien Hospital, Hamburg, Germany; *[2]Charite University Hospital, Berlin, Germany*; *[3]University of Ljubljana, Ljubljana, Slovenia*; *[4]University Hospital of Heidelberg, Heidelberg, Germany*; *[5]GRN-Klinik, Weinheim, Germany*

Background: The New York Heart Association (NYHA) classification of severity of symptoms is the most common system for evaluating function based on the patient's ability to withstand physical activity. This subjective criteria is based on the patient's perception of activity that may be confounded by pharmacological therapies, unrelated injuries, or mental condition. Alternative metrics that classify function based on objective, measurable criteria are needed to evaluate heart function status and improve detection of disease progression and impact of pharmacologic therapies and device interventions. LVEF is an insensitive quantitative metric and identifies reduction in function once damage has occurred. Fast-SENC segmental intramyocardial strain (fSENC) is a unique cardiac magnetic resonance imaging (CMR) modality that measures myocardial contraction in 1 heartbeat per image plane. The ability to quantify subtle changes in regional myocardial contraction allows detection of subclinical dysfunction before cardiac remodeling results in systemic damage and decline in LVEF. This prospective registry compares fSENC and LVEF in patients with varying degrees of progressive dysfunction based on NYHA classification.
Methods: A single center, prospective registry of CMR scans acquired with a 1.5T scanner were evaluated for conventional CMR diagnostics including LVEF, Volumes, Mass, T1/T2 mapping, and LGE. In addition, fSENC scans were acquired and processed with the MyoStrain software to quantify intramyocardial strain. Three short axis scans (basal, midventricular, & apical) were used to calculate strain in 16 longitudinal segments while three long axis scans (2-chamber, 3-chamber, & 4-chamber) were used to calculate 21 circumferential segments. fSENC and CMR LVEF were evaluated based on NYHA classification.
Results: A total of 792 scans in 619 patients were included in the study. Patients had an average (± stdev) age of 54 (17) yrs and BMI of 26 (5) kg/m2; 45% had arterial hypertension, 12% diabetes mellitus, 30% valvular heart disease, 27% cancer, 7% atrial fibrillation, and 22% coronary artery disease. Figure 1 shows a Box and Whiskers plot between NYHA classification in the x-axis versus the amount of normal myocardium (fSENC < -17%) in the y-axis respectively.
Conclusion: fSENC quantified subclinical dysfunction irrespective of symptom perception according to NYHA classification and before changes in LVEF and other global measures. The ability to monitor progressive dysfunction with an objective quantitative metric enables detection of subclinical dysfunction before symptoms or potentially irreversible damage and remodeling commonly seen with subjective and insensitive diagnostics. Even in "asymptomatic" patients with normal LVEF, fSENC quantified dysfunction due to structural heart disease to enable monitoring of disease progression and impact of drug and device therapies.

P1634

Limited diagnostic accuracy of the new ASE/EACVI algorithm for heart failure with preserved ejection fraction (VEEDia-study I)

AA Van De Bovenkamp[1]; V Enait[1]; FTP Oosterveer[1]; A Vonk Noordegraaf[1]; AC Van Rossum[1]; ML Handoko[1]

[1]VU University Medical Center, Amsterdam, Netherlands (The)

In 2016 the ASE/EACVI published a new and simplified algorithm to evaluate LV diastology. Grading of diastolic dysfunction is now based on the E/A-ratio and the presence of elevated E/e', indexed left atrial volume (LAVi) and/or peak tricuspid regurgitation velocity (TRV) only. Diastolic dysfunction grade I suggests normal LV filling pressures at rest and grade II or III elevated LV filling pressures. Thus far, validation of this algorithm has been limited. We evaluated the new algorithm and used invasively measured pulmonary capillary wedge pressure (PCWP) as the gold standard.
188 patients with a preserved LVEF (>50%) were included in the analysis (2015-2017; age: 62±14 years, 39% female; 15% had diabetes, 44% hypertension, 29% dyslipidaemia, 40% obesity). Right heart catheterization (RHC) and echocardiography were performed concomitantly for unexplained dyspnea or pulmonary hypertension (PH). Patients with reduced LVEF, significant valvular disease or congenital heart disease were excluded.
There was a fair correlation between E/e', E/A or LAVi and PCWP (R=0.44, 0.33 and 0.28 respectively, all p < .01). However no correlation was found between peak TRV and PCWP (R=-0.08, p=.40), even after exclusion of patients finally diagnosed with pre-capillary PH (R=-0.09, p=0.68). With PCWP=15mmHg as cut-off, ROC-analysis of the new algorithm revealed an AUC of 0.61, and sensitivity and specificity were 0.45 and 0.78 respectively. Overall diagnostic accuracy was 75% and it was particularly poor for diastolic dysfunction grade II (33%). PCWP did not statistically differ between diastolic dysfunction grade I (10±4 mmHg) or II (14±4 mmHg) (see Figure). Also there was a small, but significant correlation between PCWP and NT-proBNP (R=0.31 p<.001).
Conclusion: The new algorithm to evaluate LV diastology had insufficient accuracy to predict LV filling pressures at rest and is thus of limited value to non-invasively evaluate patients suspected of heart failure with preserved ejection fraction (HFpEF). RHC deserves a more central role in the diagnostic evaluation of HFpEF.

Role of 123-Iodine metaiodobenzylguanitidine imaging and cardiac MRI in ICD implantation decision making in heart failure patients

LI Lucia Ilaria Birtolo[1]; NS Nicolo Salvi[1]; VF Viviana Frantellizzi[2]; SC Sara Cimino[1]; PS Paolo Severino[1]; VM Viviana Maestrini[1]; MM Massimo Mancone[1]; GD Giuseppe De Vincentis[2]; FF Francesco Fedele[1]

[1]Sapienza University of Rome, Department of Cardiovascular and Respiratory Sciences , Rome, Italy; *[2]Sapienza University of Rome, Department of Radiologic, Oncologic and Pathological Anatomy sciences , Rome, Italy*

Background: According to guidelines, implantable cardioverter defibrillator (ICD) is recommended in prevention of sudden cardiac death (SCD) in heart failure (HF) patients (pts). Guidelines have several limitations because ICD indication is based mainly on left ventricular ejection fraction (LVEF). Recently, 123-iodine

metaiodobenzylguanidine imaging (123-I MIBG) seems to identify, independently from LVEF, pts at high risk of SCD: heart/mediastinum (H/M) ratio<1.6 and summed score (SS)>26.
Purpose: The aim is to assess the role of 123-I MIBG combined with cardiac MRI to predict malignant ventricular arrhythmias (VA) in HF pts
Methods: We enrolled 97 pts admitted to our hospital with diagnosis of HF and EF≤35%, NYHA class II-III, who underwent 123-I MIBG imaging and cardiac MRI. SS of 26 was used as cut-off to identify high risk (G1) versus low risk pts (G2). Late gadolinium enhancement (LGE) was evaluated in the two groups. All pts underwent ICD implantation. Follow up was performed at 24 months.
Results: 47 pts were included in G1 and 50 pts in G2. All baseline characteristics were similar in the two groups. The percentage of pts with LGE was 85% in G1 vs 60% in G2 (p=0.007). At 24 months follow-up VA events in G1 were 19.05% vs 4.17% in G2 (p=0.037). Moreover VA events were recorded greater in pts with both SS>26 and LGE compared to pts with only SS>26 (46.7% vs 19.6%, p=0.046).
Conclusion: Our results seem to confirm that 123-I MIBG uptake and LGE are associated with the occurrence of life-threatening VA in HF pts independently from LVEF. The use of integrated imaging could be a useful tool in the future to increase the specificity of the pts selection for ICD therapy.

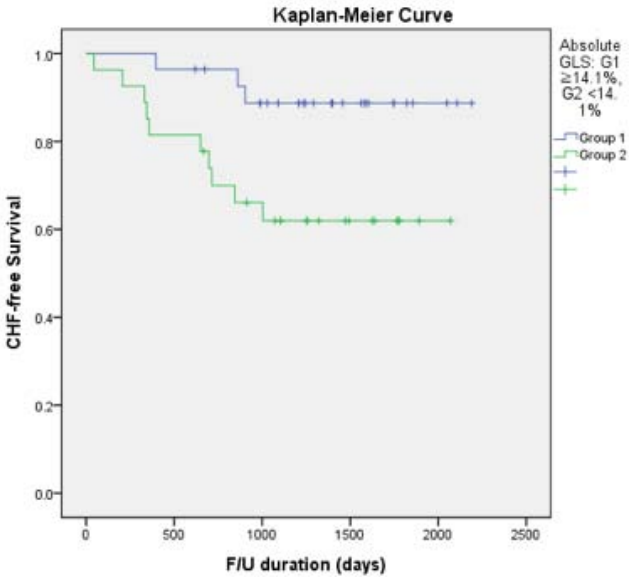
P1637
Impact of N-terminal pro-brain natriuretic peptide and 2D strain on development of cardiac events in patients with chronic kidney disease

S Sunhwa Lee[1]; JY Lee[1]; LY Jung[1]; YS Kim[1]; SR Lee[1]; KS Rhee[1]; JK Chae[1]; WH Kim[1]
[1]*Chonbuk National University Hospital, Jeonju-si, Korea (Republic of)*

Background: In patients with chronic kidney disease (CKD), cardiovascular morbidity and mortality are significantly associated with their outcome. This study was designed to investigate the usefulness of N-terminal pro-brain natriuretic peptide (NT-proBNP) and global longitudinal strain (GLS) measured by 2-dimensional speckle tracking echocardiography (2D STE) in predicting development of cardiovascular events in patients with CKD.
Methods: A total of 124 patients with CKD who had no cardiovascular symptoms were enrolled. All patients had analyzable 2D STE data and NT-proBNP levels.
Results: Mean age was 59±12 years and male was 46.8%. Mean GLS measured by 2D STE was −14.11±3.59% and mean NT-proBNP level was 23,448±13,464 pg/mL, in which showed significant correlation (r=0.553). Symptomatic heart failure (HF) developed in 24.2%, all-cause death in 16.1% and composite of HF and all-cause death in 37.1% during mean follow-up of 104.3±48.9 months. GLS showed significant difference between patients with and without HF during follow-up (−11.59±2.81% vs. −14.88±3.46 %, p=0.003) but NT-proBNP levels did not (26,528±12,268 vs. 22,464±13,803 pg/mL, p=0.313). GLS was not significantly different between patients with or without all-cause death (−14.45±4.35% vs. −14.03±3.44%, p=0.740). Patients were divided into two groups by the median value of GLS of −14.1%: Group 1 (n=56), absolute GLS ≥14.1%; Group 2 (n=54), absolute GLS <14.1%. Two groups were comparable in age and sex, risk factors and residual renal function but showed significant differences in the level of NT-proBNP (16,224±14,260 vs. 31,364±7,323 pg/mL, p<0.001), past history of HF (7.1% vs. 33.3%, p=0.015) and development of HF event during follow-up (10.7% vs. 37.0%, p=0.022) (Fig. Kaplan-Meier log rank p=0.019).
Conclusion: In patients with CKD, NT-proBNP levels were markedly elevated and GLS was depressed in spite of no clinical symptoms. GLS was more useful than NT-proBNP in prediction of future HF in patients with clinically silent CKD.



Symptomatic HF-free survival

The prognostic value of stress gated blood pool SPECT in early postoperative period prognosis in patients with ischemic cardiomyopathy

V V Shipulin[1]; K Zavadovsky[1]; S Andreev[2]; A Pryakhin[2]; V Saushkin[1]; VM Shipulin[2]
[1]*State Research Institute of Cardiology of Tomsk, Nuclear medicine department, Tomsk, Russian Federation*; [2]*State Research Institute of Cardiology of Tomsk, Cardiac surgery department, Tomsk, Russian Federation*

On behalf of: Shipulin V., Zavadovsky K., Andreev S, Pryakhin A., Saushkin V., Shipulin V.M.

Purpose. The purpose of the study was to assess the severity of early postoperative status in patients with ischemic cardiomyopathy (ICM) based on preoperative gated blood pool SPECT results.
Methods. A total of 31 patients (29 male, 2 female) with ICM were enrolled in this study in the period from March 2017 to November 2018. The average age of patients was 60.4± 6.3 years. The inclusion criteria for the study were the following: left ventricular (LV) ejection fraction (EF) equal or less than 40%; LV end diastolic index (EDVI) equal or more than 60 ml/m2 (based on echocardiography). Prior to surgical intervention all patients underwent gated blood-pool SPECT (GBPS) at rest and during stress-test with intravenous administration of dopamine. A total of 4 gated BPS SPECT were performed: 1) at rest; 2)during 5 μg/ kg/min dopamine infusion (1step); 3) during 10 μg/kg/min dopamine infusion (2step); 4) during 15 μg/kg/min dopamine infusion (3step). GBPS data was processed using Quantitative Blood Pool SPECT (QBS, Cedars-Sinai Medical Center, Los Angeles, CA, USA) and the following parameters were calculated: left and right ventricular end-systolic (ESV) and end-diastolic (EDV) volumes, ejection fraction (EF), peak ejection and filling rates as well as dyssynchrony indices (Phase Standard Deviation, Histogram Bandwidth, Entropy). The patients were divided into 2 groups. Group 1 (n=11) with a complicated course of early postoperative period (death, the usage of intra-aortic balloon pump, inotropic support for more than 5 days with the need to stay in the UAR was considered a complication) and group 2 with uncomplicated postoperative course (n=20).
Results. The values of preoperative GBPS parameters which were significantly different between (by univariate U-test) two groups are presented in a table 1. An observed difference was considered significant at a p value <0,05. Logistic regression analysis showed that the majority of these parameters allow predicting the severity of early postoperative period. The right ventricle parameters showed their prognostic significance only measured at rest examination. At the same time stress examination revealed a significant prognostic importance of LV volumes and indices in comparison to rest.
Conclusion. Left and right ventricular volumes and contractility parameters obtained from GBPS are associated with the course of an early postoperative period in patients with ischemic cardiomyopathy. Thus, GBPS could be useful in the preoperative evaluation of such patients.

P1639

Electrocardiographic predictors of ventricular tachyarrhythmias in patients with ischemic vs non-ischemic heart failure

T Vaikhanskaya[1]; OP Melnikova[1]; AP Vorobiev[1]; AV Frolov[1]
[1]*Republican Scientific and Practical Center "Cardiology", Minsk, Belarus*

Identification of patients (pts) at increased risk of arrhythmic death is a multifactorial process. Successful risk assessment based on electrocardiography (ECG) records is greatly improved by the combination of different indices reflecting not only the pathological substrate but also the autonomic regulation of cardiac electrophysiology. This study assesses the arrhythmic risk stratification capacity of heart rate turbulence (HRT) parameters, microvolt T-wave alternans (mTWA), deceleration capacity (DC), and fragmented QRS complex (frQRS).
The aim of the study was to comparatively evaluate ECG predictors of life-threatening ventricular tachyarrhythmias (ltVTA) in pts with ischemic vs non-ischemic heart failure (iF vs niHF).
Materials and methods. The study enrolled and followed up 57,4±15,9 months 357 pts (NYHA 2,3±0,68; LVEF≥35%): 160 pts with iF (aged 52,4±17,9; 117/73,1% male; LVEF 44,7±7,12%) due to coronary artery disease and 197 pts with niHF (aged 48,7±11,2; 127/64,5% male; LVEF 41,3±5,5%) due to dilated cardiomyopathy. For analysis as primary endpoints the following ltVTA events were taken: SCD, successful resuscitation, sustVT/VF with syncope, appropriated ICD discharges.
Results. In the iHF pts positive correlations of ltVTAs with frQRS (k=0.91; p=0.0001), gender male (k=0.58; =0.005), and HRT\ (k=0.87; p=0.0001) were revealed. As a result of ROC analysis only frQRS (AUC=0.96; 95% CI: 0.921-0.999; p=0.0001; sensitivity 89%, specificity 83%) confirmed prognostic value. In the niHF group significant correlations of ltVTAs with pathological test mTWA (k=0.49; p=0.0001), QRS width and fragmentation (k≥0.24; p≤0.001), and DC (k=0.14; p=0.045) were found. As a result of ROC analysis, cut-off 25% index of pathologic mTWA (AUC=0.772; 95% CI: 0,769-0,885; p=0,0001; sensitivity 79%; specificity 77%) retained prognostic significance.
Conclusion. Risk stratification for arrhythmic events in HF pts differs substantially depending on whether the underlying cardiomyopathy is ischemic or non-ischemic. Thus, for iHF pts presence of frQRS shows high sensitivity and specificity to predict ltVTA events. Pathological test mTWA can also help identify high-risk in niHF pts.

P1640

An analysis of right ventricular failure in isolated left ventricular noncompaction and idiopathic dilated cardiomyopathy

E N Libhaber[1]; S Nel[1]; F Peters[1]
[1]*University of the Witwatersrand, School of Clinical Medicine, , Johannesburg, South Africa*

Background: Despite recent cardiac magnetic resonance imaging (CMR) studies suggesting that significant right ventricular (RV) systolic dysfunction is a marker of advanced isolated left ventricular noncompaction (ILVNC), the prevalence and predictors of RV dysfunction among patients with ILVNC and idiopathic dilated cardiomyopathy (IDCMO) remains unknown. Although technically challenging, assessment and diagnosis of RV function using echocardiography is an important prognostic factor in heart failure. Unlike CMR, echocardiography has the advantage of evaluating important contributors to right-sided abnormality, namely diastolic dysfunction, mitral regurgitation and pulmonary hypertension. Echocardiography enables these key factors to be accurately studied to determine whether LV dysfunction is the sole independent predictor of RV dysfunction or do these additional functional abnormalities predispose ILVNC patients to RV dysfunction. Purpose: The aims of this study were to estimate the prevalence and predictors of RV dysfunction, using echocardiography, in ILVNC, and IDCMO patients.Methods: In a prospective cross-sectional study 49 patients with ILVNC and 49 with IDCMO were enrolled at the cardiomyopathy clinic in Chris Hani Baragwanath Academic Hospital with the approval from the Health Sciences Research Ethics Committee, University of the Witwatersrand. Baseline clinical features and echocardiographic findings of the ILVNC and IDCMO patients were compared. RV function was evaluated by tricuspid annular peak systolic velocity (S'). Results: Between both groups of patients, 58.2% had RV dysfunction, indicated by a RV S' <10. The prevalence of RV dysfunction was 49%, in ILVNC, and 67%, in IDCMO. A univariate linear regression analysis, and a stepwise multiple linear regression analysis, of ILVNC patients, indicated the most important echocardiographic parameters associated with RV dysfunction were left ventricular ejection fraction (LVEF) (p < 0.0001), in both analyses. LV sphericity indices, LV end diastolic diameter (p = 0.003), and end systolic diameter (p < 0.0001) were also independent predictors of RV dysfunction.
Conclusions: RV dysfunction is frequent among patients with ILVNC, the best predictor of which is LVEF, not dissimilar to what occurs in IDCMO. In the presence of RV dysfunction these patients develop a more adverse clinical profile, worse LV remodeling and a greater degree of mitral regurgitation when compared to those with normal RV function. Identifying LV dysfunction as a major contributing factor to the development of RV dysfunction in ILVNC or IDCMO provides insight into the hemodynamic manifestations of reduced LV systolic function.

P1641

Subclinical right ventricular dysfunction in gestational hypertension as compared to a normotensive pregnancy group

N Natalia Patrascu[1]; LF Trasca[1]; MS Neagu[1]; M Cirstoiu[1]; D Vinereanu[1]
[1]*University of Bucharest Carol Davila, Bucharest, Romania*

Background. Gestational hypertension (GHT) and preeclampsia (PE) are associated with a significant short and long term cardiovascular risk, few data indicating a subtle deleterious effect on left cardiac and vascular function that maintains after delivery. However, right cardiac structural and functional changes, as compared to normal pregnancy physiological adaptation are scarcely studied. Aim. To assess right cardiac geometry and function in a group of pregnant women with GHT and/or PE by comparison to a normotensive control group. Methods. We studied 58 pregnant women: 31 with GHT/PE (no cardiovascular or medical history) and 27 normotensives as control, using color 2D, spectral and tissue Doppler and 2D speckle tracking. Right heart geometry was assessed by indexed right atrial (RA) maximal volume and right ventricle (RV) basal and mid-diastolic diameters; global function and hemodynamics by pulmonary flow VTI, RV fractional area change (FAC) and RV Tei index; and regional RV function by TDI tricuspid annular S, E' and A' wave velocities and free RV wall longitudinal strain (as septal strain considered part of global longitudinal left ventricle function). Results. GHT/PE and control groups were similar in terms of age (32.2±5 vs. 31.7±4), pregnancy weeks (31.3±6 vs. 30.7±4), primi-/multiparity status and heart rate (89.1±12 vs. 84.4±10), with hypertensive group having higher pre-pregnancy and actual body mass index (25.8±5 vs. 22.3±2 and 29.7±4 vs. 25.4±2 respectively, both p<0.05). Indexed RV mid-diastolic diameter was higher in GHT/PE group (18.9±7 vs. 14.6±2, p=0.008) but there were no significant differences in other structural parameters or global function and all in normal range values. As for RV regional function, GHT/PE group had a decreased E' wave velocity (14.8±3 vs. 17.5±4, p=0.02) and RV free wall longitudinal strain (18.4±7 vs. 25.6±4, p=0.001).
Conclusions. While right cardiac global function and loading features were almost similar, hypertensive pregnant group showed subtle regional systolic and diastolic dysfunction. Along with left cardiac function, further studies should establish whether this condition is transitory or persistent after delivery, increasing the risk for progression to heart failure in these young patients.

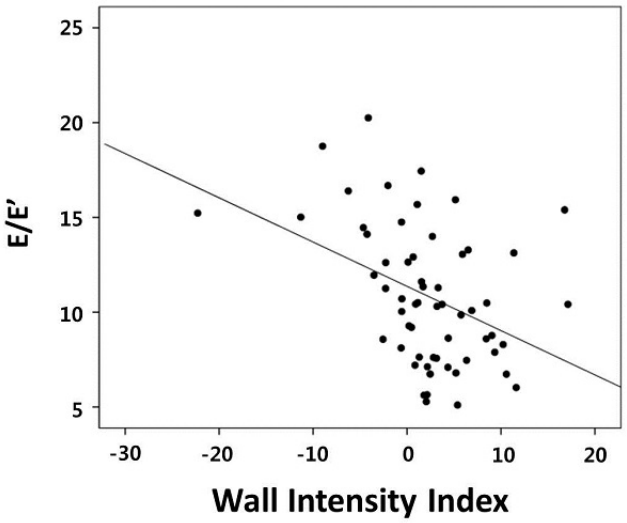
P1642

Relation between left ventricular filling pressure and change of left ventricular wall intensity

MS Misun Kim[1]; JW Beom[1]; JH Choi[1]; SY Kim[1]; KS Kim[1]; SJ Joo[1]; JG Lee[1]
[1]*Jeju National University Hospital, internal medicine, Jeju, Korea (Republic of)*

Background: The left ventricular (LV) filling pressure has been documented an important factor for expression of LV diastolic dysfunction. Coronary flow reserve (CFR), which reflects coronary microvascular function, was associated with LV filling pressure. The blood flow of the coronary microvessels was mainly in the diastolic period. The contrast medium will be mainly filled in the diastolic phase in coronary computed tomography angiography (CCTA). Therefore, the hypothesis of this study is that the change in wall intensity of LV between the diastolic and systolic phases in

CCTA(wall intensity index, WII) is related to the LV filling pressure and microvascular function.
Methods: Transthoracic Doppler echocardiography was performed that included pulsed tissue Doppler of the mitral annulus. The ratio of mitral velocity to early diastolic velocity of the mitral annulus (E/e') was used as a surrogate marker of the LV filling pressure. The average of LV wall intensities were obtained from the diastolic and systolic phase in 17 segments using CCTA. WII was defined as Hounsfield unit scale of (diastolic phase−systolic phase)/diastolic phase. Patients with aortic valve stenosis, congenital heart disease, hypertrophic cardiomyopathy, dilated cardiomyopathy, previous revascularization due to ischemic heart disease and permanent pacemaker implantation were excluded.
Results: Total 60 patients were included and mean age of patients was 59.8 years. WII was significantly low in patients with E/e' over 14 than those with E/e' less than 14 (-3.07±9.10 vs. 3.76±4.35; p<0.05). In univariate analysis, age, a velocity and E/e' were significantly associated with WII. In multivariate analysis, E/e' was independently associated with WII (β = -0.405, R^2 = 0.149, p = 0.001).
Conclusions: WII was associated with LV filling pressure and diastolic function. And we can suggest that WII can be used to evaluate microvascular function of LV.



Wall intensity index

P1643
Electrocardiography and echocardiography dyssynchrony correlation with left ventricular function in long term permanent pacemaker implantation

M-T Ming-Ting Chou[1]; FY Lin[1]; CY Chiang[1]
[1]*Chi-Mei Medical Center, section of Cardiology, Tainan, Taiwan, Province of China*

Background: Right ventricular pacing(RV) creates electrical dyssynchrony similar to a left-bundle branch block which may have detrimental effects on cardiac structure and function, leading to heart failure in some patients(pts). Several echocardiographic techniques are available for the assessment of cardiac mechanical dyssynchrony. Previous studies had demonstrated using simple ECG parameter as a predictor of pacing-induced left ventricular dysfunction.
Purpose: To evaluate ECG parameter and echocardiographic(echo) dyssynchrony correlation with left ventricular(LV) dysfunction in pts with permanent pacemaker implantation(PPM)
Method: We evaluated 151 pts who had received PPM and were dependent on RV pacing. The survey included clinical basic data, ECG parameters (pacing axis, QRS duration, QTc interval) and echo studies (LV ejection fraction[EF], LV end systolic dimension[ESD], septal flash, inter-ventricular mechanical delay[IVD], and septal-to-posterior wall motion delay [SPWMD]). Dyssynchrony was assessed by speckle-tracking strain using off-line software.
Results: Pts mean age was 75±13 years old and pacing duration was 79±61 months. Most (94%) RV lead located over apex. Mean LVEF was 61±12%. 11%(17/151) pts had EF below 40%. For ECG parameters, longer QRS and QTc are related with worse LVEF while more negative QRS axis with better EF. For echo parameters, longer SPWMD correlated with worse EF. The finding of septal flash, IVD and speckle tracking dyssynchrony had no significant relation. Duration of QRS also found to have high correlation to SPWMD(P<0.01).
Conclusion: Compared with more time consuming speckle tracking dyssnchrony, echo SPWMD and ECG parameter correlate better with LVEF in PPM pts.

P1644
Coronary venous anatomy in patients with heart failure

R Mlynarski[1]; A Mlynarska[1]; M Sosnowski[1]; KS Golba[1]
[1]*Medical University of Silesia, Katowice, Poland*

We hypothesized that heart failure (HF) during longer period of time can influence the anatomy of coronary venous system (e.g. expansion of veins). We try to research it using multi slice computed tomography.
METHODS: 110 patients (38W) were included into the research. In 67,3% ejection fraction (EF) was correct, in 17,3% it was preserved EF and in 18,46% it was reduced EF. In the last one subgroup heart failure symptoms was presented at least one year. In all, multi slice computed tomography was done. Scanning with retrospective ECG-gating was performed during a breath hold using 64 slices with a collimated slice thickness of 0.5 mm using the standard protocol for coronary arteries. We used the best mode option, the helical pitch was 12.8 and the rotation time was 0.4 s. An average of about 80-100 ml of contrast agent was used in each case. The coronary veins analysis was performed by the Vitrea 2 workstations using multi-planar reformatted (MPR) and 3D reconstructions. The analyses were performed by two experienced researchers. A dedicated Likert-based scale that was created earlier was used to evaluate the quality of the veins visualizations.
RESULTS: Quality of visualization of coronary veins was described as more then good, there was no statistical differences between groups observed (A: 4,2 ± 0,89; B: 4,11 ± 0,87; C: 4,00 ± 1,12; p=0,7821). Number of visible veins was statistically the biggest (p=0,0497) in group B (5,05 ± 1,51) if compare to the group A (4,56 ± 1,08) and C (4,64 ± 1,23). There was no statistical differences (p=07131) in vein of Marshall (oblique vein of the left atrium) presence A: 27,03%; B: 15,79%; C: 17,65%. After analysis of coronary veins variants we found that in group A variant II(B) (anterior, anterolateral, lateral, posterolateral veins present, lack of posterior vein) was the most frequent (37,84%), meanwhile in heart failure groups (B and C) it was variant I(A) (anterior, anterolateral, lateral, posterolateral and posterior veins present) 84,21% and 58,82% respectively – difference was highly statistical (p=0,0000). Variant II was absent in all heart failure affected patients.
CONCLUSIONS: The biggest number of coronary veins was found in patients with heart failure with preserved ejection fraction diagnosed. In our population, posterior coronary vein was always present in heart failure patients.

P1645
Left ventricular ejection fraction remains the best echocardiographic predictor of long-term cardiovascular mortality in heart failure with reduced ejection fraction

EE Yakubovskaya[1]; MG Poltavskaya[1]; IYU Giverts[1]; MV Serova[1]; VP Sedov[1]; MD Kuklina[1]; AL Syrkin[1]
[1]*I.M. Sechenov First Moscow State Medical University, University Clinical Hospital 1 , Moscow, Russian Federation*

Objectives: in recent years left ventricular ejection fraction (LVEF) has been much criticized while "new" echocardiographic measures such as myocardial strain or tissue doppler diastolic velocities demonstrated good performance as markers of disease severity and prognosis in various clinical settings. The aim of the study was to assess and compare the value of current echocardiographic measures for prediction of long-term mortality in heart failure patients with reduced ejection fraction (HFrEF)
Methods: 58 patients with HFrEF, NYHA classes II-III (45 male, mean age 57,0±13,3 years) were enrolled in the prospective observational study. At baseline the patients underwent standard two-dimensional transthoracic echocardiography with tissue Doppler and speckle tracking imaging. Mean LVEF amounted 26,7±7,9%. Average follow-up amounted 56,1±29,7 months. Cardiovascular mortality was considered as primary end-point.
Results: Cardiovascular death was registered in 26 patients (44,8%). Stepwise Cox regression analysis demonstrated statistically significant prognostic value of LVEF, velocity time integral (VTI), peak systolic annular velocity (s'), early diastolic and late septal mitral annular velocities (septal e' and a' accordingly) and LV global longitudinal peak systolic strain (GLPSS). Comparison of ROC curves showed the largest area under curve (AUC) for LVEF (AUC=0,871; 95%CI=0,722 to 0,957; p<0,0001) and GLPSS (for average GLPSS AUC=0,806; 95%CI=0,645 to 0,916; p=0.001) with the best cut-off = -7,0. Other parameters listed above had AUC between 0,7 and 0,8.
Conclusions: among the variety of currently used echocardiographic parameters only LVEF, VTI, s', septal e' and a' and GLPSS demonstrated prognostic value as long-term cardiovascular mortality predictors in HFrEF patients with LVEF being the best of them.

P1646

Comparison of right ventricular free wall regional deformation in patients with pulmonary hypertension of different aetiologies

N Natalia Ojrzynska[1]; E Kowalik[2]; M Kowalski[2]; A Klisiewicz[2]; M Demkow[3]; A Witkowski[4]; J Grzybowski[1]
[1]Institute of Cardiology, Department of Cardiomyopathy, Warsaw, Poland; *[2]Institute of Cardiology, Department of Congenital Heart Diseases, Warsaw, Poland*; *[3]Institute of Cardiology, Department of Coronary and Structural Heart Diseases, Warsaw, Poland*; *[4]Institute of Cardiology, Department of Interventional Cardiology and Angiology, Warsaw, Poland*

Right ventricular (RV) longitudinal deformation has not been fully investigated in variety of clinical conditions.
Purpose The purpose of this study was to compare RV regional function deformation measured by strain and strain rate (SR) in patients with pulmonary hypertension (PH) of different aetiologies and establish whether RV free wall strain and SR were related to aetiology of PH or hemodynamic variables.
Methods We retrospectively reviewed echocardiographic studies of patients with PH confirmed by cardiac catheterization. Study sample consisted of 25 pts: 13 pts (age: 46,2±13,5) with precapillary PH associated with atrial/ventricular septal defect and 12 pts (age: 45,9±11,5) with postcapillary PH due to dilated cardiomyopathy (DCM).
Echocardiographic parameters of RV function (TAPSE, tissue-Doppler imaging derived free RV wall systolic velocity S', RV inflow tract diameter, RV area) and RV free wall deformation imaging parameters were assessed. Regional systolic and diastolic strain rates and regional strain were acquired from the basal, mid and apical segments of RV free wall.
Results Mean pulmonary arterial pressure (75±18 mm Hg vs. 42±8 mm Hg; p<0,05) and pulmonary vascular resistance (16±7 WU vs. 5±3 WU; p<0,05) were higher in pts with precapillary PH.
TAPSE were decreased in group with postapillary PH (16±5 mm vs. 19±4 mm; p<0,05). Other echocardiographic parameters of RV global function did no differ significantly between pts with PH of different aetiologies.
There was an statistically significant difference between pre- and postcapillary PH patients' strain in apical and mid myocardial segments. Early diastolic SR in apical RV segment in precapillary PH patients was significantly higher than in patients with postcapillary PH. In other myocardial segments there were no differences between systolic, early diastolic and late diastolic SR.
Conclusion Our study suggests that RV free wall strain in patients with PH moderately correlate with aetiology of PH. Strain and strain rates were significantly decreased in patients with postcapillary PH due to DCM, despite lower pulmonary arterial pressure and PVR.

RV free wall strain and strain rate

	RV Segment	Precapillary PH	Postcapillary PH	p value
Strain(%)	basal	-16±7	-17±5	NS
mid	-18±8	-15±4	<0,05	
apical	-19±9	-14±5	<0,05	
SRe(1/s)	basal	1,51±0,91	1,50±0,61	NS
mid	1,23±0,94	1,19±0,52	NS	
apical	1,18±1,07	1,08±0,49	<0,05

Does metabolic syndrome influence right ventricular diastolic function in patients with preserved left ventricular systolic function?

E Sedaia[1]; V Revenco[1]; A Moiseeva[2]
[1]State University of Medicine and Pharmacy, Department of Internal Medicine, Cardiology, Chisinau, Moldova (Republic of); *[2]Institute of Cardiology , Hypertension, Chisinau, Moldova (Republic of)*

Introduction . Metabolic syndrome (MetS) is commonly associated with left ventricular (LV) diastolic dysfunction and LV hypertrophy. However, the role of MetS in right ventricular (RV) diastolic function is not completely elucidated.
Purpose. Evaluation of diastolic function of RV in patients with metabolic syndrome and preserved left ventricular systolic function.
Methods. Our study included 44 subjects with MetS and 44 controls adjusted by age. MetS was defined by the presence of 3 or more criteria of International Diabetes Federation and American Heart Association/National Heart, Lung, and Blood Institute. All subjects underwent careful clinical and physical examination, laboratory blood tests, complete two-dimensional, pulsed and tissue Doppler echocardiography. For the evaluation of diastolic function we determined tricuspid inflow peak velocity during early (Et) and late (At) filling, their ratio Et/At, early diastolic tissue Doppler velocity of the tricuspid annulus (e't), the ratio Et/e't and Et wave deceleration time (DTt).
Results. Mean values of waist circumference (WC), systolic blood pressure (SBP), diastolic blood pressure (DBP), fasting glucose (GLU), HDL-cholesterol (HDL), triglicerides (TG) were significantly higher in the group with MetS (for all parameters p<0.01). RV diastolic function parameters were also significantly changed in the group with MetS (tab.1). In patients with MetS Et/At ratio was negatively related to WC (r=-0.506), SBP (r=-0.275), DBP (r=-0.320), GLU (r=-0.454), TG (r=-0.230), HDL (r=-0.110). Also, in subjects with MetS Et/e't ratio was positively correlated with WC (r=0.420), SBP (r=0.507), DBP (r=0.450), GLU (r=0.256), TG (r=0.167), and there were no positive association with HDL (r=0.000). Multivariate analysis revealed that SBP, fasting glucose level and WC were independently associated with Et/e't ratio.
Conclusions. MetS has an important impact on RV diastolic function. Among all components of MetS WC, SBP and serum glucose level were independently associated with RV diastolic dysfunction.

Tab.1. RV diastolic function

Variables	MetS	Controls	p
Et (cm/s)	47.78±8.11	55.77±9.45	0.0009
At (cm/s)	64.62±11.97	47.6±11.39	<0.0001
Et/At	0.61±0.04	1.21±0.36	<0.0001
e't (cm/s)	10.23±2.29	13.89±3.89	0.0002
Et/e't	4.93±1.26	4.25±0.77	0.0251

Background: Many patients with non-ischaemic dilated cardiomyopathy (DCM) have only mild LV dilatation and mildly reduced LV ejection fraction (LVEF). Whilst the risk of adverse events is lower than for those with severely reduced LVEF, this represents a large patient cohort and their long-term burden of disease remains high. Current guidelines only recommend implanting cardioverter-defibrillators (ICDs) for primary prevention in patients with LVEF<35%. Presence of mid-wall myocardial fibrosis by late-gadolinium enhancement (LGE) predicts SCD in mild DCM. We sought to evaluate the association between LGE, myocardial strain by CMR and clinical outcome.
Methods: We prospectively recruited patients with DCM and LVEF≥40% referred for CMR. The primary outcome was all-cause mortality. Secondary composite outcomes were major arrhythmia (SCD or aborted SCD) and major heart failure events (HF death, HF hospitalisation or transplant). All outcome events were adjudicated by a panel of physicians blinded to CMR results. Myocardial strain was measured by feature tracking (Circle42) by a blinded expert operator. Mid-wall fibrosis was assessed by a separate blinded operator.
Results: Of 315 patients (208 men, median age 50 years, median LVEF 50%, 24.4% with LGE) followed for a median of 1588 days, 24 (7.6%) patients reached the primary end-point. On univariable analysis, global longitudinal strain (GLS by CMR: HR 0.83; 95% CI 0.72-0.95; p=0.006), radial strain (HR 0.90; 95% CI 0.83-0.97; p=0.006) and circumferential strain (HR 0.82; 95% CI 0.70-0.95; p=0.008) were all associated with the primary outcome, whereas LGE was not (HR 2.16; 95% CI 0.85-5.53; p=0.11). Following adjustment for LGE, GLS was associated with major heart failure events (HR 0.83; 95% CI 0.72-0.97; p=0.02) and all-cause mortality (HR 0.83; 95% CI 0.73-0.96; p=0.009), but not major arrhythmic events (HR 1.08; 95% CI 0.94-1.26; p=0.28). LGE was associated with major arrhythmia (HR 10.91; 95% CI 3.86-29.57; p<0.0001), but not major heart failure events (HR 2.22; 95% CI 0.90-5.48; p=0.08) or all-cause mortality (HR 1.68; 95% CI 0.71-3.97; p=0.23).
Conclusion: These findings suggest that myocardial strain measured by CMR identifies patients with non-ischaemic DCM at greatest risk of heart failure and

all-cause mortality, independent of LGE, with a 17% increase in risk for every 1 unit decrease in GLS. Despite potential limitations within a single-centre, feature tracking combined with LGE may be useful in identifying patients at greatest risk of SCD with a low competing risk of death from heart failure. Such patients might derive greater benefit from an ICD.

Chronic Heart Failure - Treatment

P1649

Effects of mineralocorticoid ceceptor antagonists (MRA) in heart failure patients after up to 12 months of follow-up.

L L Lisa Lauren Buttigieg[1]; J Delicata[1]; AM Moore[1]; RG Xuereb[1]
[1]*MaterDei Hospital, MaterDei Hospital, Malta, Malta*

Background: Studies have shown that Mineralocorticoid receptor antagonists (MRAs) have beneficial prognostic effects in patients with heart failure. However, in clinical practice, MRAs are eventually stopped due to several reasons.
Purpose: To assess the effect of MRAs in heart failure patients after 12 months of follow-up.
Method: Data collection was done using IT systems used in the Department of Cardiology (CVIS). Patients who attended heart failure clinic (HFC) between January and June 2017, who were started or were already on a MRA were followed up after 12 months. Patients who were lost to follow up and patients who passed away were excluded from the study.
Results: There were 220 patients who attended HFC between January and June 2017 who were already on or started on MRA. 73% were males and 27% females. Mean age was 67 years. 24.5% (n=54) stopped MRA after 12 months of which 35% (n=19) did not tolerate the drug due to side effects (including gynaecomastia and hypotension) and 65% (n=35) had to stop the drug due to a significant rise in creatinine and/or hyperkalaemia. Baseline (estimated glomerular filtration rate) eGFR was noted to be a predictor for stopping MRA after 12 months (p value 0.013) using multivariate logistic regression for confounders including age, gender and baseline potassium. Mean eGFR in patients stopping MRA was 58.7mls/min/1.73m2 and mean eGFR in patients who continued MRA was 70.5mls/min/1.73m2.
Conclusion: In this study we found that baseline eGFR is a predictor for stopping or continuing MRA after 12 months of follow-up. Age, gender and baseline potassium were not shown to be predictors in stopping or continuing MRA after 12 months.

P1650

Sacubitril valsartan, a multicentric experience

FJ Francisco Javier Cortes[1]; DF Arroyo Monino[1]; MI Fernandez Valenzuela[1]; MI Rivadeneira Ruiz[1]; P Ruiz Garcia[1]; M Chaparro Munoz[1]; AJ Castro Fernandez[1]; A Recio Mayoral[1]
[1]*Virgen Macarena University Hospital, Seville, Spain*

Introduction: In the years following the publication of PARADIGM-HF trial in 2014, a growing evidence supports the safety and efficacy of sacubitril/valsartan in patients with HFrEF. The purpose of this study is to analyse the impact of sacubitril/valsartan on real world heart failure cohort.
Material and methods: We performed a prospective observational study with patients with HFrEF pick out in outpatient clinic, who started treatment with Sacubitril/Valsartan between January 2016-January 2018. We analysed their baseline characteristics and the functional class, renal function and drug tolerance in one year follow-up.
Results: 336 patients were included during the observed time period, with a mean age of 67,55 ± 10,93 years, being 24,5% female. The main basaline ejection fraction was 30,1 ± 6,8. The main cause of heart failure was ischemic heart disease (42,7%). Initially, the majority were in FC II-III (87%). In a review at 12 months follow-up, ARNI was at low doses in 23%, at medium doses 32% and the rest at high doses. Only a small proportion of patients (11%) have been down-titrated after achieving the maximal target dose of sacubitril/valsartan by sintomatic hipotension. Concerning analytical parameters, we did not find significant differences in renal function or in potassium levels during follow-up.
Conclusions: The treatment with sacubitril/valsartan in a group of patients in real-life was generally well tolerated with a significant decrease in blood pressure, being able to optimize the dose of sacubitril/valsartan. It was also related to improvement in the functional class without find significant differences in renal function during follow-up.

P1651

Reduction of NT-proBNP in patients with type 2 diabetes mellitus and heart failure with preserved ejection fraction in short-term treatment with empagliflozin on top of existing therapy

B Branimir Kanazirev[1]; A Dinkov[1]; K Hristozov[1]; E Marinova[1]; V Zlateva[1]; M Boyadjieva[1]; Y Bocheva[1]
[1]*Medical University of Varna, Varna, Bulgaria*

Objective: To investigate effect of SGLT-2 inhibitor on NT-pro-BNP levels, physical capacity and selected echocardiographic parameters in patients with type 2 diabetes (T2 DM) and heart failure with preserved ejection fraction (HFpEF)
Materials and Methods: Empagliflozin 10 mg/daily was administered to 24 T2DM and HFpEF patients (64.3±7.7) on top of pre-existing standard therapy. NT-proBNP, glomerular filtration rate (GFR), 6-minute test (6MWT), left atrial area (LAA), left ventricular ejection fraction (LVEF) and systolic blood pressure(SBP) were investigated on day 30.
Results: NT-proBNP decreased after 30 days of treatment with Empagliflozin added to standard patient therapy. 6MT, LVEF and LAA and SBP show a tendency for improvement and the GFR decreased insignificantly.

Changes in NT-proBNP, GFR, 6MWT, LAA, LV

	NT-pro BNP	GFR	6W	LAA	LVEF	SBP
Before	1104±1078*	76±13**	266±88**	23.9±5.9**	57.2±5.5**	135±15**

Effects of sacubitril/valsartan on real-world patients with heart failure due to non-ischemic cardiomyopathy

C-Y Hsu[1]; Y-C Lin[2]; C-Y Huang[1]
[1]*Taipei Medical University Hospital, Division of Cardiology, Department of Medicine, Taipei, Taiwan, Province of China*; [2]*Taipei Medical University Hospital, Department of Pharmacy, Taipei, Taiwan, Province of China*

BACKGROUND: Sacubitril/valsartan significantly reduced heart failure hospitalizations and mortality in the PARADIGM-HF-trial. However, little is known about the dosing, tolerability, efficacy and safety of sacubitril/valsartan in a non-clinical trial real-world population with non-ischemic cardiomyopathy.
METHODS: Between March 2017 and December 2018 , we retrospectively collected baseline and follow-up data of all consecutive patients with heart failure with reduced ejection fraction (HFrEF) due to non-ischemic etiology (non-ischemic cardiomyopathy) receiving therapy with sacubitril/valsartan. Doses of sacubitril/valsartan were optimized to individual tolerance. In addition to clinical and echocardiographic assessment, plasma N-terminal pro-B-type natriuretic peptide (NT-pro-BNP), serum creatinine and estimated glomerular filtration rate (eGFR) levels were measured and compared between baseline and 3-18 months after treatment.
RESULTS: A total of 129 patients (70% males) were identified. At baseline, median age was 65 years, median left ventricular ejection fraction (LVEF) was 30%, and all patients had symptoms of NYHA functional class ≥II. A total of 45% of patients received dose adjustment. They received a much lower dose of sacubitril/valsartan in comparison with those in the PARADIGM-HF (113 ± 60 vs. 375 ± 75 mg). Within 6 months of being transitioned into sacubitril/valsartan therapy, only 1.6% achieved maximal dose (400 mg/day), 18.6% achieved 200 mg/day, 59.7% achieved 100

mg/day, and 20.2% achieved 50mg/day. The main reason for not achieving maximal dose was because a decrease in blood pressure (49%). However, symptomatic hypotension leading to medication discontinuation only occurred in 5 patients (4%). Over a median(IQR) follow-up of 354 (135-453) days after initiation of sacubitril/valsartan, LVEF improved (31.0 ± 9 vs 42.6 ± 11%; P = .002) and NT pro-BNP levels decreased (15375 ± 4041 vs 10443 ± 3267 pg/ml; P < .001). However, a modest but significant decrease in eGFR (61.9 ± 35 vs 51.8 ± 33 ml/min/1.73m2; P < .001) was also observed.
CONCLUSION: Real-world patients with HFrEF due to non-ischemic cardiomyopathy exhibit significant cardiac function improvement following the initiation of sacubitril/valsartan. However, the optimal target dose of sacubitril/valsartan for Asian population, who are tend to be associated with lower body mass index, lower blood pressure and less tolerable doses of ACE-inhibitors/ARBs, should be observed in larger scale real-world clinical studies.

P1653

Effects of ivabradine on patients with depressed left ventricular ejection fraction after cardiac resynchronization therapy

H-Y Hung-Yu Chang[1]; C-W Hsieh[1]; M-C Fong[1]; A-N Feng[1]; K-C Huang[1]; W-T Lai[1]; W-H Yin[1]
[1]*Cheng-Hsin General Hospital, Taipei, Taiwan, Province of China*

Introduction: Cardiac resynchronization therapy (CRT) and ivabradine therapy should be considered for appropriately selected heart failure (HF) patients with reduced ejection fraction after optimized medical therapy. However, ivabradine might increase atrial fibrillation (AF) burden and decrease the percentage of biventricular pacing in CRT recipients. We aimed to evaluate clinical effects of ivabradine on patients with left ventricular ejection fraction (LVEF) less than 40% after CRT implantation.
Methods: We consecutively examined 115 CRT recipients between 2014 and 2016. After exclusion of those with improvement of LVEF more than 40%; permanent AF; or concomitant sick sinus syndrome, 65 patients with LVEF less than 40% 6 months after CRT implantation and resting sinus rates greater than 70 beats per minute were studied. Eighteen patients received ivabradine treatment in addition to other guideline-recommended medical therapy, and 47 patients continued to receive standard treatment. Clinical endpoints and relevant CRT parameters were collected till December 2018.
Results: Baseline characteristics were not significantly different in the Ivabradine versus Control groups. During a mean follow-up period of 587 days, patients in Ivabradine group had significantly lower resting heart rate (71.7±11.2 vs. 78.7±10.5 bpm, p=0.021) and numerically higher LVEF improvement (+9.6±13.7% vs. +4.4±8.2%, p=0.064) than those in Control group. Two patients (11.1%) in Ivabradine group developed new-onset AF, requiring electrical and/or pharmacological cardioversion, whereas new-onset AF occurred in 5 patients (10.6%) in Control group (p=0.956). Biventricular pacing were 99.3±0.7% and 98.6±1.2% before and after the prescription of ivabradine (p=0.111). Mortality rates were numerically higher in the Control group than the Ivabradine group (22.2% vs. 5.6%, p=0.155).
Conclusion: In patients with prior CRT implantation and depressed LVEF, ivabradine therapy effectively reduced resting heart rate, and showed trends in improving LVEF and reducing mortality. Moreover, usage of ivabradine did not significantly affect biventricular pacing percentage in CRT recipients.

P1654

Benefits of early administration of ivabradine in stabilized patients hospitalized due to worsening heart failure: insights from the Optimize Heart Failure Care Program

LG Mircheva[1]; Y T Yoto Trifonov Yotov[1]
[1]*Medical University, Varna, Bulgaria*

On behalf of: Optimize Heart Failure Care Program

Heart failure (HF) affects quality of life (QoL). High heart rate (HR) is an important prognostic factor and worsens further the QoL in patients with HF.
Aim: to assess the benefits of early administration of Ivabradine (Iv) on QoL in patients with HF.
Subjects and methods: Overall, 156 patients at a mean age 68 years, 69% males, were actively followed for 6 months. All patients were evaluated for their demographic data and etiology and by echocardiography at baseline before dehospitalization from the Clinic and lab tests including NTproBNP, quality of life measures, 6-minute walking test (6MWT), NYHA class, and clinical examination at follow-up visits were done.
Results: Iv was administered in 18.4% of all patients, 27% of the patients in sinus rhythm. The administration of Iv improved all measures of QoL (Table1). The distance covered at 6MWT increased more with 53.9 m in Iv group.
Conclusions: The early administration of HR reducing therapy including Iv improve the QoL in all dimensions.

Series of patients treated with sacubitril-valsartan in a cardiology day clinic: efficacy and safety after 6 months of follow-up

C Cristina Beltran Herrera[1]; V Suberviola Sanchez-Caballero[1]; S Briongos[1]; M Sarrion[1]; A Sanchez[1]; C Cortina[1]; A Estevez[1]; ML Giganto[1]; I Ponz[1]; D Vaqueriza[1]; M Dominguez[1]; E Gomez[1]; S Jimenez[1]; L Mora[1]; R Munoz[1]
[1]*University Hospital Infanta Leonor, Madrid, Spain*

Introduction Sacubitril-valsartan (ARNI) has demonstrated to improve functional class (FC) by NYHA in patients (pts) with heart failure (HF) compared to ACEI with no higher complications rate. Our objective is to describe FC and real-life complications in pts treated with ARNI .Methods We analyzed 63 pts, we evaluated FC by NYHA and complications (hypotension, impaired renal function and hyperkalemia) 3 and 6 months after ARNI. HF decompensations and drug withdrawals were evaluated after 6 months. Results:ARNI improves FC by NYHA at 3 and 6 months. There is no hypotension, impaired renal function or significant hyperkalemia at 3 and 6 months. 31.7% had history of HF in the 12 months before ARNI. At 6 months there were only 5 HF, 2 with severe anemia as a trigger, 3 required admission and 2 were resolved on an outpatient basis. 2 drug withdrawals due to symptomatic hypotension and impaired renal function (Cr> 2.5 mg / dl) Conclusions:ARNI improves FC by NYHA without significant complications.There were a very small number of decompensations and drug withdrawals at 6 months.

Effects of empagliflozin on exercise capacity and LV diastolic function in HFpEF and type-2 diabetes mellitus: rationale and design of prospective intervention study

A Ovchinnikov[1]; A Anton Borisov[1]; C Zherebchikova[1]; O Ryabtseva[1]; O Svirida[1]; F Ageev[1]
[1]*National Medical Research Center for Cardiology, Moscow, Russian Federation*

Funding Acknowledgements: Ministry of Health of the Russian Federation

Background: To date, no specific treatment has been shown to improve outcomes in heart failure with preserved left ventricular ejection fraction (HFpEF). Type-2 diabetes mellitus (T2DM) has been identified as a major cause of HFpEF. EMPA-REG OUTCOME trial showed that empagliflozin is associated with reduction in heart failure death and hospitalization, making empagliflozin a new promising agent that could potentially improve outcomes in patients with HFpEF.
Purpose: to assess whether sodium glucose cotransporter 2 (SGLT2) inhibitor empagliflozin improves exercise capacity and left ventricular diastolic function in patients with HFpEF and T2DM.
Methods/Design: A total of 100 patients with stable HFpEF, NYHA functional class II-III and T2DM will be randomly allocated either to empagliflozin (10 mg o.d.; n=50) or control (n=50) group. In both groups patients will be receiving standard treatment for HF and T2DM. Echocardiography at rest and during exercise (diastolic stress-test, DST), 6-minute walk test (6MWT), Minnesota Living with Heart Failure Questionnaire (MLHFQ) score assessment, complete blood count, urinalysis, and biomarker blood tests (N-terminal pro b-type natriuretic peptide, endothelin 1, growth/differentiation factor 15, soluble ST2, galectin-3, interleukin-6, high-sensitivity C-reactive protein, carboxyterminal propeptide of type I collagen, pentraxin 3) will be performed at baseline and 24 weeks after randomization. DST will be performed as a supine bicycle test at 60 rpm starting at a 3-min period of low-level 25-W workload followed by 25-W increments every 3-min to maximum tolerated levels. During DST, mitral inflow velocities, mitral annulus tissue Doppler velocities, and peak tricuspid regurgitation velocity by continuous wave Doppler will be analyzed at baseline, during each stage including peak exercise and in recovery. Outcome measures: Timeframe for all outcome measures is 24 weeks. The primary outcome measure is change from baseline in 6-minute walk distance (6MWD). Secondary outcome measures include change from baseline in DST exercise time, NYHA functional class, MLHFQ score, pulmonary capillary wedge pressure and pulmonary artery systolic pressure (assessed by echocardiography) both at rest and during DST, LV mass index, LA volume index, LA stiffness (assessed as a ratio of mitral E/e′ ratio to LA strains), and biomarker blood levels.

Acute Effect of Sacubitril/Valsartan on Depression Score in patients with Acute Decompansed Heart Failure on the First Day of Theraphy:A Prospective Analysis from Our Center Experiences

TARIK Kivrak[1]; YUSUF Akin[1]; OZKAN Karaca[1]; MEHMET Yilmaz[2]
[1]*Firat University, Department of Cardiology, Elazig, Turkey*; [2]*Cumhuriyet University, Department of Cardiology, Sivas, Turkey*

Background: Angiotensin receptor neprilysin inhibitor(ARNi)enhances beneficial natriuretic peptides by inhibiting their break down through neprilysin. Although the first-in-class ARNi sacubitril/valsartan (LCZ696)reduced mortality and morbidity in heart failure(HF)with reduced ejection fraction(EF) compared to angiotensin-converting enzyme inhibitor(ACEi), psychiatric desirable effects of sacubitril/valsartan in acute decompensated heart failure are unknown such as depression.
Purpose: The aim of our study is to investigate the effect of valsartan-sacubitril on depression in acute decompensated heart failure.
Methods: We characterized patients by whether they received the mid-dose (49/51 mg sacubitril/valsartan twice dose and optimal medical therapy or 5 mg ramipril once dose and optimal medical therapy).70 patients with acute decompensated heart failure in patients with reduced ejection fraction had repeated assessments with the hospital depression scale in the first 24 hours. The difference between the two groups was compared.
Results: The depression score reduction was significantly greater in the sacubitril–valsartan group than in the ramipril group. Changes of before and after valsartan-sacubitril treatment in depression score of patients was showed significantly (before value: 23.43 ± 8.527; after value: 21.34 ± 7.74, p < 0.001).There was no change in ramipril group(before value:22.45±7.75;after value:22.01±6.67, p=0.78)(Table 1).
Conclusions: Depression increased mortality and hospitalization in patients with acute decompensated heart failure. Our trial is an essential trial because of ARNi improve depression score in patients with acute decompensated heart failure in the early term. We think that ARNi may be more effective on depression in long-term.

Variation of Depression Score

	Before	After	Mean	Standard Deviation	Confidence Interval	p value
Valsartan Sacubitril	23.43±8.527	21.34±7.74	2.086	2.769	1.034≈3.037	0.000086
Ramipril	22.45±7.75	22.01±6.67	0.877	1.235	2.661±4.045	0.78

P1658

Titration process and predictors of achieving target dose of sacubitril/valsartan in patients with chronic heart failure and reduced ejection fraction attending to an outpatient heart failure clinic.

M Marcelo Rizzo[1]; I Colomer-Asenjo[1]; S Marin-Lopez[1]; M Sutil-Vega[1]; F Taibi-Hajjami[1]; C Roca-Guerrero[1]; N Mallofre-Vila[1]; S Galan-Fernandez[1]; M Lloreda-Surribas[1]; D Garcia-Vega[1]; M Bonastre-Thio[1]; M Panelo-Rubio[1]; D Valcarcel-Paz[1]; J Orus-Puigvert[1]; A Martinez-Rubio[1]
[1]*Hospital of Sabadell, Sabadell, Spain*

Background Data from recent clinical trials indicate that sacubitril/valsartan can be successfully initiated and uptitrated to the maximum target dose in most patients with stable chronic heart failure. However, there is relatively little information about the titration process in real-world heart failure patients.
Purpose To assess the characteristics and clinical outcome of unselected patients with stable chronic heart failure during the titration period of sacubitril/valsartan and to identify predictors of achieving maximum target dose.
Methods We collected data from 64 consecutive patients attending to our outpatient heart failure clinic who started sacubitril/valsartan between May 2018 and November 2018. Patients were uptitrated based on the attending physician judgment with the goal of achieving sacubitril/valsartan 200 mg twice daily. Variables were collected baseline and at the end of the titration period.
Results At baseline, mean age was 63±10 and 76,6% men. Mean LVEF 28±6%. 39% had ischemic etiology. Mean NYHA class 2,3±0,4. Median NT-proBNP level 1176 pg/ml (IQR 364-3945), mean glomerular filtration rate (GFR CKD-EPI) 71,7±20,6 mL/min, serum potassium 4,4±0,4 mEq/L. 84% of patients received ACE inhibitors (median enalapril equivalent dose 7,5 mg/day, IQR 5-13.7) or angiotensin receptor blockers (median equivalent valsartan dose 80 mg/day, IQR 60-160). 95% received beta-blockers and 86% mineralocorticoid receptor antagonists (MRA). The median time between starting medication and the end of the titration (titration period) was 6,5 weeks (IQR 3-13,2). 10 patients (15.6%) discontinued therapy due to adverse events. Among patients tolerating therapy, 23 (42,6%) achieved the maximum target dose. At the end of the titration period 18 patients (33,3%) improved at least one stage in NYHA class. A reduction in furosemide equivalent dose (52,3±39,2 mg vs 45,5±41,4 mg, p=0.005) was observed. Before starting sacubitril/valsartan, lower systolic blood pressure (SBP), lower GFR CKD-EPI and previous treatment with MRA were associated with not achieving maximum target dose (all p<0.05). In a multivariate analysis adjusted by age, GFR CKD-EPI, SBP, kalaemia and previous treatment with MRA, a lower GFR CKD-EPI before starting titration (OR 0,95 95% CI 0,91-0,99 p=0.01) and previous treatment with MRA (OR 16,4 95% CI 1,6-164 p=0.01) were independently associated with not achieving maximum target dose.
Conclusions In this cohort of unselected patients with stable chronic heart failure, the proportion who achieved maximum target dose of sacubitril/valsartan was lower than the reported in controlled clinical trials, despite a longer titration time. However, clinical benefit was observed at the end of the titration period. The difficulty to achieve maximum doses in patients treated with MRA could suggest a subgroup

with a higher degree of neurohormonal blockade, needing a more careful adjustment of concomitant treatment, mainly diuretics and vasodilators.

P1659

Nitrates in female patients with diabetes mellitus and without diabetes mellitus in reduced ejection fraction heart failure

G Guliz Kozdag[1]; D Ural[2]; K Karauzum[1]; I Karauzum[1]; J Wiley[3]; C Sanina[4]; C Baydemir[5]; T Sahin[1]; E Ural[1]; U Bildirici[1]; A Agacdiken Agir[1]
[1]Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey; *[2]Koc University, Cardiology, Istanbul, Turkey*; *[3]Albert Einstein College of Medicine, Cardiology, New York, United States of America*; *[4]Montefiore Medical Center (Bronx), New York, United States of America*; *[5]Kocaeli University, Department of Biostatistics, Kocaeli, Turkey*

Back Ground: Although sex-specific differences in cardiovascular medicine are well known, the exact influences of sex on the effect of cardiovascular drugs remain unclear. Women and men differ in body composition and physiology and pharmacodynamics, so that is not rare that they may respond differently to cardiovascular drugs. Patients may also have multiple comorbidities at the same time. Clinical guidelines for the management of type 2 diabetes (DMII) recommend individual therapy. If treatment is individualized for every patients the prognosis could be better in patients with multiple comorbidities. Organic nitrates remain among the oldest and most commonly employed drugs in cardiology. This study aims to evaluate the effects of oral nitrates on all-cause mortality in reduced ejection fraction heart failure (HFrEF) patients according to their genders and the presence or the absence of DM using GDMT.
Method: 399 male patients and 231 female patients with HFreF were recruited into the study. There was no age differences between the groups, the male patients' ejection fraction was lower than the female patients' EF. Almost 40% of the males and the females had DM. There was no difference for the treatment of oral nitrates between the female group and the male group (Table 1). 66 patients (44%) who had DM were on the nitrates in the male group, 33 patients (33%) who had DM were on the nitrates in the female group, p=Not significant (NS).
Results: 207 male patients (52 %) and 106 female patients (46%) of the cohort died during a median follow-up duration of 54 months, p=NS. While 24 of female patients (62%) without DM who were on the oral nitrate treatment died, 36 of female patients (39%) without DM who weren't on the oral nitrate treatment died p=0.016 during follow-up. There was no statistical difference for all-cause mortality between the females with the oral nitrate treatment and the females without the oral nitrate treatment in patients with DM. We did not determine any difference among the males with or without DM who were on the nitrate or were not on the nitrate in the patients with HFreF in this study.
Conclusion: We determined that there was more all-cause mortality in the female patients without DM who was on the nitrate treatment in the study.

Table 1. General characteristics of pat

	Male (n=399)	Female (n=231)	p
Age (years)	66± 11	66± 13	NS
Ejection fraction (%)	24 ± 9	27± 10	0.001
Diabetes	151 (38%)	99 (43%)	NS
Nitrate treatment	72 (31%)	154 (39%)	NS

P1660

Microcirculation changes in combination therapy in patients with heart failure with preserved ejection fraction.

ZM Akhilgova[1]; MV Kurkina[2]; ZR Dzhioeva[1]; AG Avtandilov[1]
[1]Russian Medical Academy of Continuous Professional Education, Moscow, Russian Federation; *[2]City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation*

Introduction Nowadays, heart failure (HF) with preserved ejection fraction (EF) (HFpEF) is an increasing public health problem and accounts for almost 50% of the total number of patients with HF.
Considering diversity of factors affecting the development of HFpEF, the main of which are age and arterial hypertension (AH), and the heterogeneity of the pathophysiology, it is necessary to consider the role of the combined treatment of this syndrome to prevent further microcirculation rarefication.
Aim: To assess the effect of triple combination therapy on vascular reactivity and microcirculation changes in patients with HFpEF.
Methods: The study includes 26 patients (3 males and 23 females), aged from 55 to 81 yrs (mean age 65,1±7,6 yrs), with preliminarily diagnosed HFpEF in previous hospitalizations during 2017 using ESC criteria for diagnosing chronic HF. All patients suffered from AH and class I-III obesity, in some patients had diabetes melitus, the level of NT-proBNP ranged from 192 to 276 pg/ml in the group. The echocardiography showed the EF 61±2,5% and the ratio of early left ventricular diastolic filling and diastolic mitral annulus velocity ($E/^{'}$) 14,2±2,0 in the group.
Patients were examined before and 3 months after administration a triple combination of drugs, including perindopril 10 mg, indapamide 2,5 mg and amlodipine 5 mg.
The peripheral hemodynamics and vascular reactivity was estimated using a photoplethysmographic method on a PulseTrace device with determination of vascular stiffness index (SI) and pulse wave reflection index (RI). Oscillometry was perfomed to evaluate systemic vascular resistance (SVR), specific peripheral resistance (SPR), reflecting the condition of the arterioles, and brachial artery compliance.
Results: The data obtained during therapy shows a significant decrease in SVR from 2667 ± 356 dyn*cm-5 to 2195 ± 247 dyn*cm-5 (p <0,001) and in SPR from 33,2 ± 5,05 dyn/sec/cm-5 to 27,9 ± 3,03 dyn/sec/cm-5 (p <0,001).
In assessing the stiffness of the muscular arteries, there was a decrease in RI from 71,6 ± 5,05% to 58 ± 11,1% (p <0,001), and a significant decrease in SI from 11 ± 0,46 m/sec to 7,6 ± 1,5 m/sec (p <0,001), indicating a decrease in the vascular tone of the major branches of the aorta.
At the same time, the brachial artery compliance increased from 1,025 ± 0,25*106/mmHg to 1,243 ± 0,35*106/mmHg (p <0,001).
Conclusions: Preliminary data suggest a positive effect of triple combination therapy on the vascular system, with a predominant influence on its microcirculatory section.

P1661

Effects of perindopril on levels of endothelial dysfunction biomarkers in chronic heart failure patients with mid-range ejection fraction after 12-month therapy

I Irina Ilgisonis[1]; YU Danilogorskaya[1]; E Zheleznykh[1]; YU Belenkov[1]; M Kozhevnikona[1]; G Shakaryants[1]; A Shchendrigina[1]; E Privalova[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background. The pathogenesis and progression of chronic heart failure is associated with endothelial dysfunction and severe cardiovascular remodeling. Thus, correction of these important processes may improve the course of the disease and long-term outcomes.
Purpose. To evaluate effects of perindopril A long-term therapy on endothelial dysfunction biomarkers in patients with chronic heart failure with mid-range ejection fraction (HFmrEF).
Methods. Thirty patients with HFmrEF of II-III functional class (NYHA) were enrolled in the study (men/women = 20/10; average age 65 (61;72) years old; duration of HF – 6 (3; 9) years; average body mass index 27.7 (25.3;30.8) kg/sqm) of ischemic etiology (coronary artery disease duration – 10 (5; 17) years; myocardial infarction - 20 patients (64%)). HFmrEF was verified by transthoracic echocardiography (average EF 46% (44; 49); average NT-proBNP levels 215 (135;256) pg/ml). The cohort was represented by patients with II NYHA class (n=18, 60%) and III NYHA class (n=12, 40%). All patients underwent specific laboratory testing by ELISA for identification of biomarkers of endothelial dysfunction and vessel remodeling (metalloproteinase-9 (MMP-9), tissue inhibitor of metalloproteinase 1 (TIMP-1), E-selectin, endothelin-1 (ET-1), transforming growth factor β1 (TGF-β1), vessel endothelial growth factor A (VEGF A)) before and after 12-month treatment with perindopril A 10 mg/d.
Results. After 12-month treatment of HFmrEF patients with perindopril A in the maximum tolerated dose of 5 mg/day (n=19) and 10 mg/day (n=11) a significant decrease of MMP-9 level was observed: from 209.5 ng/ml (145.75;266.75) to 157 ng/ml (116.5;221.75) (p<0.05), N up to 134 ng/ml; while the level of TIMP-1 did not significantly change. A significant decrease also was noted in the level of E-selectin from 42.7 ng/ml (30.2;62.88) to 35.7 ng/ml (24.1;47.95) (p<0.05), N 21-186 ng/ml; as well as the level of growth factors: VEGF-A from 156 ng/ml (9.05;271,7) to 34,85 ng/ml (8.05;142.28) (p<0.05), N up to 128 ng/ml, TGF- β1 from 24665 pg/ml (5136.5;5300.25) to 14637 pg/ml (5300.25; 29354) (p<0.05), N 5222-13731 pg/ml. The level of ET-1 decreased from 0.845 ng/ml (0.43;1.45) to 0.735 ng/ml (0.4125;1.3775), (p <0.05), N less than 0.26 ng/ml. The change in the level of these indicators was associated with a significant increase in the left ventricular EF from 46% (44;49) to 49.5% (48;54) (p <0.05).
Conclusion. 12-month therapy with perindopril A 5-10 mg/day was associated with significant decrease of the analyzed biomarkers, thus improving endothelial function, vessel remodeling and myocardial contractility in HFmrEF patients.

P1662

Sacubitril/valsartan in chronic symptomatic heart failure: a real world experience of delivery and outcomes.

A Aileen Kearney[1]; L Hill[1]; J Davidson[1]; C Mc Clure[1]; L Dixon[1]
[1]*Royal Victoria Hospital, Belfast, United Kingdom of Great Britain & Northern Ireland*

Introduction: The PARADIGM-HF trial demonstrated a reduction in cardiovascular mortality and heart failure hospitalisation with sacubitril/valsartan compared to standard therapy in patients with chronic heart failure with reduced ejection fraction. Sacubitril/valsartan is recommended by NICE in patients with left ventricular ejection fraction ≤35% and NYHA class II-IV symptoms who are established on ACE-inhibitors (ACE-I) or angiotensin II receptor blockers (ARB).
Purpose: We report our clinical experience of sacubitril/valsartan use in a real world heart failure cohort.
Methods: Eligible patients were identified from our electronic database and initiated on low dose sacubitril/valsartan. Patients were reviewed and uptitrated at 4 weekly intervals until the maximum tolerated dose was achieved. Data on New York Heart Association (NYHA) class, maximum tolerated dose, heart failure hospitalisation, mortality and discontinuation rates were collected and analysed on all patients who started sacubitril/valsartan between June 2016 and January 2018.
Results: A total of 86 patients (mean age 65.3 ± 11.4 years) were commenced on sacubitril/valsartan. The mean length of follow-up was 11.4 months at the time of data collection. All patients were receiving stable doses of ACE-I or ARB prior to initiating sacubitril/valsartan with 94% and 85% established on beta-blockers and mineralocorticoid receptor antagonists respectively. 4 patients (4.7%) were admitted to hospital with decompensated heart failure and 4 patients (4.7%) died during the follow-up period of which 2 deaths occurred due to progressive heart failure, 1 due to myocardial infarction and 1 non-cardiovascular related death. 19 patients (22.1%) discontinued sacubitril/valsartan due to adverse side effects during the follow-up period. Reasons for discontinuation of therapy included symptomatic hypotension (n=5), deterioration in renal function (n=5), hyperkalaemia (n=3), gastrointestinal disturbance (n=3), rash (n=2) and cough (n=1). Of those who tolerated therapy 22 patients (32.8%) achieved and maintained titration to the maximum dose of 97/103mg twice daily whereas 24 patients (35.8%) tolerated the lowest dose of 24/26mg twice daily. 18 patients (26.9%) had an improvement in NYHA class compared to 1 patient (1.5%) who had a deterioration in NYHA class. 19 patients (28.4%) had a reduction in loop diuretic dose compared with 2 patients (3%) requiring higher loop diuretic dose.
Conclusions: These results support the efficacy of sacubitril/valsartan in a well-treated real world heart failure cohort. A large proportion of patients did not achieve the maximum dose mainly because of symptomatic hypotension, deteriorating renal function and hyperkalaemia. This highlights the requirement for close monitoring of symptoms and renal function when initiating therapy and with dose titration. This can be achieved through a nurse-led heart failure clinic.

P1663

Outpatient inotrope administration in advanced heart failure patients: a single centre experience.

J James Curtain[1]; E Kavanagh[1]; C Howley[1]; C Tracey[1]; C Halley[1]; J O'neill[1]; NG Mahon[1]
[1]*Mater Misericordiae University Hospital , Dublin, Ireland*

Background: Inotropic agents are used in the treatment of advanced heart failure patients. Inotrope dependency is one of the indications for cardiac transplantation. Inotropes may have side effects, including arrhythmia and hypotension, so their use is mostly restricted to specialist units. Transplant candidate patients often have prolonged coronary care unit (CCU) admissions receiving inotropes. Opportunities for outpatient leave may provide psychological support for long-term inpatients.
Aim: We assessed the feasibility and safety of outpatient administration of inotropes in patients in a cardiac transplant centre.
Methods: A retrospective analysis of advanced heart failure patient records from 2010 – 2018 was conducted. Data was obtained on the type and dose of inotrope and diuretics used, venous access, right heart catheterisation (RHC) results, history of implantable cardiac defibrillator (ICD), renal function, blood pressure, heart rate, duration of outpatient leave, time from admission until first outpatient leave, time from admission until transplant or left ventricular assist device (LVAD), patient's county of residence and complications during outpatient leave.
Results: 5 patients received outpatient inotropes. 3 patients received milirone, 1 patient received dobutamine. 1 patient received both milirone and dobutamine at different stages during their admission. All patients had PICC line central venous access with pump devices for drug administration. All patients had an ICD. Mean time until first outpatient leave from admission was 66 days (17-150). Mean time on inotropes to transplant or LVAD was 418 days (375-489). Mean blood pressure was 100/60 mmHg (90-122 / 56–79). Mean heart rate was 78 bpm (64–90). Mean cardiac output was 4.2L/min (3.6-4.7). Mean pulmonary capillary wedge pressure was 12mmHg (7-24). 2 patients received outpatient inotropes while on full weekend leave. 2 patients were administered inotropes during day leave. 1 patient was discharged home on dobutamine as part of a palliative care process. 3 patients lived in Dublin.
No changes to inotrope or diuretic therapy were made within one week of outpatient leave. No changes to therapy were made following the most recent RHC prior to outpatient leave. A planned dobutamine weaning process had been started in the palliative care patient prior to discharge. One patient had an unscheduled return to CCU for a PICC line occlusion. All 4 transplant candidate patients had anticipated leave postponed for clinical reasons. One patient had documented non-sustained ventricular tachycardia in the week prior to leave. No ICD therapies were documented during the outpatient periods. Improvement in mood was documented following a leave period in all returning patients.
Conclusions: Outpatient inotrope administration can be safely provided to selected patients, in diverse settings, including as bridge to transplant or as part of an end-stage palliative process.

Atrial fibrillation in Dutch chronic heart failure with reduced ejection fraction patients: the CHECK-HF registry

J F Veenis[1]; HP Brunner-La Rocca[2]; AW Hoes[3]; GCM Linssen[4]; JJ Brugts[1]
[1]*Erasmus MC, University Medical Center Rotterdam, Cardiology, Rotterdam, Netherlands (The)*; [2]*Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands (The)*; [3]*University Medical Center Utrecht, Utrecht, Netherlands (The)*; [4]*Hospital Group Twente, Cardiology, Twente, Netherlands (The)*

On behalf of: CHECK-HF investigators
Funding Acknowledgements: Servier, the Netherlands, funded data inclusion and software programme. Analysis was conducted, interpreted, and reported independently of the sponsor

Background/introduction: Atrial fibrillation (AF) is a common finding in chronic heart failure (HF) patients, associated with an increased risk of mortality and thromboembolic events. The ESC provides guidelines for both AF and HF, however information on the adherence to these guidelines in patients with both AF and HF is scarce.
Purpose: Evaluation of current HF therapy and adherence to the ESC HF Guidelines in patients with and without AF in the Netherlands.
Methods: The current analysis is part of a cross-sectional registry of 10,910 chronic HF patients at 34 Dutch outpatient clinics in the period of 2013 until 2016 (CHECK-HF). Demographic parameters, laboratory and echocardiographic values as well as medication use (type, dosage and frequency and total daily dose) were recorded.

Table 1. AF and HF therapy in HFrEF

	Unadjusted analysis	Age and gender adjusted analysis (OR [95% CI])	Multivariate analysis (OR [95% CI])*			
Pharmaco-therapy (n=8,120)	With AF	Without AF	p-value			
	Beta-blocker,%	81.7	79.7	0.04	1.26 [1.11-1.44]	1.33 [1.16-1.52]
	RAS-inhibitors, %	76.1	83.1	<0.01	0.79 [0.70-0.90]	0.87 [0.77-0.99]
	MRA, %	57.1	51.7	<0.01	1.33 [1.20-1.48]	1.37 [1.23-1.53]
	Diuretics, %	89.7	80.6	<0.01	1.72 [1.47-2.01]	1.65 [1.40-1.95]

	ICD	15.4	35.7	<0.01	0.40 [0.34-0.46]	0.42 [0.36-0.49]
	CRT	7.3	20.2	<0.01	0.32 [0.26-0.39]	0.31 [0.26-0.39]
	Pacemaker	8.5	8.3	0.77	0.69 [0.56-0.85]	0.60 [0.49-0.75]

* Adjusted for age, gender, NYHA classification, LVEF, HR>70, hypertension, diabetes and renal insufficiency

Results: We studied 8,253 patients with HF with reduced ejection fraction (HFrEF), of which 2,109 (25.6%) had AF. Patients with AF were significantly older (76.8±9.2 vs. 70.7±12.2 years, p<0.01), were more often in NYHA III/IV (33.4% vs. 25.2% resp., p<0.01), and had more hypertension (44.3% vs. 38.3, p<0.01), diabetes (31.0% vs. 28.4%, p<0.01) and renal insufficiency (63.3% vs. 53.8%, p<0.01) compared to HFrEF patients without AF.HF medication use is presented in Table 1. HFrEF patients with AF receive more often beta-blockers, MRA and diuretics, and less often RAS-inhibitor. We observed a lower percentage of ICD, CRT and pacemaker in patients with AF.
Conclusion: In this large registry, we observed a lower prescription of RAS-inhibitors, and implantation of ICD, CRT and pacemaker, but a higher prescription of beta-blocker, MRA and diuretics in HFrEF patients with AF, compared to those without AF.

P1665
Reduced diuretic requirements in HFreF patients taking Entresto (ARNI)

T Mannion[1]; L O'connor[1]; J Kelly O'haire[1]; G O'gara[1]; B Mcadam[1]
[1]*Beaumont Hospital, Supportive Heart Service, Dublin, Ireland*

Background: Post hoc analysis of PARADIGM-HF has shown treatment with Entresto was associated with greater diuretic dose reductions compared to Enalapril.
Purpose:To examine clinical & medication changes in HFrEF patients following treatment with ARNI.
Methods: Employing a One-Group Pre-Test Post-Test Design, data was collected on 90 HFrEF patients (74 male: 16 female) prior to initiating ARNI therapy & 12 months post achieving maximum tolerated dose. Indices of cardiac function were recorded (LVEF, LVIDd), biochemical measures (NTproBNP, potassium and creatinine), while medications were recorded & functional capacity was assessed using NYHA Classification. Paired sample t-test was completed to assess for significant changes.
Results: Dose reductions of both loop and thiazide diuretics- mean dose reduction for each diuretic drug (see figure 1). A statistically significant increase in LVEF of 7.9% (p0.00) and reduction in LVIDd of 0.4cm (p0.04) over the 12-month period. Also, a significant reduction in NYHA Classification (p 0.00) and NTproBNP levels (p0.01), with systolic BP reducing by mean 3.9 mmHg (p0.04). Serum Creatinine levels increased (p0.03), however there was no significant change in EGFR or serum potassium over time (see table 1).
Conclusion(s):Diuretics are frequently used in HFrEF patients but are associated with electrolyte abnormalities and renal dysfunction. In this small investigation, treatment with ARNI was associated with more loop & thiazide diuretic dose reductions. This data suggests that treatment with ARNI results in reduced diuretic requirement. Additionally, a modest increase in LVEF with reduced LVIDd as measured by echo and a reduction in NYHA Classification was revealed.

Table 1

	pre	post	p
LVEF	25.9 ± 6.2	33.9 ± 9.5	0.00*
LVIDd	6.1 ± 1.3	5.7 ± 1.3	0.04*

P1666
Sacubitril/Valsartan in real world heart failure proctice in Asia

PH Chu[1]; FC Hsia[1]
[1]*Linkou Chang Gung Memorial Hospital, Cardiology, Tao-Yuan, Taiwan, Province of China*

Funding Acknowledgements: Chang Gung Medical Foundation

Background: Sacubitril/valsartan was recommended by major guidelines as the frontline therapy for heart failure with reduced ejection fraction (HFrEF) since its clinical benefit was proved by the PARADIGM-HF trial. However, little is known about its safety and effectiveness in real-world practice, often with sicker and more fragile patients. In addition, east Asia population is underrepresented in PARADIGM-HF trial.
Methods: We performed a retrospective analysis of patients received sacubitril/valsartan in Chang Gung Resaerch database (CGRD). CGRD is a de-identified database derived from original medical records of our Memorial Hospital, which include three medical institutes located in northern Taiwan. Patients received a prescription of a least 30 days of sacubitril/valsartan were enrolled. The date of first prescription was defined as the index date, and a period of 12 months preceding the index date was defined as the baseline period.
Results: A total of 440 patients were identified (age 61.58±15.07, male 78%, LVEF 31.32±9.66%). Comparing to PARADIGM-HF trial, our patients had higher baseline serum creatinine (mean 1.52 mg/dl) and BNP (mean 956.9 pg/ml) level. In addition, 75.9% of the patients had been hospitalized for heart failure during the baseline period. After a mean duration of 234 days, overall readmission rate was 21.1% and mortality rate was 2.93%. LVEF significantly improved from baseline to 6 months (31.32 vs. 38.46 p<0.001). After 1:1 propensity score matching to patients treated with ACEi/ARB, sacubitril/valsartan significantly reduce mortality (4.78% vs. 11.5%, p=0.02). 139 patients (31.7%) had moderate to severe chronic kidney disease (CKD) (eGFR< 60ml/min/1.73m2). Patient had stage 3 CKD (eGFR 30-59) had similar all cause readmission and death rate to patient with normal to mild CKD. However, patients with stage 4 to 5 CKD (eGFR<30) had higher all cause readmission rate than mortality. In addition, patients who received daily dose over 200mg had lower mortality rate.
Conclusion: Sacubitril/valsartan improved LV systolic function in 6 months. Real-world sicker patient also demonstrates survival benefit of Sacubitril/valsartan. The efficacy was comparable between patients with stage 3 CKD to those with normal to mild CKD. However, its safety and efficacy in stage 4 to 5 CKD warrant further investigation.

P1667
Reduction of loop diuretic requirements in HFrEF patients treated with Sacubitril/Valsartan

C Goena[1]; C Gomez[2]; R Natividad[3]; A Lozano[4]; V Escolar[4]; A Laskibar[4]; A Romero[5]; G Zugazabeitia[5]; I Rodriguez[5]; L Quintas[1]; P Gil[6]; I Solla[7]; I Rilo[7]; I Urreta[8]; M Perez De Nanclares[6]
[1]*Mendaro Hospital, Cardiology, Mendaro, Spain*; [2]*Cruces University Hospital, Cardiology, Barakaldo, Spain*; [3]*San Eloy Hospital, Cardiology, Barakaldo, Spain*; [4]*Basurto University Hospital, Cardiology, Bilbao, Spain*; [5]*Galdakao Hospital, Cardiology, Galdakao, Spain*; [6]*Araba University Hospital, Cardiology, Vitoria, Spain*; [7]*Donostia University Hospital, Cardiology, Donostia, Spain*; [8]*Donostia University Hospital, Epidemiology, Donostia, Spain*

Introduction: The requirement and dose of loop diuretics is a functional and useful marker in HFrEF symptom control. Sacubitril/Valsartan (SV) decreases mortality in HFrEF patients. In addition, it exists certain evidence supporting that SV improves the functional situation and diminishes the need for loop diuretics in these patients; however, there was no difference in the mean daily dose of furosemide in the PARADIGM-HF trial.
Purpose: To analyze the percentage of change in loop diuretic doses three months after having reached the maximum tolerated dose of SV in a real-life population.
Methods: Retrospective multicenter study of HFrEF outpatients (NYHA≥II and LVEF<40%) with optimized medical/devices treatment starting on SV initiation. Data was recorded at baseline and three months after having reached the maximum tolerated SV dose (three SV dose categories were defined: low <150 mg/24h, medium 150-200 mg/24h and high ≥300 mg/24h). Admissions, diuretic dose adjustments and pre-renal events were recorded during follow-up.
Results: The study population was made up of 260 patients: 75% men, 69±10 years and NYHA class II: N=120 (44%); II-III: N=95 (35%); III: N=58 (21%). Main comorbidities were: hypertension (64.5%), diabetes (35%), ischemic cardiomyopathy (IC) (49.4%) and severe myocardial infarction (13.5%). Most frequent baseline medications were: BB (89%), MRA (76%) and ACEI/ARB (86.7%). The number of patients that reached the different SV dose categories were: low: N=65 (25%), medium: N=100 (38.46%) and high: N=95 (36.53%). Final SV doses were higher in men (p=0.003), IC (p=0.02), use of BB (p=0.03) and previous intake of ACEI/ARB (p=0.006). Most common adverse events were: HF hospitalization (13%), non-HF

hospitalization (9%), diuretic adjustment (27%) and pre-renal events (12.5%). At the end of the monitoring, a reduction in loop diuretic doses was observed in 32% (N=84; p<0.0001) of patients treated with furosemide; whereas, no change was observed in patients treated with torasemide (N=11; non-significant). An increase in loop diuretic doses was observed in 7% of the patients (N=18); the rest of the population did not experience any change. Furosemide withdrawal was achieved by 16.5% (N=43) of the population. Patients receiving higher doses of SV were more likely to reduce diuretic dose when compared to the low-dose group (p=0.012). Furthermore, these findings were associated with an improvement in NYHA class.
Conclusions: This study shows that the use of SV is associated with a clinically-relevant loop diuretic dose reduction (exceeding 30%) in a short period of time; in addition, it shows that this reduction occurs more frequently in patients who tolerate higher doses of SV. The reduction of the daily needs for loop diuretics is an objective parameter that allows clinicians to corroborate the benefit in the functional situation of a patient treated with SV.

P1669

Recovery of left ventricular dysfunction after Sacubitril/valsartan: predictors and managements

H-Y Hung-Yu Chang[1]; C-W Hsieh[1]; M-C Fong[1]; A-N Feng[1]; K-C Huang[1]; W-T Lai[1]; W-H Yin[1]
[1]Cheng-Hsin General Hospital, Taipei, Taiwan, Province of China

Introduction: Current heart failure (HF) guidelines give class I, level of evidence B recommendation to replace renin-angiotensin system (RAS) blockers with sacubitril/valsartan in patients with chronic symptomatic HF with reduced ejection fraction (HFrEF) despite optimal treatment. However, data regarding recovery of left ventricular function after sacubitril/valsartan treatment and how to manage these patients remained sparse.
Methods: We consecutively enrolled 432 HFrEF patients treated with sacubitril/valsartan between January and December 2017. All patients underwent routine echocardiographic measurement. Baseline characteristics were collected and compared between patients with had recovery of LVEF ≥ 50% (HFrecEF) and patients without recovery of LVEF. Among patients with HFrecEF, serial echocardiographic studies and clinical outcomes were compared between patients with different treatment strategies (Maintenance and Taper Group).
Results: During treatment period, 68 (15.7%) patients had LVEF ≥ 50%. After multivariate analysis, recovery of left ventricular dysfunction after sacubitril/valsartan treatment was associated with non-ischemic etiology of HF (odds ratio 3.05; 95% CI 1.63 to 5.70; p<0.001), smaller baseline left ventricular end-diastolic diameter (odds ratio 0.92 per decrease of 1 mm; 95% CI 0.89 to 0.95; p<0.001) and initial daily dosage of sacubitril/valsartan ≥ 100mg (odds ratio 2.70; 95% CI 1.30 to 5.62; p=0.008). Among these 68 HFrecEF patients, 42 patients continued to receive the same dosage of sacubitril/valsartan, whereas 26 patients received either tapering dose of sacubitril/valsartan or switched from sacubitril/valsartan to RAS blockers. Follow-up echocardiography showed that patients in the Maintenance Group had higher LVEF and less likely to have deterioration of LVEF than those in the Taper Group (LVEF 55.4±6.3% vs. 47.3±13.6%, p=0.007; ΔLVEF 0.5±5.8% vs. -5.9±11.4%, p=0.013). Unplanned hospitalization for HF tends to occur in the Taper group than the Maintenance group (15.4% vs. 2.4%, p=0.067).
Conclusion: Non-ischemic etiology of HF, smaller baseline left ventricular end-diastolic diameter and higher initial dosage of sacubitril/valsartan could predict a better recovery of left ventricular dysfunction. In HFrecEF patients, decreasing dosage of sacubitril/valsartan or switching from sacubitril/valsartan to RAS blockers were associated with re-deterioration of heart function.

P1671

Safety, tolerability and discontinuation causes of sacubitril/valsartan treatment in patients with heart failure and reduced ejection fraction attending to an outpatient heart failure clinic.

M Marcelo Rizzo[1]; I Colomer-Asenjo[1]; S Marin-Lopez[1]; M Sutil-Vega[1]; F Taibi-Hajjami[1]; C Roca-Guerrero[1]; N Mallofre-Vila[1]; S Galan-Fernandez[1]; M Lloreda-Surribas[1]; D Garcia-Vega[1]; M Bonastre-Thio[1]; M Panelo-Rubio[1]; D Valcarcel-Paz[1]; J Orus-Puigvert[1]; A Martinez-Rubio[1]
[1]Hospital of Sabadell, Sabadell, Spain

Background Data from controlled clinical trials indicate that sacubitril/valsartan is an effective treatment for heart failure with reduced ejection fraction (HFrEF) with an acceptable safety and tolerability profile. However, more information is needed in real world HFrEF patients.
Purpose To describe the clinical characteristics, the safety and tolerability profile, and the discontinuation causes of the sacubitril/valsartan treatment in patients with HFrEF followed in an outpatient heart failure clinic.
Methods We collected data from 119 consecutive patients attending to our heart failure outpatient clinic between May 2018 and November 2018. 64 (53,8%) were treated with sacubitril/valsartan. Patients were uptitrated with the goal of achieving sacubitril/valsartan 200 mg twice daily. Clinical and neurohormonal variables including those related with adverse effects and discontinuation were collected baseline and at the end of the titration period.
Results At baseline, mean age was 63±10 and 76,6% men. Mean LVEF 28±6%. 39% ischemic etiology. 67,2% were in NYHA class II. Median NT-proBNP level 1176 pg/ml (IQR 364-3945). Mean glomerular filtration rate (GFR CKD-EPI) 71,7±20,6 mL/min and serum potassium 4,4±0,4 mEq/L. 84% received ACE inhibitors (median enalapril equivalent dose 7,5 mg/day, IQR 5-13.7) or angiotensin receptor blockers (median equivalent valsartan dose 80 mg/day, IQR 60-160). 95% received beta-blockers and 86% mineralocorticoid receptor antagonists. At the end of the titration period (6,5 weeks, IQR 3-13,2), target dose was achieved in 23 patients (40%). 24 (37,5%) needed any dose reduction. The main cause of dose reduction was hypotension, defined as systolic blood pressure (SBP) <90 mmHg (n=12, 18,8%), followed by dizziness (n=6, 9,4%), worsening of renal function, defined as serum creatinine >3.0 mg/dL (n=4, 6,3%) and diarrhea (n=2, 3,1%). 10 patients (15.6%) discontinued therapy due to adverse events. Causes for therapy discontinuation were hypotension (n=4, 6,2%), cost of medication (n=4, 6,3%), hyperkalaemia, defined as serum potassium >5,5 meq/L (n=2, 3,1%) and diarrhea (n=1, 1,6%). Angioedema was not detected. Patients with at least one adverse event were older, and with lower SBP and GFR (all p<0.05). In a multivariate analysis adjusted by age, levels of creatinine and NT-proBNP, a lower SBP (OR 0,94 95% CI 0.90-0,99) was the only variable independently associated with adverse events.
Conclusion The treatment with sacubitril/valsartan has a tolerability profile in line with other recommended HFrEF treatments. In our cohort, hypotension remains as the main cause of reduction or discontinuation of sacubitril/valsartan. In this population of relatively young patients the cost of medication was a major cause of discontinuation. In countries with co-payment system, like ours, the non-pensioners have to pay between 40 to 60% towards the cost of medication. This aspect could be a barrier to equitable access to novel treatments.

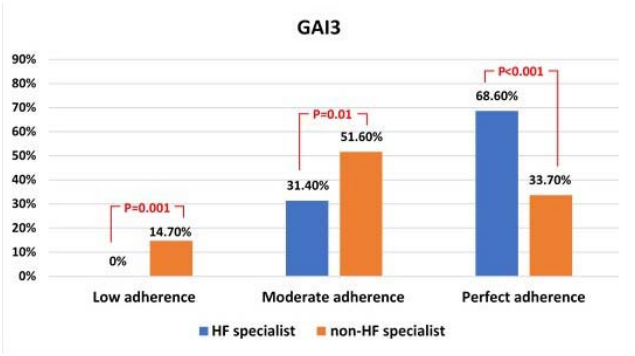
P1672

Outcomes of adherence to guideline in heart failure management: the role of heart failure specialist

H Skouri[1]; M Mariam Zahwe[2]; H Tamim[1]; A Al-Hajje[2]; S Rachidi[2]; M Khoury[1]; H Isma'eel[1]
[1]American University of Beirut Medical Center, Beirut, Lebanon; *[2]Lebanese University, Beirut, Lebanon*

Background: Heart failure (HF) is a chronic disease that affects millions of people every year and associated with high levels of mortality and morbidity worldwide. The adherence to guidelines in treating HF patients is an important predictor of their clinical worsening.
Purpose: is to evaluate the level of adherence to ESC guidelines in the management of HF patients in a tertiary care center in Lebanon, as well as assessing the impact of poor adherence on mortality and readmission after a 1-year follow-up period. This study also aims to evaluate the role of a HF-specialist in implementing these guidelines.
Methods: This study is using a prospective longitudinal design, targeting 165 adult HF patients, with ejection fraction <40%, who are being recruited from a tertiary care center. Therapeutic data were collected at discharge and then after 1 year for readmission and death. We computed a Guideline Adherence Indicator-3 (GAI3) for the three evidence-based HF medications; angiotensin converting enzyme inhibitor (ACEI)/angiotensin receptor blocker (ARB)/ angiotensin receptor neplirysin inhibitor (ARNI), beta-blocker (BB), and mineralocorticoid receptor antagonist (MRA). Subjects were divided into three groups; those with low adherence (GAI3=0/3 or 1/3), moderate adherence (GAI3=2/3), or perfect adherence (GAI3=3/3), and then divided based on their treating physician into HF-specialist versus non-HF specialist. Survival analyses were used to compare between endpoints and guideline adherence levels.
Results: The mean age of our sample was 64.62±15.32. In total, 73.5% were males, 55.8% had moderate ejection fraction (30-39%), and 54.5% had a history of coronary artery disease. The adherence to drugs at discharge was 90.3% for ACEI/ARB/ARNI, 89.7% for BB, and 58.2% for MRA. The overall baseline adherence GAI3 was 48.5%. The level of adherence was perfect in 48.5% of patients, but moderate and low in 43.0% and 8.5% respectively. Log rank test showed a significant difference in event-free survival rate of mortality after 1 year (95.2% versus 60.0%, log rank p=0.048) and readmission for HF exacerbation (76.2% versus 40.0%, log rank p=0.038) between perfect and low adherence levels. After comparing patients followed up by a HF specialist versus a non-HF specialist, we found a significant difference in adherence to ACEI/ARB/ARNI (97.1% versus 86.3%, p=0.017) and to MRA (77.1% versus 44.2%, p<0.001), but not for BB (94.3% versus 86.3%, p=0.096). Similarly, for the GAI3 levels, there was a significant difference in the guideline adherence levels between HF-specialist and non-HF specialist (p<0.001).

Conclusion: The more adherence to guidelines in HF management is associated with better patients' clinical outcomes. There is a major need for referring patients to a HF specialist before reaching the advanced HF stage.



Difference in GAI3 adherence levels

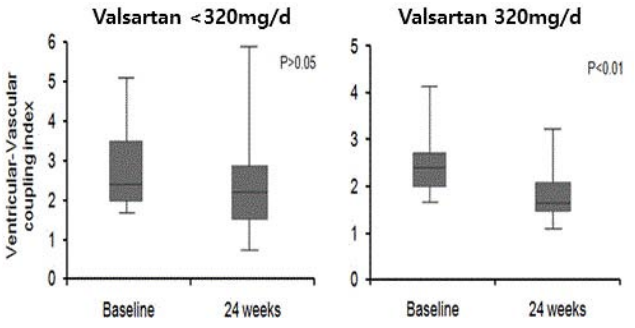
P1673

Valsartan improves ventriculo-vascular coupling index dose-dependently in heart failure with reduced left ventricular ejection fraction

W-J Wook-Jin Chung[1]; H Choi[1]; AY Chang[1]; MS Shin[1]; KY Park[2]
[1]Gachon University, Cardiology, Gachon Cardiovascular Research Institute, Incheon, Korea (Republic of); *[2]Gachon University, CV Surgery, Gachon Cardiovascular Research Institute, Incheon, Korea (Republic of)*

Funding Acknowledgements: This research was supported by a fund(2018-ER6304-00, 2018-ER6304-01) by Research of Korea Centers for Disease Control and Prevention.

Objectives: We evaluated the effect of forced titration of valsartan in patients with HF.
Backgrounds: Heart failure is a clinical syndrome that causes significant morbidity and mortality. Recently, the ventriculo-vascular coupling index (VVI) was introduced as an independent prognostic factor that reflects the overall cardiovascular performance index in HF. However, it is not well elucidated whether forced titration of valsartan is effective or not on VVI in patients with HFrEF.
Methods: We evaluated the effect of valsartan stratified by dosage (non-ceiling dose vs ceiling dose). One-hundred-thirty-eight patients (59.3 ± 12.4 years old; 66% male) were force-titrated to the ceiling dose (n=81), but 57 patients did not reach the ceiling dose (non-ceiling dose; n=57). Biochemical studies including NT-proBNP, echocardiography including VVI, the treadmill test and the activity scale index (KASI) were assessed at baseline and after 24-weeks of therapy.
Results: The six month follow up showed significant improvement in NT-proBNP, LVEF, E/E' ratio, and activity scale index in both groups. LVMI was significantly improved in the ceiling dose group but not in the non-ceiling dose group. Interestingly, a significant improvement in VVI was only observed in the ceiling dose group (from 2.4 ± 0.6 to 1.8±0.5, p<0.01).
Conclusions: The ceiling dose of valsartan for six months showed better improvement of VVI in patients with HFrEF compared with non-ceiling doses. We may need to consider escalating valsartan to the ceiling dose for the overall cardiovascular performance index in patients with HFrEF.



VVI on cieling dose of valsartan

Factors that influence Heart Failure treatment titration in a Heart Failure Unit

GL Gonzalo Luis Alonso Salinas[1]; E Gonzalez Ferrer[1]; S Del Prado Diaz[1]; M Castillo Orive[1]; S Fernandez Santos[1]; I Rayo Llerena[1]; M Abellas Sequeiros[1]; JD Sanchez Vega[1]; JM Vieitez Florez[1]; M Pascual Izco[1]; JL Zamorano[1]
[1]Hospital Universitario Ramón y Cajal, Cardiology, Madrid, Spain

Background Heart Failure (HF) treatment titration remain one of HF Units (HFU) main problems as showed in national and European latest registries. This study aims to identify the factors that lead to an unsuccessful treatment titration.
Methods and Results: Patients seen in a HFU were consecutively included in a prospective registry from November 18 to January 19. Clinical, echocardiographic, analytic and treatment data were recorded.
A total of 114 patients were consecutively included. Mean age was 71.6±12.8 years, 26 (22.8%) patients were female, 19 (16.7%) were frail and 24 (42.1%) had Chronic Kidney Disease (CKD) (GFR < 60ml/min/1.73m2).
Table 1 shows treatment titration differentiation according age ≥ 75-years (elderly population), female sex, frailty and CKD among depressed LVEF patients.
Conclusions Age, female sex, frailty and CKD constitute factors that may influence HF treatment titration. Larger and longer studies should confirm these data

	Elderly Population (n=19)	Non-Elderly Population (n=38)	P
MRA use	12, 63.2%	32, 84.2%	0.074

Effectiveness of early administration of tolvaptan after admission of heart failure for cardiac prognosis

T Toshio Kaneda[1]; M Suzuki[1]; K Hara[1]; M Omori[1]; Y Taomoto[1]; M Iya[1]; Y Yamakami[1]; H Shimada[1]; T Manno[1]; A Isshiki[1]; S Kimura[1]; M Shimizu[1]; H Fujii[1]
[1]Yokohama Minami Kyosai Hospital, Cardiology, Yokohama, Japan

Backgrounds: Tolvaptan is recognized to have effects on congestive heart failure (CHF). However, the prognostic value of the timing of Tolvaptan administration for prognosis was not elucidated.
Methods: We enrolled consecutive 155patients with CHF (81.7±10.5years, 83males) who took Tolvaptan treatment, and observed them for max 60days retrospectively (median 19days) [25%:13days, 75%:31days]). After 5days observation, 6 drop-out cases were excluded, and finally 149 patients were enrolled. Cardiac

death was set as primary endpoint. The patients were assigned into two groups: patients taking Tolvaptan within 48hours after hospitalization (Early group) or over 2 days (Non-early group).
Results: Twenty-one patients died for observation period. The mortality rate was significantly lower in Early groups (Early:3, Non-early:10, P=0.002). Multivariate Cox regression analysis showed the early administration was a significant negative predictor of cardiac death (hazard ratio:0.237, P=0.029). Kaplan-Meier curve analysis revealed the survival curve was significantly better in Early group (logrank P=0.018)
Conclusion: Early administration (within 48hours) of Tolvaptan was a significant negative predictor of cardiac death in patients with CHF hospitalization.

		Early group (N=97)	No early group (N=52)	P

Potentially inappropriate medication use in elderly patients with heart failure: beers criteria-based review

M Mariam Zahwe[1]; H Skouri[2]; A Al-Hajje[1]; H Tamim[2]; S Rachidi[1]; H Isma'eel[2]
[1]Lebanese University, Beirut, Lebanon; *[2]American University of Beirut Medical Center, Beirut, Lebanon*

Background: Elderly heart failure (HF) patients are considered among the highest consumers of drugs. Their complex drug regimens and various comorbidities predispose them to inappropriate prescribing of medications. "Beers criteria" is among the most widely used criteria for the evaluation of potentially inappropriate medications (PIMs) use in elderly patients.Purposes: The aim of this study is to evaluate the proportion of PIMs in elderly HF patients as well as the factors associated with the number of PIMs. Also, to test for the correlation between PIMs and the impairment in quality of life and depression in this vulnerable population.
Methods: This study is using an observational cross-sectional design, targeting 120 consecutive HF outpatients ≥65 years, with ejection fraction <50%, who are being recruited from a tertiary care center. Patients with history of acute coronary event in the preceding 3 months and patients with severe cognitive impairments are excluded. Data for medications, doses, clinical data, and demographics are collected at discharge from the clinic. Patient is interviewed with the Minnesota Living with Heart Failure Questionnaire (MLHFQ) for measuring quality of life and the patient health questionnaire (PHQ9) for depression. Data are then evaluated for the use of PIMs using the updated Beer's criteria 2015.
Results: In total, 74.8% of our sample are males, 58.9% are young-old patients (65-74 years), and 68.2% had a history of hypertension. The total number of medications taken by our sample is 924 with an average of 8.64±2.82 medication per prescription. Preliminary results showed that the percentage of patients receiving at least one PIM is 80.4%, with an average of 1.70 ± 1.26 PIM per prescription, and 29.0% of HF patients are having 2 PIM in their prescription. Most of the PIMs are from the category of medications to use with caution (63.6%) and to be avoided in many or most older adults (53.3%). Diuretics (57.0%), proton pump inhibitors (41.1%), aspirin (14.0%), and benzodiazepines (9.3%) are the most commonly prescribed PIMs. Significant correlation is found between number of PIMs per patient with the MLHFQ score (pearson's coefficient r= 0.28, p=0.003), PHQ9 score (r=0.23, p=0.017), and number of medications per prescription (r=0.49, p<0.001). Multivariate Linear regression showed a significant association between the number of PIMs per prescription with the number of medications (regression coefficient beta=0.190, p<0.001), oldest-old age (beta=1.136, p=0.006), and having a chronic kidney disease (beta=0.588, p=0.031).
Conclusions: Elderly HF patients are having a high percentage of PIMs. An excessive unnecessary use of proton pump inhibitors is observed in this population. The PIMs are affecting negatively the quality of life of HF patients and associated with more depression. There is a need for a multidisciplinary team to help in controlling the prescription of PIMs in this vulnerable population.

P1677

Baseline characteristics, treatment dosage, and clinical outcomes of post-acute HFrEF patients initiated with Sacubitril/Valsartan

H Huai-Wen Liang[1]
[1]E-Da hospital, cardiovascular department, Kaohsiung, Taiwan, Province of China

Purpose: Current study focused on a retrospective cohort; we characterize the real-world timing of S/V initiation.
Method: This is a single center retrospective cohort study from January 2017 to December 2018 in our hospital, focusing on patients switched to S/V. Patients were divided into three groups: Group 1. Patients switched to S/V at outpatient clinic without recent heart failure admission; Group 2. Switched at outpatient clinic with recent (within 1 month) heart failure admission; and Group 3. Switched during heart failure hospitalization after hemodynamic stabilization.
Result: A total number of 162 patients switched to S/V during January 2017 to December 2018 in our hospital. There were 91 patients in Group 1, 29 in Group 2, and 42 in Group3. Among these three group patients, there is no significant difference between baseline characteristics on factors such as age, gender, diabetes, atrial fibrillation, history of stroke, ischemic etiology of heart failure, prior hospitalization rate and baseline LVEF. However, heart failure status for patients in Group 3 were much severe(NYHA class P< 0.05) and the length of index hospitalization was longer in Group 3 than Group 2 (13.5 ± 7.7 vs 7.9 ± 6.5 days, P<0.05).
Initiation dose and titration pattern were similar between these three groups.
At 1 year follow-up, there were 7 cases discontinue S/V(2 hypotension, 2 acute kidney injury, 1 cough and 2 physician choice) in Group 1(N=53), 3(1 hypotension and 2 physician choice) in Group 2(N=17) and 5(2 hypotension and 3 physician choice) in Group 3(N=26). Although compared with Group 1, baseline characteristics of Group 2 and 3 showed higher BNP level and much severe NYHA class, treatment withdraw due to side effect of drug were all rare.
At 1 year follow-up, 2 cases died in Group 1, 1 in Group 2, and 3 in Group 3.
Among these three groups, there were 9 patient heart failure rehospitalization within 1 year at Group 1(N=53), 6 in Group 2(N=17), and 14 in Group 3(N=26). In Group 3, there are 14 cases readmitted within 1 year after S/V treatment. Mean length of heart failure hospitalization(LOH) in these 14 patients was 17 days before treatment and 14 days after treatment. 6 patients readmitted in Group 2, and decreased LOH from 8(before treatment) to 5.3(after treatment) days.
Among these three groups, the LVEF presented at baseline characteristics were indicated as 32 ± 8, 32 ± 8 and 34 ± 10% (P=0.352639). After S/V treatment, all three groups presented improvement in LVEF, with 37.4 ± 13.6% in Group 1, 48.7 ± 16.3% in Group 2, and 34.4 ± 12% in Group 3. Notably, a 16.3 % improvement was observed in Group 2.
Conclusions: Initiation of S/V in stabilized post-acute HFrEF patients seemed to be safe in real-world setting. Treatment withdraw due to side effect was rare. A reduced length of stay for heart failure re-hospitalization were observed within 3 month in both Group 2 and Group 3.

P1678

Central sleep apnea in patients with chronic heart failure and its treatment with acetazolamide

K Kliya Sorokina[1]; M Poltavskaya[1]; A Palman[1]; M Kuklina[1]; K Kharkevich[2]
[1]I.M. Sechenov First Moscow State Medical University, Department of preventive and emergency cardiology, Moscow, Russian Federation; *[2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Introduction . Central sleep apnea (CSA) is a specific respiratory abnormality during sleep, defined as periodical cessation of breathing with the absence of respiratory flow as well as thoracic and abdominal breathing efforts. Cardiovascular prognosis for individuals with chronic heart failure (CHF) and CSA can be potentially worse.
Purpose. The aim of our study was to assess the incidence and risk factors for CSA in patients with CHF and to assess the effect of acetazolamide in such patients.
Methods. We have studied 37 consecutive adult patients (35 males and 2 females) with CHF ranged from II to III New York Heart Association (NYHA) functional classes. All patients got standard medication. Patients with chronic respiratory failure, renal failure, previous stroke, anemia and obesity were not included. All patients underwent echocardiographic investigation, 6-minute walking test, arterial blood gases test and cardio-respiratory monitoring during sleep. Sleep and life quality questionnaires were also obtained. Patients with apnea-hypopnea index (AHI) more than 15 events per hour were considered as suffering from CSA.
Results. CSA was found in 62% of observed patients (23/37). There were no significant differences between the groups in age, gender, heart rate or blood pressure. Mean SpO2 during sleep was 91.8±0.8% among the patients with CSA, and 94±0.8% in the control group (p>0.05). Mean pCO2 in arterial blood in patients with or without CSA were 35.2±0.5 mm Hg and 35.0±0.9 mm Hg, respectively (p>0.05). Mean distance walked in 6 minutes was 297.1±23.2 meters in group with CSA and 310.1±32.6 meters among the other patients (p>0.05). According to the

questionnaires there was no significant difference in sleep and life quality in both groups.
18 patients with CSA were randomized into two groups. In group I patients received acetazolamide and standard medical treatment (8 patients). Control group without acetazolamide admission consisted of 10 persons. In 6 month patients in group I showed significant decrease in AHI (from 33.14±3.9 to 14.7±4.0). In the control group there was no significant change in AHI (22.84±1.1 and 21.68±3.9). In a 12-month period was revealed a decreasing tendency in cardiovascular mortality among patients receiving acetazolamide (1 patient in group I and 4 patients in group II) (>0.05).
Conclusions. Considering the results of the study we can conclude that the prevalence of CSA in CHF patients is up to 60%. Patients with CSA showed no tendency to lower exercise tolerance or lower levels of CO2 in arterial blood. Taking into account that patients in both groups did not differ by heart failure severity, received data contradict the idea that lower left ventricular ejection fraction and lower pCO2 levels lead to CSA in patients with CHF. Administration of acetazolamide result in decrease of respiratory disorders during sleep and probably decrease cardiovascular mortality in such patients.

P1679

The investigation of efficacy and safety about the clinical pathway for congestive heart failure specified immediate use of tolvaptan after admission in super-elderly patients.

Y Yuichi Kato[1]; A Takaishi[1]; T Nakayama[1]; K Yasuhara[1]; N Matsuo[1]; M Tanimoto[1]; K Kagawa[1]; Y Nakano[1]; N Onishi[1]; S Hirohata[2]; M Ueeda[3]
[1]Mitoyo General Hospital, cardiocascular, Kagawa, Japan; *[2]Okayama University, Postgraduate school of medicine, Okayama, Japan*; *[3]Ueeda Cardiovascular medicine clinic, Kagawa, Japan*

Background: In Japan, for congestive heart failure(CHF) cases we had been able to prescribe new and strong diuretic, Tolvaptan from 2010. We introduced original clinical pathway with immediate use of Tolvaptan after admission for chronic heart failure cases(CHF-PATH) from August 2015, and confirmed its large shortening effect of hospitalization period by efficient medical treatment. We often apply CHF-PATH even in super-elder patients with CHF.
Purpose: we verified the usefulness and safety of CHF-PATH use in super-elder patients with CHF.
Method: We enrolled 376 CHF patients, with clear pulmonary congestion findings in their chest X-ray, who admitted in our hospital and applied CHF-PATH for the first time between August 2015 to November 2018 (mean age:80.6+/-10.8 years old, male/female:193/183). We divided them into two groups, 73 cases who were 90 years old or older(E-group; mean age: 92.8+/-2.5 years old, male/female: 33/39), and 303 cases who are less than 89 years old(Y-group; mean age: 77.7+/-10.0 years old, male/female: 160/143). We examined their clinical characteristics, various situation of their medical care and incidence of adverse events that might influence use continuation of Tolvaptan such as more worsening of renal function or hypernatremia after admission.
Results: In E-group the ejection fraction of left ventricle by echocardiography was higher(56+/-15 vs 48+/-19%; p<0.01), the mean renal function(eGFR) on admission was lower(39+/-18 vs 48+/-20 mL/min; p<0.01) and the prevalence of dementia was higher(81 vs 56%; p<0.001) than that in Y-group. In E-group and Y-group, the performance rate of continuous venous infusion(71 vs 66%; NS) and its mean performance duration(5.5+/-7.5 vs 4.7+/-5.4 days; NS), the performance rate of urethral catheterization(45 vs 47%; NS) and its mean duration(6.6+/-6.7 vs 5.9+/-7.97 days; NS) and mean starting time of cardiac rehabilitation after admission(3.1+/-1.6th vs 2.9+/-1.5th day; NS) were not different. The mean hospitalization period was longer in E-group (20.6+/-19.1 vs 15.5+/-11.6days; p<0.05). In E-group the serious worsening of renal function or hypernatremia which needed to stop use of Tolvaptan occurred more often(15.1 vs 3.0 %; p<0.001). The CHF re-admission rate within 1 year after discharge was not different in E-group and Y-group(32 vs 26%; NS).
CONCLUSION: Even in Super-elderly patients with congestive heart failure, each medical care was performed efficiently by our original clinical pathway and there was not significant difference about re-admission rate with the worsening of heart failure between two groups. But we thought that considering peculiar factors of elderly patients such as existence of renal dysfunction or dementia, we should be careful to occurrence of adverse events related to use of Tolvaptan in super-elderly cases introduced our original clinical pathway.

P1680

Sacubitril/valsartan in heart failure with reduced ejection fraction patients: real world experience on advanced chronic kidney disease, hypotension and dose titration

H-Y Hung-Yu Chang[1]; C-W Hsieh[1]; M-C Fong[1]; A-N Feng[1]; K-C Huang[1]; W-T Lai[1]; W-H Yin[1]
[1]Cheng-Hsin General Hospital, Taipei, Taiwan, Province of China

Introduction: The angiotensin-receptor and neprilysin inhibition (ARNI) with a combination of sacubitril and valsartan had been shown to reduce cardiovascular mortality by 20% and all-cause mortality by 16% as compared with enalapril in the randomized controlled PARADIGM-HF trial. However, there is a paucity of real-world data on the effects of ARNI in heart failure patients with reduced ejection fraction (HFrEF), especially with concurrent renal impairment or hypotension.
Methods: Between January and December 2017, 466 HFrEF patients treated with sacubitril/valsartan (Group A) in a heart failure referral center were recruited consecutively. Between 2015 and 2016, another 466 HFrEF patients acting as control, who were managed with standard HF treatment without ARNI (Group B) were recruited. Baseline characteristics and clinical outcomes were collected and compared between both groups.
Results: Baseline characteristics were comparable between the two groups. During a mean follow-up period of 567 days, death from cardiovascular causes or first unplanned hospitalization for HF occurred in 106 patients in Group A (22.7%) and 175 patients in Group B (37.6%, hazard ratio 0.65; 95% CI 0.51 to 0.83; p=0.001). The incidences of deaths from any causes, cardiovascular death, sudden death, and HF re-hospitalization were all significantly lower in Group A than Group B patients. Among patients with different chronic kidney disease stages and normotensive patients, treatment with sacubitril/valsartan showed favorable outcomes than treatment with standard HF care without ARNI. However, in patients with baseline systolic blood pressure lower than 100mmHg, there were no significant differences of outcomes in both groups. Among Group A patients, de-escalation of sacubitril/valsartan was associated with poorer outcomes.
Conclusion: Our study demonstrated the effectiveness of sacubitril/valsartan on HFrEF patients in the real world practice, including those with advanced renal impairment.

Sacubitril-valsartan treatment furtherly improves response to intermittent parenteral levosimendan in ambulatory patients with advanced heart failure with reduced ejection fraction

B Benjamin Munoz Calvo[1]; C Ganan-Gomez[1]; A Quiles-Recuenco[1]; B Calvo-Llorente[1]; I Mendo-Pedrajas[1]; J Navarro-Lopez[1]; F Roman-Garcia[1]
[1]Hospital Universitario Príncipe de Asturias , Alcala de Henares, Spain

BACKGROUND: : Intravenous intermittent administration of levosimendan (IALEVO) to ambulatory patients with advanced chronic heart failure (ACHF) with severely reduced (<35%) ejection fraction (EF) has been shown in several randomized trials (LAICA, LION-HEART, Levo-Rep) to improve their clinical status and to reduce NT-proBNP plasma levels and rehospitalizations. However, recruitment of patients in these trials were conducted in the pre-ARNI era, so the impact of simultaneous treatment with sacubitril-valsartan (SAV) on IALEVO strategy is unknown.
AIMS: To assess whether SAV treatment may affect the results of IALEVO in patients with ACHF.
METHODS AND RESULTS: we conducted an observational, non-randomized study on 36 patients with ACHF of a similar profile with SAV treatment for at least the previous 12 months. Patients were randomly assigned at a 1:1 ratio to IALEVO or non-intervention groups; those receiving IALEVO were given a 6-hour intravenous infusion (0.2 μg/kg/min without bolus) every 2 weeks for 12 weeks. The primary endpoint was the effect on serum concentrations of NT-proBNP throughout the treatment period. Secondary endpoints included evaluation of 18-months rehospitalizations due to HF decompensation and score at the Kansas City Cardiomyopathy test. The area under the curve of the levels of NT-proBNP for patients who received IALEVO was significantly lower than for the non-intervened group (259 × 103 [95% Confidence Interval (CI) 189 × 103–395 × 103] vs. 328 × 103 [240 × 103–517 × 103], p = 0.004). In comparison with non-intervened group, the patients on IALEVO experienced a reduction in the rate of heart failure hospitalisation (hazard ratio 0.20; 95% CI 0.10–0.49; P = 0.001). Patients on IALEVO were less likely to experience a significant reduction in KCC score (P = 0.04). Adverse effects were similar in both groups.
Conclusions: In this small non-randomized, non controlled study, IALEVO to ambulatory patients with ACHF with EF < 35% already treated with SAV reduced plasma concentrations of NT-proBNP and hospitalization for HF decompensation. As with other patients in the pre-ARNI era, IALEVO seems to furtherly improve clinical and functional benefits provided by SAV in ACHF.

Significant underutilization of angiotensin receptor neprolysin inhibitor (ARNI) and other evidence-based heart failure (HF) therapies in an outpatient clinic setting

N Singh[1]; S Premji[1]; D Ramakrishnan[2]
[1]Medical College of Georgia at Augusta University , Cardiology, Atlanta, United States of America; *[2]Atlanta Heart Specialists, LLC, Atlanta, United States of America*

On behalf of: Atlanta Heart Specialists

Background: Multiple guidelines since 2016 have endorsed as a Class 1 recommendation, the use of an ARNI in pts with heart failure (HF) and reduced ejection fraction (HFrEF).
Methods: Retrospective chart review of all pts being treated for HF in a single, multi-site suburban, outpatient cardiology practice for the calendar year 2016.
Results: Of the 1607 pts identified 560 (35%) had HFrEF, 218 (14%) had mid range EF (HFmEF) and 819 (51%) had preserved EF (HFpEF). In comparison to the HFpEF group, HFrEF pts had a lower EF (26.9% vs 58.9%) were significantly younger (64.4 yrs vs 68.2 yrs, $p < 0.0001$) and more likely to have ischemic cardiomyopathy (37% vs 19.2%, $p < 0.00001$). Table 1 looks at evidence based therapy use at the first and last visit of 2016.In the HFrEF pts, the greatest % change in drug therapy was ARNI use with an appropriate decrease in ACEI/ARB use. There was however substantial overall underutilization of spironolactone, ARNI and device therapy in the HFrEF group. EF improved significantly in the HFrEF group (26.9% vs 32.4%, $p < 0.0001$) while decreased in HFpEF group (58.4% vs 56.3%, $p < 0.0005$). In comparison to the HFpEF group, HFrEF pts were more often hospitalized for HF (17% vs 11.5%, $p < 0.004$) and had a higher 1 year mortality rate (11.1% vs 6.2%, $p < 0.002$).
Conclusions: Our findings suggest that there is significant underutilization of ARNI therapy in contemporary cardiology practice. There is also some inappropriate use of ARNI in HFpEF pts. Even more concerning is the underutilization of spironolactone and device therapy in HFrEF pts despite longstanding national guidelines and a high 1-yr HF hospitalization and mortality rate.

Table 1.

Therapy		HFrEF				HFpEF		
% use	1st visit	Last visit	% change	P	1st visit	Last visit	% change	P

Effectiveness of early administration of Tolvaptan for cardiac prognosis in acute decompensated heart failure

T Kaneda[1]; M Suzuki[1]; K Hara[1]; M Omori[1]; Y Taomoto[1]; M Iya[1]; Y Yamakami[1]; H Shimada[1]; T Manno[1]; A Isshiki[1]; S Kimura[1]; M Shimizu[1]; H Fujii[1]
[1]*Yokohama Minami Kyosai Hospital, Cardiology, Yokohama, Japan*

Backgrounds: Tolvaptan is recognized to have effects on acute decompensated heart failure (ADHF). However, the prognostic value of the timing of Tolvaptan administration in hospitalization was not elucidated.
Methods: We enrolled consecutive 155 patients with ADHF (81.7±10.5 years, 83 males) who took Tolvaptan treatment in hospitalization, and observed them for max 60 days retrospectively. The patients were assigned into two groups: patients taking Tolvaptan within 48 hours or over after hospitalization (Early group vs Non-early group). Cardiac death was set as primary endpoint.
Results: Twenty-one patients died for observation period. The mortality rate was better in Early groups (Early:3, Non-early:10, P=0.002). Multivariate Cox regression analysis showed the early administration was a significant negative predictor of cardiac death (hazard ratio:0.237, P=0.029). Kaplan-Meier curve analysis revealed the survival curve was significantly better in Early group (log rank P=0.018)
Conclusion: Early administration (within 48 hours) of Tolvaptan after hospitalization was a significant negative predictor of cardiac death in patients with ADHF.

		Early group (N=97)	No early group (N=52)	P

Sacubitril/Valsartan: for all patients?

B Bebiana Faria[1]; F Almeida[1]; M Oliveira[1]; P Hafe[1]; G Dias[1]; F Cardoso[1]; S Ribeiro[1]; A Lourenco[1]
[1]*Hospital Guimaraes, Guimaraes, Portugal*

Heart failure (HF) presents high morbimortality and high consumption of care resources conditioned by acute exacerbations. Therefore, it is defensible to approach these patients by differentiated teams in the treatment of HF with experience in the management of prognostic modifying factors, including immunomodulatory drugs. Sacubitril/valsartan (ARNI) was shown a significant reduction of cardiovascular events and mortality without worsening renal function or hyperkalaemia but higher proportions of patients with hypotension and angioedema.
The objective of this study is to characterize a population of patients oriented in consultation of HF and to evaluate limiting factors of the use of sacubitril/valsartan (ARNI).
A retrospective cohort study that included all patients observed at the IC consultation between January 2 and December 5, 2018. Clinical and analytical data were collected.
A total of 128 patients were observed, 82.8% males, mean age 64 years; 82% of patients had HF with reduced FE, FE intermediate 15% and FE preserved 3%. The mean value of LVEF was 30.4 ± 9.9%. The most frequent HF etiology was dilated cardiomyopathy (44.5%) followed by ischemic heart disease (43.8%). 38% of patients were in NYHA class II, 29% in NYHA III and 4% in NYHA IV.
Regarding pharmacological therapy, 93% of patients had ACEI/ARA (prior to ARNI), 95.3% beta-blocker (BB), 88.3% mineralocorticoid receptor antagonists (ARM) and 15.6% ivabradine. However, only 23% of the patients under ACEI/ARA, 25% of the patients under BB and 16% of the patients under MRA were at the recommended maximum dose of drugs.
Of the total of patients evaluated with LVEF ≤35% and symptomatic (n = 69), 35% were medicated with ARNI (n=24). It was possible to titrate ARNI to a higher dose than ACEI/ARA in 44% of patients and 45% maintained equipotent dose, with titration mean time up to the maximum tolerated dose of 48 days.
During follow-up 2 patients discontinued ARNI due to itch and 3 reduced dose (1 for symptomatic hypotension, 1 for worsening renal function, and 1 due to hyperkalemia). No patient had angioedema. After onset ARNI there was a significant increase in creatinine (p=0.031), however, only 5 patients had increase of more than 25% of the baseline value. No significant increase was observed in the plasma levels of potassium, only 2 patients presented hyperkalaemia, 1 of the cases requiring hospitalization.
With regard to the 45 patients who would have indicated, but did not initiate ARNI the main reasons were: 34% for economic failure, 27% for hemodynamic profile and 15% for severe chronic kidney disease.
In conclusion, there is also a low prevalence of ARNI use (35%) and one of the main reasons is its high cost. The majority of patients tolerated the drug and in 44% of cases it was possible to titrate to a dose higher than the dose of ACEI/ARA.

P1685

Effects of statins on major adverse cardiovascular events in patients with ischemic chronic heart failure with reduced ejection fraction and renal dysfunction

D Dmytro Lashkul[1]
[1]*Zaporizhzhya State Medical University, Zaporizhzhya, Ukraine*

The aim of the study to investigate the effect of different doses of statins on long-term prognosis in patients with ischemic chronic heart failure (CHF) with reduced ejection fraction (EF) and renal dysfunction (RD).
Materials and methods. The study involved 140 patients (114 (81.4 %) men) with ischemic CHF, mean age 60 [54-68] years. 2 functional class (FC) of chronic heart failure was diagnosed in 27 (19.3 %) patients, 3 FC - in 98 (70 %) patients. Prior myocardial infarction was in 106 (75,7 %) patients. The glomerular filtration rate (eGFR) was calculated using the formula MDRD (Modification of Diet in Renal Disease). Mean GFR was 70.2±15.5 ml/min/1.73cm2, mean ejection fraction 34.7±7.2 %. Therapy included: ACE inhibitors/ARBs (90 %), beta blockers (94.3 %), diuretics (87.8 %), antagonists mineralocorticoid receptor (75 %), antiplatelet agents (70.7 %), calcium antagonists (14.3 %), amiodarone (18.6 %), ivabradine (15 %). Statins received 118 (84.3 %) patients in doses that meet mild and moderate intensity lowering low-density lipoprotein cholesterol (mean dose of atorvastatin amounted to 21.9 mg, rosuvastatin - 12.9 mg). The period of follow-up was 3 years. As clinical endpoints were considered all fatal and non-fatal atherothrombotic events, including re-infarction, ischemic stroke, sudden cardiac death, heart failure and all cases of hospitalization due to this reason, registered within 3 years after signing informed consent. The cumulative survival curves were constructed with the use of the Kaplan-Meier method and groups were compared with the log-rank test.
Results. Analysis of the observations showed that adverse cardiovascular events during the observation period occurred in 92 (65.7 %) patients, among them - the fatal re-infarction in 8 (8.7 %), sudden cardiac death in 25 (27.2 %) patients, 53 patients (57.6 %) was hospitalized due to HF decompensation, 4 patients (4.3 %) reported non-fatal re-infarction, 2 (2.2 %) patients non-fatal stroke. Found that inclusion statins in the standard pharmacological therapy of ischemic CHF patients with reduced EF and RD reduces the risk of a cumulative endpoint by 51% (HR 0.49; 95 % CI 0.26-0.91; p=0.02), mainly due to reduction of episodes of hospitalization due to decompensation of HF (HR 0.32; 95 % CI 0.14-0.72; <0.01). The positive effect was independent of the intensity statin therapy (HR 0.96; 95 % CI 0.52-1.78; p=0.91), but among the statins atorvastatin had the advantage (HR 0.37; 95 % C 0.21-0.69; <0.001).
Conclusions. The inclusion of statins in the standard pharmacological therapy of patients with ischemic CHF with reduced left ventricular EF and renal dysfunction significantly reduces the risk of cumulative endpoint, mainly due to the prevention of hospitalizations regarding decompensation of HF. Regimen of administration of statins (mild and moderate intensity) did not significantly affect the risk of cardiovascular events.

P1686

Statins improves functional capacity and restores LV diastolic reserve in patients with heart failure with preserved left ventricular ejection fraction

AG Ovchinnikov[1]; ZV Dreeva[1]; AV Potekhina[1]; TI Arefieva[1]; VP Masenko[1]; FT Ageev[1]
[1]*Russian Cardiology Research and Production Complex, Moscow, Russian Federation*

Background. The novel heart failure with preserved left ventricular ejection fraction (HFpEF) pathophysiologic paradigm proposes that coronary microvascular endothelial inflammation promotes LV diastolic dysfunction. It remains to be explored whether approaches to treat systemic inflammation might be effective in HFpEF.
Purpose. We aimed to investigate whether therapy with statins improves exercise tolerability and exercise hemodynamics in patients with HFpEF.
Methods. In present randomized, open single-center 6-month study we enrolled 52 patients with stable HF in NYHA functional class IIIII, preserved EF (>50%), and increased LV filling pressures at rest and/or during exercise. All patients have never taken statins before and were randomly assigned to atorvastatin (40-80 mg; n=26) or rosuvastatin (20-40 mg; n=25) for 24 weeks. Echocardiography, 6-minute walk test (6MWT), diastolic stress-test (DST), and biomarker blood level analysis (N-terminal pro-B-type natriuretic peptide [NT-proBNP], high-sensitivity C-reactive protein [hsCRP], monocyte chemoattractant protein [MCP]-1) were performed at baseline and 24 weeks after randomization. The primary endpoint was change in 6MWT after 24 weeks of treatment. Secondary objectives included changes in DST-exercise time, transmitral inflow velocity to early mitral annulus velocity ratio at rest and peak exercise (E/e′ ratio). Mean age was 68 years and 63% were women. Study subjects were mainly obese (67%) with multiple comorbidities including long-standing hypertension (100%), ischemic heart disease (31%), impaired glucose metabolism (67%) and chronic renal failure (45%).
Results. Both distance during 6MWT and exercise time during DST were increased after 6 month of statin therapy (+ 31 [95% CI 16 to 46] m, P=0.0001 and + 51 [95% CI 18 to 84] s, P=0.0004 vs. baseline, respectively). Therapy with statins was associated with LV diastolic reserve restoration, as evidenced by increase in exercise e′ velocity elevation (by 0.59 [95% CI 0.29 to 0.89] sm/s, P=0.0003), and lower level of E/e′ ratio both at rest (by 0.7 [95% CI −1.2 to −0.2], P=0.011) and during DST (by 1.0 [95% CI −1.6 to −0.3], P=0.005 vs. baseline). Plasma level of NT-proBNP, hsCRP, and MCP-1 remained unchanged, however there was a significant decrease in NT-proBNP level in patients with baseline level >220 pg/ml (-125 [95% CI -241 to -6] pg/ml), hsCRP level in those with baseline level >2 mg/l (-1.26 [95% CI -2.59 to -0.17] pg/ml), and MCP-1 level in those with baseline level >100 pg/ml (-20 [95% CI -31 to -1] pg/ml, P<0.05 for all vs. baseline values). There were no significant differences between atorvastatin and rosuvastatin, except more marked increase in 6MWT distance in atorvastatin group (p=0.052 vs. rosuvastatin group).
Conclusion. In patients with HFpEF, 6-month therapy with statins improved exercise capacity and was associated with the restoration of LV diastolic reserve, presumably via anti-inflammatory effect.

P1687

An evaluation of consultant and registrar prescribing in the outpatient setting

C L Thomson[1]; G L Campbell[1]; S Rita[2]
[1]*Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom of Great Britain & Northern Ireland*; [2]*Kings College London, London, United Kingdom of Great Britain & Northern Ireland*

Background Despite the presence of national and European guidelines, prescribing for heart failure with a reduced ejection fraction remains sub-optimal. The UK National Heart Failure Audit (2016-17) shows that only 44% of patients are discharged on a combination of ACE-inhibitor, beta blocker and aldosterone antagonist. A local audit in 2016 has shown that at 6 months post-discharge, only 25% patients are on maximal therapy, despite attending out-patient appointments.
Purpose This study looked at clinical documentation in out-patient appointments to review whether changes were made to medication. The main aim was to determine current prescribing practice and impact on medicines optimisation.
Methods This study looked at all heart failure out-patient appointments in January and February 2018. Patients were reviewed by a registrar or consultant.
A range of clinical and demographic information was collected, including medication changes made and drug class. The letters were checked for clarity of documentation of medication, allergy status and patients' adherence with prescribed medicines for heart failure.
Any recommendations were categorised and then reviewed whether change had occurred at the next out-patient appointment. Patients were excluded if they did not have a follow-up appointment, had passed away before their appointment, or did not attend.
Results 694 patients attended an out-patient appointment in January and February 2018 and 50% (n=347) had a change to their medication recommended.The majority of patients (67.4%) had their current medications only partly documented. Very few patients had their allergy status (1.6%) or adherence (5.3%) documented. 3.5% of patients had none of their current medications documented.
A total of 485 medication changes were recommended with half (50.5%) requiring the patient's community general practitioner to action the change. 21.0% of patients were issued a prescription. The most commonly prescribed class of medication were beta blockers (22.7%), ACE-inhibitors (17.7%) and diuretics (16.9%).
Of the 214 patients who had a change recommended and attended a follow-up appointment, adherence to medication changes was 77.4%. Asking the general practitioner to action the change made up the highest proportion of medication changes (41.5%) but the lowest rate of advice followed (68.1%).
Conclusion Prescribing for patients at heart failure outpatient appointments is low and general documentation of medication and adherence is poor.
Half of medication changes are recommended for the general practitioner to action, which can incur a delay in medicines optimisation, as only 68.1% of these changes had been made when the patient attended for follow-up. The lowest percentage was when a change was recommended by a registrar.
Further extension of this study is needed to understand the barriers to prescribing and review the current processes to reduce the delay in medicines optimisation.

P1688

Frailty quick test, effective for risk stratification of inadequate treatment of heart failure

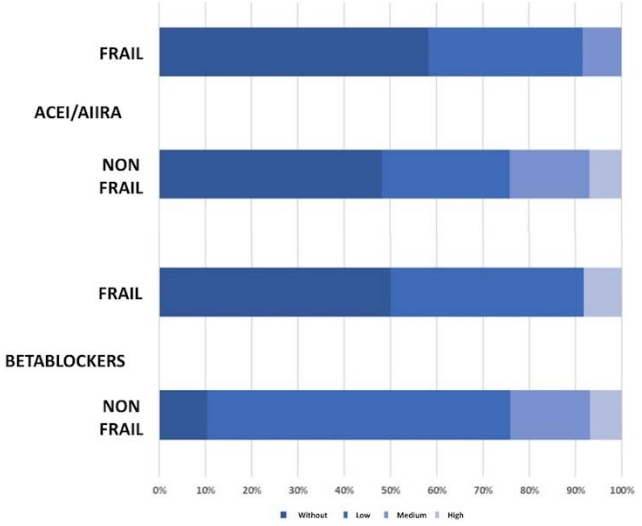
JD Juan Diego Sanchez Vega[1]; GL Alonso Salinas[1]; S Del Prado Diaz[1]; JM Vieitez Florez[1]; E Gonzalez Ferrer[1]; JL Zamorano[1]
[1]*University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain*

Backgroung: In the treatment of heart failure, the adequate titration of effective therapies that change the natural evolution of this disease are necessary to improve

the clinical status of our patients. Despite this, the extended under dosage of these treatments are acknowledge. It appears necessary to develop the proper tools to alert this risk population, especially in the most advanced stages of heart failure.
The FRAIL scale, which can be administrated in less than 5 minutes in a consult setting, can be a useful to detect frailty, a known risk factor for under dosage.
Material and methods: We designed a transversal study, including 42 consecutive patients from the Advanced Heart Failure consult. Participants complete the FRAIL questionnaire, self administered in the waiting room before their consult. We analyzed the percentage of patients who were under different dosage (high, medium, low) of betablockers (BB), angiotensin converter enzyme inhibitors (ACEI) or angiotensin II receptor antagonists (AIIRA), and aldosterone antagonists. The patients were divided in two groups: frail (≥ 3 points in the FRAIL scale) and non-frail patients.
Results The results obtained are included in Table 1. Frail patients received lower treatment with ACEI/AIIRA, BB and aldosterone antagonist, statistically significant in the last two drugs. In Figure 1 we observed how the dosage of BB and ACEI/AIIRA are lower in frail patients. Specific for ACEI, despite the absence of statistically significant differences, the dosage showed a trend for being lower, compared to non-frail patients.
Conclusion The diagnosis of frailty through a quick and self-administered questionnaire (FRAIL) is useful to detect under dosage in effective medications in patients with heart failure.

Table 1 Titration of drugs

	NONFRAIL(n=29)	FRAIL(n=12)	p
Betablockers	26 (89,7%)	6 (50%)	0,005
ACEI/AIIRA	18 (62,1%)	6 (50%)	0,475
AldosteroneAntagonistas	25 (86,2%)	6 (50%)	0,014



Dosage of drugs in both groups

P1689

Effect of sacubitril/valsartan in real-world patients in South London

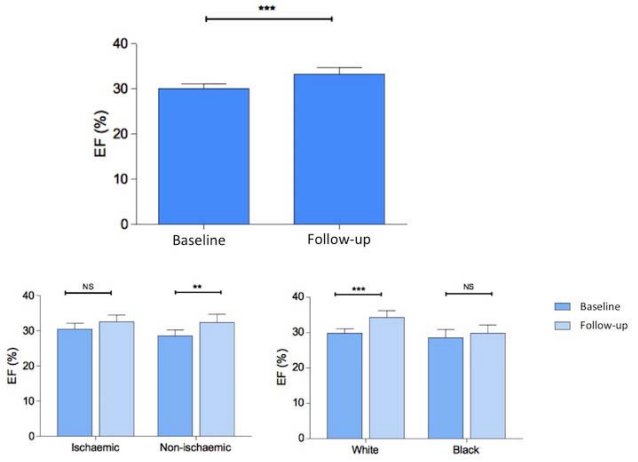
N Niels Holm[1]; D Bromage[2]; J Decourcey[2]; TA Mcdonagh[2]
[1]Triemli Hospital, Klinik für Kardiologie, Zurich, Switzerland; *[2]Kings College Hospital, Cardiology, London, United Kingdom of Great Britain & Northern Ireland*

Introduction Our Heart Failure Unit in South London provides specialist care for a socially and economically diverse community. We present our experience with sacubitril/valsartan in this cohort.
Purpose: There is limited real-world data of sacubitril/valsartan, especially in black patients. Therefore we investigated the efficacy of this drug in a diverse patient population, which included a significant proportion of black patients.
Methods This is a retrospective, observational, single-centre study of patients with symptomatic heart failure (LVEF <35%) on optimal medical therapy, who were transitioned to sacubitril/valsartan. Data were collected manually from our electronic patient records. Statistical analysis was performed with GraphPad Prism 7.04.
Results: A total of 87 patients were analysed (mean age 58 years, 39% female, 44% of black ethnicity, 59% with non-ischaemic cardiomyopathy, 80% on target dose of 200mg BD). Sacubitril/valsartan lead to an improvement of LVEF. This effect was significant only in patients with non-ischaemic cardiomyopathy, in white individuals, and in males.
Sacubitril/valsartan had no impact on heart rate, while reducing blood pressure in white, but not black patients. After 3 months of treatment, there was clinical improvement assessed by NYHA class, independent of ethnicity, and by Minnesota living with heart failure questionnaire, but only in white patients. In addition, NT-proBNP levels dropped significantly after 3 months of treatment.
Conclusion Sacubitril/valsartan improves LVEF, but there may be individual factors leading to non-response, such as black ethnicity, ischaemic cardiomyopathy, and female gender. Improvement of LVEF to >35% was observed in 18% of patients, most of whom had non-ischaemic cardiomyopathy. This could be clinically relevant considering the current criteria for primary prevention ICD implantation. In our cohort, the positive effect of sacubitril/valsartan is mainly seen in white, but not in black patients. It remains unclear if there is reduced efficacy of the drug in black patients, or whether there are other explanations.

Results

	Baseline	Follow-up	p-value
LVEF (n = 38)	30.3 ± 1.1%	33.3 ± 1.4 %	0.004
NT-proBNP (n = 81)	3657 ± 619 ng/l	3044 ± 782 ng/l	0.0012
Heart rate (n = 38)	67.9 ± 1.9 bpm	63.1 ± 1.9 bpm	ns
Systolic BP (n = 87)	120 ± 1.8 mmHg	114 ± 2.0 mmHg	0.0018
NYHA class (n = 87)	2.5 ± 0.1	1.9 ± 0.1	< 0.001
MLWHF Score (n = 64)	43.0 ± 3.4	32 ± 3.0	0.001

Results are presented as mean ± SEM.



LVEF improves with sacubitril/valsartan

P1691

Impact of beta blockers therapy on right ventricular function in heart failure patients with reduced ejection fraction a prospective evaluation

R Galves[1]; R Romain Pierrard[1]; K Isaaz[1]; A Da Costa[1]
[1]CHU Saint Etienne Hopital Nord, Cardiology, Saint Etienne, France

Background. ß-Blocker Therapy has been shown to improve mortality and reduce hospitalizations in patients with heart failure (HF) with reduced ejection fraction (HFrEF). Although the physiological action mechanisms of ß-Blocker Therapy are well described, its effects on rigth ventricular (RV) function have not been prospectively well studied. Objective. The aim of this prospective study was to: (1) evaluate if ß-Blocker Therapy impacts RV remodellingbased on echo parameters; (2) sought the echo predictive factors of ß-Blocker therapy response.Methods. From

september 2017 to September 2018, HF patients were prospectively enrolled using CIBIS criteria: Class II, III, or IV HF; left ventricular ejection fraction (LVEF) of 40% or less; hospitalized for HF within the previous 12 months. Echo evaluation was performed before initiating ß-Blocker therapy and 3 months after optimal dose adjustment. Based on previous studies, patients with (absolute) improvement in LVEF ≥5% were considered significant ß-Blocker therapy responders. Results. Forty patients completing the study were characterized by age: 70±10 years; gender: 10 women; cardiomyopathy aetiology: idiopathic in 24 and ischaemic in 16; NYHA Class: II in 22 and III in 10; LVEF: 32±5%; NTProBNP: 2665±2400pg/ml.The final population comprised 32 pts (79%), given that 8 pts (21%) were excluded: 2 did not tolerate ß-Blocker therapy, 1 was lost of follow-up, 5 did not pursue the protocol. Under ß-Blocker therapy, several echo parameters significantly improved: LVEF from 31.7±9to 40.5±9 (p<0.0001); LV end-diastolic volume (EDV) from 154±54 to 143±45 ml (p=0.06); LV end-systolic volume (ESV) from 107±49 to 88±37 ml (p=0.0006); LV ES from 46±11to 64±13 ml (p=0.008); LV end-diastolic diameter (EDD) (57±9 to 54±6 mm; p=0.04); LV end-systolic diameter (ESD) (48±10 to 44±7 mm; p=0.007); right ventricular systolic pressure (RV SP) from 39±10 to 32±8 (p=0.0001). Significant modifications were observed in terms of RV echo parameters: right ventricular size decreased (30±4 vs. 27±5; p=0.03) and right ventricular systolic function improved significantly based on the tricuspid annular plane systolic excursion (TAPSE) (16.5±4 vs. 19±4 mm; .0006); DTI-derived tricuspid lateral annular systolic velocity wave (S')(10±2 vs. 11.3±3 cm/s; p=0.03); RIMP (Tei index) (0.5±.1 vs. 0.46±.1; p=0.04) (Table II). RV 2D FAC (fractional area change) was not significantly different despite a clear improvement tendency (35±6 vs. 37±4 %; p=0.1). No significant modifications were observed concerning LV diastolic parameters. ß-Blocker echo responders (n=23/32; 72%) exhibited the same left and right echo parameters. No echo variables predicted the ß-Blocker response. Conclusions. In HFrEFpatients, ß-Blocker therapy significantly improves significantly LV and RV systolic remodelling. Accordingly, ß-Blocker therapy could be used as soon as possible in HFrEF patients associated with right ventricular dysfunction in order to limit RV remodelling.

P1692

Clinical experience with ambulatory perfusion of levosimendan in an advanced heart failure unit

J Pamies-Besora[1]; C Moliner-Abos[1]; P Fluvia[1]; M Rivas-Lasarte[1]; J Alvarez-Garcia[1]; S Mirabet[1]; L Lopez[1]; V Brossa[1]; E Roig[1]
[1]*Hospital de la Santa Creu i Sant Pau, Cardiology, Barcelona, Spain*

Introduction: ambulatory inotropic treatment in patients with advanced heart failure has been associated with clinical benefits and with a reduction in the hospitalization rate.
Purpose: To analyse the clinical benefit of ambulatory levosimendan perfusion in an advanced heart failure unit.
Methods: retrospective, unicentric study involving patients with chronic heart failure in NYHA III-IV with low cardiac output symptoms who received ambulatory levosimendan infusions between December 2015 and April 2018. We analysed baseline characteristics, the indication of inotropic treatment, the number of infusions, the number of hospitalizations 6 months before and after the infusions and mortality and transplant follow-up.
Results: During the study 149 ambulatory infusions were performed in 61 patients, aged 66±12 years old and 82% men, with LVEF of 26 ±7% and glomerular filtration rate of 52±21 ml/min. Baseline treatment is registered in Table 1 and the underlying disease in figure 1. 46% of all patients received ≥ 2 infusions and 23% received ≥3. We found a non-significant (p=0,06) decrease in hospitalisation rate (RRR 35%) and a clinical improvement.

Baseline farmacological treatment

Drug	% treated patients	Dose≥50%

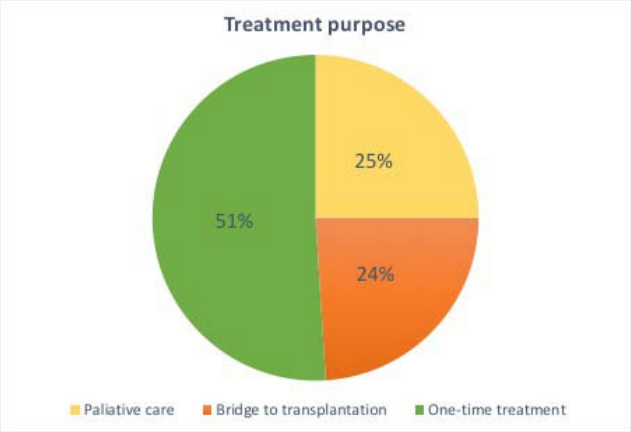
Digoxin	23	

BB- BetablockerACEI- Angiotensin Converter Enzime InhibitorARB- Angiotensin II Receptor BlockerMRA- Mineralocorticoid Receptor AntagonistARNI- Angiotensin Receptor Neprilisine Inhibitor



Treatment purpose

In a follow-up over a period of 9,6±6 months 18 patients died (30%), 15 due to a cardiovascular event. Death was associated with worse renal function (p=0,02). Out of 14 patients in list for heart transplant, none died, 10 (71%) reached transplant and 1 underwent ventricular assist device (Heart-Mate III) implantation.
Conclusions: Ambulatory infusion of levosimendan was related with a clinical improvement and a non-significant decrease in hospitalisation for acute heart failure. In 23% of cases, the indication was a bridge to transplant.

P1693

Treatment of patients with chronic heart failure: does management in heart failure clinic improve adherence to guidelines for the treatment of heart failure?

T Furlan[1]; D Kosuta[1]; V Grilj[1]; S Poznic[1]; B Leskovar[1]
[1]*Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia*

Background. Despite major advances in treatment options for heart failure patients, studies show that they remain undertreated.
Purpose. The aim of our study was to evaluate the therapeutic management of heart failure in our outpatient heart failure clinic.
Methods. We retrospectively evaluated all patients that were treated in our outpatient heart failure clinic between January 2017 and December 2018. We compared the number of patients receiving angiotensin receptor-neprilysin inhibitors (ARNI), angiotensin-converting enzyme inhibitors (ACEi), angiotensin receptor blockers (ARB), beta blockers and mineralocorticoid receptor antagonists (MRA) before being managed in the heart failure clinic and at last clinic follow-up with independent samples t-test.
Results. We evaluated 215 patients with heart failure; 84 patients (39%) had heart failure with reduced ejection fraction (HFrEF), 35 patients (16%) had heart failure with mid-range ejection fraction (HFmrEF) and 96 patients (45%) had heart failure with preserved ejection fraction (HFpEF).
In HFrEF group, 14% of patients were treated with ARNI (4% were receiving target doses), 65% with ACEi/ARB (26% on target doses), 92% with beta blockers (45% on target doses) and 51% with MRA (2% on target doses). After a mean period of 8.5±6.7 months, 29% of HFrEF patients were treated with ARNI (p=0.000; target dose 23%, p=0.001), 61% with ACEi/ARB (p=0.397; target dose 36%, p=0.073), 96% with beta blockers (p=0.103; target dose 60%, p=0.01), 54% with MRA (p=0.47; target dose 11%, p=0.708).
In HFmrEF group 69% of patients were treated with ACEi/ARB (31% on target doses) and 83% with beta blockers (40% on target doses). After a mean period of 7.1±5.4 months, 83% of patients with HFmrEF were treated with ACEi/ARB (p=0.023; target dose 43%, p=0.044) and 89% with beta blockers (p=0.16; target dose 51%, p=0.044).
In HFpEF group 77% of patients were treated with ACEi/ARB (45% on target doses) and 89% with beta blockers (35% on target doses). After a mean period of 8.6±5.7 months, 83% of patients with HFpEF were treated with ACEi/ARB (p=0.134; target dose 55%, p=0.041) and 89% with beta blockers (p=0.16; target dose 51%, p=0.044).
Conclusions. Our data suggests that current guidelines for the treatment of heart failure are still not being reflected in clinical practice, especially if patients are not managed in heart failure clinic. With outpatient management in a dedicated heart failure clinic, medication can be titrated in a relatively short period of time and better adherence to the guidelines can be achieved despite possible side effects that can be overcome with frequent patient monitoring.

P1694

Intermittent infusions of levosimendan in advanced heart failure: last but not least; a single-centre clinical experience on the efficacy of repeated levosimendan infusions.

P Romano[1]; F Francesco Cannata[1]; C Panico[1]; A Cappelleri[1]; M Pellegrino[1]; B Pagliaro[1]; L Ardino[1]; G Condorelli[1]; D Pini[1]
[1]*Clinical Institute Humanitas IRCCS, Rozzano, Italy*

Background: Advanced Heart Failure(AdHF)is a therapeutic challenge.AdHF patients progressively face worsening functional capacity and quality of life, recurrent episodes of congestion and related hospitalizations, in spite of maximal optimized therapy.While few are candidates for life-saving therapies such as left ventricular assist devices and heart transplant, most AdHF patients are treated with a symptom palliation strategy.Levosimendan(Levo)is a calcium sensitizer inodilator whose effects in AdHF have been evaluated in 3 trials and one registry with encouraging results.Publications in this area are limited, further trials and real-world data are needed to fully elucidate the effects of Levo.
Purpose:To retrospectively investigate the clinical, echo, lab and arrhythmic effects of intermittent Levo infusions in AdHF patients treated for at least 6 months in a real-world setting.
Methods:This is an observational retrospective study.We retrospectively collected the data of patients(29)treated with repeated Levo infusions for at least 6 months in our unit from 2006 to 2018.Most patients were treated for symptoms relief(76%), the others as a bridge to transplant/LVAD or decision(34%).Clinical, echo and lab data were recorded from medical records.Data regarding arrhythmias and ICD shocks were retrieved from device ambulatory control reports.The outcomes of the same population of patients was compared for the 6 months before levosimendan initiation and for the 6 months thereafter.
Results: Male were 73%, average age was 69 years, mean Charlson Comorbidity score was>7, cardiomyopathy was ischemic in 45% and dilatative in 35%.Levo determined an improvement in NYHA class(p=0.012), ejection fraction(28.6%±7.1 vs 22.6%±6.7,p=0.006) and pulmonary artery systolic pressure(42.2±13mmHg vs 51.5±9mmHg,p=0.017), and reduced BNP levels(1054±812 vs 1779±1280,p=0.003).Creatinine levels remained stable (1.96±0.8 mg/dl vs 1.88±0.8 mg/dl,p=0.593). No differences were found in sustained ventricular arrhythmias or defibrillator therapies before and after Levo (0.4 vs 0.7, p=0.5). Mitral regurgitation was >moderate in 16 patients before Levo and in 6 patients after 6 months of infusions(not significant, p=0.7).Levo significantly reduced emergency room visits (0.1+0.4 vs 1.1+1.6,p=0.02).When considering only the patients treated after 2013(when the Italian palliative care network became operational),the in-hospital-days were significantly reduced(2.8±5.3 vs 10.7±9.4,p=0.012).
Conclusions: Intermittent Levo appears to be an effective and safe option in AdHF.It improves NYHA class and ejection fraction, reduces pulmonary systolic pressure, BNP levels, HF hospitalizations and emergency room visits. Furthermore, it seems to stabilize renal function.Reassuringly, these benefits are reached without an increase in the arrhythmic burden.In this regard, it is noteworthy that this is the first registry to use the ICD reports to investigate the arrhythmic safety of Levo.

P1695

Study of effect of therapy of chronic obstructive pulmonary disease on coexistent chronic heart failure

SAMIR Rafla[1]; ALY Aboelhoda[1]; AZZA Khamis[1]; RANIA Swied[1]
[1]*Alexandria University, Faculty of Medicine, Alexandria, Egypt*

The aim of this study was to determine the impact of chronic obstructive pulmonary disease treatment on the clinical condition of patients with heart failure. Forty Patients were enrolled in this study with co-existent heart failure (EF < 50%) with chronic obstructive pulmonary disease. Most of the studied patients (40%) were aged between 61 &70 years old. Smoking cessation: 25 patients stopped smoking (62.5%), and 15 patients didn't stop smoking (37.5%). Risk factors: Among studied cases, 34 cases (85%) suffered from systolic hypertension, 18 cases (45%) suffered from diabetes, and 28 cases (70%) had dyslipidemia. All patients were smoker (97.5%) except 1 patient was passively smoking and 17 patients were NYHA class III (42.5%), 23 patients were NYHA class II. Mean body mass index was 29.2 ± 6 kg/m2. ECG findings: Among studied patients, ischemic changes in ECG were present in 37 cases (92.5%).
Methods: Spirometry: The following results were obtained: FEV: (Forced Expiratory Volume in one second), FVC: (Forced Vital Capacity), FEV/FVC ratio, FEF 25-75%: (Forced Expiratory Flow between 25-75% of vital capacity), PEF (peak expiratory flow). Echocardiography was done. All patients were on treatment for heart failure and for COPD. Patients were followed for two months, and then echocardiography and spirometry were repeated for assessment of LV function and respiratory functions. Drugs given angiotensin blockers in 90%, beta-blockers (selective) in 94%, Sympathomimetics (long-acting β2-agonist LABA) in 100%, long-acting muscarinic antagonist (LAMA) in 55%; Figure. Results: Echo data Baseline EF ranged from19 to 50 % with a mean 32.7 ± 9.1. Two months later, EF ranged from 19.3 – 56.6% with a mean 36.18 ± 10 showing obvious improvement after addition of COPD treatment to patients on anti-failure treatment. Right ventricular systolic pressure (RVSP) ranged from 18.0 – 86.0 mmHg in baseline echocardiography assessment with a mean 47.9 ± 18.7. Two months later, follow up echo showed (RVSP) ranged from 16 – 81 mmHg with a mean 45.40 ± 18.0 showing obvious improvement after addition of COPD treatment to patients on anti-failure treatment. Spirometry Data: FVC ranged from 0.55 – 2.60 liters in pre-treatment of COPD with a mean 1.31 ± 0.52. Two months later, F VC ranged from 0.36 – 2.84 liters with a mean 1.62 ± 0.59 showing obvious improvement after addition of COPD treatment to patients on anti-failure treatment.
EF improved in 25 patients in whom COPD improved in all, EF did not improve in 15, in whom COPD did not improve also. All patients who stopped smoking had improvement in EF and COPD; all who did not stop smoking had no improvement in both parameters.
Conclusions: Improvement of COPD is associated with improvement of heart failure. Cessation of smoking is the best marker of possible improvement of both diseases. The use of sympathomimetics as inhalers or tablets had no deleterious effect on cardiac function.

P1696

Polypharmacy in patients with chronic heart failure

MA Mihnea-Alexandru Gaman[1]; EC Dobrica[1]; MA Cozma[1]; AM Gaman[2]; CC Diaconu[1]
[1]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*;
[2]*University of Medicine and Pharmacy of Craiova, Pathophysiology, Craiova, Romania*

Background: Ageing is associated with an increased number of comorbidities that frequently require medical treatment. Since the incidence of chronic heart failure (HF) is age-related, it is more likely that HF patients will be subjected to polypharmacy. However, polypharmacy often involves potentially dangerous drug-drug and food-drug interactions that complicate the management of both HF and other possible afflictions. Purpose: Our aim was to investigate the use of polypharmacy in HF patients. Methods: We conducted a retrospective, observational study on patients referred between January and February 2018 to the Internal Medicine Department of an emergency hospital in Romania. Patients were identified by a database search of diagnostic codes of discharge diagnoses. Patient characteristics and medical prescriptions were retrieved from medical records. Student t-test was used to assess differences between groups. Results: The study group (74.02±10.62 years, range 46-92 years) included 55 heart failure patients: 26 women (47.30%) and 29 men (52.70%). The control group (64.48±13.62 years, range 22-93 years) included 153 non-HF patients: 75 women (49.02%) and 78 men (50.98%). In HF patients, the number of comorbidities per-patient was 10.69±3.26 (vs. 7.88±3.27 in controls), the number of prescribed drugs at discharge was 7.93±1.97 per-patient (vs. 5.83±2.80 in controls) and the number of drug-to-drug interactions was 9.15±5.41 per-patient (vs. 4.80±5.02 in controls). 98.18% (54 patients) of the study group was at risk for at least one potentially harmful interaction vs. 79.08% (121 patients) in the control group. In HF patients, age correlated positively with the number of comorbidities, but negatively with the number of drugs, drug-drug and food-drug interactions.

Table 1	*HF patients*	*range*	*Controls*	*range*	*p-value*
Comorbidities	10.69±3.26	5-21	7.88±3.27	0-16	<0.001
Prescribed drugs	7.93±1.97	4-13	5.83±2.80	1-15	<0.001
Drug-drug interactions	9.15±5.41	0-22	4.80±5.02	0-23	<0.001
Minor drug-drug interactions	1.67±1.83	0-9	0.99±1.43	0-9	<0.02
Moderate drug-drug interactions	6.64±4.65	0-20	3.65±3.94	0-16	<0.001
Major drug-drug interactions	0.89±0.93	0-4	0.24±0.64	0-4	<0.001
Food-drug interactions	2.71±1.20	0-6	2.21±1.48	0-8	<0.02

Variable 1	Variable 2	Pearson's correlation coefficient (r)	
		HF patients	Controls
Age	Comorbidities	+ 0.29	+ 0.32
Age	No. drugs	– 0.40	+ 0.22
Age	No. interactions	– 0.35	+ 0.21
Age	No. minor interactions	– 0.33	+ 0.10
Age	No. moderate interactions	– 0.24	+ 0.24
Age	No. major interactions	– 0.38	+ 0.08
Age	Food-drug interactions	– 0.06	+ 0.18
Comorbidities	No. drugs	+ 0.10	+ 0.52
Comorbidities	No. interactions	– 0.04	+ 0.45
Comorbidities	No. minor interactions	– 0.04	+ 0.23
Comorbidities	No. moderate interactions	– 0.07	+ 0.46
Comorbidities	No. major interactions	+ 0.27	+ 0.28
Comorbidities	No. food-drug interactions	+ 0.20	+ 0.42
No. drugs	No. drug-drug interactions	+ 0.57	+ 0.82
No. drugs	No. minor interactions	+ 0.10	+ 0.47
No. drugs	No. moderate interactions	+ 0.55	+ 0.81
No. drugs	No. major interactions	+ 0.51	+ 0.40
No. drugs	No. food-drug interactions	+ 0.16	+ 0.67

Results

Conclusions: Chronic HF patients were prescribed more drugs at discharge and had a higher number of potentially harmful drug-drug or food-drug interactions vs. non-HF patients, as reinforced by our data. Chronic HF patients also had more comorbidities vs. non-HF subjects. Polypharmacy management must be taken into consideration by the clinician when treating chronic HF patients in order reduce drug burden and avoid unnecessary medication.

P1697

Changes in hemodynamic profile in patients with severe systolic dysfunction treated with sacubitril-valsartan

F Corazza[1]; A Ceccarelli[1]; G Vitale[1]; S Boschi[1]; L Giovannini[1]; M Masetti[1]; A Russo[1]; L Luciano Potena[1]
[1]*Bologna University Hospital, Bologna, Italy*

Background. Post-capillary pulmonary hypertension (PC-PH) is a frequent complication and prognostic marker in patients with advanced heart failure (HF). No specific treatments are available for PC-PH other than optimal HF therapy. In this context, we tested the hypothesis that therapy optimization with sacubitril-valsartan (LCZ), known to reduce the risk of death and hospitalizations for HF, could improve the hemodynamic profile of patients with HF and PC-PH.
Methods. Among the patients included in our institutional prospective HF Registry, we included in this analysis those who underwent two right heart catheterizations (RHC) and started LCZ in between, in the period July 2017 to December 2018. All patients were evaluated for heart transplantation and RHC is part of our routine clinical practice as follow-up strategy in these patients. Baseline and follow-up RHC were compared by paired T-test. Changes in guideline directed therapy (GDT) were also assessed.
Results. 35 patients (86% males; aged 53.3 ± 8.4y, 10(29%) with ischemic etiology, and 12 (34%) in NYHA class III-IV) with severe left ventricular dysfunction (ejection fraction: 25.6±7.5%) underwent two RHC at 187±85 days interval. All patients were receiving therapy with diuretics (187±85mg/day), ACE-i/ARBs (43±27% of GDT dose), and beta-blockers (57±33% of GDT dose) at the time of baseline RHC. LCZ was started at a median of 21(0-116) days after the baseline RHC. By comparing baseline with follow-up RHC in a matched paired fashion, we observed significant reduction of mean pulmonary artery pressure (from 31±11 to 26±9 mmHg; P<0.01), pulmonary capillary wedge pressure (from 21±7 to 18±8 mmHg; P<0.01) and pulmonary vascular resistances (from 2.8±1.7 to 2.0±1.0 WU; P<0.01), associated with a significant increased of cardiac index (from 2.1±0.4 to 2.3±0.6 l/min/m2; P=0.03). Conversely, systolic systemic pressure did not change significantly (from 110±12 to 107±12 mmHg; P=0.16). Of note, diuretics and beta-blockers dose did not change significantly between the two RHC.
Conclusions. In the context of stable and optimized at the maximal tolerated dose of GDT, this pilot experience suggests that LCZ may improve the management of PC-PH in patients with severe LV dysfunction. The changes in hemodynamic profile, including the increase in cardiac index, provide a pathophysiological background of the clinical benefits observed in the LCZ randomized trial.

P1698

Sacubitril/valsartan inverse remodeling - a prospective echocardiographic study

G Bayard[1]; R Romain Pierrard[1]; K Isaaz[1]; A Da Costa[1]
[1]*CHU Saint Etienne Hopital Nord, Cardiology, Saint Etienne, France*

Background. Sacubitril/valsartan has been shown to improve mortality and reduce hospitalizations in patients with heart failure (HF) with reduced ejection fraction (HFrEF). Although the physiological action mechanisms of sacubitril/valsartan are well described, its effects on left ventricular (LV) remodelling and other echocardiographic (echo) parameters have not been prospectively studied. Objective. The aim of this prospective study was to: (1) evaluate if sacubitril/valsartan impacts LV remodelling based on echo parameters; (2) identify the predictive factors of sacubitril/valsartan response or intolerance. Methods. From May 2017 to September 2018, 52 HF patients were prospectively enrolled using Paradigm-HF criteria: Class II, III, or IV HF; ejection fraction (EF) of 40% or less; hospitalized for HF within the previous 12 months. Echo evaluation was performed before initiating sacubitril/valsartan and 3 months after optimal dose adjustment. Based on previous studies, patients with (absolute) improvement in left ventricular ejection fraction (LVEF) ≥5% were considered significant sacubitril/valsartan responders. Results. The 52 patients completing the study were characterized by age: 70±10 years; gender: 11 women; aetiology: idiopathic in 20 and ischaemic in 32; NYHA Class: II in 17 and III in 35; LVEF: 32±5%; NTProBNP: 1805±1914pg/mL. The final population comprised 41 pts (79%), as 11 (21%) did not tolerate sacubitril/valsartan therapy. Under sacubitril/valsartan, several echo parameters significantly improved: LVEF from 32.6±5 to 36±6% (p<0.0001); LVES volume from 117±40 to 108±46mL (p=0.0051; LVEDD from 60±4 to 57±5mm (p=0.0002); mean right ventricular systolic pressure (RVSP) from 39±10 to 32±8 (p=0.0001). No significant modifications were observed concerning LV diastolic parameters or RV echo parameters. Sacubitril/valsartan echo responders (n=18/41; 42%) had less severe LV remodelling, as shown by LVEDV: 144±37 vs. 193±47mL, p=0.0009; LVESV: 96±28 vs. 133±42mL; p=0.003; LVTDD: 61±4 vs. 57±5mm; p=0.02; significant mitral regurgitation: 6/18 (33%) vs. 16/23 (69%), p=0.02; no diastolic LV or RV parameters impacted sacubitril/valsartan response. Predictors of sacubitril/valsartan intolerance were baseline creatinine level: 137±99 vs. 100±24, p=0.03; LVEF: 29±6 vs. 33±5%; p=0.04. Conclusions. In HFrEF patients, sacubitril/valsartan significantly improves LV systolic remodelling, without any significant effects on LV diastolic or RV systolic echo parameters. Sacubitril/valsartan responders exhibit both less severe LV remodelling and less significant mitral regurgitation. Accordingly, sacubitril/valsartan could be used as soon as possible in HFrEF patients in order to limit LV remodelling, while precluding non-response or intolerance.

P1699

Initial clinical experience with the first drug (sacubitril/valsartan) in a new class -arni- in afro-caribbean patients with heart failure and reduced ejection fraction

F Felix Nunura[1]; ETR Tulloch-Reid[1]; DN Nepaul[1]; EM Madu[1]
[1]*HEART INSTITUTE OF THE CARIBBEAN, CARDIOVASCULAR MEDICINE , KINGSTON, Jamaica*

Background: Among Afro-Caribbean patients with heart failure and reduced ejection fraction (HFrEF), non-ischemic dilated cardiomyopathy is the most frequent etiology. There are no studies on the use of the Angiotensin II Receptor Blocker Neprilysin Inhibitor (ARNI), Sacubitril/Valsartan in this population. We present the initial experience concerning the tolerance, safety, adverse effects and efficacy of ARNI among Afro-Caribbean. Methods: An observational, non-interventional, real-world study was done based on 44 patients with HFrEF, in Jamaica between October, 2017, and June , 2018. Clinical characteristics, features of heart failure and adverse events (AE) were documented. Eligible patients were prescribed Sacubitril/Valsartan, titrating the dose up to 200 mg twice daily over 4 to 8 weeks. Subsequently, echocardiographic Ejection Fraction (EF) at baseline and post intervention were reviewed. Wilcoxon signed-rank test and paired sample t-test were used to compare groups. Results: The most frequent AE were symptomatic hypotension 11.36%, cough 6.81%, and renal dysfunction 2.27%. None developed angioedema. Post-treatment echocardiograms of 26 patients, demonstrated an average of 14.7% (±2) increase in EF, from 29.4% to 44.1% (p<0.001) over a median of 3.15 months of therapy. Conclusion: Sacubitril/Valsartan was demonstrated to be safe, well tolerated and associated with significant functional improvement among Afro-Caribbean patients with HFrEF.

P1700

Empagliflozin in heart failure: beyond clinical endpoints

M Maria Abellas Sequeiros[1]; S Del Prado[1]; G Alonso Salinas[1]; JM Vieitez Florez[1]; A Lorente Ros[1]; JL Moya Mur[1]; A Garcia Martin[1]; JJ Jimenez Nacher[1]; C Fernandez-Golfin[1]; JL Zamorano Gomez[1]
[1]*University Hospital Ramon y Cajal de Madrid, Madrid, Spain*

Introduction: Since publication of the EMPAREG trial demonstrated a beneficial prognostic impact, reducing death from cardiovascular causes and hospitalization for heart failure, the use of inhibitors of the sodium-glucose transport protein 2 has raised. Left ventricular ejection fraction (LVEF) and other echocardiographic parameters are independent prognostic factors in heart failure. Does empagliflozin improve ventricular remodeling? Does it improve diastolic function?
Methods: To answer these questions, a series of patients with heart failure who initiated empagliflozin between December 2016-June 2017 was prospectively assessed. Aetiology and baseline characteristics were collected. LVEF, ventricular volumes and diastolic function parameters were evaluated by transthoracic echocardiogram before and after 6-month treatment. Patients with reversible aetiologies, and those with modified treatment during follow-up were excluded. Patients without echocardiogram before and 6 months after therapy were also excluded. Wilcoxon test was conducted.
Results: Twenty patients were included; mean age was 72 years old; 14 (70%) patients were men and 60% had ischaemic aetiology. Mean LVEF was 36,7% and median estimated glomerular filtration rate was 70 ml/min. Regarding to optimal medical treatment: 79% were on angiotensin-converting-enzyme inhibitor, 21% sacubitril-valsartan, 84% beta-blocker and 75% were receiving a mineralocorticoid-receptor antagonist. Empagliflozin was discontinued in 1 patient because of persistent genital candidiasis.
LVEF did not show significant changes 6 months after treatment (36,7±13,5 vs 39,9±12,6; p=0,16). However, lower left ventricular end systolic (111,6±62,2 vs

92,7±56,5; p=0,022) and left ventricular end diastolic volumes (170,5±72,5 vs 153,1±73,3; p=0,028) were described. The study of diastolic function showed no differences in E/e'(15,5±4,6 vs 9,5±2,6; p=0,138), tricuspid regurgitation velocity (3,0±0,4 vs 3,0±0,3; p=0,462) nor left atrium volume (94,8±26,2 vs 76,3±33,1; p=0,059).
Conclusion: Empagliflozin significantly improves left ventricular end diastolic and end systolic volumes. In our small sample, its beneficial effect does not show an important difference in LVEF or diastolic function. Studies with larger number of patients included and longer follow-up periods are needed to characterise the influence of empagliflozin on heart structural remodeling.

ARNI use in clinical practice: PARADIGM-HF trial results applied to the real world

T E Graca Rodrigues[1]; JR Agostinho[1]; J Rigueira[1]; I Aguiar-Ricardo[1]; A Nunes-Ferreira[1]; R Santos[1]; N Cunha[1]; T Guimaraes[1]; M Almeida Ribeiro[1]; S Longo[2]; N Lousada[2]; F Veiga[1]; M Mendes Pedro[1]; FJ Pinto[1]; D Brito[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal; *[2]Hospital Pulido Valente/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal*

On behalf of: RICA-HFTeam

Introduction: The PARADIGM-HF trial showed the clinical benefits of the addition of sacubitril to the conventional neurohormonal antagonist therapy regimen for heart failure (HF) with reduced ejection fraction (rEF). However, national data on the effects of sacubitril/valsartan (S/V) introduction in real-life patients (pts) is scarce.
Objective: To evaluate the clinical effects of S/V introduction in a population of pts with HFrEF followed in a tertiary hospital HF Clinic.
Methods: Prospective study of consecutive pts with HFrEF treated with S/V. Clinical, echocardiographic and laboratorial data were collected before and after the introduction of the drug. Episodes of HF decompensation (defined as the need to increase oral dose of diuretics or intravenous administration of diuretics) and hospitalizations during the follow-up period were registered.
The number of decompensation episodes or hospitalization were compared with the number of similar events that occurred in a period with exactly the same time duration but preceding the first dose of S/V. Comparative statistical analysis was performed using Wilcoxon test.
Results: One hundred and two pts were included. The median follow-up time was 6 (4-10) months. There was a significant improvement in NYHA functional class (FC), mainly due to a marked decrease in the number of pts in FC III (15.7 vs. 2%, P <0.001) (Table 1). Mean left ventricle ejection fraction (29.5±3.2 vs. 34±5.8%, P =0.005) also improved, and NTproBNP was significantly reduced (3107±2128 vs. 2619±1437pg/mL, P <0.001) after S/V prescription.
There was no significant change in serum creatinine (1.24±0.49 vs. 1.26±0.46 mg/dL, P =NS) or systolic blood pressure (120.2±18.8 vs. 119.2 ± 18.8mmHg, P =NS).
Importantly, there was a significant reduction in the number of HF decompensations (49 episodes in 37 pts vs. 10 episodes in 8 pts, P <0.001) and hospitalizations (31 episodes in 23 pts vs. 10 events in 7 pts, P <0.001) after initiation of the drug.
Conclusion: Starting sacubitril/valsartan in a population of patients followed in a HF Clinic was associated with significant clinical improvement, marginal echocardiographic improvement, and NTproBNP reduction. In parallel, the introduction of the drug led to a significant reduction of HF decompensation episodes and hospitalizations. These data derived from a real-lifepopulation confirm the benefits of sacubitril/valsartan firstly demonstrated in the PARADIGM-HF Trial.

Funding Acknowledgements: MyoKardia, Inc.

Background: MYK-491 is a novel small-molecule selective cardiac myosin activator, in clinical development for the treatment of heart failure with reduced ejection fraction. In non-clinical studies, MYK-491 increased myocardial contraction, with minimal impact on relaxation and without perturbing calcium homeostasis. We report results of the first-in-human study.
Methods: The effects of oral MYK-491 were evaluated in a single ascending dose study conducted in healthy volunteers across 8 sequential dose cohorts (6 active and 2 placebo subjects per cohort). Assessments included evaluation of clinical safety and tolerability, serial plasma drug concentrations, cardiac echo-doppler, ECG and clinical laboratory values.
Results: 64 healthy volunteers were studied (40 male, 24 female, median age 27 years).
MYK-491 was safe and well tolerated. One subject experienced a serious adverse event (brief asymptomatic episodes of heart block lasting 4-8 sec during sleep that resolved spontaneously and led to prolongation of monitoring). Dose-proportional increases in drug exposure (Cmax, AUC) were observed up to dose cohort 7. Echocardiography parameters by MYK-491 Plasma Concentration Groups (6h post dose) are shown in Table (placebo-corrected LS mean changes from baseline) are shown
Conclusions: MYK-491 administration in healthy volunteers was safe and led to an increase in echocardiographic measures of cardiac contractility which were associated with a modest increase in SET and no discernable effect on diastolic function.

Comparative effectiveness of loop diuretics on mortality in the treatment of patients with chronic heart failure - A multicenter propensity score matched analysis

L Lutz Frankenstein[1]; H Froehlich[1]; M Grundtvig[2]; M Seiz[1]; D Schellberg[1]; K Goode[3]; S Kazmi[3]; T Hole[4]; HA Katus[1]; D Atar[5]; JGF Cleland[6]; S Agewall[5]; AL Clark[3]; L Frankenstein[1]
[1]The Medical Faculty of Heidelberg, Heidelberg, Germany; *[2]Innlandet Hospital, Lillehammer, Norway*; *[3]Castle Hill Hospital, Cottingham, United Kingdom of Great Britain & Northern Ireland*; *[4]Norwegian University of Science and Technology,*

Trondheim, Norway; [5]*University of Oslo, Oslo, Norway*; [6]*Imperial College London, National Heart & Lung Institute, London, United Kingdom of Great Britain & Northern Ireland*

Background: Loop diuretics are given to the majority of patients with chronic heart failure (HF). Whether the different pharmacological properties of the three guideline-recommended loop diuretics result in differential effects on survival is unknown.
Methods: 6,293 patients with chronic HF using either bumetanide, furosemide or torasemide were identified in three European HF registries. Patients were individually matched on both the respective propensity scores for receipt of either drug and dose-equivalents thereof.
Results: During a follow-up of 35,038 patient-years, 652 (53.7%), 2,179 (51.9%), and 268 (30.4%) patients died amongst those prescribed bumetanide, furosemide, and torasemide, respectively. In univariable analyses of the general sample, bumetanide and furosemide were both associated with higher mortality as compared with torasemide treatment (HR 1.50, 95% CI 1.31-1.73, p<0.001, and HR 1.34, CI 1.18-1.52, p<0.001, respectively). Mortality was higher in bumetanide users when compared to furosemide users (HR 1.11, 95% CI 1.02-1.20, p=0.01). However, there was no significant association between loop diuretic choice and all-cause mortality in any of the matched samples (bumetanide vs. furosemide, HR 1.03, 95% CI 0.93-1.14, p=0.53; bumetanide vs. torasemide, HR 0.98, 95% CI 0.78-1.24, p=0.89; furosemide vs. torasemide, HR 1.02, 95% CI 0.84-1.24, p=0.82). The results were confirmed in subgroup analyses with respect to age, sex, left ventricular ejection fraction, NYHA functional class, cause of HF, rhythm, and systolic blood pressure.
Conclusions: In patients with HF, after adjustment for potential prescribing-biases, mortality does not appear to be affected by choice of loop diuretic in clinical practice. The results of randomised trials comparing diuretic agents are awaited.

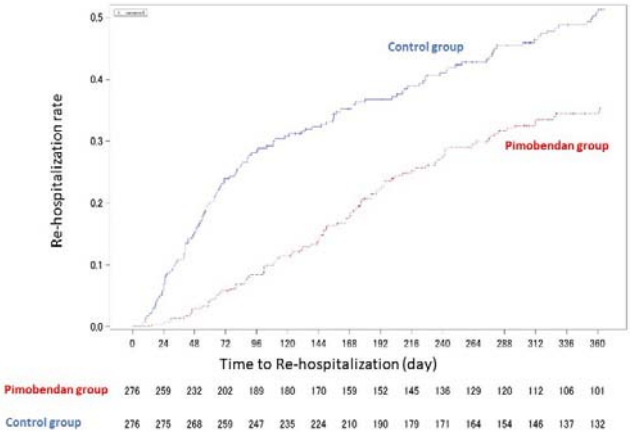
Background One of the therapeutic goals in treatment of patients with advanced heart failure is prevention of re-hospitalization. The oral calcium sensitizer Pimobendan is one of the drugs expected to show efficacy in this situation.
Purpose: We investigated whether Pimobendan could contribute to prolongation of the period until re-hospitalization for heart failure and decrease the frequency of hospitalization. (UMIN 000034228)
Methods This retrospective cohort study is based on anonymized electronic health records from acute-care hospitals in Japan as gathered during the period April 2008 – February 2018.Patients who experienced two or more hospitalizations for heart failure during the observation period were enrolled. Patients were allocated to one of two groups. In one of the groups patients continued to receive Pimobendan on an outpatient basis, whereas patients in the other group were not prescribed Pimobendan upon discharge from hospital. The one-to-one propensity-score matching and IPTW methods were used to balance patient characteristics in these 2 groups.
Results: We identified 10,258 patients who satisfied our inclusion and exclusion criteria. Out of those 473 patients were prescribed Pimobendan during the follow-up period, whereas Pimobendan was not prescribed for 9,785 patients, who constitute the control group.276 propensity score matched pairs were identified for Pimobendan group versus control group. Mean age ± standard deviation [SD] was 74.3 ± 10.9 and 74.4 ± 11.3 years, Male was 65.2 and 67.8 %, NYHA class 3 or 4 was 68.1 and 66.0 %, atrial fibrillation observed 60.5 and 62.0 % for Pimobendan group and control group, respectively. The cumulative incidence of heart failure hospitalization at 1 year was 0.35 (95% confidence interval [CI] 0.30 - 0.42) in Pimobendan group, and it was significantly lower than the control group (0.51, 95% CI 0.45 - 0.58) (p <0.002). Similar result about prolongation of period to rehospitalization for heart failure by Pimobendan observed by IPTW method.
The number of hospitalizations due to heart failure at 1 year was 0.5 ± 1.0 for the Pimobendan group, which was significantly less than for the control group (0.8 ± 1.3, p=0.021) as revealed by the Propensity score match method. No significant difference, however, was observed by the IPTW method0.5±1.0 vs 0.6±1.0, p=0.532. Accordingly, it is a controversial issue whether Pimobendan can decrease hospitalization frequency.
The cumulative incidence of hospitalizations due to life-threatening arrhythmia was 6.41 (95%CI 1.45 – 11.37] and 2.41 (95% CI -0.63 – 5.45) /1000 person-year for the Pimobendan group and the control group, respectively. There was no difference between the 2 groups (p=0.315) when analyzing for life-threatening arrhythmia.
Conclusion: Pimobendan might safely contributes to prolonging the period until re-hospitalization in Japanese patients with advanced heart failure, especially in the post-discharge vulnerable phase.



P1705

microRNA-21 as a prognostic biomarker of sacubitril/valsartan treatment response in heart failure with reduced ejection fraction

M Maria Marketou[1]; H Nakou[2]; J Kontaraki[1]; S Maragkoudakis[1]; J Konstantinou[1]; A Kostaki[1]; D Papadopoulos[1]; S Kassotakis[1]; A Patrianakos[1]; K Fragiadakis[1]; M Plataki[1]; O Theodosaki[1]; A Alevizaki[1]; P Vardas[1]; F Parthenakis[1]
[1]*Heraklion University Hospital, Heraklion, Greece*; [2]*Barts Health NHS Trust, arts Heart Centre, Barts Health NHS Trust / Institute of Cardiovascular Science, London, United Kingdom of Great Britain & Northern Ireland*

Purpose: MicroRNAs (miRs) modulate cardiovascular development and disease by post-transcriptional gene expression regulation and thus they are emerging as potential biomarkers and promising therapeutic targets in cardiovascular disease. Although sacubitril/valsartan, a first in class angiotensin-receptor-neprylisin inhibitor (ARNI), has recently shown its benefits and safety in symptomatic patients with chronic heart failure with reduced ejection fraction (HFrEF), there is no evidence yet on predicted markers for its efficacy. The aim of this study is to evaluate miR-208b, miR-499, miR-21, miR-1, miR-133a and miR-26b gene expression levels as prognostic markers of sacubitril/valsartan treatment response in patients with HFrEF
Methods: We included 26 symptomatic patients (aged 68 ± 12 years) with chronic HFrEF (LVEF <35%) and New York Heart Association (NYHA) class II/III, who received sacubitril/valsartan (mean dose of 94 ± 43 mg/day) on optimal medical treatment. All patients underwent a serial assessment with standard conventional transthoracic and a two-dimensional speckle tracking echocardiography at baseline and at 6 months follow-up. MiRs expression levels in peripheral blood mononuclear cells were quantified by real-time reverse transcription polymerase chain reaction.

Results: Blood pressure 114/70 ± 9/6 mmHg did not show any significant change (from 114/72 ± 9/6 mmHg to 111/69 ± 10/5 mmHg, p=NS). Left ventricular global longitudinal peak strain (GLPS) showed a significant improvement during the 6 months follow-up (from -7.22 ± -1.2 % at baseline to -8.2 ± -0.9 %, p= 0.01). miR-21 gene expression levels at baseline revealed a significant positive correlation with the reduction of GLPS ($r = 0.5$, $p < 0.001$) which was independent of the patients' clinical parameters.
Conclusions: Our data reveal that miR-21 is a strong prognostic marker of GLPS improvement following sacubitril/valsartan initiation and may discriminate patients with HFrEF at high likelihood of responding in sacubitril/valsartan therapy.

P1706

Metabolism and pharmacokinetic drug interaction profile of vericiguat, a soluble guanylate cyclase stimulator

M Maximilian Lobmeyer[1]; M Gerisch[2]; M-F Boettcher[1]; D Thomas[3]; M Gerrits[4]; W Mueck[1]; N Besche[5]; C Becker[1]
[1]Bayer AG, Clinical Pharmacology, Wuppertal, Germany; *[2]Bayer AG, DMPK, Wuppertal, Germany*; *[3]Bayer AG, Experimental Medicine, Wuppertal, Germany*; *[4]Merck & Co., Inc., Kenilworth, New Jersey, United States of America*; *[5]Chrestos Concept GmbH & Co. KG, Essen, Germany*

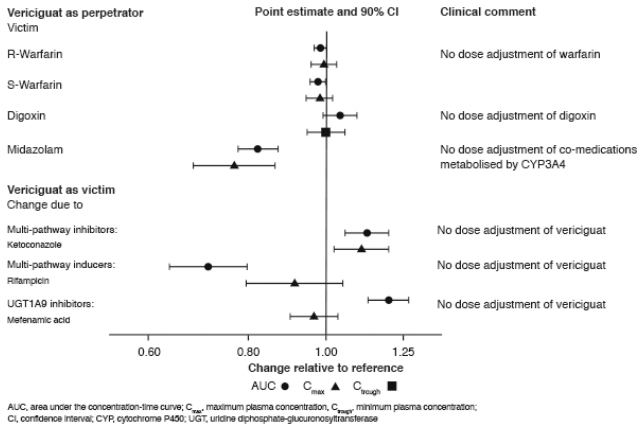
Funding Acknowledgements: Funding for this research was provided by Bayer and Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Kenilworth, NJ, USA

Background/Introduction: Vericiguat is under investigation in patients with heart failure (HF; NCT02861534). This patient population is characterised by multiple comorbidities and concomitant medications.
Purpose: An understanding of the clearance mechanisms, elimination and potential for drug–drug interactions (DDIs) of vericiguat is a pre-requisite for dose recommendations.
Methods: Biotransformation of vericiguat was characterised in vitro using hepatocytes, liver microsomes, recombinant uridine diphosphate-glucuronosyltransferase (UGT) isoforms and with selective UGT inhibitors in liver microsomes. These were complemented by a human mass balance study with a single dose of 14C-labelled vericiguat 5 mg and six DDI studies in healthy volunteers (Table 1). The perpetrator DDI potential of vericiguat was investigated in vitro.

Table 1

Healthy volunteer study	Design	Vericiguat treatment	Co-medication
Mass balance	Open-label, non-randomised, non-placebo-controlled	5 mg radiolabelled [^{14}C] SD	Not applicable
DDI with warfarin	Randomised, double-blind, 2-fold crossover	10 mg OD for 9 days	Warfarin 25 mg SD
DDI with digoxin	Randomised, open-label, 2-fold crossover with additional fixed treatment period	10 mg OD for 10 days; 10 mg SD	Digoxin 0.375 mg OD for 14 days
DDI with CYP3A4 index substrate	Randomised, open-label, 2-fold crossover	10 mg OD for 4 days	Midazolam 7.5 mg SD
DDI with multi-pathway inhibitor	Randomised, open-label, 2-fold crossover	1.25 mg SD	Pre- and co-administration of ketoconazole 200 mg BID for 3 days
DDI with multi-pathway inducer	Non-randomised, open-label, fixed sequence	10 mg SD	Pre- and co-administration of rifampicin 600 mg OD for 9 days
DDI with UGT1A9 inhibitor	Randomised, open-label, 2-fold crossover	2.5 mg SD	Pre- and co-administration of mefenamic acid 500 mg followed by MDs of mefenamic acid 250 mg every 6 hours for 3 days

BID, twice-daily; CYP, cytochrome P450; DDI, drug–drug interaction; MD, multiple dose; OD, once-daily; SD, single dose; UGT uridine diphosphate-glucuronosyltransferase



AUC, area under the concentration-time curve; C_{max}, maximum plasma concentration, C_{trough}, minimum plasma concentration; CI, confidence interval; CYP, cytochrome P450; UGT, uridine diphosphate-glucuronosyltransferase

Clinically, the perpetrator DDI potential was assessed with the narrow-therapeutic index drugs digoxin and warfarin, and the cytochrome P450 (CYP) 3A4 index substrate midazolam. Vericiguat was administered as a victim drug with ketoconazole, rifampicin and mefenamic acid.
Results: After administration of 14C-labelled vericiguat, 53.1% and 45.2% of the dose was excreted via urine and faeces, respectively. The main metabolic pathway of vericiguat is glucuronidation via UGT1A9 and UGT1A1.
In vitro studies revealed that the risk of pharmacokinetic (PK) DDIs with substrates of CYP and UGT isoforms, as well as major transport proteins, is low. These were confirmed by the clinical studies (Figure 1).
Conclusion(s): A low PK interaction potential of vericiguat was estimated from in vitro data and confirmed in six studies. Maximum changes in vericiguat exposure (˜30%) were within the range of overall PK vericiguat variability. These results indicate that the PK DDI profile of vericiguat is suited to the treatment of a HF population.

P1707

Are we optimizing medical therapy during a heart failure hospitalisation ?

K Kim Girard[1]; H Provencher Couture[1]; F Dupont[1]; N Desgagnes[2]; SL Lepage[1]
[1]University Hospital of Sherbrooke (CHUS), Sherbrooke, Canada; *[2]Sherbrooke University, Sherbrooke, Canada*

Funding Acknowledgements: Société Québécoise d'Insuffisance Cardiaque (SQIC)

Background Over the past 20 years, number of guideline recommended medical therapies have been added to our therapeutic arsenal for heart failure with reduced ejection fraction (HFrEF). Despite their proven efficacy, prescription rates of such medications are still less than optimal and every opportunity should be taken to improve them.
Purpose: This study aim to establish if clinicians take an acute decompensated heart failure (ADHF) hospitalisation as an opportunity to optimise the patient's heart failure medication.
Methods Consecutive patients hospitalized for ADHF with LVEF ≤ 40% between January 1st and December 31st 2015 (n=124) were identified using our institution's database. All of their files were reviewed for their baselines characteristics and their heart failure treatment at admission and at discharge.
Results: Most of our patients were male (61%) with a mean age of 77 ± 11 years old. The mean LVEF was 28% ± 9% and the underling cause being ischemic cardiopathy in the majority (65%) of patients. 32% of them ad a new diagnosis of HFrEF and the median length of hospital stay was 10 days. At admission, the prescription rate of beta blockers (β-blockers), angiotensin-converting enzyme inhibitors/angiotensin II receptor blockers (ACEI/ARB) and mineralocorticoid receptor antagonists (MRA) were 71%, 54% and 21% respectively vs 87% for β-blockers, 63% for ACEI/ARB and 44% for MRA at hospital discharge. Only 10% of the patient had all three medication classes prescribed at admission vs 27% at discharge. Figure 1 show the prescription rate of the different heart failure medication. Only a small proportion of patients were prescribed the guideline recommended dose of β-blockers (23%) and MRA (2%) at admission and this proportion only slightly increased at discharge (27% and 8% respectively).
Conclusion: Although an episode of ADHF is an important moment to try to optimise disease modifying drug for our patients it is seldom the case. Prescription rate of guideline directed medical therapies significantly increased but was still less than optimal and dosage optimisation of already prescribed heart failure medication was low. To improve cardiovascular morbidity and mortality this gap should be address.

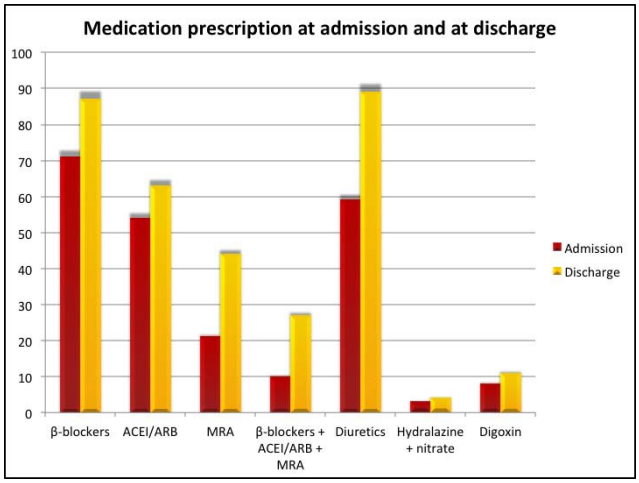


Figure 1

P1708

Sacubitril/Valsartan in clinical practice, how does it work?

C Nordberg Backelin[1]; A Pivodic[2]; M Fu[3]; C Ljungman[1]

[1]Sahlgrenska University Hospital, Sahlgrenska Academy, University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden; [2]Statistiska Konsultgruppen, Gothenburg, Sweden; [3]Sahlgrenska Academy, Cardiology Unit, Department of Medicine, Östra, Gothenburg, Sweden

Background Sacubitril/Valsartan (Sac/Val) an angiotensin receptor blocker–neprilysin inhibitor (ARNI) has been proven to be more effective than enalapril for symptomatic patients with heart failure (HF) with reduced ejection fraction (HFrEF) despite optimal therapy. It was introduced in ESC guidelines and in Swedish guidelines in 2016. However, the real world HF population differ from patients in randomized controlled trials in many clinical aspects.

Aim This study was aimed to investigate eligibility, titration and tolerability for Sac/Val in a real-world clinical setting.

Methods This retrospective cohort study consisted of two parts; part 1 (eligibility study): consecutive inclusion of all patients discharged from a hospital due to HF (ICD10 I50) from 2016-11-01 until 2017-10-31. Patients were judged to be eligible to Sac/Val based on ESC criteria (EF ≤40%, NT-proBNP >400 ng/L, target dose of ACE-inhibitor/angiotensin receptor blocker (ARB), GFR>30 ml/h/1,73m2, S-Potassium<5.2 mmol/L, treatment with beta blocker and MRA) or Swedish criteria (EF ≤35%, highest tolerable dose of ACE-inhibitor/ARB + Beta blocker and MRA, GFR>30, S-potassium <5,2).

Part 2 (tolerability study): from patients who received Sac/Val during the same study period data regarding initial dose, up-titration, adverse events, hospitalisation and mortality during follow-up (from 6 months to one year) were collected.

Results During one year, 1355 patients (mean age 78±13 yrs) were hospitalized due to HF. Among them, 562 patients had ejection fraction ≤40% in which 10.9% of the patients were eligible for initiation of Sac/Val based on ESC criteria, and additionally 15.9% were eligible according to Swedish recommendations. During the same period, 96 patients (mean age 66±12 yrs) were initiated with Sac/Val, 18 % discontinued, 15.6% developed S-K≥5.5 mmol/L, 13.5% S-creatinine>221 µmol/L and 7.3% hypotension. During follow-up 24.0% were readmitted for HF and 13.8% died (fig1). Logistic regression analysis showed lower starting dose, renal disease and higher NTpro-BNP level as predictors for worsening of renal function and higher number of comorbidities as predictors for readmission due to HF. Analysis also showed renal disease as predictor for hypotension and further, high age, elevated NTpro-BNP and more comorbidities as predictors for death.

Conclusions In our consecutive hospital HF cohort, 26.8% of patients with reduced EF were eligible for Sac/Val. Those who received Sac/Val were younger. Side effects and discontinuation rates were comparable to those observed in the PARADIGM trial except a higher percentage of hypotension, worsening of renal function and HF readmission.

Chronic Heart Failure - Clinical

P1710

Evaluation of the effectiveness of lisinicore and losartan in patients with chronic heart failure

U Umida Kamilova[1]; Z Rasulova[1]; D Masharipova[1]; G Zakirova[2]

[1]Republican specialized scientific-practical Medical Center Therapy and Medical Rehabilitation, Tashkent, Uzbekistan; [2]Tashkent medical academy, Tashkent, Uzbekistan

Purpose. To study the effect of lisinopril and losartan on the functional state of the kidneys of patients with I-III functional class (FC) of chronic heart failure (CHF), depending on the degree of renal dysfunction (RD).

Methods. A total of 223 patients with ischemic heart disease with I-III FC of CHF were examined, initially and after 6 months of treatment. The first group (I) consisted of 118 patients taking lisinopril as part of standard therapy; the second group (II) - 105 patients taking losartan. Also, all patients were divided into 2 groups depending on the estimated glomerular filtration rate (eGFR): 30 <eGFR ≤60 ml / min / 1,73 m2 - 67 patients (29 patients in the I group, 38 - in the II group), and eGFR > 60 ml / min / 1,73m2 -156 patients (89 patients in group 1,67 patients in group 2).

Results. The nephroprotective effect of standard therapy with the inclusion of lisinopril or losartan was noted, with a significant decrease in the level of enzymes in the urine, as a sign of dysfunction of the tubular kidney apparatus, a decrease in creatinine, and an increase in GFR. In patients with CHF with a preserved eGFR> 60 ml / min / 1,73 m2 and moderate RD with eGFR = 59-45 ml / min / 1,73 m2, the use of standard lisinopril or losartan showed reliable nephroprotection. In patients with CHF with kidney dysfunction with 30> eGFR <45 ml / min / 1,73 m2, a significant improvement in renal dysfunction was observed in the group of patients taking standard therapy - losartan.

Conclusion. The results of our studies in patients with CHF showed that RD appeared at the subclinical stage, when the majority of patients do not have clinical signs of renal failure, which is also correlated with the findings of other researchers. According to many studies, the positive effect of ACE I and ARA is due to the fact that they reduce the initially high blood pressure in glomeruli of the kidneys, which stops the development of glomerulosclerosis

Profile and follow up of the elderly patient with heart failure

D Enriquez Vazquez[1]; CN Perez Garcia[1]; M Ferrandez Escarabajal[1]; TS Luque Diaz[1]; A Travieso Gonzalez[1]; M Perez Serrano[1]; E Martinez Gomez[1]; N Ramos Lopez[1]; A Jeronimo Baza[1]; C Olmos Blanco[1]; D Vivas Balcones[1]; J Goirigolzarri[1]; R Bover Freire[1]; I Vilacosta[1]; C Macaya[1]

[1]Hospital Clinic San Carlos, Cardiovascular Institute, Madrid, Spain

Introduction The prevalence of heart failure (HF) has increased, due to the increased survival of these patients. The elderly patient sometimes presents multiple comorbidities.Therefore, the objective of this study is to know this subgroup more and more frequent, and its follow-up.
Methods Patients with a diagnosis of HF admitted to a Cardiology Service of a tertiary hospital between July 2016 and March 2017 have been collected prospectively and consecutively, recording their characteristics and management, and their follow up.
Results Of the total of 336 patients analyzed, 150 patients were 80 years old or older, with a median follow-up of 403 days. Baseline characteristics of these patients are in Table 1. Less impact has been placed on the control of heart rate (HR) in these patients, presenting at discharge an average HR at discharge of 81.65 vs 69.85 bpm in those under 80 years of age. (p 0.024). Within depressed LVEF patients, a lower percentage of beta-blockers was used in elderly patients (70.97% vs 84.26%, p 0.039) as well as ACEi or ARA2 (56.45% vs 72, 22%; p 0.036) and mineralocorticoid receptor antagonists (38.71% vs 62.04%; p 0.003). The use of devices has been significantly lower, with a percentage of 0% DAI vs 4.9% in the younger age group (p 0.007). The profile of diuretics used was different, with greater use of thiazides in elderly patients (6.35% vs. 1.83%, p 0.014). In the follow-up, the group of elderly patients presented higher mortality (p 0.05), the main cause being the HF.
Conclusion Elderly patient admitted with HF are mostly women, predominantly with preserved EF, hypertension, and worse baseline. Indicated drugs were used in a lower percentage. Mortality is higher in this subgroup, mainly due to HF.

Table 1. Baseline Characteristics

Characteristics	80 years or older	Younger patients	p value
Mean age (years)	84,69	68,76	<0,001
Sex women	59,3%	38,2%	<0,001
Hypertension	89,3%	75,8%	0,001
Diabetes Mellitus	43,3%	48,9%	0,307
Dyslipemia	68%	59,1%	0,094
Smoker	4%	14,5%	0,001
Atrial fibrillation	62,7%	48,4%	0,009
Dependiente o parcialmente dependiente	22%	10,8%	0,019
Mean EF	44,306	49,989	0,004
Preserved EF	60,66%	44,62%	0,003

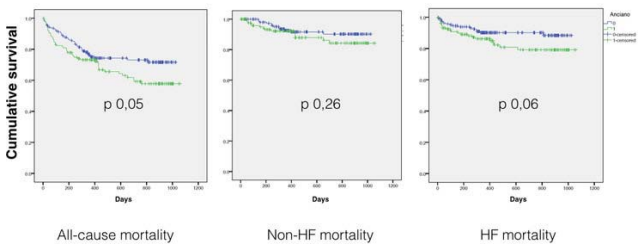

Figure 1. Mortality in follow up

Impaired filtration and tubular kidney functions in patients with chronic heart failure with a moderately reduced left ventricular ejection fraction and persistent atrial fibrillation

N Natalia Koziolova[1]; S Mironova[1]; E Polyanskaya[1]
[1]Perm Medical University, Perm, Russian Federation

Objective: To evaluate the filtration and tubular kidney functions in patients with chronic heart failure (CHF) with a moderately reduced left ventricular ejection fraction and a persistent form of atrial fibrillation (AF).
Materials and methods: The study included 48 patients with a moderately reduced left ventricular ejection fraction (mrLVEF), which were divided into 2 groups depending on a heart rhythm disorder. The first group included 28 patients with persistent AF, the second one - 20 patients with sinus rhythm. The diagnosis of CHF with a moderately reduced LV EF was confirmed by the presence of LV EF in the range of 40–49%. Diastolic dysfunction was diagnosed according to tissue visualization of diastolic velocity of the mitral valve fibrous ring and an increase in the concentration of the N-terminal fragment of brain natriuretic peptide (NT-proBNP) in the blood using ELISA.To assess the filtration function of the kidneys, serum creatinine, cystatin C concentrations in the blood, glomerular filtration rate (eGFR) were calculated using the CKD-EPI formula for creatinine and cystatin C. Serum Neutrophil gelatinase-associated lipocalin (NGAL) was determined to detect early tubular kidney damage.
Results: the groups did not differ in sex, age, comorbidity, therapy (except for anticoagulants and antiarrhythmic agents), severity of CHF. Indicators of diastolic LV function differed statistically significantly between groups: in the first group, septal e '(p = 0.007), lateral e' (p <0.001), E / e '(p = 0.001) were higher than in the second group. There were no statistically significant differences in serum creatinine and creatinine-based eGFR (p = 0.107 and p = 0.143, respectively) between the groups. Cystatin C in the blood in the first group was statistically significantly higher than in the second group: 2.7 [2.3; 3.2] ng / ml versus 1.6 [1.3; 3.0] ng / ml (p = 0.019). Cystatin-based eGFR was statistically significantly lower in the first group than in the second (p = 0.019). A statistically significantly higher level of NGAL in the 1st group was noted - 1.8 [1.0; 2.9] ng / ml compared with the 2nd group - 0.6 [0.5; 0.8] ng / ml (p <0.001). A correlation analysis revealed a direct, strong interconnection between the concentration of cystatin C in the blood and E/e'(r = 0.723, p <0.05), a direct moderate interconnection between NGAL levels and E/e' (r = 0.419, p < 0.05). Conclusion: the presence of a persistent AF in CHF patients with moderately reduced LV EF contributes negatively to the formation of cardio-renal syndrome and tubular dysfunction due to more severe LV diastolic dysfunction compared with CHF patients who have sinus rhythm.

Funding Acknowledgements: This research was financially supported by a PhD Research Grant from the University of Medicine and Pharmacy "Iuliu Haieganu", Cluj-Napoca, Romania.

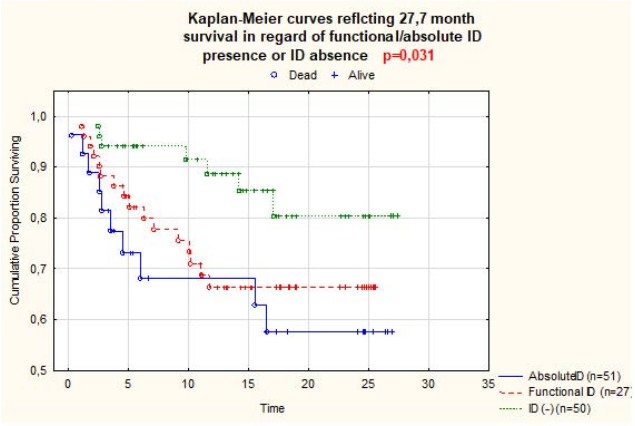
Background: The prevalence of heart failure (HF) is increased in diabetic patients. Several studies confirmed the prognostic role of ST2 and Galectin-3 (Gal-3) in HF patients, but the relationship between diabetes mellitus (DM) along with its complications and the new biomarkers is still uncertain.
Methods: 88 subjects with decompensated heart failure (NYHA classes III-IV) were enrolled, with a mean age of 69.82 ± 9.5 years, 61.7% of which were men and 47.9% of them with previous DM. All patients were evaluated both clinically and echocardiographically. The entire cohort had serum concentrations of ST2, Gal-3 and NT-proBNP measured upon admission. Patients with DM were divided into two groups: those with DM microvascular complications (retinopathy, nephropathy or polyneuropathy - 58.9%) or without- 41.1%.
Results: Mean left ventricular ejection fraction (LVEF) was 38.84 ± 11.3%, without significant differences between the two groups (p-NS).
Concerning HF biomarkers, the following mean values were obtained: ST2 - 46.32 ± 25.8 ng/ml, Gal 3-15.19 ± 6.7 ng/ml, NT-pro BNP - 3493.04 ± 3884.8 pg/ml. There were no statistically significant differences between patients with or without DM: ST2 : 47.51 ± 28.7ng/ml vs 44.89 ± 23.1 ng/ml; Gal-3: 15.25 ± 7.7ng/ml vs 15.07 ± 5.7ng/ml; NT-proBNP: 3857.42 ± 3844.2 pg/ml vs 3104.28 ± 3940.4 pg/ml.
When comparing the two groups of diabetic subjects, only Gal-3 values were found to be consistently higher in subjects with microvascular complications: 16.23 ± 4.9 ng/ml vs 13.74 ± 10.4 ng/ml (p=0.005); ST2 : 53.21 ± 31.9ng/ml vs 39.5 ± 23.3 ng/ml (p-NS); NT-proBNP : 4364.9 ± 4213.9 pg/ml vs 3188.96 ± 3350.0 pg/ml (p=NS).
ST 2 levels correlated significantly with NT-proBNP levels (r=0.24; p=0.03), hypocholesterolemia (r= 0.22; p=0.048) and GFR (r=-0.22) in both groups. There was no direct correlation between ST2 levels and the NYHA class (p=0.334). Gal-3 levels also correlated well with LVEF value (r=0.22; p=0.048), NT-pro BNP levels (r=0.40; p < 0.0001) and NYHA class (p <0.0001).
Conclusions: Biomarkers of HF used for screening the general population are also useful in patients with DM, with Galectin-3 levels being significantly higher in diabetic patients with microvascular complications than in those without.

P1714

What is the difference in clinical, instrumental characteristics and prognosis in patients with CHF and rLVEF in regard to the presence and nature of the iron deficiency state?

VG Vera Gorbachova[1]; AV Lyasheko[1]; TI Gavrilenko[1]; LS Mhityaryan[1]; LG Voronkov[1]
[1]NSC Institute of Cardiology M.D. Strazhesko, Heart failure, Kiev, Ukraine

The aim is to compare chronic heart failure (CHF) and reduced left ventricular ejection fraction (rLVEF) patients with absolute and functional iron deficiency (ID) according to the main clinical, hemodynamic, laboratory parameters and clinical outcomes.
Methods. 128 stable compensated patients (pts) with CHF (111 men, 17 women), 18-75 years old, NYHA class II-IV, LVEF<40% were examined. Beside routine clinical and laboratory examination, iron panel test, 6 min walk test (6MWT), standardized endurance leg extensor test were performed. Quality of life was assessed by the Minnesota living with heart failure questionnaire (MLHFQ). Statistical calculations were made using Spearman's rank correlation coefficient, Pearson's chi-squared test and Kaplan-Meyer estimator.
Results. ID was observed in 78 pts. All pts were divided into 3 groups: group #1 – functional ID (n=27), #2 – absolute ID (n=51), #3 – without ID (n=50). Patients with both ID types were in higher (NYHA III-IV) functional class (85% pts from group #1 vs. 71% from group #2 vs. 48% #3, p=0,02; 0,001), had a poorer quality of life (MLHFQ score 56 in group #1 vs. 53 in #2 vs. 45 in #3, p=0,01; 0,03) and worse clinical and laboratory indices than patients without ID (Hb 145 g/l in group #1 vs. 136 g/l in group #2 vs. 151 g/l in #3, p<0,001. NTproBNP 637 ng/dl in #1 vs. 356 ng/dl in #2 vs. 247 in #3, p=0,007; <0,001. IL6 5 pg/ml in group #1 vs. 2,4 pg/ml in #2 vs. 1,7 pg/ml in #3, p=0,03; <0,001. Citrulline 135 mmol/L #1 vs. 107 mmol/L #2 vs. 90 mmol/L #3, p= 0,04; <0,01). Regardless of the difference in the functional and absolute ID formation mechanisms, no significant distinctions in the clinical and functional parameters, quality of life, as well as the intracardiac hemodynamics parameters were found (LVEF 26% in group #1 vs. 27% in #2, p=0,9. Leg extensor endurance test 23 times in #1 vs. 22 times in #2, p=0,6. 6MWT 265 m in #1 vs. 346 m in #2, p=0,06. MLHFQ score 56 in #1 vs. 53 in #2, p=0,57). Contrary to expectations, elevated levels of hepcidin were not detected in patients with functional ID group compared to the absolute ID group (62 ng/ml in group #1 vs. 70 ng/ml in #2, p =0,22). The reliable difference in survival (p=0,031) / hospitalization (p=0,04) rate between patients without ID and both groups with ID allows us to recommend the ID screening in all pts with CHF and rLVEF.
Conclusions. ID was found in 61% of patients. 27 pts (21%) had functional ID, 51 pts (39.6%) had absolute ID. There were no differences between groups with absolute and functional ID in regard to age, functional class, LVEF, aneamic patients percentage, 6MWT distance, thigh quadriceps endurance, quality of life, physical activity index, NTproBNP, citrulline and hepcidin levels. Compared to patients with absolute ID, patients with functional ID had higher levels of hemoglobin, MCV, MCH, interleukin 6. Presence of both ID types was associated with worse survival rate and more frequent hospitalization.



Kaplan-Meier survival curves

Left ventricular systolic dysfunction in asymptomatic patients with diabetes mellitus type 1 is associated with duration of disease, obesity and poor glycemic control

C Chris Kapelios[1]; S Liatis[1]; M Bonou[1]; A Tentolouris[1]; A Barmpagianni[1]; M Driva[1]; I Eleftheriadou[1]; E Papachristoforou[1]; E Athanasiadi[1]; D Tsilingiris[1]; V Lambadiari[2]; J Barbetseas[1]
[1]Laiko University General Hospital, Athens, Greece; [2]Attikon University Hospital, Athens, Greece

Background: Diabetes mellitus type 1 (DM1) primarily affects children and young, otherwise healthy, individuals. Cardiomyopathy presenting in these patients is mainly attributed to the direct effect of hyperglycemia. Pre-symptomatic diagnosis of myocardial dysfunction could facilitate timely and effective implementation of therapeutic interventions. However, the prevalence and risk factors of pre-symptomatic left ventricular systolic dysfunction (LVSD) in individuals with DM1 have not been systematically studied.
Purpose: To investigate the prevalence and risk factors for LVSD in asymptomatic patients with DM1.
Methods: We studied the association between presence of LVSD, assessed by abnormal values of global longitudinal strain (GLS), and a) patient history, b) demographic and clinical characteristics, c) autonomic nervous system function, measured using the battery of the 4 standardized tests proposed by Ewing, d) arterial stiffness, assessed by calculation of pulse wave velocity between the carotid and common femoral artery, e) body lipometry and f) prevalence and severity of diabetic complications in patients with DM1 and no history of cardiovascular disease. Results: We prospectively enrolled one hundred and forty-one asymptomatic patients with DM1. Forty-one (29.1%) were men, while mean age, disease duration and glycated hemoglobin were 37.6 ± 13.0 years, 19.2 ± 9.8 years and 7.4 ± 1.4%, respectively. LVSD, defined as a value of GLS> -19.6%, was prevalent in 65/141 (46.1%) patients. Patients with LVSD had a longer history of DM (21.0 ± 9.3 vs. 17.6 ± 10.1 years, P=0.045), a higher body mass index (BMI) (26.9 ± 5.1 vs. 24.3 ± 4.4 kg/m2, P=0.001) and higher levels of blood glycated hemoglobin (7.8 ± 1.5 vs. 7.1 ± 1.2%, P=0.007) compared with patients without LVSD.
In multivariable analysis, glycated hemoglobin levels (OR: 1.54; 95% CI: 1.11-2.13, P=0.011), duration of DM1 (OR: 1.05; 95% CI: 1.01-1.10, P=0.035), and waist circumference (WC, OR: 1.04; 95% CI: 1.01-1.07, P=0.015) or body mass index (BMI, used interchangeably with WC, OR: 1.11; 95% CI: 1.02-1.21, P=0.023) were independently associated with the presence of LVSD.
Conclusions: Our results indicate that apart from chronic hyperglycemia, increased adiposity, possibly indicating a dysmetabolic state, as expressed by a higher BMI/WC, may be implicated in the pathogenesis of LVSD, which leads to diabetic cardiomyopathy in patients with DM1. Interventions leading to weight loss could be considered as a therapeutic target to potentially prevent or/and reverse LVSD in these patients.

P1716

Association analysis of N-terminal prohormone of B-type natriuretic peptide (NT-proBNP) and growth differentiation factor 15 (GDF-15) in cardiac and non-cardiac frailty

Q Li[1]; L T Lui[1]; X Yang[1]; S Liu[1]; K F Cheng[1]; J Lupon[2]; A Bayes-Genis[2]; D Sahota[3]; J Woo[1]; E Fung[1]
[1]The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, Hong Kong; [2]Autonomous University of Barcelona, Department of Medicine, Barcelona, Spain; [3]The Chinese University of Hong Kong, Obstetrics & Gynaecology, Hong Kong, Hong Kong

Background/Introduction:
Frailty is a clinical syndrome characterised by reduced physiologic reserve including easy fatigability, skeletal muscle wasting and weight loss that overlap with attributes of chronic heart failure (HF). Whereas elevated NT-proBNP can indicate ventricular stress and cardiac dysfunction, there remains no blood biomarker to discriminate between frailty subtypes. GDF-15 is increased in inflammatory states, chronic disease, and following tissue injury, and recent animal studies support its functional role in inhibiting muscle growth and body weight.
Purpose: To elucidate cardiac and non-cardiac frailty subtypes using echocardiography in combination with NT-proBNP and GDF-15.
Methods: Participant recruitment in the Undiagnosed heart Failure in frail Older individuals (UFO) study was purposeful sampling to target approx. one-third in each of 3 frailty subgroups using the 5-point multi-domain FRAIL scale: 0, robust (R); 1–2, pre-frail (PF); 3–5, frail (F). Cardiac structure and function were assessed by echocardiography, and serum NT-proBNP and GDF-15 levels were dichotomised at

the median as 'high' or 'low' in a 2x2 matrix. Physical performance metrics including 6-minute walk distance (6MWD), gait speed (GS) and handgrip strength per body mass index (HGS) were assessed for strength of association using the method of polynomial contrasts for linear trend test; P <0.05 was considered statistically significant.

Results: FRAIL stratification of 306 individuals (mean age 74.7 y) resulted in classification of 34% R, 35% PF, and 31% F, with female-to-male ratios of 0.7, 4.4 and 5.3, respectively. The prevalence of diastolic (LVEF >50%) and systolic (≤50%) dysfunction were 67% and 4.3%, respectively. Serum NT-proBNP levels in R, PF and F older adults were 181, 239 and 361 pg/ml, respectively, and GDF-15 levels were 1667, 2220, and 3206 pg/ml, respectively. NT-proBNP was not significantly associated with GDF-15 (r=0.09, adjusted P=0.13), suggesting complementary pathways. In association with FRAIL score, log10-NT-proBNP reached borderline significance (β 0.33, adjusted P=0.046), whereas log10-GDF-15 was strongly associated (β 1.18, adjusted P=3.1 x 10e-5).

In 2x2 analysis, physical performance ranking from worst to best (">") was as follows: NT-proBNP^high GDF-15^high (cardiac frailty; 6MWD, 265 m; GS, 0.72 m/s; HGS, 0.64) > NT-proBNP^low GDF-15^high (non-cardiac frailty; 6MWD, 320 m; GS, 0.85 m/s; HGS, 0.70) > NT-proBNP^high GDF-15^low (6MWD, 360 m; GS, 0.95 m/s; HGS, 0.79) > NT-proBNP^low GDF-15^low (6MWD, 376 m; GS, 0.96 m/s; HGS, 0.88). Age- and sex-adjusted P-values of linear trend pattern among the paired biomarker subgroups for 6MWD, GS and HGS were 3 x 10e-6, 5.6 x 10e-5, and 1.1 x 10e-4, respectively.

Conclusion: In combination with echocardiography, serum NT-proBNP and GDF-15 can be used to classify cardiac and non-cardiac frailty, as supported by statistically associated metrics of physical performance.

[1]University of Yaounde I, Facult of Medecine and Biomedical Sciences, Internal Medecine and Specialities, Yaounde, Cameroon; *[2]University of Yaounde I, Faculty of Medicine and Biomedical Sciences , Yaounde, Cameroon*; *[3]University of Yaounde I, Faculty of Medicine and Biomedical Sciences , Biochemistry, Yaounde, Cameroon*; *[4]Yaounde Teaching Hospital, Yaounde, Cameroon*; *[5]Biyem-Assi District Hospital, Yaounde, Cameroon*; *[6]University of Lausanne, Lausanne, Switzerland*; *[7]University of Douala, Faculty of Medicine and Pharmaceutical Sciences, Douala, Cameroon*

Background/ Introduction: Oxidative stress is a condition in which there is an excessive production of reactive oxygen species over antioxidant defense. Reactive oxygen species plays a major role in the pathophysiology of cardiac remodelling in chronic heart failure. In addition, oxidative status may be de worsen by other comorbidities like iron deficiency (ID) which is frequent in chronic heart failure CHF). Alteration in oxidative/anti oxidative balance after parenteral iron supplementation in patient with CHF and ID was virtually unknown.

Purpose: To compare, in a double-blind three arms design, the short term effect of parenteral iron supplementation through intravenous and intramuscular route versus placebo on the oxidative status in patients with CHF and ID.

Methods: In FREERADICALS-HF study, iron-deficient CHF patients were randomized to intravenous (IV) iron Sucrose, intramuscular (IM) iron Polymaltose Hydroxide Complex (PHC) or placebo (normal Saline) in 1:1:1 ratio. The total doses required to correct the ID were calculated by using the Ganzoni's formula. These doses were divided by half and administer at day 0 and at day 14. The oxidative stress parameters were measured by using a spectrophotometric method. The antioxidant markers measured was the catalase and the peroxidase activities, glutathione (GSH) concentration and the total anti-oxidant capacity using the Ferric Reducing Antioxidant Power (FRAP) methods. Malondiadehyde (MDA) and nitric oxide (NO) were oxidant markers. Oxidative status was assessed at day 0 and at week 04.

Results: From a total cohort of 101 patients, we included 45 patients with CHF and ID. Such as 15 in IV arm, 16 in IM arm and 14 in placebo arm. Treatment with intravenous iron sucrose significantly decrease the peroxidase activity (difference iron sucrose vs placebo:1.6 UI/ml, p=0.038) and increase the nitric oxide (NO) concentration (difference iron sucrose vs placebo:-0.09 mol/l, p=0.063). Throughout the study, a decrease of catalase activity and an increase of the MDA, FRAP and GSH concentration after treated by iron sucrose was detected with no significant difference at week 04. Treatment with intramuscular polymaltose hydroxide complex decrease the peroxidase activity and MDA, FRAP and GSH concentration with no significant difference at week 04. We also observed an increase in catalase activity and NO concentration which was not significant. There was no significant difference observed when we compared the three groups.

Conclusion: Both Intravenous and intramuscular iron supplementation over a period of 04 weeks result globally in an oxidative stress by significantly reducing the activity of the peroxidase and by the increase of reactive nitrogen species by production of nitric oxide. Other effect of our intervention showed a little benefit effect in reduction of lipids peroxidation by decreasing MDA concentration in both group.

P1718

Cardiopulmonary exercise testing for assessing frailty status in stable elderly patients with heart failure

A Akihiro Hirashiki[1]; K Kawashima[1]; K Nomoto[1]; M Kokubo[1]; A Shimizu[1]; H Arai[1]

[1]National Center for Geriatrics and Gerontology, Obu, Japan

Introduction: Frailty is a syndrome associated with aging that produces subclinical dysfunction across multiple organ systems and leads to increased risk of mortality. The Kihon Checklist (KCL) was developed by the Japanese Ministry of Health, Labor and Welfare to identify older persons in need of care; it is a reliable tool for predicting general frailty in older adults. There is little information about the relationship between frailty status and exercise capacity.

Hypothesis: Cardiopulmonary exercise testing (CPX) parameters are associated with frailty in stable elderly patients with heart failure (HF).

Methods: Ninety-two stable elderly patients with HF were evaluated by using CPX and the total KCL (t-KCL). A t-KCL score of 0–3 was classified as robust, 4–7 as pre-frail, and ≥8 as frail. Diagnostic performance (DP) -plot analysis was used to assess the utility of CPX parameters to distinguish between the presence and absence of frailty.

Results: Mean age, left ventricular ejection fraction, plasma brain natriuretic peptide, peak work rate (WR), peak VO2, and t-KCL score were 81.7 years, 57.9%, 184 pg/mL, 48.8 W, 13.2 mL/kg/min, and 13.1, respectively. t-KCL score was significantly correlated with peak VO2 (r = −0.53, p < 0.001) and peak WR (r = −0.63, p < 0.001). In the patients with frailty (n = 63), peak WR was significantly lower than that in patients without frailty (n = 29; 40.8 and 71.0 W, respectively, p 0.001). Multivariate analysis revealed that peak WR was the only significant independent predictor of frailty (β = −0.111, p 0.001). In the DP-plot analysis, a cut-off value for peak WR of 51.9 W was the best predictor of frailty (accuracy; 0.706).

Conclusions: Frailty status was significantly associated with peak WR in stable elderly patients with HF. CPX may be useful for assessing frailty status in stable elderly patients with HF.

P1719

Segmental water distribution in hospitalized patients with Chronic Obstructive Pulmonary Disease and Right Heart Failure.

AA Ibarra-Fernandez[1]; D Gonzalez-Islas[1]; A Orea Tejeda[1]; A Jimenez-Valentin[1]; F Salgado-Fernandez[1]; AJ Flores-Vargas[1]; L Hernandez-Urquieta[1]; R Hernandez-Zenteno[1]; R Sanchez-Santillan[1]; K Balderas-Munoz[1]; V Pelaez-Hernandez[1]; F Flores-Trujillo[1]; N Garcia-Galvez[1]; V Fernandez-Badillo[1]

[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico

Background: Heart failure is the most common cardiovascular complication in Chronic Obstructive Pulmonary disease (COPD) with prevalence around 20.9%. Subjects with COPD and Right Heart Failure (RHF) have a major risk of death than COPD subjects without RHF. COPD and RHF patients have water alterations. However, segmental water distribution are unknow in this population.

Objective: To determine the segmental water distribution in patients with COPD and RHF

Methodos: Cross-sectional study. Patients with COPD diagnosis with and without RHF were included. Patients with asthma was excluded. Water distribution were evaluated by Bioelectrical impedance (BODYSTAT). Segmental water alterations in thorax, abdomen and trunk focous were determinated by impedance index > 0.80. total.

Results: 82 Patients were included, with RHF (n= 44) without RHF (n= 38), the median age was 68 ± 14.08, serum albumin 3.22 ± 0.85, total body water was (TBW) 54.512 ± 12.55. Patients with RHF had higher prevalent sistemic arterial hypertension (56.8% vs 34.21, p=0.05), pulmonary arterial hypertension (40.91 % vs 0 %, p < 0.01) Heart failure with preserved ejection fraction (70.45 % vs 18.42 %, p < 0.001) as well less extracellular water (24.94 ± 4.98 vs 25.38 ± 5.72 p= 0.028) and greater abdominal impedance index (0.837 ± 0.10 vs 0.7585 ± 0.146 p = 0.045) than subjects whithout RHF. There was not diferentes between the groups in TBW, impedance index of trunk and thorax.

Conclusion: Patients with COPD and RHF have more abdominal overload althougth less extrecellular water probablly due to bowel congestion without diferences in TBW.

Effects of phrenic nerve stimulation in subjects with central sleep apnoea and heart failure with reduced, mid-range, and preserved ejection fraction: findings from the remede system pivotal trial

MR Costanzo[1]; L Goldberg[2]; S Mckane[3]; O Oldenburg[4]; A Kao[5]; R Kawash[6]; REG Robin Germany[7]; P Ponikowski[8]; C Stellbrink[9]; WT Abraham[6]
[1]Advocate Heart Institute, Naperville, United States of America; *[2]University of Pennsylvania, Philadelphia, United States of America*; *[3]Respicardia, Inc., Minnetonka, United States of America*; *[4]Clemens Hospital Munster, Munster, Germany*; *[5]University of Missouri - Kansas City, Kansas City, United States of America*; *[6]Davis Heart & Lung Research Institute, Columbus, United States of America*; *[7]University of Oklahoma, Oklahoma City, United States of America*; *[8]Wroclaw Medical University, Cardiology, Wroclaw, Poland*; *[9]Bielefeld Hospital, Bielefeld, Germany*

Funding Acknowledgements: Respicardia, Inc.

Background: Patients with heart failure (HF) often have central sleep apnoea (CSA). Treating CSA with phrenic nerve stimulation (PNS) may help improve the prognosis of patients with HF. However, impact of PNS has not been elucidated in patients with HF according to left ventricular ejection fraction (LVEF).
Purpose: Investigate the effects of PNS on sleep metrics and quality of life (QoL) in patients with HF and reduced ejection fraction (HFrEF: <40%), mid-range EF (HFmrEF 40-<50%), and preserved EF (HFpEF: >50%).
Methods: A PNS system was implanted in patients with CSA and therapy delivered for 6 months. Sleep was assessed at attended in-lab polysomnograms. The Epworth Sleepiness Scale (ESS) and Patient Global Assessment (PGA) were completed by the subjects. Subjects with HF were divided by LVEF into subgroups: HFrEF, HFmrEF, HFpEF.
Results: The HFrEF, HFmrEF, and HFpEF subgroups were similar in age (mean 67, 69 and 64 years, respectively) and were primarily male (98%, 85%, 79%) with severe CSA (mean apnoea-hypopnoea index [AHI] of 44, 45 and 51 events/hour). Baseline demographics were similar including hypertension, CAD, and atrial fibrillation. Forty percent, 30% and 29% of patients were NYHA class III.
Improvements in sleep metrics, sleep quality and QoL were observed in all subgroups following 6 months of active PNS therapy. A ≥50% reduction in AHI from baseline was experienced by 48-64% of subjects in each subgroup (table). AHI improved across the subgroups, with much of the reduction driven by improvements in the central apnoea index. Improvements in PGA and ESS were seen in all subgroups. Means or percentages and 95% confidence intervals are provided in the table.
Conclusion: Despite small sample sizes in the HFmrEF and HFpEF subgroups, the results from this study suggest the improvements from phrenic nerve stimulation on sleep, daytime sleepiness and quality of life are similar for patients with central sleep apnoea and HF, regardless of LVEF.

Paired Change from Baseline by EF Level

6 Month Results	EF <40% (n=48)	EF 40-50% (n=16)	EF ≥50% (n=11)

P1721

Sleep disordered breathing in patients with heart failure: association with biomarkers and clinical parameters

EA Medvedeva[1]; LS Korostovtseva[1]; MA Simonenko[1]; YV Sviryaev[1]
[1]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation

Sleep disordered breathing (SDB) is frequent in patients with chronic heart failure (CHF). The assessment of the severity of sleep apnea is mainly based on the apnea-hypopnea index (AHI), but this event-based parameter alone may not sufficiently reflect the complex pathophysiological mechanisms underlying SDB potentially contributing to adverse outcomes in patients with heart failure.
Purpose. To assess SDB in patients with CHF with reduced ejection fraction (EF), their prognostic role and relationship with biomarkers and clinical parameters.
Methods. 117 patients (mean age 52.4 ± 4.7 years) with NYHA class II-IV were included in the prospective cohort study, follow-up period was 5 years. The left ventricular ejection fraction (LVEF) was 28.05±9.57%. All patients underwent a comprehensive clinical examination, echocardiography, polysomnography (PSG, Embla N7000, Natus, USA). The plasma level of NT-proBNP and hs-CRP were analyzed by immunoassay (ELISA). The SPSS statistical software (version 23.0) was used.
Results. PSG showed the following types of SDB in the studied cohort: obstructive sleep apnoea (OSA) was diagnosed in 48 patients (41%), central - in 20 (17%), mixed - in 26 (22%). Among them mild SDB diagnosed in 29 cases, moderate in 32 and severe in 33 patients. SDB was not found in 23 patients. The comparison of 2 groups with EF>35% and <35% demonstrated significant differences in obstructive (7.1 and 3.96 episodes per hour, respectively, p = 0.039) and central apnea indices (1.38 / 5.32 episodes per hour, p = 0.05). Moreover, in the group with EF <35% there was a significant higher concentration of plasma hs-CRP (p = 0.026) and NT-proBNP (p = 0.01). The following correlations were identified: NT-proBNP and obstructive apnea index (OAI) (r = -0.44, p = 0.007), NT-proBNP and sleep efficiency (r = -0.71, p = 0.006), AHI and body mass index (BMI) (r = 0.32, p = 0.01), OAI and BMI index (r = 0.34, p <0.001), desaturation index and BMI (r = 0.43, p <0.001), average saturation oxygen and BMI (r = -0,6, p <0,001). Patients with CHF with reduced EF (<35%) and moderate apnea showed worse survival rates (χ^2 = 3.699; p = 0.05).
Conclusion. We found very high rate of SDB (80%) in patients with systolic HF, the predominant type was OSA. AHI, OAI and indicators of oxygen saturation correlate with BMI and biomarkers. In patients with CHF with reduced EF moderate apnea is associated with adverse outcome.

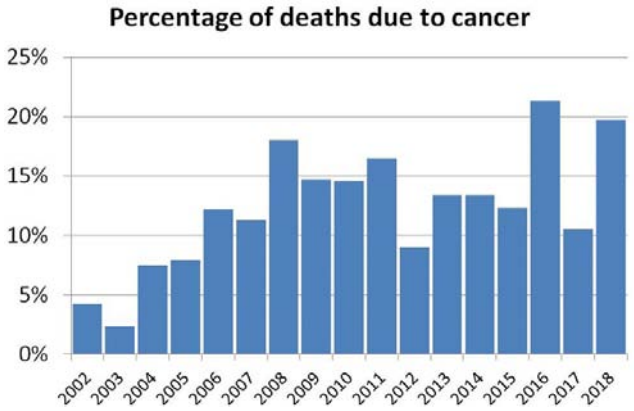
Evolution of death due to cancer in heart failure ambulatory patients during 17 years follow-up

P Moliner[1]; J Josep Lupon[1]; M De Antonio[1]; M Domingo[1]; E Santiago-Vacas[1]; E Zamora[1]; B Gonzalez[1]; C Rivas[1]; V Diaz[1]; P Velayos[1]; J Santesmases[1]; C Diez-Quevedo[1]; M Boldo[1]; J Nunez[2]; A Bayes-Genis[1]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; *[2]University Hospital Clinic of Valencia, Valencia, Spain*

Background: Cancer is one of the main causes of death in general population in developed countries together with cardiovascular causes. A bidirectional relationship between heart failure (HF) and cancer has been suggested. Cancer survivors carry a greater burden of HF than the non-cancer population, while it increasingly appears that HF migh facilitate the development of cancer. Both entities share several risk factors which have the common pathophysiological characteristic of chronic inflammation, which is associated with both cardiomyopathic and neoplastic processes. Indeed cancer treatment might favour HF while HF might preclude cancer treatment.
Purpose: To assess the incidence of cancer as cause of death since the year 2002 up to the year 2018 in ambulatory patients attended in a HF clinic.
Methods: Patients who died of unknown cause were excluded from the analysis. Cancer and other fatal events were identified from the clinical records of patients with HF, hospital wards, the emergency room, general practitioners, or by contacting the patient's relatives. Furthermore, data were verified from the databases of the Catalan and Spanish Health Systems. Trends on cancer as cause of was were assessed by linear regression.

Results: Since August 2001 to May 2018, 2295 HF patients were admitted to the HF clinic (age 66.4 ± 12.8 years, 71% men, 49% from ischemic aetiology, mean LVEF 35.2% ± 14). During the 17 years of the study, 1201 deaths were recorded. Seventy-eight patients (6.5% of deaths) were excluded due to unknown cause of death. Out of the other 1123 deaths, 149 were due to cancer. The percentage of cancer as cause of death by years is shown in the figure. A significant trend was observed towards a progressive increase in cancer deaths over time (p=0.003).
Conclusions: During the 17 years of the study, a very significant trend towards higher percentage of cancer deaths was progressively observed.



P1723

Sleep apnea screening in heart failure: an exploratory analysis

R Ventura Gomes[1]; B Rocha[2]; G Cunha[2]; R Morais[3]; L Fernandes[3]; L Campos[4]; I Araujo[3]; C Fonseca[3]
[1]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal; *[2]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal*; *[3]Hospital São Francisco Xavier, CHLO, Clínica de Insuficiência Cardíaca, Lisbon, Portugal*; *[4]Hospital de Sao Francisco Xavier, Medicine, Lisbon, Portugal*

Background: Sleep Apnea (SA) is increasingly recognized in patients (pts) with Heart Failure (HF). Nocturnal polysomnography (PSG) is the gold-standard to diagnose SA. Currently, portable devices have been thoroughly validated in HF cohorts.
Purpose: To determine the correlation between clinical, laboratory and respiratory measurements with the presence of SA (defined as apnea-hypopnea index (AHI) >15/h) and desaturation time with SpO2 <90% (T90) ≥22 minutes, a strong mortality predictor in HF with reduced ejection fraction (HFrEF); and to compare the features of pts with HFrEF vs HF with preserved ejection fraction (HFpEF).
Methods: Our work is based on a single-center retrospective cohort of pts hospitalized for decompensated HF during 2013-2018. All pts were screened for SA with ApneaLinkTMafter compensation the night preceding discharge. HF was defined as recommended by the European Society of Cardiology guidelines. A left ventricular ejection fraction ≤45% and >45% was used to define HFrEF and HFpEF, respectively, as per SERVE-HF trial.
Results: A total of 228 pts were included in the analysis (mean age 75.3 ± 10.5 years, 48.9% male). SA was present in 135 (59.2%) pts and 41.2% had HFrEF. Mean AHI was 24.5 ± 19.2/h, mean O2 desaturation index (ODI) was 24.4 ± 21.0/h and mean T90 was 169.6 ± 151.2 minutes. In multivariate models, ODI, gender and ischemic HF were predictors of AHI >15/h (R265.8%), with ODI being the strongest predictor (standardized coefficient 64.8%). Similarly, mean SpO2 was the only predictor of T90 ≥22minutes (R265.8%) (Figure 1). HFrEF pts had more often AHI>15/h (73.4% vs 48.5%, p<0.001), more total apneas (62 ± 148 vs 16 ± 79, p<0.001), obstructive apneas (28 ± 76 vs 8 ± 43, p<0.001) and central apneas (6 ± 20 vs 0 ± 5, p<0.001) than those with HFpEF. In multivariate models, ODI (OR 1.14, CI 1.03-1.26, p=0.013 for HFrEF; OR 1.21, CI 1.11-1.33, p<0.0001 for HFpEF) and mean SpO2 (OR 0.29, CI 0.14-0.60, p=0.001 for HFrEF; OR 0.23, CI 0.10-0.52, p<0.0001 for HFpEF) were the only predictors of AHI >15/h and T90 ≥22 minutes in both groups, respectively.
Conclusions: SA was highly prevalent in HFrEF and HFpEF. ODI and mean SpO2 were highly predictive of AHI >15/h and T90 ≥22minutes, respectively, both prognostic markers validated in a population with HFrEF, and equally so in HFrEF and HFpEF. These findings hypothesize a similar pathophysiology of SA in HF, regardless of left ventricular systolic function. Also, whether simple pulse oximetry can be routinely used for SA screening, since PSG and portable devices are often not widely available, is a finding worth being prospectively assessed.

Diabetes is the strongest predictor of limited exercise capacity in patients with chronic heart failure

G Gani Bajraktari[1]; V Berisha-Muharremi[1]; E Haliti[1]; I Bytyci[1]; A Poniku[1]; A Ahmeti[1]; A Batalli[1]; P Ibrahimi[1]; R Tafarshiku[1]; Z Rexhaj[1]; S Elezi[1]
[1]University Clinical Centre of Kosova (UCC), Service of Cardiology, Pristina, Kosovo Republic of

Background and Aim: Heart failure is a common cardiovascular complication of diabetes mellitus (DM) and these two diseases often co-exist. The aim of this study was to prospectively examine the relationship between diabetes and functional exercise capacity assessed by by 6 min walk test (6-MWT) in patients with chronic HF.
Methods: In 344 included chronic HF patients (mean age 61 ± 10 years, 54% female), clinical, biochemical and antropometric data were registered. In all study patients an echo-Doppler study and a six-minute walk test (6-MWT) were performed in the same day. Patients were divided into two groups based on the 6-MWT distance (Group I: ≤ 300 m and Group II: >300 m).Based on the left ventricular (LV) ejection fraction (EF), patients were divided into three groups (patients with HF and preserved EF [HFpEF], patients with HF and reduced EF [HFrEF] and patients with HF and mid-range EF [HFmrEF]).
Results: Among 344 HF patients 111 (32%) had DM. Group I were older (p = 0.019), had higher prevalence of diabetes (p < 0.001) and atrial fibrillation (p = 0.001), larger left atrium - LA (p = 0.018), lower hemoglobin level (p = 0.028), lower septal mitral annular plane systolic excursion – MAPSE (p=0.001) and lower tricuspid annular plane systolic excursion - TAPSE (p = 0.027), compared with Group II.
In multivariate analysis, only age of patients [1.031 (1.001-1.061), p=0.042], presence of atrial fibrillation [2.377 (1.020 - 5.539), p=0.045] and diabetes [3.743 (1.988 – 7.048), p<0.001] independently predicted poor 6-MWT performance in HF patients.
Conclusion: Diabetes mellitus is the independent and strongest predictor of limited exercise capacity in chronic HF patients, irrespective of LV ejection fraction. This finding highlights the need for better optimization of medical therapy and regular exercise in diabetic patients with chronic HF.

P1725

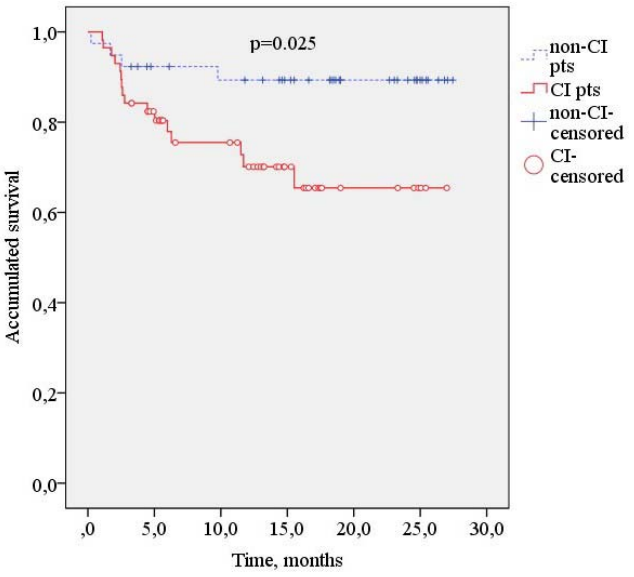
Prognostic value of cognitive tests in chronic heart failure with reduced left ventricular ejection fraction

A Anastasiia Solonovych[1]; A V Liashenko[1]; I L Revenko[1]; L G Voronkov[1]
[1]NSC Institute of Cardiology M.D. Strazhesko, Heart Failure Department, Kiev, Ukraine

Background. Cognitive impairment (CI) is the most common co-morbidity in patients (pts) with chronic heart failure (CHF). CI is an important factor which reduces quality of life, adherence to therapy and, consequently, clinical prognosis in this pts. Nevertheless, prognostic informativity of different cognitive tests and their combination remains unclear.
Purpose. to study the prognostic meaning of different cognitive tests and their combinations in pts with CHF and reduced left ventricular ejection fraction (rLV EF).
Methods. 124 stable CHF pts aged 18 to 75 years NYHA II-IV were examined. Cognitive function was assessed by using standard MMSE, Shulte tests and the HADS questionnaire. CI was defined as MMSE≤ 26 points. The observation period was 27,5 months. All-cause mortality and combined death-or-readmission event were estimated by Kaplan-Meier curves.
Results. It was shown that the MMSE has high validity related to prediction of survival and the onset of combined death-or-readmission event in pts with CHF and rLV EF (p=0.043 and p=0.026, respectively). After adjustment the compared groups by age and NYHA class the above-mentioned statistically significant differences were

preserved (p = 0.025 and p = 0.049, respectively). Schulte test showed low predictive value related to survival and reliable validity - to combined death-or-readmission event, which, however, was reduced after age and NYHA class adjustment (p = 0.798 and p = 0.240, respectively). Inclusion in the predictive algorithm the HADS depression subscale allowed to increase the significance of differences in survival and the onset of combined death-or-readmission event (p = 0.006 and p = 0.001, respectively) between CI and non-CI pts.

Conclusion. MMSE scale is informative regarding the prediction of survival and the onset of combined death-or-readmission event in patients with CHF and rLVEF even after adjustment the compared groups by age and NYHA class. Schulte test does not have above-mentioned prognostic informativity. However, inclusion in the prognostic algorithm HADS depression subscale increases statistical confidence in the compared groups.



Survival curves

Diabetes is associated with unique pathological mechanisms in heart failure.

J Jasper Tromp[1]; AA Voors[2]; A Sharma[3]; JP Ferreira[4]; W Ouwerkerk[5]; HL Hillege[2]; P Van Der Harst[2]; DJ Van Veldhuisen[2]; P Van Der Meer[2]; I Sama[2]

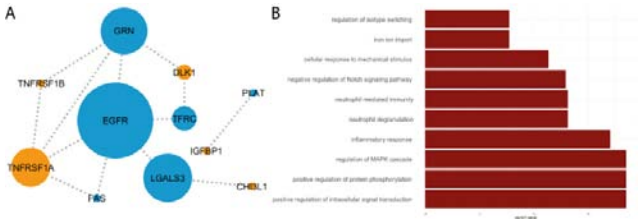
[1]National Heart Centre Singapore, Cardiology, Singapore, Singapore; [2]University Medical Center Groningen, Groningen, Netherlands (The); [3]Mcgill University, Montreal, Canada; [4]Clinical Investigation Centre Pierre Drouin (CIC-P), Nancy, France; [5]Academic Medical Center of Amsterdam, Amsterdam, Netherlands (The)

Background. Diabetes mellitus (DM) adversely affects clinical outcomes and complicates treatment in patients with heart failure (HF). A clear understanding of the pathophysiologic processes involved with DM type 2 in HF is lacking.

Methods. We performed network analyses and pathway over-representation analysis to identify unique pathological pathways in patients with HF and DM using 92 biomarkers from different pathophysiological domains measured in 1572 patients with HF (32% DM) and reduced ejection fraction (HFrEF; LVEF <40%). We validated our results in an independent cohort of 729 patients with HFrEF (30% DM). In addition, we investigated the association of DM with a composite outcome with all-cause mortality or hospitalization for HF within 2 years and whether this association was modified by biomarkers significantly related to DM.

Results. In both the index and validation cohort, 8 proteins were up-regulated and 1 protein was down-regulated in HF patients with diabetes compared to non-diabetics Network analyses identified epidermal growth factor receptor (EGFR) as a central protein in patients with DM and HF (Figure 1A). Biological pathways upregulated in patients with HF and DM were related to inflammation and protein phosphorylation (Figure 1B). DM conferred worse outcomes after correction for an establish risk model (hazard ratio [HR] 1.20; 95% CI 1.01-1.42). These differences in outcome were modified by differences in biomarker levels.

Conclusion. Concomitant DM in patients with HFrEF worsens clinical outcomes and is associated with pathological processes related to inflammation and protein phosphorylation. The role of EGFR in the relationship between DM and HF warrants further evaluation.



P1727

Safety and effectiveness of phrenic nerve stimulation in male and female patients with central sleep apnoea

MR Costanzo[1]; S Mckane[2]; A Hasan[3]; A Kao[4]; H Fox[5]; REG Robin Germany[6]; C Stellbrink[7]; S Joseph[8]

[1]Advocate Heart Institute, Naperville, United States of America; [2]Respicardia, Inc., Minnetonka, United States of America; [3]Davis Heart & Lung Research Institute, Columbus, United States of America; [4]University of Missouri - Kansas City, Kansas City, United States of America; [5]Heart and Diabetes Center NRW, Bad Oeynhausen, Germany; [6]University of Oklahoma, Oklahoma City, United States of America; [7]Bielefeld Hospital, Bielefeld, Germany; [8]Baylor University Medical Center, Dallas, United States of America

Funding Acknowledgements: Respicardia, Inc.

Background: Central sleep apnoea (CSA) is more common in men than in women. Phrenic nerve stimulation uses an implanted neurostimulator that has been shown to restore a normal breathing pattern in patients by stimulating the phrenic nerve, but little is known about sex differences in safety and effectiveness.

Purpose: The aim of this analysis was to evaluate whether response to phrenic nerve stimulation varies according to sex in patients with CSA.

Methods: All patients enrolled in the remedē System pivotal trial were included in this analysis. Therapy was activated 1-month post implant in the Treatment group and after 6 months in Control. The randomised groups were pooled based on months of active therapy for analysis. The effects of therapy are reported following 12 months of therapy.

Results: In the remedē System Pivotal Trial, 11% (16/151) of subjects were female (F) and 89% (135/151) male (M). Mean age was 66 years for F and 65 M, mean BMI was 29.5 and 31.2 kg/m2, and mean ejection fraction was 46.3% and 38.8%. Severe CSA was present at baseline in 81% of subjects for each sex (median apnea hypopnea index [AHI] 38 events/hour F and 44 M). Concomitant diseases included hypertension (69% F, 76% M), CAD (38% F, 59% M) and atrial fibrillation (50% F, 41% M). Also, 56% F had heart failure (NYHA class I/II/III in 25%/13%/19%) compared to 64% M (NYHA I/II/III in 10%/29%/25%). At the 12-month active therapy polysomnogram, 60% (6/10) F and 58% (63/109) M achieved ≥50% reduction in AHI from baseline. The mean AHI improved at 12-months by approximately 23 events/hour in each sex, driven by a reduction in the central apnoea index. Patient global assessment was markedly/moderately improved in 82% F and 57% M. The Epworth Sleepiness Scale improved by a mean of 3-4 points in each sex. While 10% M experienced a related SAE through 12 months, no F experienced an event (95% CI for the difference [-10%, 16%]). Table 1 shows the results by sex.Conclusion: Despite the lower incidence of CSA in women, both sexes benefit similarly from

Sleep and Quality of Life Results by Sex

12 Month results	Female (n=10)	Male (n=109)	Difference and 95% CI for Female-Male
Percentage of subjects with a 50% reduction in Apnoea-Hypopnoea Index from baseline	60%	58%	2% (-27%, 27%)
Apnoea-Hypopnoea Index (events/hour)	-22.7±17.7	-22.9±20.1	0.3 (-12.8, 13.3)
Central apnoea index (events/hour)	-20.3±19.5	-23.4±17.7	3.1 (-8.6, 14.8)
Percentage of subjects with Marked/Moderate improved patient global assessment	82%	57%	25% (-6%, 41%)
Epworth Sleepiness Scale (points)	-4.0±4.5	-3.6±5.0	-0.4 (-3.5, 2.8)

Percent or mean±standard deviation at 12 months.

phrenic nerve stimulation. There was no difference in adverse events between sexes. Women seemed to have greater improvements in quality of life than men.

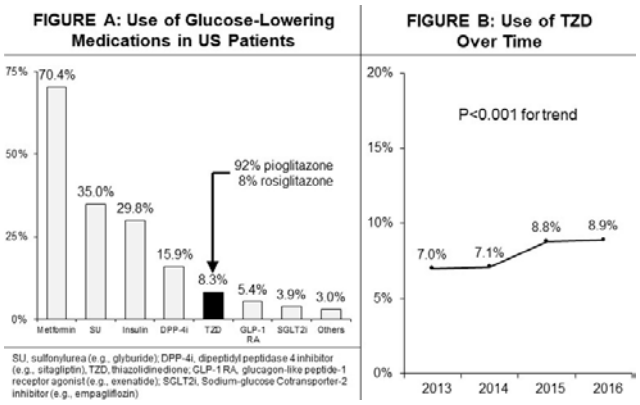
Understanding the contemporary use of thiazolidinediones. An analysis of the Diabetes Collaborative Registry

S Arnold[1]; S Inzucchi[2]; J Echouffo-Tcheugui[3]; F Tang[1]; C Lam[4]; L Sperling[5]; M Kosiborod[1]

[1]St. Luke's Mid America Heart Institute, Kansas City, United States of America; *[2]Yale University, New Haven, United States of America*; *[3]Johns Hopkins University of Baltimore, Baltimore, United States of America*; *[4]Duke-NUS Graduate Medical School Singapore, Singapore, Singapore*; *[5]Emory University School of Medicine, Atlanta, United States of America*

Background: Thiazolidinediones (TZDs; rosiglitazone, pioglitazone) are oral medications for type 2 diabetes (T2D) with unique benefits and risks. TZDs effectively reduce blood glucose with minimal risk of hypoglycemia and have potential beneficial effects on atherosclerosis. However, TZDs can cause fluid retention thereby increasing the risk of heart failure–a common complication of T2D.
Purpose: To examine the use of TZDs among patients in the Diabetes Collaborative Registry (DCR) according to patient characteristics and over time.
Methods: DCR is a US outpatient registry of T2D patients recruited from cardiology, endocrinology, and primary care practices and currently encompasses 203 practices and 3074 providers.
Results: Among 424,061 US adults with T2D who were taking ≥1 glucose-lowering medication, 35,018 patients (8.3%) were on a TZD, which has gradually increased over time (Figure). TZDs were most often used as a 2nd (28.4%) or 3rd drug (32.0%), with only 9.4% of patients on a TZD as monotherapy. Patients on TZDs tended to be older (mean age 69.2 ± 10.7 years), 61.9% had coronary disease, 14.8% with prior stroke, and 17.2% were morbidly obese (BMI >40 kg/m2). A clinical diagnosis of heart failure was present in 23.7% of patients on TZDs, 18.1% had left ventricular dysfunction (7.7% with EF <40%), and 29.9% were on a loop diuretic.
Discussion: Although TZDs lost significant market share in 2007-2010 when concerns arose regarding their safety, TZDs are still the 4th most used oral glucose-lowering medication in the DCR, and their use may be slightly increasing over time. It is not known if this trend relates to the low cost of these now generic drugs or emerging evidence of their cardiovascular benefits. At least a quarter of patients who are currently treated with TZDs in the DCR population have some evidence of heart failure and therefore should not be candidates for this therapy. Accordingly, heart failure concerns with TZDs may be under-recognized.



P1729

Left ventricular dysfunction in HIV infected anti-retroviral therapy naive patients

C Mystakelis[1]; A Lisco[1]; M Manion[1]; A Rupert[2]; G Roby[2]; V Sheikh[1]; I Sereti[1]

[1]National Institutes of Health, National Institute of Allergy and Infectious Diseases, Bethesda, United States of America; *[2]Leidos Biomedical Research, AIDS Monitoring Laboratory, Frederick, MD, United States of America*

Background Cardiovascular disease is one of the leading causes of mortality in individuals with chronic human immunodeficiency virus (HIV) infection. In particular, antiretroviral therapy (ART) naïve patients with low CD4+ counts have higher incidence of co-infections, systemic inflammation and coagulopathy which can be associated with both ischemic and non-ischemic cardiomyopathy. The prevalence of heart failure/left ventricular dysfunction in ART naïve individuals with severe CD4 lymphopenia is unknown.
Objective Identify the prevalence of left ventricular dysfunction/heart failure in patients with less than 100 CD4+ T cells/μL at the time of ART initiation and identification of immunological correlates that can guide management.
Methods 206 HIV+ ART naïve patients with CD4<100 cells/μL were included in a prospective study and followed longitudinally for 192 weeks after ART initiation. Demographic, virologic and clinical data were analyzed. Plasma cytokines were measured with ELISA and electrochemiluminescence assays. Echocardiograms were performed as clinically indicated. Statistical analyses were performed using Mann-Whitney non-parametric tests.
Results The median age at enrollment was 38 years old (yo),(range: 21-75), 75.7% of the patients were male and 57.7% were African American. The median HIV viral load (VL) was 138,005 copies/ml and the median CD4 was 24 cells/μl. Out of the 206 patients, 80 had an echocardiogram, 67 of which were performed in the first 100 days of ART (64% male, median age 41yo). 13 out of these 67 patients (19%) had reduced ejection fraction (EF <50%) and 6 out of these 13 had EF<40%. Four patients had right ventricular systolic pressure > 40 mm Hg. The median CD4 count and HIV viral load of the patients with echocardiographic abnormalities on the day of the study did not differ from those without echocardiographic abnormalities (14 cells/μl vs 32 cells/ μl, p=0.0793, and 108,444 copies/ml vs 28,279 copies/ml, p=0.3059). Patients with ventricular dysfunction had significantly higher plasma levels of D-Dimer (1719 vs 949.8 ng/ml), (p=0.0271) and IL-6 (4.288 vs 1.656 pg/ml), (p<0.0001) prior to ART. No significant differences were found in plasma levels of TNF, CRP and sCD14.From the 17 patients with evidence of ventricular dysfunction, 11 had a follow up echocardiogram, out of which 5 had ventricular function improvement (EF>50) after therapy (median follow up 9 months, range 4-24 months). Two patients died during the first 100 days of ART initiation, of whom one had heart failure with EF<40% and one did not.
Conclusions Left ventricular dysfunction is an important comorbidity in ART naïve patients with severe lymphopenia and is associated with higher levels of IL-6 and D-dimer. These data suggest that specific cardiac screening for ART-naïve HIV patients with severe lymphopenia should be further evaluated.

P1730

CMR in the evaluation of the results of percutaneous coronary interventions in patients with diabetes mellitus type 2 and chronic heart failure

Y Rustamova[1]; V Azizov[1]; G Imanov[1]; D A Maximkin[2]; A Faibushevich[2]

[1]Azerbaijan Medical University, Internal Medicine, Baku, Azerbaijan; *[2]RUDN University, Moscow, Russian Federation*

Funding Acknowledgements: Russian Academic Excellence Project 5-100

Aim: to evaluate the effectiveness of PCI in patients with multivessel coronary disease and concomitant diabetes and chronic heart failure.
Methods: 102 patients were divided into 2 groups: group 1 (n=48) - patients with diabetes, and group 2 (n=54) - patients with coronary artery disease and heart failure without diabetes. Inclusion criteria: myocardial infarction in previously; angina II-III (CCS); silent ischemia; multivessel disease (SYNTAX score I <32); segments with abnormality local kinetic of the left ventricle; chronic heart failure I-III (NYHA); left ventricular ejection fraction (LVEF) is less than 45%. Visualization of post-infarction myocardial changes was performed using CMR, both before PCI and during the evaluation of long-term results. Primary endpoints: MACE (death, MI, repeated interventions).
Results: after 24 months, MACE in groups 1 and 2 was 10.4 and 8.1%, respectively (p=0.264). After PCI, in both groups there was a significant decrease a number of segments with abnormality local kinetic, compared with baseline data (p<0.05). In patients with diabetes, as well as in patients without diabetes, there is a significant increase in LVEF by as early as 12 months after PCI, as well as a decrease in end-diasystolic volume (EDV) and end-diasystolic size (EDS) of the left ventricle. A similar steady trend continues to 24 months of observation. The average data of the transmurality index in group 1 decreased, as compared with the pre-operative values, from 0.39±0.07 to 0.32±0.02. The average difference was 0.07 [0.02-0.08; 95% CI, p = 0.01]. In patients with diabetes, the number of pathological segments in the zone of hibernated myocardium directly correlates with the index of transmurality. The lower the transmurality index, the smaller the number of pathological segments detected and the better the recovery processes of dysfunctional myocardium occur. Unlike the index of trasmurality, the index of cardiac fibrosis does not correlate with the number of pathological segments in the hibernation zone. Factors associated with the development of MACE in patients with diabetes: HbA1c ≥6.5% to PCI, fasting plasma glucose ≥6.0 mmol / l, total cholesterol ≥5.2 mmol / l, triglycerides ≥1.7 mmol / l, LDL cholesterol ≥2.5 mmol / l. In addition, performing PCI after 30 days from myocardial infarction, as well as incomplete myocardial revascularization, SYNTAX score> 25, transmural index ≥0.45, cardiac fibrosis volume ≥45%, were also unfavorable risk factors for the development of MACE. At the same time, reduced LVEF was not a predictor of an unfavorable prognosis of PCI in such patients.

Conclusion: the frequency of MACE, as well as the dynamics of recovery of hibernated myocardium function, in patients with diabetes and chronic heart failure, is comparable to that in patients without diabetes mellitus. At the same time, the smaller the value of the transmurality index, the better the recovery processes of dysfunctional myocardium occur.

Evaluation of lung ultrasound for differential diagnosis of pneumonia and heart failure decompensation

O Olga Zorya[1]; S Omar[1]; Bayarsaikhan[1]; SA Rachina[1]; Z D Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Background: challenges of pneumonia (PN) diagnosis in presence of concomitant chronic heart failure (CHF) can be attributed to difficulties of assessment of symptoms as well as presence of pitfalls in adopted clinical diagnostic algorithms.
Purpose: study aimed to evaluate the utility of lung ultrasound (LUS) in differential diagnosis of PN and CHF decompensation.
Methods: prospective case-control study enrolled adults with CHF and suspicion for PN. All participants underwent conventional procedures including lab tests and instrumental investigations. Infiltration consistent with PN was confirmed using chest computed tomography (CT) or X-ray in case of unilateral lesions; films were reviewed by 2 radiologists. Each PN case was matched in 1:1 ratio with CHF decompensation control on the basis of age, sex, etiology, course of CHF and comorbidities. LUS was performed using Bedside Lung Ultrasound in Emergency (BLUE) protocol blindly from the result of radiographical findings. Standard statistical tools were applied, p-value <0.05 was considered statistically significant.
Results: A total of 60 patients, median age 76 years old, 57% males, were enrolled. Groups were comparable regarding the main characteristics with exception of body temperature (table). LUS patterns of PN were identified in 27/30 (90%) of cases vs 0/30 of controls, patterns of pulmonary congestion were revealed in 14/30 (47%) and 30/30 (100%) patients with PN and CHF decompensation, respectively. Diagnostic performance of LUS in PN verification was as follows: sensitivity of 90%, specificity, positive predictive value and negative predictive value of 100% for each parameter, respectively.
Conclusion: BLUE protocol is sensitive and specific method of PN verification in patients with concomitant CHF. Being rapid and noninvasive, it could have significant role in diagnostic workup of pneumonia and CHF worsening particularly in settings with limited CT access.

Table 1. Characteristics of patients

Characteristic	Group 1 (n=30)	Group 2 (n=30)
Cough,%	86,0	80,0*
Breathlessness, %	96,7	100*
Reduced exercise tolerance, %	100	100*

BackgroundSleep disordered breathing (SDB) is a common comorbid condition with cardiac patients especially those with heart failure (HF) reportedly due to the changes in chemosensitivity, stimulation of pulmonary stretch receptors or prolonged circulation time. It is well known circulation time is prolonged in those with depressed cardiac function and can be a marker of cardiac output. Previously, we developed a novel automatic algorithm to determine finger to lung circulation time (LFCT) from nocturnal cardiorespiratory polygraphy data. As we hypothesized that this technique may be applied as a simplified and simultaneous detection tool of the changes in SDB severity and cardiac function, we tried to prove the usefulness of this technique in hospitalized cardiac patients.PurposeTo determine whether a set of cardiorespiratory polygraphy data, one at just after admission and another at just before discharge after treatment, can trace the changes in SDB and cardiac function among cardiac patients including HF with preserved ejection (EF) fraction and with reduced EF.MethodsWe enrolled consecutively 118 cardiac patients with and without HF, of whom 98 patients completed nocturnal polygraphy including oxygen saturation monitoring and respiration twice before/after treatment. We measured SDB parameters and automatically detected LFCT from the data. We divided the patients into worsening HF group (n=55) and non-worsening HF group (n=35), though 8 patients were excluded because the judgements of worsening HF or not were controversial. Echocardiography data (EF, left ventricular end diastolic and end systolic diameter (LVDd/LVDs) and BNP were obtained.ResultsOn admission, 63.7% of worsening HF and 54.2% of non-worsening HF had moderate to severe SDB. Patients with worsening HF group showed higher BNP values and improvement through HF treatment (563.6 ± 513.6 to 334.7 ± 265.6 pg/ml, p<0.05). 1st and 2nd cardiopulmonary polygraphy was performed at 3.5 ± 3.5 days and 11.2 ± 6.2 days after admission respectively (mean interval: 7.7 ± 4.5 days). RDI of patients with worsening HF improved through the treatment from 25.5 ± 16.5 to 18.2±12.9 (/h) significantly but not in non-worsening HF group. We could obtain LFCT data from 100% of the patients even from those with RDI<5/h. LFCT values significantly shortened only in patients with worsening HF group with low EF (EF < 40%: 26.9 ± 7.6 to 24.2 ± 6.1 (s), p<0.05), dilated LVDd (LVDd50mm: 27.3±7.2 to 25.1±6.4 (s), p<0.05) or dilated LVDs (LVDs40mm: 26.9±7.3 to 24.9±6.7, p<0.05).
ConclusionSimple nocturnal cardiopulmonary monitor can simultaneously trace the changes in the status of SDB and cardiac output represented by LFCT during treatment. In the patients with HF with preserved EF, SDB improved though cardiac output remained at same level, while both parameters improved in HF with reduced EF, suggesting that this technique can be a useful tool for treating cardiac patients.

P1733

Short term respiratory monitoring during tilt-table testing predicts periodic breathing/Cheyne-Stokes severity in patients with heart failure with reduced ejection fraction

C Chiara Borrelli[1]; F Gentile[1]; F Rossari[1]; P Sciarrone[1]; C Passino[2]; G Mirizzi[2]; F Bramanti[2]; G Iudice[2]; M Emdin[2]; A Giannoni[2]
[1]*University Hospital of Pisa, Pisa, Italy*; [2]*Gabriele Monasterio Foundation, Pisa, Italy*

Background: In patients with heart failure with reduced ejection fraction (HFrEF), periodic breathing (PB: hyperventilation/hypopneas) and Cheyne-Stokes respiration (CSR: hyperventilation/apneas) are usually thought to occur only at night in supine position.
Aim: We aimed to evaluate whether PB/CSR can be observed in patients with HFrEF in awake and orthostatic conditions.
Methods: A total of 461 patients with HFrEF on optimal guideline-recommended treatment (left ventricular ejection fraction: 29 ± 7%; age: 65 ± 12 years; 81% males) underwent echocardiography, pulmonary function test, 24-h electrocardiographic and respiratory recording and neurohormonal evaluation (natriuretic peptides, plasma norepinephrine, renin activity and aldosterone levels). Each patient also underwent a short term attended respiratory monitoring (SRM) during tilt table testing (10 minutes in clinostatism and 5 minutes in orthostatism).
A score from 0 to 2 for the SRM was created, with 0 being normal respiration, 1 being PB/CSR disappearing in orthostatism and 2 being PB/CSR persisting in orthostatism.
Results: The prevalence of scores 0-1-2 were 50%, 35% and 15%, respectively.
The score was predictive of apnea-hypopnea index (AHI) and central apnea index (CAI) severity at the 24-h recording (all p<0.001) during daytime (from 0 to 2, AHI: 4 IR 1-11 vs 11 IR 4-20 vs 22 IR 13-32 events/h; CAI: 0 IR 0-2 vs 3 IR 0-9 vs 13 IR 5-26, all p<0.001), nighttime (AHI: 12 IR 4-25 vs 23 IR 13-33 vs 36 IR 22-42 events/h; CAI: 1 IR 1-4 vs 6 IR 1-18 vs 16 IR 6-29, all p<0.001) and the 24-hour (AHI: 7 IR 2-17 vs 15 IR 9-25 vs 27 IR 18-36 events/h; CAI: 0 IR 0-4 vs 5 IR 1-14 vs 13 IR 5-26, all p<0.001). SRM score was also predictive of time spent with an oxygen saturation <90% (T90 4.0 IR 1.0-10.3 vs 6.5 IR 3.3-14.8 vs 11.0 IR 6.0-17.0 minutes, p<0.005). At univariate, logistic multinomial analysis predictors of presence of PB/CSR were left ventricular ejection fraction, moderate to severe mitral regurgitation (MR), left atrial volume, baseline atrial fibrillation (AF), right atrial diameter, systolic pulmonary artery pressure, NT-proBNP and norepinephrine levels, while at multivariate analysis only AF (OR 4.93, CI 1.30-18-57, p=0,019) resulted as independent predictor. At univariate, logistic multinomial analysis only AF was found to be predictor of PB/CSR persistence during orthostatism (OR 2.09; CI 1.16-3.77, p=0.01).
Conclusions: In HFrEF patients, a diurnal short term recording performed during tilt testing can stratify the severity of PB/CSR during daytime, nighttime and the

24-hour. Atrial fibrillation is the only independent predictor of PB/CSR presence and persistence in awake, orthostatic conditions.

P1734

Vitamin D deficiency and treatment: impact in major outcomes and functional capacity in heart failure patients

M Marcia Cravo[1]; A Vigario[1]; T Ferreira[1]; R Rego[1]; I Marques[1]; C Mendonca[1]
[1]*Centro Hospitalar Universitário do Porto, Internal Medicine, Porto, Portugal*

On behalf of: GEstIC - Grupo de Estudo da Insuficiência Cardíaca

Background: Vitamin D (VD) deficiency is very common in population. Low VD status is associated with poor prognosis in heart failure (HF) patients which increases cardiovascular events and mortality. Although, despite of the well established effects of the VD in the cardiovascular system, impact of it supplementation is still uncertain with disparities in various studies. In our HF clinic, VD deficit and bone disease are systematically screened using tools like Fracture Risk Assessment Tool (FRAX) and Dual-energy X-ray absorptiometry (DEXA) and treated, under a predefined protocol.
Purpose: Evaluate the prevalence of VD deficiency and the prognostic impact of its treatment in a cohort of HF patients admitted to a HF clinic at tertiary university hospital.
Methods: Retrospective observational study recruiting patients admitted to our HF clinic from January 2013 to December 2017. All patients with HF and VD deficiency (<50nmol/L) were included after reviewing electronic medical records, performing a total of 232 patients. VD status was analyzed after oral supplementation, dividing the study population in two clusters: patients with normal and low VD levels. They were compared by functional variables: reduced ejection fraction (rEF), NYHA e Duke Activity Status Index (DASI); and vital outcomes: mortality, hospital readmission. Stage 5 kidney disease or loss of follow up excluded 68 patients.
Results: The 164 patients analyzed had a median age of 79 years old and 54.9% was female. At pre-VD supplementation, 39.6% of the population had rEF, 83.5% were symptomatic (NYHA class $\geq$ II) and median DASI was 18.95 points. In the 84 evaluated DEXA, 15.9% were normal, 19.5% had osteopenia and 15.9% had osteoporosis. Bone fractures were identified in 9.8% of patients.
VD supplementation was prescribed to 151 patients, in which 75.6% (n=124) achieved normal VD levels. Comparing these with the cluster who maintained VD deficit, respectively: 12.7% vs. 5.6% (p=0.683) maintained or improved left ventricular ejection fraction (LVFE); NYHA class improved at least one class in 32.5% vs. 33.3% (p=0.924); median DASI improved to 20.0 vs. 19.5 (p=0.725). One-year mortality and re-hospitalization for HF post VD supplementation were 9.7% vs. 17.5% (p=0.253) and 25.8 % vs. 30% (p=0.271) in HF patients with normal vs. low VD levels, respectively.
Conclusions: VD deficiency was very prevalent in our cohort of HF patients. Oral supplementation was effective in the majority. Despite of VD normal levels were associated with improved LVFE and decreased mortality and re-hospitalization for HF, we could not find any significant statistical impact in these outcomes. These results must be validated in larger studies.

Acute Heart Failure

P1735

Treatment of cardiogenic shock complicating peripartum cardiomyopathy with the calcium sensitizer, levosimendan - data from the german PPCM registry

T J Pfeffer[1]; M List[1]; M Ricke-Hoch[1]; JT Sieweke[1]; A Schaefer[1]; J Bauersachs[1]; D Hilfiker-Kleiner[1]
[1]*Hannover Medical School, Cardiology, Hannover, Germany*

Background: Peripartum cardiomyopathy (PPCM) is a life-threatening heart disease, characterized by acute or subacute heart failure due to reduced left ventricular ejection fraction (LVEF). Treatment of cardiogenic shock (CS) complicating PPCM is challenging; therapeutic regimes for PPCM patients with CS seem to influence the ability of patients to recover. We could recently show that dobutamine may be associated with progression to irreversible terminal heart failure in PPCM patients with acute severe heart failure.
The calcium sensitizer levosimendan (LE) is currently considered as a beneficial therapy in selected patients with acute heart failure/CS. However, recent analyses of sarcomere physiology in cardiac biopsies from PPCM patients point to impaired PKA-cAMP signaling and already increased Ca2+ sensitivity.
This study sought to investigate the effect of administration of LE on outcome and clinical course of PPCM patients with CS.
Methods and Results: Out of 19 PPCM patients with CS 13 patients obtained LE (LE-patients) and 6 patients did not obtain this drug (no-LE-patients). Notably LE-patients had a significant lower LVEF at diagnosis (18.5±8.29 vs 27.0±5.62; p: 0.0297) and a trend to higher NT-proBNP values (12716±10196 ng/l vs 4414±5451 ng/l; p: 0.0733) compared to no-LE-patients. Both groups were comparable regarding age, parity, comorbidities and lactate levels. The Card-Shock-Score, SAPS II-Score, APACHE II-Score and initial SOFA-Score did not differ significantly between the two groups. All patients survived the acute phase of CS but more patients in the LE-group were treared with mechanical circulatory support (Impella or ECMO) compared to the no-LE group (8/13 vs. 0/6; p: 0.1358).
At follow up (FU: 20.5 [3-67] vs. 15 [1-76] months) none of the no-LE patients (0/6) had received a HTX, LVAD or had died, while 69.2% (9/13) of the LE-patients underwent LVAD implantation or HTX (p: 0.0108) and 23.1% (3/13) LE-patients had died.
In our mouse model of PPCM (mice with a cardiomyocyte specific STAT3 deficiency, CKO), we observe similar impairment of cAMP and Ca2+ signaling. Postpartum treatment (on day 1-2 and day 8-9 after delivery, 2 pregnancies and nursing periodes) of CKO mice with LE (0.012 mg/kgBW) showed a trend to a reduced cardiac function and accelerated PPCM .
Conclusion: PPCM patients treated with LE displayed a higher rate of terminal heart failure, HTX, LVAD and less LV recovery, compared to no-LE-patients. Although both groups were comparable regarding several heart failure markers and shock-scores, worse LVEF and higher NT-proBNP levels at diagnosis show that CS was more severe in LE-patients and the two groups are not statistically comparable. Therefore, these data have to be interpreted with great caution, and outcome can not be attributed directly to the treatment with LE. However, first experimental data support the notion that LE may not be beneficial in all PPCM patients.

P1737

The effect of levosimendan on the short-term outcome of cardiopulmonary bypass surgery in cardiomyopathic patients

MMH Alnajjar[1]; MFM Rajab[1]; WA Abukhudair[1]; MM Shinnawy[1]; HM Albutti[1]; AA Badawy[1]; EFHA Kaddah[1]; AAAA Badawy[1]; EA Salman[1]
[1]*King Fahd Armed Forces Hospital , Jeddah, Saudi Arabia*

On behalf of: Post Cardiac Surgery ICU team, King Fahd Armed Forces Hospital

Background This study evaluated the efficacy and safety of levosimendan, given intravenously to cardiomyopathic patients during and after cardiopulmonary bypass surgery. Levosimendan improves cardiac function by a novel mechanism of action compared to currently available drugs. We hypothesized that, in patients with severely compromised ventricular function, the use of levosimendan would be associated with better postoperative cardiac function than with inotropic drugs that increase myocardial oxygen consumption.
Methods 250 patients with a preoperative ejection fraction ≤30% scheduled for elective cardiac surgery with cardiopulmonary bypass were subjected to two different inotropic protocols: group A (levosemindan goup) levosimendan started immediately after the release of the aortic cross clamp by loading dose 6 μg / kg administered in 10 minutes then 0.1 mg /kg/ min continuous intravenous infusion in addition to our standard protocol started immediately after finishing the loading dose and maintained for 48 hours infusion. And group B (usual protocol group) received our standard protocol for these cases milrinone ± dobutamine and noradrenalin, adrenalin and dopamine according to blood pressure. The treatment was masked to the observers.
We assessed Haemodynamics of patients using Flotrac, Invasive arterial pressure monitoring, blood lactate level in ABG samples.
Results Cardiac Index was similar between groups initially after surgery, but it declined 12 h after surgery in the usual inotropic group but not in the levosemindan group ($P < 0.05$ between groups) despite similar filling pressures. Total dose, duration of inotropic drug administration and norepinephrine dose were lower in the levosimendan group than in the usual inotropic group ($P < 0.05$). The duration of tracheal intubation and Intensive care length of stay were shorter in the Levosemindan group compared with the group B ($P < 005$). Three patients in the group B died within 30 days of surgery but only one in levosemindan group.
Conclusions In cardiac surgery patients with a low preoperative ejection fraction, Cardiac index and stroke volume was better maintained when adding levosimendan to our inotropic protocol. Also, ICU LOS (Intensive Care Unit Length of Stay) was decreased with no increased risk of adverse Cardiovascular events.

The efficacy of tolvaptan in acute heart failure - an updated meta-analysis

K Kristel Tanhui[1]; R Maravilla[1]; A Buelva-Martin[1]; E Ongjoco[1]; A Sy-Lim[1]; M Villa[1]
[1]*St. Luke's Medical Center - Quezon City, Internal Medicine, Manila, Philippines*

Background Effective decongestion is important in the management of acute decompensated heart failure. Currently, guidelines recommend the use of loop diuretics. However, there are many challenges associated with it. One of them is diuretic resistance. Another is acute renal injury. At present, there are no evidenced based recommendations that target the preservation and/or restoration of renal

function in the treatment of heart failure. Tolvaptan can be a promising treatment in the management of heart failure by acting on a unique segment of the renal tubule.
Objective This paper aimed to establish the efficacy of Tolvaptan in the treatment for acute heart failure.
Methods We searched the available literature from the databases of MEDLINE, Cochrane CENTRAL and ClinicalTrials.gov for studies investigating the effects of Tolvaptan on acute heart failure published until October 30, 2018. Two reviewers independently screened studies then extracted relevant data against the pre-specified eligibility criteria. We assessed for risk for bias in the individual studies using the Cochrane Risk of Bias Tool Approach. Outcomes assessed included effects on mortality, length of hospitalization, incidence of worsening renal function (WRF), change in body weight, change in urine output and hypernatremia. We pooled data using a random effects model with Revman 5.3.
Results Eight studies with 5169 patients were included. Tolvaptan resulted to significantly decreased incidence of worsening renal function (risk ratio 0.51 (CI: 0.27, 0.96)). On subgroup analysis, relative risk of worsening renal function was 0.40 (CI: 0.21, 0.76) for studies with patients with higher mean Ejection fraction (>40). Tolvaptan could result to a small increase in creatinine in patients with reduced Ejection Fraction (Mean difference 0.05 (CI: 0.03, 0.07). Tolvaptan had significantly better effect on decreasing body weight (mean difference -0.79 (CI: -0.91, -0.68)) and increasing urine output (Mean difference 1.61 (CI 1.08, 2.13)). There was a significant increase in the incidence of hypernatremia with the use of Tolvaptan (risk ratio 3.29 (CI: 1.77, 6.12)). Assessment of other outcomes showed no significant effects when it came to long term (risk ratio 0.98 (CI: 0.88, 1.08)) and short term (risk ratio 0.69 (CI: 0.33, 1.45)) mortality and length of hospital stay (mean difference -0.22 days (CI -9.71, 9.28)).
Conclusion Tolvaptan is effective in the promotion of fluid loss. It may also be beneficial in decreasing the incidence of worsening renal function and may be an alternative option to loop diuretics in decongesting patients in acute heart failure. However, it may have more benefit for heart failure patients with preserved ejection fraction. Further studies need to be done to investigate this relationship.

P1739

Levosimendan alone or combined with inotropes in an acute heart failure unit

B Rocha[1]; R Ventura Gomes[2]; G Cunha[1]; M Ferraz[3]; R Morais[4]; L Fernandes[4]; L Campos[5]; I Araujo[4]; C Fonseca[4]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; *[2]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal*; *[3]Centro Hospitalar Universitário Lisboa Central, Medicine, Lisbon, Portugal*; *[4]Hospital São Francisco Xavier, CHLO, Clínica de Insuficiência Cardíaca, Lisbon, Portugal*; *[5]Hospital de Sao Francisco Xavier, Medicine, Lisbon, Portugal*

Background: Levosimendan (LS) may be the used in the management of selected patients (pts) with acute Heart Failure (AHF). Given its vasodilator properties, it is not suitable to treat those with hypotension [i.e. systolic blood pressure (SBP) < 85mmHg], unless combined with other inotropes. However, such strategy is yet scarcely investigated.
Purpose: The main goals of this study were to investigate the variation of clinical and laboratory during 24-hour LS infusion and to determine the differences between patients receiving LS vs levosimendan with another inotrope or vasopressor (LSc), as well as differences in adverse events (AE) and outcomes.
Methods: This is a single-center cohort study of hospitalized pts with AHF who received LS in an AHF care Unit between 2012 and 2018.
Results: A total of 88 pts were included (70.5% male; mean age 67±12years; mean left ventricular ejection fraction 28.6±11.6%). 23 (26.1%) pts received LSc. There were no significant differences in baseline demographics between groups, except for diabetes (13.0% vs 53.8%, p=0.010). The LSc group was more likely to present with cardiogenic shock (47.6% vs 9.8%, p=0.001), lower initial mean arterial pressure (75±10 vs 81±10 mmHg, p=0.025) and minimum SBP after starting LS (82±9 vs 92±12mmHg, p=0.002). No differences were noted in maximum LS dose achieved, urinary output or laboratory evaluation between groups (table I). Likewise, there were no differences in need for LS suspension (26.1% vs 7.9%, p=0.061), supraventricular tachycardia (40.9% vs 21.0%, p=0.068) and a composite of intra-hospital death, 30-day HF hospitalization or 30-day death (30.4% vs 24.6%, p=0.585). Finally, there was no difference in intra-hospital mortality (26.1% vs 13.8%, p=0.205).
Conclusion: In a dedicated HF unit, LS was well-tolerated, with few documented AE. Nearly 1 in every 4 pts received LSc, with no in LS suspension, AE or outcomes. This strategy appears to be an useful, well-tolerated and safe option, allowing a broader LS use in the AHF population. However, this hypothesis warrants further investigation, as this analysis is limited by its single-center retrospective design, biased population, heterogeneity and small number of pts.

Table I Subpopulation demographics

	LS (n=65)	LSc (n=23)	p-value*
Maximum LS dose achieved, N (%)	48 (82,8%)	14 (82,4%)	0,978

Effects of levosimendan in patients with chagas cardiomyopathy hospitalized for acute heart failure

G K Perez Cortes[1]; A Arango-Carrasco[1]; A Orea-Tejeda[2]; D Gonzalez-Islas[2]; LF Castillo-Aguilar[2]; JF Hernandez-Diaz[3]; A Jimenez-Cepeda[2]
[1]Hospital Regional de Alta Especialidad de Oaxaca, Internal Medicine, Oaxaca de Juarez, Mexico; *[2]Instituto Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, Heart Failure and Respiratory Distress Clinic, Mexico City, Mexico*; *[3]Hospital Regional de Alta Especialidad de Oaxaca, Cardiology Department, Oaxaca de Juarez, Mexico*

Introduction: Hospitalizations for acute heart failure (AHF) are frequent in patients with Chagas cardiomyopathy (CCM). Levosimendan, a calcium sensitizer and inodilator, has shown positive clinical, functional and neurohormonal effects, but its use in patients with CCM hospitalized for AHF has not been evaluated.
Purpose: To evaluate the effect of levosimendan administration on renal function, serum B-type natriuretic peptide (BNP) levels, hospital stay and readmissions in patients with CCM hospitalized for AHF.
Methods: A retrospective cohort study was performed including hospitalized patients with AHF aged 18 years or older, with positive serological test for T. cruzi and electrocardiographic and echocardiographic findings compatible with CCM. Those with renal failure were excluded. During the hospitalization, renal function, serum BNP levels, serum sodium levels and fluid balance were evaluated. Hospital readmissions to one year were evaluated.
Results: Were evaluated 37 patients. Mean age was 69.94 ± 9.31 years, 56.76% were women. Eleven patients recibed levosimendan (29.7%). No statistically significant differences were found in BNP level change (-393.66 ± 991.15 vs. -254.20 ± 1042.8, p=0.739), percent change in creatinine level (17.09 ± 28.42% vs. 5.57 ± 52.42%, p=0.189) and hospital stay (5 [4-8] vs. 6 [5-8], p=0.322) between the the group with levosimendan and control, respectively. The group with levosimendan showed greater prevalence of readmissions (36.36% vs. 19.23%, p=0.404) and shorter time to next hospitalization (24.5 [19-55] vs. 83 16-209], p=0.538), although it was not statistically significant.
Conclusions: In patients with CCM hospitalized for AHF, the administration of levosimendan did not show benefits in hospital stay, renal function and natriuretic peptide B levels. On the other side, although it was not significant, it was associated with a greater number of readmissions and shorter time to next hospitalization.

P1741

A formula to calculate discharge furosemide dose after an acute heart failure hospitalization

P Lourenco[1]; F Cunha[2]; J Pereira[1]; M Carreira[1]; P Marques[1]; A Ribeiro[1]; JP Araujo[3]; P Bettencourt[4]
[1]Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal; *[2]Hospital Centre do Tamega e Sousa, Endocrinology, Penafiel, Portugal*; *[3]Sao Joao Hospital, Department of Internal Medicine - University of Porto Medical School, Porto, Portugal*; *[4]Hospital CUF, Department of Internal Medicine - University of Porto Medical School, Porto, Portugal*

Background: Loop diuretics are symptomatic heart failure (HF) therapies, expected to control congestive symptoms. Its impact on HF prognosis is unclear but they are regarded as potentially hazardous. The dose tends to be the lowest possible to maintain euvolemic status.
Purpose: To determine a formula to calculate the discharge furosemide dose in acute HF patients.

Methods: We retrospectively studied a derivation cohort of acute HF patients that were part of a registry conducted in our Hospital between 2009-2010. Patients with preserved or reduced systolic function were studied. Linear regression analysis was used to evaluate determinants independently associated with the discharge furosemide dose. A multivariate model was built based on variables independently associated with discharge furosemide. The intercept was the constant value in the formula and β coefficients of each determinant used as the relative weight/multiplier of the corresponding variable: furosemide dose = intercept + β1 x variable 1 +...+βn x variable n. The formula was tested in a validation cohort of acute HF patients that were part of a registry conducted in the same hospital in 2006-2007. Estimated and real furosemide dose was compared: correlation coefficient and Wilcoxon test.
Results: The derivation cohort had 622 patients. Mean age 76 years, 45.2% male, and 43.4% had preserved ejection fraction. Ischemic aetiology 40%, diabetes mellitus (DM) 41.5%, median discharge B-type natriuretic peptide (BNP) 741.9pg/mL and upon discharge 67% were on beta blocker (BB), 66.2% on ACEi/ARB and 20.1% on mineralocorticoid receptor antagonists (MRA). Median discharge furosemide dose was 80mg. The validation cohort had 214 patients: mean age 70 years, 69.2% male, and 23.8% with preserved ejection fraction. Ischemic aetiology 49.1%, DM 44.9%, median BNP 760.2pg/mL; 65.4% discharged on BB, 78.5% on ACEi/ARB and 33.6% on MRA. Median discharge furosemide dose 80mg. Independent determinants of furosemide dose were male gender, DM, BNP and previous furosemide dose; R value 0.62. The formula based on this model was: 40.5 + 13.5 x gender + 4.6 x DM + 0.003 x discharge BNP + 0.46 x previous furosemide dose (gender=1 if male, DM=1 if present, discharge BNP in pg/mL and previous furosemide dose in mg/day). In the derivation cohort, Wilcoxon test comparing discharge and estimated furosemide dose was 80 (40-120) vs. 76 (59-96) mg/day, respectively, p=0.51; Correlation coefficient 0.62. In the validation cohort, discharge and estimated furosemide dose was 80 (60-120) vs. 78 (60-102) mg/day, respectively, p=0.14; Correlation coefficient 0.54.
Conclusions: Male gender, DM, higher discharge BNP and higher previous furosemide dose are independent determinants of the furosemide discharge dose. We propose the formula to calculate furosemidedose when discharging an acute HF patient: 40.5 + 13.5 x gender + 4.6 x DM + 0.003 x discharge BNP + 0.46 x previous furosemide dose.

P1742

Decrease in heart rate have more impact than up-titration of beta blocker for acute decompensated heart failure with atrial fibrillation

T Takashi Morinaga[1]; A Isotani[1]; S Fujioka[1]; K Hirose[1]; S Mori[1]; K Ishizu[1]; S Ito[1]; M Yano[1]; M Fukunaga[1]; S Shirai[1]; K Ando[1]
[1]Kokura Memorial Hospital, Kokura, Japan

Background: Beta blocker (BB) is one of the most important drugs for heart failure (HF). The effect of BB is related to decrease in heart rate (HR). However, among HF patient with atrial fibrillation (AF), the relationship between BB and decrease in HR is unknown. Method and result: We enrolled consecutive 631 patients were admitted to our hospital for acute decompensated HF in 2015. 150 patients with AF both on admission and discharge was selected. 62 (41.3%) of whom received up-titration of BB in hospitalization. 127 (84.6%) of whom decreased HR on discharge comparing with on admission. The incidence of all cause death and HF re-hospitalization was not significant different between up-titration of BB group and without up-titration group (48.3% vs. 56.8%, P=0.71). The incidence of all cause death and HF re-hospitalization was significant lower in decrease in HR group than in without decrease in HR group (50.3% vs. 69.5%, P0.01). We analyzed up-titration of BB group and without up-titration group, respectively. The incidence of all cause death and HF re-hospitalization in up-titration of BB group was significant lower in decrease in HR group than in without decrease in HR group (45.6% vs. 80.0%, P=0.03). And similar result was obtained from without up-titration of BB group (54.2% vs. 66.6%, P=0.02). Conclusion: Decrease in HR may have a better prognosis than up-titration of beta blocker for acute decompensated HF with AF.

P1743

Optimized medical therapy at admission vs the moment of discharged in patient acute heart failure

LCSP Luiz Carlos Passos[1]; AGQJ Grimaldi[2]; WC Carvalho[2]; TC Silva[2]; TM Trindade[2]; EG Lopes[2]; AC Guimaraes[2]; A Seabra[2]; MC Campos[2]; ILS Santana[2]; HM Santos[2]; DC Monteiro[2]; VO Santos[2]; L Kassia[2]; MV Barreto[2]
[1]Federal University of Bahia, Internal Medicine, Salvador, Brazil; *[2]Ana Nery Hospital, Salvador, Brazil*

On behalf of: EPICO - Estudo para Investigação de Causas Tratáveis e Otimização terapêutica da Insuficiência Cardíaca

BACKGROUND: The Acute Heart Failure (AHF) is the main cause of hospitalization among adults in Brazil. In the last ten years, costs attributable to hospital services a related to HF corresponded to almost 90% of the total mobilized by this pathology of the Sistema Único de Saúde (Unified Health System - SUS) and these are mostly caused by in-hospital treatment.
OBJETIVE: The objective of this study was to compare the optimized medical therapy at AHF admission with the time of discharge in patients admitted to a referral center in cardiology in Bahia - Brazil.
METHODS: This is a prospective cohort study "Study for the identification of treatable causes and therapeutic optimization of heart failure" (EPICO) consisting of people admitted to a tertiary center for cardiovascular care in Salvador between January 2016 and December 2018. The heart failure (HF) was defined according to the guidelines of the European Society of Cardiology (ESC) and only cases of systolic heart failure, defined as Left Ventricular Ejection Fraction (LVEF) <50%, were eligible. It is considered as optimized drug therapy the use drugs of the classes ACEI or ARB, Beta-blocker and spironolactone, if indicated, in optimal doses according to the individual tolerance. The patient follow up is made for Team multiprofissional in HF. The clinical, laboratory, drug and other data were collected from medical records. The statistical analysis used the SPSS® software (Statistical Package for Social Sciences)
RESULTS: The 318 patients was analyzed in relation to drug therapy prior to hospital admission at AHF and at moment of discharge. Of these, 15% (48) were pharmacologically optimized prior to hospitalization, 94% (45) of whom had ACE inhibitors or ARB, 94% (45) Beta-blocker, 98% (47) spironolactone. In patient Discharge moment 87% (276) was optimal clinical treatment, with 73% (202) receiving ACEi or ARB, 90% (249) using a beta-blocker, 75% (206) using spironolactone. It can be noticed that the clinical descompensation of HF is, for the most part, due to the lack of clinical and therapeutic optimization. The Team HF work optimized drug treatment at discharge showed a significant increase in relation to the prescription of prior pharmacological therapy for essential heart failure.
CONCLUSIONS: The adoption of a multidisciplinary care strategy with specific guidelines and measures for HF during hospitalization and at the time of hospital discharge and continuous follow-up of the patients, enables optimized attention focused on compensation of the clinical picture, self-care, recognition and prevention of HF symptoms.

P1744

Population pharmacokinetics of intravenous sufentanil in critically ill patients supported with extracorporeal membrane oxygenation therapy

J Jin Wi[1]
[1]Severance Cardiovascular Hospital, Seoul, Korea (Republic of)

Background: Sufentanil is commonly used for analgosedation during extracorporeal membrane oxygenation (ECMO). ECMO has significant effects on the pharmacokinetics (PK) of drugs. This study aimed to develop a population PK model of sufentanil in ECMO patients and to suggest dosing recommendations.
Methods: This prospective cohort PK study included 20 patients who received sufentanil during venoarterial-ECMO (VA-ECMO). Blood samples were collected for 96 h during infusion and 72 h after cessation of sufentanil. The population PK model was developed using nonlinear mixed effects modelling. Monte Carlo simulations were performed using the final PK parameters with three standard doses.
Results: A two-compartment model best described the PK of sufentanil. Body temperature and total plasma protein were significant covariates of systemic clearance (CL) and peripheral volume of distribution (V2). The parameter estimates of the final model were as follows: CL = 36.8 × (temperature/36.8)9 L h-1, central volume of distribution (V1) = 235 L, V2 = 55.3 × (total plasma protein)2.26 L, intercompartmental clearance (Q) = 40 L h-1.
Conclusions: Compared with previous PK data from patients not undergoing ECMO, we observed increased volumes of distribution and decreased clearance values. Covariate analysis showed that body temperature and total plasma protein level correlated positively with CL and V2, respectively. We suggest that clinicians should consider a reduced dosing of sufentanil in patients with hypothermia and hypoproteinaemia. Overall, close monitoring of the body temperature and total plasma protein level and assessment of sedation and analgesia status are crucial to provide effective analgosedation and promote recovery.

P1745

Problem of 30-day readmission for Heart Failure could be improved. Results of IMPEDANCE-HF extended trial

M Michael Kleiner Shochat[1]; D Kapustin[2]; M Fudim[3]; Y Levy[1]; M Kazatsker[1]; I Kleiner[4]; JM Weinstein[4]; P Panjrath[5]; A Roguin[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]University of Toronto, Internal disease , Toronto, Canada*; *[3]Duke University Medical Center, Cardiology, Durham, United States of America*; *[4]Saroka Medical Center, Cardiology, Beer Sheva, Israel*; *[5]George Washington University School of Medicine and Health Sciences, Cardiology, Washington, United States of America*

Readmissions for heart failure (HF) are a major burden. The aim of secondary analyses of the IMPEDANCE-HF extended trial was to find out if degree of residual congestion on discharge for HF could predict 30-day readmission.
The analysis of IMPEDANCE-HF extended trial was based on the data collected during the index hospitalization for HF. The IMPEDANCE-HF extended trial was a randomized controlled single-blinded trial of HF with reduced LVEF patients. Inclusion criteria were LVEF ≤ 45%, NYHA class II-IV and patients were hospitalized for HF within 12 months (ClinicalTrials.gov NCT01315223). Half of the patients (N=145) were assigned to the active Lung Impedance (LI)-guided treatment arm where clinicians were based therapy on LI level. The other half was assigned to the control arm where LI values were recorded but not conveyed to the clinical treatment team. In the case of hospitalization, LI was recorded in all patients at discharge. The decisions regarding discharge and choice of treatment were at the discretion of the hospital staff .
A non-invasive impedance device was used in this study to assess the lung fluid content. Unlike the existing impedance devices, the present device has the ability to differentiate a true signal from the lungs from the noise signal of surrounding chest wall. Such approach enables to measure a small change in lung fluid content. A method to determine individual "dry" baseline LI (BLI) for each HF patient has been reported. BLI for each patient was used to calculate a new parameter, the LIR= [(current LI/BLI)-1] ×100%, which determinate the degree of pulmonary congestion in time of measurement.
Method. Degree of pulmonary congestion at discharge for HF hospitalization was divided into 5 brackets. (1) LIR= 0 to – 18% - minimal interstitial edema (IE), (2) LIR= - 18.1 to -28% - mild IE, (3) LIR= -28.1 to – 38 – moderate IE, (4) LIR= -38.1 to -48% - severe IE to mild alveolar edema (AE) and (5) LIR < -48.1% - moderate AE.
Results: LI-guided patients were followed for 61.9.4±39.6 months and control patients for 46.7±33.3 months (p<0.01) accounting for 269 and 470 HF hospitalizations, respectively (p<0.01). Average ΔLIR at discharge was -33.0±14% vs. -37.3±12% in LI-guided and control groups, respectively (p<0.01). The distribution of patients at discharge according to the different levels of pulmonary congestion by brackets 1-5 were 21:19:24:19:17% in the LI-guided and 6:18:34:23:19% in the control group (p<0.01). The probability to 30-day readmission calculated for both groups together according degree of pulmonary congestion on discharge was: HR Bracket 2 to 1 = 1.8 [1.4 – 2.3, p <0.01], HR Bracket 3 to 1 = 11.0 [8.4 – 14.3, p <0.01], HR Bracket 4 to 1 = 43.5 [31.3 – 62.5, p <0.01], HR Bracket 5 to 1 = 142.9 [83.3 – 250.0, p <0.01].
Conclusion: The degree of pre-discharge pulmonary congestion as assessed by LI is a very robust and reliable predictor for 30-day readmission.

P1746

Use of non- invasive positive pressure ventilation is associated with worse short-term outcome after discharge for elderly patients with acute decompensated heart failure

M Midori Yukino[1]; Y Nagatomo[1]; A Goda[2]; Y Sujino[3]; A Mizuno[4]; T Kohno[5]; Y Shiraishi[5]; S Kohsaka[5]; T Yoshikawa[6]
[1]National Defense Medical College, Tokorozawa, Japan; *[2]Kyorin University School of Medicine, Department of Cardiology, Tokyo, Japan*; *[3]Saitama International Medical Center, Department of Cardiology, Hidaka, Japan*; *[4]St. Luke's International Hospital, Department of Cardiology, Tokyo, Japan*; *[5]Keio University School of Medicine, Department of Cardiology, Tokyo, Japan*; *[6]Sakakibara Heart Institute, Department of Cardiology, Tokyo, Japan*

Background: Non-invasive positive pressure ventilation (NIPPV) is usually adopted as a support to medical therapy in patients with acute decompensated heart failure (ADHF). However, the effects of NIPPV on the outcome of patients with ADHF has yet to be fully investigated. Herein, we aimed to evaluate the characteristics of ADHF patients who received NIPPV and assess its impact on short-term clinical outcome. Methods and Results: WET-HF (West Tokyo Heart Failure) Registry is a multicenter prospective cohort registry enrolling all patients hospitalized for ADHF, which enrolled 4000 subjects from 2006 through 2017. Excluding 247 patients undergoing tracheal intubation or those lacking information on NIPPV use, 3753 patients (74±13 years, male 60%) were available for the present analysis. Overall, 707 (18.8%) used NIPPV (Group A) and the remaining did not (Group B). Group A had lower proportion of prior ADHF admission (A, 25%, B, 32%, P<0.001) on less anti-HF medication and severe degree of HF represented by lower oxygen saturation (A, 93% [88-97], B, 96% [94-98], P<0.0001), higher heart rate (A, 102 bpm [82-121], B, 88bpm [70-107], P<0.001), and higher BNP level (A, 897 pg/ml [495-1592], B, 691 pg/ml [353-1226], P<0.001) at the time of admission. Despite comparable cardiac function parameters such as left ventricular ejection fraction or E/e', Group A showed longer hospital stay (A, 16 days [10-26], B, 14 days [9, 22], P<0.001) and higher in-hospital mortality (A, 5%, B, 3%, P=0.02). Group A also had higher rate of the composite endpoint of all-cause death or ADHF rehospitalization within 90 days after discharge (P=0.043). Additionally, one-to-one nearest-neighbor propensity match analysis (n=550 in each group) was conducted to adjust the confounding factors such as the severity of HF and in-hospital treatment between the 2 groups. There were no significant differences regarding in-hospital or post-discharge outcome between the 2 groups in the matched cohort.
However, in the elderly (≥85 years) patients NIPPV use was still associated with higher rate of the composite endpoint of all-cause death or ADHF readmission within 90 days after discharge (HR 1.77 [1.03-3.13], P=0.038), although in the younger (<85 years) patients no such difference was observed between the patients with NIPPV and those without (HR 0.82 [0.56-1.21], P=0.33; P for interaction = 0.03).
Conclusions: Although in-hospital and early post-discharge outcomes of patients with NIPPV was comparable within the matched cohort, short-term post-discharge outcome was still worse for NIPPV users in the elderly patients (> 85 years). Although NIPPV can be a reasonable option for the treatment of ADHF patients with respiratory distress, it should be cautious in the management of elderly patients (> 85 years) who required NIPPV even after discharge.

P1747

Influence of circulatory support devices on morbidity and mortality of cardiogenic shock after acute myocardial infarction.

R Mourilhe Rocha[1]; GV Santos[1]; DXB Setta[1]; JP Mourilhe-Rocha[1]; MI Bittencourt[1]; RS Schneider[1]; MLS Bandeira[1]; OE Farias[1]; TF Carvalho[1]; RM Carneiro[1]; CL Weksler[1]; FOD Rangel[1]; R Esporcatte[1]
[1]Hospital Pro Cardiaco, Rio de Janeiro, Brazil

Introduction: cardiogenic shock is a state of low cardiac output that results in life risk due to organic hypoperfusion and hypoxia, and acute myocardial infarction (AMI) with left ventricular dysfunction continues to be its most frequent cause. Advances in reperfusion therapy have been associated with survival improvement, but significant regional disparities in care are reported and in-hospital mortality remains very high. Objectives: to define the risk factors, epidemiological data and outcomes of patients admitted due to AMI who presented cardiogenic shock at admission or during admission to a tertiary hospital.
Methods: a longitudinal, observational study of consecutive patients admitted with acute coronary syndrome (ACS) from June 1, 2015 to October 31, 2017. Data were obtained from the medical records, as well as interviews of patients during hospitalization. We compared the demographic, clinical and outcomes data of patients with cardiogenic shock (wCC) and without cardiogenic shock (woCC) in this population.
Results: there were 216 patients analyzed and the incidence of cardiogenic shock was 9.7% and was manifested at admission in 33.3% of the cases. The characteristics in the wCC group and woCC were, respectively: mean age of 76.1±10.56 x 70.8±11.39 years (p=0.04), male (66.7% x 70.3%, p=0.75), smoking (28.6% x 52.3%, p=0.03), dyslipidemia (57.1% x 55.9%, p = 0.91), systemic arterial hypertension (66.7% x 77.9%, p=0.24) and diabetes mellitus (42.9% x 33.3%, p=0.38); ST elevation AMI (47.6% x 28.7%, p=0.07) and non-ST elevation AMI (52.4% x 71.3%, p=0.07). Other complications were renal dysfunction (14.3% x 7.7%, p=0.29), atrial fibrillation (19% x 7.2%, p=0.06), pericardial effusion (95.2% x 32.8%, p<0.001), cardiorespiratory arrest during hospitalization (42.9% x 1%, p<0.001), use of mechanical circulatory support device (57.1% x 1%, p <0.001). In the wCC group: intra-aortic balloon (58.3%), Centrimag (9.5%), extracorporeal membrane circulation (14.2%); and in woCC group: intra-aortic balloon (1%). Overall mortality were 61% in wCC group and 1% in woCC group (p<0.001).
Conclusion: cardiogenic shock occurred in older patients, that presented with more renal dysfunction, atrial fibrillation, pericardial effusion and cardiorespiratory arrest. Despite the technological advances in the treatment of AMI, the circulatory support devices did not reduce the morbidity and mortality of this entity, remaining extremely high.

P1748

Precipitants of admission in heart failure; adherence & alteration of medication by other clinical services pose a challenge even in disease management programs

F Faizan Rathore[1]; RB Pharithi[1]; K Mcdonald[1]
[1]St Vincent's University Hospital, Department of Cardiology, Dublin, Ireland

Background Identification, treatment & prevention of precipitants leading to heart failure (HF) hospitalization is of paramount importance. However, to date, precipitants have primarily been analysed retrospectively, with relatively little focus on heart failure phenotype. Furthermore, no studies have reported on precipitants within a population managed in a heart failure disease management programs(DMP), wherein, care would be anticipated to have altered the relative importance of standard causes for readmission, in particular, adherence to therapy. We sought to address the gaps identified above
Methods 135 patients, presenting with ADHF were prospectively recruited and precipitants recorded. This cohort included patients with first presentation of denovo HF (dHF) and those managed within a DMP with established HF(eHF) HF phenotype

was classified based on LVEF into HFpEF (>=50%)& HFrEF (<50%). The precipitants were defined as Infections -Diagnosed based on clinical,laboratory and imaging findings,felt to be clinically contributing Medication Adherence-assessed using Morisky 8 Point medication adherence scale, Arrhythmias-documented on ECG & clinically felt to be contributing, predominantly atrial fibrillation Ischemia-based on history, clinical and ECG findings with or without cardiac enzyme rise, Medication change by other services involved in care of HF patient-defined as a reduction in HF therapies or use of contraindicated therapies Dietary non-compliance defined as excess sodium intake, Excess alcohol intake-defined as >1iu/d for women & >2iu for men Others-precipitants not falling in the above categories The identified precipitants were analysed against variables of interest, using chi squared , independent t test & fisher exact test , a p value of <0.05 was considered significant.
Results Single Precipitant was identified in 43.7 %(n=59), multiple precipitants were identified in 29.5%(n=35), no precipitant was identified in 30.4%(n=41). In dHF (n=67) predominant precipitants were LRTI (43%), Arrhythmias(39%), non compliant diet(34%), Ischemia(21%) ,Excess Alcohol(15%) ,Medication Change(7%),Others (4%) & Low Medication Adherence (1%). In eHF(68) predominant precipitants were LRTI(27%),Non compliant diet (24%),Arrhythmias(22%),Medication change(18%) ,Low Medication Adherence(15%),Excessive alcohol (15%) Ischemia (6%) & others (1%). No statistically significant difference was observed between HFrEF & HFpEF.
Conclusion Major observations from this prospective analysis highlight no significant difference between precipitants recorded comparing HFpEF & HFrEF in the total population. In eHF these precipitants remain prevalent ,but of note, medication adjustment & medication adherence remain a significant problem despite emphasis on self care education in these programs. These findings highlight the need for improvement in patient education & communication among different services involved in care of HF patient.

Development and validation of a Portuguese questionnaire to evaluate knowledge about heart failure

T Fidelis[1]; A Azzam[1]; A Nunes[1]; T Limpo[1]; E Moreira[2]; JS Cardoso[2]; SL Castro[1]
[1]University of Porto, Centre of Psychology at University of Porto, Porto, Portugal; *[2]CINTESIS - Centro de Investigação em Tecnologias e Serviços de Saúde, Porto, Portugal*

Funding Acknowledgements: "Symbiotic technology for societal efficiency gains: Deus Deus ex Machina" (co-funded by NORTE 2020 and FEDER, NORTE-01-0145-FEDER-00026)

Introduction . Heart Failure (HF) has a difficult diagnosis and, once diagnosed, it is essential to give patients critical knowledge to deal with it. The greater the information patients have about their illness, the lower the chances of hospital readmission. Knowledge of the disease includes the cause, symptoms, probable duration and expected evolution of the clinical condition.
Purpose. The present research aimed to adapt the "Knowledge Questionnaire on Chronic Heart Failure" developed by De Walt et al. (2004) to the Portuguese context. Method. The Portuguese version was developed across six stages: independent translation; discussion to obtain a single version; retroversion; questionnaire evaluation by cardiologists; first amendment; pilot test; second amendment. The final version achieved was then tested across three studies. In Study 1, 57 subjects (of which 37 women), aged between 14 and 66 years (M = 40, SD = 35.3), were randomly divided by two experimental conditions: flyer-questionnaire (FQ) vs. questionnaire-flyer (QF). In the FQ condition, after a presentation of an informative flyer about on HF, participants were asked to complete the questionnaire independently. In the QF condition, the reverse procedure was followed (i.e., the questionnaire was filled in before the flyer presentation). In Study 2, 21 participants (of which 10 women), aged between 20 and 34 years (M = 25.86, SD = 3.59), were asked to fill in the HF questionnaire before and after a 5-min period to read the flyer. Finally, in Study 3, 169 subjects with HF (of which 47 women), aged between 32 and 87 years (M = 62.57, SD = 10.93), were asked to fill in the questionnaire.
Results. In Study 1, FQ participants (M = 9.31, SD = 1.81) gave more correct responses than those in the QF condition (M = 5.90, SD = 2.40), $t(55) = -5.95$, $p < .001$, $d = 1.60$. In Study 2, participants gave more correct responses after reading the flyer (M = 10.38, SD = 1.69) than before reading it (M = 6.48, SD = 2.89), $t(30) = -6.77$, $p < .001$, $d = 1.64$. Finally, Study 3 participants with HF were found to give 8.53 correct answers out of 14 (SD = 2.19). Additionally, results showed that women had more knowledge than men (M = 9.13, SD = 2.08 vs. M = 8.30, SD = 2.19), $t(167) = 2.25$, $p = .026$, $d = 0.38$, and that greater knowledge was associated with higher education ($r = .34$, $p < .001$) and younger age ($r = .17$, $p = .03$).
Conclusion. Overall, the present research showed that the Portuguese version of the HF knowledge questionnaire is valid instrument for the assessment of knowledge about HF. This seems a useful tool for doctors to assess their patients' knowledge of the disease and act accordingly. Patients who have a chronic illness, such as HF, should have an adequate awareness about their condition, as this awareness can make a make a significant difference in the treatment.

P1750

Active screening using electronic medical record system for patient recruitment in case management of heart failure with reduced ejection fraction

CT Chia-Te Liao[1]; FH Kuo[1]; MC Lee[2]; SL Lio[3]; HY Lai[3]; EC Chu[4]; PL Ko[3]; YS Yen[5]; ZC Chen[1]; HS Toh[6]
[1]Chi-Mei Medical Center, Cardiology, Tainan, Taiwan, Province of China; *[2]Chi-Mei Medical Center, Department of pharmacology , Tainan, Taiwan, Province of China*; *[3]Chi-Mei Medical Center, Department of Internal medicine, Tainan, Taiwan, Province of China*; *[4]Chi-Mei Medical Center, Nutritional Service, Tainan, Taiwan, Province of China*; *[5]Chi-Mei Medical Center, Rehabilitation, Tainan, Taiwan, Province of China*; *[6]Chi-Mei Medical Center, Department of intensive care unit, Tainan, Taiwan, Province of China*

Introduction Patients with heart failure (HF), especially those with reduced ejection fraction (HFrEF) usually have longer hospitalisation days and higher re-hospitalisation rate. Case management and multidisciplinary teamwork have been reported to improve these outcomes. However, the recognition of patients with HF might be missed or delayed during the hospital stay, and these interventions are traditionally initiated only after the consultation of the cardiologists.
Purpose We aimed to assess if the active screening for the HF patients with the electronic medical record (EMR) system would shorten their hospital days and decrease re-hospitalisation rate.
Methods We constructed and launched a mobile system which can connect to the EMR since 01 July 2018. The system was designed to actively identify all hospitalised patients with a diagnosis of heart failure (ICD-10: I50) and left ventricular ejection fraction (LVEF) $\leq$ 35% during admission. It notified the HF multidisciplinary team automatically, and the team will provide healthcare and the relevant education to the patients like the way before this system was launched. Regarding the outcome evaluation, we compared the length of hospitalisation and three-months re-hospitalisation rate before and after launching the system.
ResultA total of 15 patients were actively identified three months after launching the mobile system with the connection of EMR. Their mean age was 59.4 $\pm$ 14.9 years, and 80% of them are men. The mean LVEF was 26.6 $\pm$ 6.3%. Comparing to the 36 patients before using the system, the demographic characteristics are similar, except a lower prevalence of coronary artery disease and hypertension. Regarding the primary outcome, three-months re-hospitalization rate after launching mobile system significantly decreased from 12% to 0% ($p = 0.01$) and the hospitalisation days marginally decreased from 10.6 to 7.2 days ($p = 0.06$).
Conclusion The preliminary analysis showed that active screening system through the connection of the EMR system might recognise the patients with HErEF earlier. By early recognition, we could initiate interventions promptly and hence, improve the HFrEF outcomes. In the future, longer follow-up and larger cohort studies are needed to confirm the benefits of the active screening and the continuing multidisciplinary team care for patients with heart failure.

The examination about the clinical feature related to re-admission in congestive heart failure patients introduced our original clinical pathway

H Hiroyuki Wake[1]; A Iwai[1]; Y Kuroiwa[1]; T Kubo[1]; J Inoue[1]; N Kajiwara[1]; K Kimura[1]; Y Katou[2]; A Takaishi[2]
[1]Mitoyo General Hospital, rehabilitation , Kanonji, Japan; *[2]Mitoyo General Hospital, Cardiovascular disease center, Kanonji, Japan*

Background: We had introduced original clinical pathway(PATH) in congestive heart failure(CHF) cases for efficient medical care from August 2015. Introducing PATH, the great shortening of hospitalization period was achieved. But we can not still confirm the reducing effect about re-admission with CHF exacerbation even in the cases introduced PATH.
Purpose: For finding of the clue about suppression of re-admission, we retrospectively investigated the clinical feature about the CHF cases who ware introduced PATH and re-admitted with worsening of CHF after discharge.
Methods: We enrolled 246 cases(mean age: 80$\pm$11 years old, male/female: 139/107 cases) , admitted with CHF in our hospital and introduced PATH for the first time between August 2015 and November 2017. And we divided them in two groups, Y-group consisted of the 67 cases who ware re-admitted by worsening of CHF within 1year after discharge and N-group consisted of 179 cases who ware not re-admitted within 1 year. About all cases in both groups we investigated patient characteristics, various clinical data on first admission and clinical course until discharge. And we examined the difference of each survey item between two groups.
Results: In Y-group, the mean age was significantly higher(82$\pm$9 vs 79$\pm$11 years old); $p<0.05$) and the ratio of cases with admission history by CHF within the past 3 years was higher than N-group(43 vs17%; $p<0.0001$). The ratio of cases who had the past history of any coronary heart disease as an underlying disease of CHF was higher in Y-group(40 vs 26%; $p<0.05$). About cardiac function, the mean value of brain natriuretic peptide concentration in blood and the ejection fraction

of left ventricle by echocardiography was not significantly different in both groups. About blood test data on admission, the mean blood concentration value of creatinine and urea nitrogen was higher in Y-group(1.4±0.6 vs 1.2±0.6mg/dl; p<0.05, 30±115 vs 24±12mg/dl; p<0.01 respectively). The mean blood concentration of total cholesterol(153±34 vs 168±-46mg/dl; p<0.05) and high density lipoprotein cholesterol(43±14 vs 49±17mg/dl; p<0.05) was significantly lower, and the all of another lipid data was also tended to be low in Y-group. In Y-group and N-group, the mean starting time of cardiac rehabilitation(3.0±1.3 vs 3.2±1.7th hospital day), the mean duration of continuous venous infusion(4.2±3.9 vs 4.6±5.8days) and the mean duration of urethral catheterization(6.6±7.4 vs 6.0±9.2days) were not different. As a result, the hospitalization period was not so long(19±16 vs 17±14days).
Conclusion: In this study, we confirmed the achievement of efficient medical care for congestive heart failure by original clinical pathway again. And we found residual factor that could affect to occurrence of re-admission with re-exacerbation of heart failure, such as the old age, past heart failure history, renal dysfunction or malnutrition of patients.

P1752

The examination of the clinical feature to cause the further reduction of daily life independence level after admission in elderly cases with congestive heart failure

T Teruaki Kubo[1]; H Wake[1]; A Iwai[1]; Y Kuroiwa[1]; J Inoue[1]; N Kajiwara[1]; K Kimura[1]; Y Kato[2]; A Takaishi[2]
[1]Mitoyo General Hospital, Rehabilitation, Kanonji, Japan; *[2]Mitoyo General Hospital, Cardiovascular Center, Kanonji, Japan*

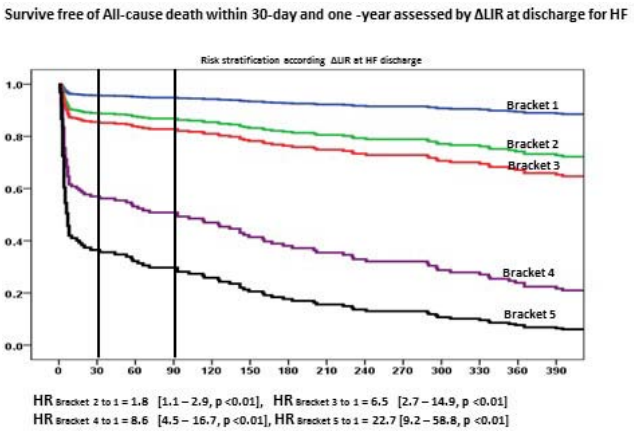
Background: For efficient medical care and comprehensive education in congestive heart failure(CHF) cases, we had begun to use our original clinical pathway(PATH) from August 2015. By introducing PATH, we confirmed clear effects about the shortening of mean hospitalization period and about the prevention against the reduction of daily life independence level (DLIL) during admission even in elderly CHF cases. But in some elderly cases, we still found the reduction of their DLIL and its influence to clinical course.
Purpose: For prevention against reduction of DLIL, we examined about clinical features in elderly CHF patients whose DLIL had been down during admission.
Methods: We enrolled 225 CHF cases who ware 75 years old or older, admitted in our hospital and introduced PATH from August 2015 to July 2018(mean age 85±5 years old, male/female 107/118). We evaluated their DLIL before admission and at discharge with the scale which was presented by ministry of health, labor and welfare in Japanese government. It was consisted of 4 classes(the bedridden level to the level that one can act alone outdoors). We divided them in two groups, Y-group(20 cases whose DLIL level at discharge was down compared with that before admission) and N-group(205 cases whose DLIL was not changed during admission). In all cases, we investigated patient characteristics before admission, various clinical data on admission and enforcement situation of physical therapy during admission, and examined about their difference between two groups.
Results: The mean age was higher in Y-group(89±5 vs 85±5 years old; p<0.01). But in Y-group and N-group, the prevalence of dementia(58 vs 52%; ns) and the past admission history with CHF(25 vs 22%; ns) was not different. The mean ejection fraction of left ventricle(56±19 vs 53±17%; ns) and mean blood concentration of brain natriuretic peptide on admission(1037±1089 vs 800±648pg/ml; ns) was not different. The mean serum albumin level was lower in Y-group(3.2±0.5 vs 3.5±0.7g/dl; p<0.05). In Y-group and N-group, the starting time of physical therapy after admission was not diiferent(3.0±1.5 vs 3.0±1.4th hospital days; ns). But the starting time of exercise to keep standing positionwith or without the help by physical therapist(4.3±2.1 vs 2.5±1.7th hospital day; p<0.001) and the starting time of walking exercise(13.4±21.7 vs 4.1±3.0th hospital day; p<0.001) ware more late in Y-group. As a result the mean hospitalization period widely prolonged in Y-group(40.2±26.3 vs 15.2±11.0days; p<0.001).
Conclusions: In this study we found that the starting time delay of walking exercise with or without help might cause the reduction of activity level, and furthermore it might affect later walk training in elderly cases with congestive heart failure. It seemed that we should be careful their nutritional condition on admission and make various efforts by physical therapy for early getting out of bed.

P1753

Residual congestion on discharge for Heart Failure assessed by impedance technique predicts 30-day and one-year All-cause death. Results of IMPEDANCE-HF extended trial

M Michael Kleiner Shochat[1]; D Kapustin[2]; M Fudim[3]; M Kazatsker[1]; A Asif[1]; Y Levy[1]; I Kleiner[4]; JM Weinstein[4]; G Panjrath[5]; A Roguin[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]University of Toronto, Internal disease , Toronto, Canada*; *[3]Duke University Medical Center, Cardiology, Durham, United States of America*; *[4]Saroka Medical Center, Cardiology, Beer Sheva, Israel*; *[5]George Washington University School of Medicine and Health Sciences, Cardiology, Washington, United States of America*

The aim of secondary analyses of the IMPEDANCE-HF extended trial was to find out if residual congestion on discharge for HF could predict 30-day and one-year Heart Failure death.
The analysis of IMPEDANCE-HF extended trial was based on the data collected during the index hospitalization for HF. The IMPEDANCE-HF extended trial was a randomized controlled single-blinded trial of HF with reduced LVEF patients. Inclusion criteria were LVEF ≤ 45%, NYHA class II-IV and patients were hospitalized for HF within 12 months (ClinicalTrials.gov NCT01315223). Half of the patients (N=145) were assigned to the active Lung Impedance (LI)-guided treatment arm where clinicians were based therapy on LI level. The other half was assigned to the control arm where LI values were recorded but not conveyed to the clinical treatment team. In the case of hospitalization, LI was recorded in all patients at discharge. The decisions regarding discharge and choice of treatment were at the discretion of the hospital staff .
A non-invasive impedance device was used in this study to assess the lung fluid content. Unlike the existing impedance devices, the present device has the ability to differentiate a true signal from the lungs from the noise signal of surrounding chest wall. Such approach enables to measure a small change in lung fluid content. A method to determine individual "dry" baseline LI (BLI) for each HF patient has been reported. BLI for each patient was used to calculate a new parameter, the LIR= [(current LI/BLI)-1] ×100%, which determinate the degree of pulmonary congestion in time of measurement.
Method. Degree of pulmonary congestion at discharge for HF hospitalization was divided into 5 brackets. (1) LIR= 0 to – 18% - minimal interstitial edema (IE), (2) LIR= - 18.1 to -28% - mild IE, (3) LIR= -28.1 to – 38 – moderate IE, (4) LIR= -38.1 to -48% - severe IE to mild alveolar edema (AE) and (5) LIR < -48.1% - moderate AE.
Results: LI-guided patients were followed for 61.9.4±39.6 months and control patients for 46.7±33.3 months (p<0.01) accounting for 269 and 470 HF hospitalizations, respectively (p<0.01). Sixty-six patients in the LI-guided group and 87 patients in control group died during follow up (p=0.28). Stated differently there were 0.09 and 0.15 deaths per patient×year follow up in the LI-guided and control groups, respectively (p=0.02). Probability of All-cause death within 30-day and one year is presented on figure. Conclusion The degree of pre-discharge pulmonary congestion as assessed by LI is a very robust and reliable predictor for 30-day and one-year All-cause death.



All-cause mortality

Heart failure digital coach: pilot findings of an avatar style application to improve symptoms, self-care and knowledge of heart failure

G Georgios Zisis[1]; MJ Carrington[1]; J Ball[1]; T Marwick[1]
[1]Baker IDI Heart and Diabetes Institute, Melbourne, Australia

Introduction Heart Failure (HF) is a clinical syndrome that affects 26 million individuals globally. It has high rates of hospital admissions, readmissions, mortality and morbidity. Effective patient education and self-care can reduce and improve the adverse effects of HF. The use of artificial intelligence to provide education with avatar figures has been previously shown to provide promising results in patients with chronic disease and could be a powerful tool in patient engagement.
Purpose This project aimed to develop and conduct a pilot experiment of a digital coaching program for patients with HF (HF-Digital Coach) for improving quality of life (QoL) and symptoms, self-care behaviours and knowledge for HF.

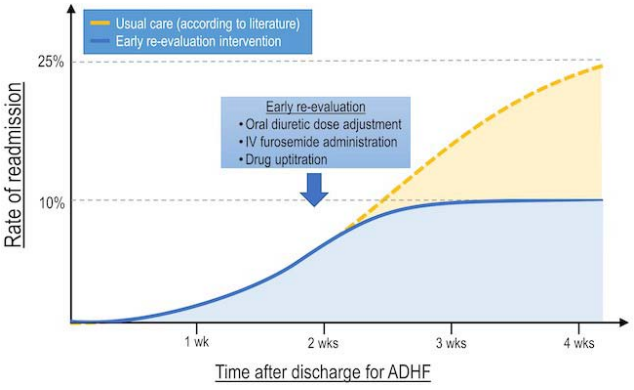
Methods Recently discharged HF patients living in the community and aged 75 years and over were invited to participate. Digital devices were provided to participants who did not have access to one. The HF-Digital Coach was made up of 10 sessions completed over approximately 8 weeks. Changes at the completion of the program in patients' self-care behaviours, health related QoL and knowledge of HF were analysed. Self-report questionnaires regarding QoL were assessed within the app at both the beginning and end of the program via the Kansas City Cardiomyopathy Questionnaire (KCCQ), self-care via the European Heart Failure Self-Care Behaviours Scale (EHFSCBS) and knowledge about HF via the Dutch Heart Failure Knowledge Scale (DHFKS). Daily weight recording, education, tailored management and guidance, to-do ("homework") tasks and goal setting assignments were key program features.
Results Overall 21 enrolled participants completed both baseline and the 8 weeks follow up program. Improvements in HF knowledge (13 of 21), self-care (12 of 21) and QoL (13 of 21) were observed for more than half of participants. The median of differences between pre and post scores showed no statistically significant change for overall QoL (median 68.2 [interquartile range 32.7-85.0] vs. 66.3 [44.0–78.8]; p=.702), self-care behaviours (72.2 [58.3-87.5] vs. 66.7 [54.2-90.3]; p=.834) or knowledge about HF (12 [10-13] vs. 12 [11-13];p=.052).
Conclusion Our preliminary study of a HF Digital Coach indicated improvements in QoL, self-care behaviours and knowledge for HF in a small sample of HF patients. Patient education about HF using avatar figures holds promise for improving longer term health outcomes and reducing costly hospital readmissions. However, more extensive testing and validation in larger clinical trials is required.

P1755

Early reevaluation after acute heart failure: experience from a dedicated clinic

G Cunha[1]; B Rocha[1]; R Ventura Gomes[2]; R Morais[3]; S Quintao[3]; C Bastos[3]; J Campos[3]; I Araujo[3]; C Fonseca[3]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; *[2]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal*; *[3]Hospital São Francisco Xavier, CHLO, Clínica de Insuficiência Cardíaca, Lisbon, Portugal*

Background Heart failure (HF) is an increasingly prevalent syndrome with a 30-day re-hospitalization rate of approximately 25%. Indeed, after a 1st hospitalization, patients are at increased risk for early readmission, the so-called vulnerable phase. Early reevaluation is recommended by the ESC guidelines in order to reduce HF readmissions. However, evidence supporting its benefits is yet scarce. Therefore, we aimed to study the role of such strategy as per our HF Management Program.
Methods This was a single-center retrospective cohort study enrolling patients with acute decompensated HF patients consecutively admitted to our HF Clinic from January to September 2018.
Results Of the 138 patients, 53,6% were male, with a mean age of 77 ± 12 years. Reduced, mid-range and preserved ejection fraction was observed in 45,3%, 6,6% and 48,2% of the cases, respectively, and HF etiology was mostly ischemic (35,7%) or hypertensive (31,8%). All were euvolemic at discharge. During hospital stay, 8 (5,8%) patients were transferred and 9 (6,5%) died. Of the remaining 121 patients, 94 (79,0%) were referred to our early reevaluation HF Management Program. Eight (8,5%) patients missed this appointment and were excluded from further analysis. When assessing the remaining 86 patients, mean time to day Hospital re-evaluation was 14 ± 7 days. On the first appointment, 32 (37,2%) were congestive, of which



Re-evaluation after discharge for ADHF

16 (50%) received intravenous furosemide. Their mean weight gain from discharge to evaluation appointment was 2,6 ± 2,2Kg. Patients were again compensated after a median time of 15 ± 21 days and 2 ± 2 appointments, with a 50% median oral furosemide dose increase, i.e., 40 ± 40mg compared to the previous dose. Their rate of HF readmission at 30-days was 9,4% (3 patients). No clinical or demographic predictors of decompensation were found.
Conclusions More than one-third of recently discharged HF patients were congestive at early reevaluation, of which roughly half needed IV diuretics for compensation before definite oral dose readjustment. These findings emphasize the importance of early post discharge reevaluation for adequate HF stabilization during the vulnerable phase, thus potentially reducing re-hospitalizations.

P1757

The relation between inflammatory biomarkers, persistent congestion and kidney dysfunction in acute heart failure with reduced ejection fraction: a prognosis study.

N Pugliese[1]; I Fabiani[1]; L Conte[1]; L Nesi[1]; A Christou[1]; A D'agostino[1]; R Pedrinelli[1]; S Masi[1]; A Natali[1]; PC Colombo[2]; FL Dini[1]
[1]Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy; *[2]Columbia University Medical Center, New York, United States of America*

Funding Acknowledgements: No fundings

Background. Kidney dysfunction (KD) and persistent congestion influence heart failure (HF) prognosis, but the role of inflammation in this association is unknown.
Objectives. We assessed the relation between inflammatory biomarkers, persistent congestion and KD in patients with acute HF.
Methods. We enrolled 97 hospitalized patients (mean age: 66 ± 12 years, ejection fraction: 30±8%) with acute HF. Before discharge, congestion was assessed using HF scoring system based on Framingham criteria. Circulating levels of high-sensitivity C-reactive protein, transforming growth factor (TGF) beta-1, interleukin (IL) IL-1, IL-6, IL-10, tumour necrosis factor (TNF) alpha, soluble TNF receptor type 1 and 2 (sTNFR-1 and sTNFR-2) were measured. Patients were divided into four groups according to the presence of KD (estimated glomerular filtration rate <60 ml/min/1.73m2) and congestion (Framingham HF score ≥2). We considered a composite end-point: death and rehospitalisation for acute HF.
Results. During a median follow-up of 32 months, 37 patients died, and 14 were rehospitalized for acute HF. Patients with KD and Framingham HF score ≥2 had the poorest event-free survival compared to the groups with only KD or only persistent congestion or neither KD nor congestion (log-rank: 32.14, p<0.0001; Figure 1). Patients with KD and congestion had significantly higher TNF-alpha (p=0.037), sTNFR-1 (p=0.0042) and sTNFR-2 (p=0.001), lower TGF beta-1 (p=0.02) levels, and the worst outcome (p<0.0001). Cox regression analysis indicated KD (p=0.02), Framingham HF score ≥2 (p=0.01), NT-proBNP (p=0.002) and TNF-alpha (p=0.004) were independent predictors of the composite end-point. TNF-alpha attenuated the direct relation between KD, congestion and outcome, explaining 40% of the difference in the outcome between the groups.
Conclusion. KD and congestion at discharge portended a worse prognosis in acute HF. TNF-alpha turned out to be a causal mediator of this relationship.

Funding Acknowledgements: Victorian Cardiac Clinical Network

Introduction: Heart failure (HF) is one of the most prevalent forms of chronic cardiovascular disease. It is amongst the greatest contributors to the ongoing rise in health-care costs, and recognized as a potentially avoidable hospitalization. There is a need for better models of care which can address current health care gaps.
Aim: To design and implement a model of care for HF patients admitted to a tertiary institution to maximize time patients with HF spend in the community.
Method: An integrated patient-centred model of care was designed incorporating particular components of healthcare shown to be effective in HF patients, including an electronic HF care bundle comprising guideline mandated care, a patient education pack on self-management, referral to the Hospital Admissions Risk Program (HARP) for a structured phone call within 72 hours followed by home visit if required, and a nurse-pharmacist early follow up clinic. The model of care was co-designed with key stakeholders including specialist health professionals, the National Heart Foundation and patients. The model was introduced as a quality improvement initiative to general cardiology and general medicine units, and was targeted at reducing variation in care that HF patients receive. Hospital administrative datasets and Victorian Cardiac Outcomes Registry HF Snapshot data were used. Interrupted time series analysis was performed to determine the impact of the intervention.
Results: Outcomes for patients discharged from cardiology and general medicine with a primary diagnosis of HF were compared 19 months prior to and 19 months after the introduction of the model of care. 30-day readmissions reduced but not significantly (19.5% to 17.4%, p=0.471), 90-day readmissions were significantly reduced (34.3% to 30.6%, p=0.017), emergency department presentations at 30 days were reduced but not significantly (20.2% to 17.4%, p=0.17) and at 90 days were significantly reduced (35.0% to 31.4%, p=0.019). In-patient mortality was unchanged (6.8% to 7.0%, p=0.109), and length of stay was unchanged (5.9 to 6.1 days, p=0.109). Administrative data dating from 2013 suggests the quality improvement project corrected a trend towards rising HF readmissions in the 18 months prior to its introduction.
Conclusion: Introduction of an integrated, patient-centred model of care showed no statistically significant effect on 30 day readmissions or ED presentations, but significantly reduced both at 90 days, with no change in in-patient mortality or length of stay. This model of care helped to increase the time HF patients spend in the community.

P1759

The care pathway prior to hospitalisation with acute decompensated heart failure: a comparison between two healthcare systems

J Joseph Mccambridge[1]; C Keane[1]; M Walshe[1]; P Campbell[1]; J Heyes[2]; PR Kalra[2]; MR Cowie[3]; JP Riley[3]; R O' Hanlon[1]; M Ledwidge[1]; J Gallagher[1]; K Mcdonald[1]

Funding Acknowledgements: Enterprise Ireland, Boston Scientific, ResMed

Introduction: A comprehensive analysis of the clinical care pathway in acute heart failure (HF) leading up to hospitalisation is needed to form a thorough understanding of this time period and improve HF care.
Purpose: To analyse the management of patients in the community and the patient experience during the symptomatic period prior to admission with acute decompensated heart failure (ADHF).
Methods: This analysis is from a prospective two-centre, two-country observational study evaluating care pathways in patients who had an unplanned admission with ADHF. Data were gathered via medical chart reviews and patient questionnaires. Qualitative data were also collected from patients, carers and, via postal questionnaires, general practitioners (GPs).
Results: A total of 114 patients were enrolled from the Irish centre; 57 had a new diagnosis of heart failure (dnHF) and 57 had an established history of HF (eHF). A total of 50 patients were enrolled from the English centre; 16 had dnHF and 34 had eHF. A prolonged symptom duration prior to presentation to hospital was noted with 70% of Irish and 80% of English patients experiencing symptoms for more than 72 hours. There was no significant difference in symptom duration between dnHF and eHF patients in either cohort (p= 0.165 and p= 0.707 respectively). Dyspnoea was the dominant symptom in both cohorts. However, 63% of Irish patients and 47% of English patients did not recognise this as a HF symptom with no significant difference in symptom recognition between dnHF and eHF patients (p= 0.095 and p= 0.955 respectively). More than two thirds of patients in both cohorts sought a medical assessment in the community prior to admission, predominantly at a GP practice. Of the 46% of Irish and 38% of English patients seen exclusively by GPs, the numbers prescribed diuretics or diuretic dose adjustment were low (11% and 16% respectively) and those with eHF were no more likely to receive diuretics than those with dnHF (p= 0.485 and p> 0.999 respectively). Perceived barriers to care highlighted in GP questionnaire responses (46 Irish GPs, 21 English GPs) included lack of access to basic diagnostics, specialist support or up-to-date patient information. A lack of GP comfort in managing HF was noted as a barrier to appropriate care in 49% of Irish GPs and 43% of English GPs.
Conclusion: In both healthcare systems, we noted prolonged symptom duration, lack of patient understanding of symptoms and an inadequate prehospital medical response for patients with emerging clinical deterioration of HF. These problems appeared as commonly in those with an established history of HF as in those with a new diagnosis. Lack of access to basic tests and specialist support, and a low level of GP comfort in managing heart failure were obvious barriers to optimal care. There remains much potential to improve the management of HF prior to hospitalisation or to prevent the need for hospitalisation, even in high income European countries.

Acute Heart Failure - Epidemiology, Prognosis, Outcome

P1761

Cardiogenic shock in intensive medicine care: are the old scores still useful?

H Hugo Miranda[1]; I Milet[2]; N Barros[2]; I Militao[2]; F Esteves[2]
[1]Hospitalar Center Barreiro-Montijo, Lisboa, Portugal; *[2]Hospital Center of Tras-os-Montes and Alto Douro, Intensive Medicine, Vila Real, Portugal*

Introduction: Cardiogenic shock (CS) is a state of critical end-organ hypoperfusion due to primary cardiac dysfunction. Several clinical and biological factors have been used for prognosis assessment. Those factors have been recently regrouped into scores combining independent parameters — the Sleeper, CardShock and IABP-SHOCK II score, which aren't used daily in general ICU.
Objectives: Evaluate usefulness of SOFA, APACHE II and SAPS II scores in predicting the outcome in CS patients (P) and identify the most useful one, if applicable.
Methods: Retrospective analysis of P admitted in our ICU, with confirmed diagnosis of CS, within a period of 5 years. We analyzed common epidemiological variables, evolution during ICU stay, established therapeutics and outcome. wE estimated SOFA, APACHE II and SAPS II score at admission and discharge when applicable.
Results: 90 P were included. Mean age of 69,59 ± 12,23 years, with a predominance of males (56,7%). Admission SOFA of 10,39 ± 3,19. The main cause of CS was non-ischemic, with only 33,3% caused by acute coronary syndromes. 68,9% needed mechanical invasive ventilation in the first 24h, maximum PEEP used of 8,22±2,76. VCPVG was the most used ventilatory mode, with median weaning time of 3 days. PaO2/FiO2 ratio and lactactes at admission of 178,5 and 2,85, respectively. All the P needed aminergic support. Renal replacement therapy was used in 34,4% P. Step-up and step-down in ICU unit in 6,7 and 26,7% of the cases, respectively. Infectious intercurrence (nosocomial infection) in 35,51% cases. Limitation of the therapeutic effort in 42,22% P.
At discharge, P presented median ICU stay of 5 days (hospital stay of 10,5 days) with SOFA, APACHE II and SAPS II of 7.6±5,06, 24,5 and 56,61 ± 19,71, respectively. Hospital mortality of 45,6%.
We found a statistically significant association between outcome and: 1) admission SOFA (p=0,006), 2) APACHE II (p<0,001), 3) SAPS II (p< 0,001). We also point out that after applying a logistic regression only APACHE II (OR: 1,13; IC95%: 1,028-1,253) had relevant prediction power.
Conclusion: In our study, we found that APACHE II was the only score capable of predicting the outcome of our P. It provides an estimate of ICU mortality based on a number of laboratory values and patient signs taking both acute and chronic disease into account.

P1762

The effect of rapid evaluation and treatment units on heart failure readmission rates: a retrospective analysis

R Ganesh[1]; K Favila[1]; P Perry Fisher[1]
[1]Beth Israel Medical Center, New York, United States of America

Introduction: Heart failure affects over 6.5 million Americans with prevalence expected to increase to over 8 million within the next ten years. The hospitalization of an estimated 80–85% of patients with acute heart failure (AHF) largely contributes to

the health related expenses. Under the Affordable Care Act, a hospital's performance is quantified by the excess readmission ratio. The observation unit provides short term management for patients with AHF who do not meet criteria for inpatient admission and may be used to reduce health related expense. This study aims to compare readmission and mortality rates for patients with AHF before and after the initiation of the observation unit in late 2014.
Methods: A retrospective chart review of patients with acute heart failure from 2013-2017 was conducted. From the data, the total number of admissions, 30-day readmissions, and mortality rates for patients admitted for AHF were obtained. Statistical comparison for raw heart failure readmission rates and raw heart failure mortality rates before and after the opening of the observation unit was made using paired t-tests.
Results: The mean readmission rate in 2013-2014 was 1.23 with a standard deviation of 0.127. The mean readmission rate in 2015-2017 was 0.853 with a standard deviation of 0.145. The mean mortality rate in 2013-2014 was 0.67 with a standard deviation of 0.155. The mean mortality rate in 2015-2017 was 0.483 with a standard deviation of 0.151.The t-value for readmission rates was 3.256 (p=0.156). The t-value for mortality rates was 1.338 (p=0.136).
Conclusion: The data supports a statistically significant difference in hospital readmission rates for patients with AHF after the initiation of the observation unit in late 2014. Additionally, there was not a statistically significant difference in mortality rates. The evidence supports observation unit management for patients with AHF can help to reduce readmission rates while not affecting mortality.

P1763
Predictive factors for recovery of left ventricular systolic function in stress cardiomyopathy

Y Kajikawa[1]; M Ikeda[1]; A Ueda[1]; M Hirota[1]
[1]*Fukuyama Medical Center, Fukuyama, Japan*

Introduction Stress cardiomyopathy is a reversible systolic dysfunction of the left ventricle that is characterized by defined wall motion abnormalities in the absence of significant coronary stenosis. It is prevalent among elderly women, and often arises following a physical or emotionally stressful event. Little is known about the prognostic factors affecting the recovery of systolic function.
Objective: The present study aimed to identify factors affecting the recovery of left ventricular systolic function.
Materials and Methods: This retrospective review analyzed the electronic medical records of 41 patients diagnosed with stress cardiomyopathy at our Medical Centre between April 2008 and March 2018.
Results: The median time to the recovery of ejection fraction (EF) was 7.0 days. Demographic and clinical factors were compared between groups with early recovery (≤ 7 days; group E) and late recovery (> 8 days; group L).
Age (75.5 ± 10.7 vs. 73.9 ± 14.6 years), physical stress (89.1% vs. 72.3%), emotional stress (10.6% vs. 27.3%) and in-hospital death (15.8% vs. 9.1%) did not differ significantly between the L and the E groups, respectively. Heart rate and the prevalence of Killip class > 2 heart failure upon admission was higher in the L, than the E group (101.1 ± 24.4 vs. 86.2 ± 24.2 bpm, $p < 0.05$ and 13% vs. 6%, $p < 0.01$), respectively.
Echocardiography revealed significantly lower left ventricular ejection fraction in the L, than the E group (38.4 ± 7.0% vs. 49.6 ± 13.0% $p < 0.001$).
Laboratory findings showed significantly higher C reactive protein (7.67 ± 6.49 vs. 4.90 ± 8.97 mg/dL, $p < 0.05$) and creatinine phosphokinase (556.1 ± 864.3 vs. 127.3 ± 162.2 IU/L, $p < 0.01$) and significantly lower hemoglobin (10.27 ± 2.23 vs. 11.51 ± 1.95 g/dL, $p < 0.05$) and LDL-cholesterol (80.5 ± 26.9 vs. 111.9 ± 41.6 mg/dL, $p < 0.05$) in the L, than in the E group.
Significantly more patients were medicated with warfarin/Directly acting oral anticoagulants (DOACs) (42.1% vs. 18.2%), β-blockers (47.4% vs. 31.8%), catecholamine (42.1% vs. 13.6%) and required non-invasive positive pressure ventilation (NIPPV)(26.3% vs. 0.0%) in the L, than the E group ($p < 0.05$ for all).
Conclusion: Severe cardiac dysfunction at onset and triggering septic or inflammatory disease were seen more commonly in the L group. Although more patients in the L group required warfarin/DOAC, β-blockers, catecholamine and even NIPPV more often than the E group, the prognosis was fairly good for both groups with stress cardiomyopathy.

P1764
Registry of Severe Acute Heart Failure. Impact of Renal Insufficiency for In-Hospital Mortality and Readmissions

MA Quintana Da Silva[1]; D Viveros[1]; J Gimenez[1]; D Bedoya[1]; J Martinez[1]; D Venialgo[1]
[1]*Migone Hospital, Cardiovascular Institute, Asuncion, Paraguay*

Background: There is a great variation of data regarding in-hospital mortality and readmission rate at 60 days in patients with different clinical forms of severe acute heart failure (AHF) who develop acute renal insufficiency (ARI) or aggravate a chronic renal insufficiency (ACRI).
Purpose: To assess rates of in-hospital mortality and readmission at 60 days in patients with severe forms of presentation of AHF, de novo AHF or acute decompensated chronic heart failure (ADCHF), with o without renal insufficiency (RI), stratified by left ventricle ejection fraction (LVEF) ranges.
Methods: From August 2015 to August 2018, patients with diagnosis of severe AHF who required admission to a cardiovascular intensive care unit were consecutively included. Severity of the AHF was validated by the high values of the MEESSI and the GWTG Scores. Cardiorenal insufficiency was defined according to NHLBI recommendations. Forms of AHF were classified into de novo AHF and ADCHF, renal insufficiency was classified into ARI or ACRI and LVEF was stratified by ranges in accordance with the new guidelines of the ESC. For univariate analysis, the qualitative variables were expressed in percentages and the quantitative variables by means with their standard deviations of 95%. For the bivariate analysis, chi squared was performed for qualitative variables and T test for quantitative variables. Logistic regression was performed for the independent variables.
Results: A total of 305 consecutive patients were evaluated. The mean age was 75 ± 12, 41% women, 42% hypertension, 52% dyslipidemia, 48% obesity, 42% diabetes type II and smoking 31%. De novo AHF were 31% and 70% were classified as ADCHF. RI was present in 37%. Of these, 24% had ARI and 76% had ACRI. The mean EF was 51 ± 15 %; preserved 57%, intermediate 19% and reduced 25%. Overall IH mortality was 7.9% and 60-day readmission rate was 23%. The bivariate analysis showed that the IH mortality was 13.15% in AHF patient who had RI and 4.7% en AHF patients with no RI ($p<0.001$), whereas for 60 day-readmission was 43% in AHF patients with RI and 44.2% in AHF patients without RI (p=NS), ARI was observed as an independent variable of IH mortality in patients with AHF ($p<0.001$), independently of the clinical forms of presentation of AHF and EF ranges. ACRI was observed as an independent variable ($p = 0.002$) for readmissions at 60 days, independently of the clinical forms of presentation of AHF and EF ranges. The multivariate analysis showed that only the presence of ARI remains statistically significant for IH mortality ($p<0.001$); whereas readmission was significantly higher among patients with ACRI ($p = 0.044$).
Conclusion: In patients with severe AHF, the presence of acute renal insufficiency is an independent variable of in-hospital mortality and the presence of acute on chronic renal insufficiency was associated with hospital readmissions at 60 days, in both cases independently of the clinical forms of AHF and EF ranges.

P1765
Impact of COPD on short-term mortality of patients hospitalized for treatment of acute heart failure

I Arosi[1]; A Shahzadi[1]; H Hamdan[1]; S Carruthers[1]; S Asgari[1]; A Sultan[1]
[1]*Royal Albert Edward Infirmary, Cardiology, Wigan, United Kingdom of Great Britain & Northern Ireland*

On behalf of: WWL Cardiac Research Group

Introduction COPD in patients with heart failure is a common clinical condition and associated with poor survival in chronic heart failure. Yet, the effect of COPD on the outcomes of patients with acute heart failure (AHF) is not well established. We evaluated the impact of COPD on in-hospital mortality and short-term mortality of the patients hospitalized with AHF.
Methods We identified patients who were hospitalized with AHF over six-month period. Data was collected from NICOR HF UK database including demographic information, comorbidities and outcomes (re-admission and mortality). We analyzed the characteristics and outcomes of the patients according to baseline COPD status.
Results 124 patients were admitted with AHF over study period in UK district general hospital with catchment area of 320,000 people. 21.7% (27) had history of COPD at the time of hospitalization. Patients with COPD were older (mean age 78.2 vs 76.7), suffered higher heart rate at admission ($p<0.05$) and serum urea ($p<0.05$).
Patients with COPD had significantly higher mortality (44.1% vs 22.6%; p=0.02) within six-months of discharge. Similarly, patients with COPD had significantly higher re-admission rate (63% vs 27.8%; p=0.0008) within six-months of discharge.
Conclusion COPD is an important co-morbidity in patients hospitalized with acute heart failure, and significantly increases their morbidity and mortality. We suggest that this selected high-risk cohort of patients requires appropriate risk stratification, optimised transition of care to community, effective patient education and support to improve outcomes and resource allocation.

P1766
Clinical characteristics and quality of life of patients with atrial fibrillation in the Colombian Heart Failure Registry - RECOLFACA

JUAN Gomez-Mesa[1]; LUIS Echeverria[2]; CLARA Saldarriaga[3]
[1]*Fundación Universitaria Valle del Lili, Cali, Colombia*; [2]*Fundación Cardiovascular de Colombia, Floridablanca, Colombia*; [3]*Clinica Cardio Vid, Medellin, Colombia*

On behalf of: RECOLFACA Investigators

Background: The prevalence of atrial fibrillation (AF) in patients with heart failure (HF) has been reported between 13% and 27%. The explanation for this coexistence has been the presence of common risk factors. The objective of this work is to compare demographic, clinic characteristics and quality of life (QoL) of patients with and without AF in a cohort of HF patients in Colombia.
Methods: RECOLFACA registry collected data prospectively from September 2016 to September 2018, including 2,099 patients from 60 institutions: 416 patients with AF and 1683 patients without AF. Demographic, clinical characteristics and QoL (EQ5D-3L instrument) were evaluated using Chi-Square, Student T and Mann Whitney Tests. Multivariable analysis was performed through logistic regression. Significance difference was defined as 0.05.
Results: The prevalence of AF was 20%. Mean age of patients with AF was 73.87 (10.42), older than patients without AF (p<0.0001). There was no difference in sex. Multivariable analysis demonstrated that AF was associated with higher arterial hypertension (p<0.010), higher depression (p=0.015), lower type 2 diabetes mellitus (p=0.0001) and more proportion of patients in ACC/AHA stage A (p=0.022). On the follow up, AF was associated with higher non-controlled arterial hypertension (p=0.006), higher progression of the disease (p=0.001) and higher arrhythmias (p>0.0001) as factor of decompensated of HF. Mean score of QoL was 74.72 (21.49) on patients with AF and 80.04 (20.92) on patients without AF, where the domains of mobility, self-care, usual activities, and pain/discomfort showed statistically significant difference.
Conclusions: Atrial fibrillation is a common comorbidity in our HF population. AF is related to more uncontrolled arterial hypertension, depression and elderly age. QoL is lower in AF group. Arrhythmias are more frequent as a factor of HF decompensation.

On behalf of: OPTIMIZE COLOMBIA
Funding Acknowledgements: This study was done with the support of Servier

A period of vulnerability is observed after acute heart failure, there is an increased risk of death or rehospitalization , especially during the first 30 days after the initial admission. The OPTIMIZE COLOMBIA PROGRAM was a strategy implemented at hospital discharge that included: education , uptitration of medications , and early initiation of ivabradine to obtain a target heart rate of 60–70 bpm.
Objective: To identify the clinical factors related to the risk of a new event (any hospitalization, emergency room visit, or death) 30 days after the initial admission for acute heart failure and to analyze event-free survival in patients with and without ivabradine.
Methods: prospective cohort study. Correlation between variables was studied using the Chi square test. Event-free survival was calculated using the Kaplan-Meier method. (Statistical significance: $P \leq 0.05$.)
Results: 267 patients with HRrEF who completed the 30-day follow-up were included (67.8% male, mean age 66±14 years, mean LVEF 32%). Ivabradine was used by 42%. The 30-day rate of events was as follows: rehospitalization 3%, emergency room visits 4.1%, death 0.7% (5.6% had more than 1 event). The correlation between the clinical characteristics and the occurrence of a new event is presented in Table 1. The use of ivabradine was the only factor that decreased the risk of a new event (20% with ivabradine vs 52.4% without ivabradine, P = 0.015). Event-free survival was 97.6% with ivabradine vs 90.9% without ivabradine.
Conclusion: Optimization of heart failure treatment with ivabradine during the hospitalization decrease the risk of a new hospitalization, emergency room visit death during the next 30 days of the admission.

Variables related with events
30 days new event (hospitalization , emergency room visit or death)

Factor	Without an event	With an event	p		
n	%	n	%

Gender-related differences in patients with acute heart failure: patient characteristics and clinical outcomes

M Moongmun Anuntasainont[1]; P Sriparn[1]; P Lalitnithi[1]; S Kittiprachakul[1]; C Thimphitthaya[1]; A Trongtorsak[1]; A Ariyachaipanich[1]
[1]King Chulalongkorn Memorial Hospital, Department of Internal Medicine, Bangkok, Thailand

Background: There was some evidence that women benefited less from medical advancement including various cardiovascular diseases. However, there was limited data on gender inequality in patients with acute heart failure (AHF).
Purpose: The aim of this study was to determine the effect of gender on 180-day all-cause mortality or rehospitalisation in patients admitted for AHF.
Methods: This was a prospective cohort study of consecutive patients with a diagnosis of AHF who were admitted at an academic tertiary care hospital from July 2017 to February 2018. The patients had to fulfill Framingham criteria for the diagnosis of AHF. Patient characteristics and 180-day all-cause mortality or rehospitalisation were gathered. Chi-square and multivariate analysis were used for statistical analysis.
Results: Total of 422 patients were screened and 191 patients met inclusion criteria (mean age of 68.4 years, 46.6% female). Women were significantly older (mean age of 72±13 vs. 65±12.8, p<0.001), and had lower prevalence of reduced left ventricular ejection fraction (22.1% vs. 48.9%, p=0.001). On the other hand, men significantly had more coronary artery disease (50% vs. 33%, p=0.025). All-cause mortality or rehospitalisation in 180 days was significantly higher in men (58.8% vs. 41.6%, p=0.021). With multivariate logistic regression analysis, we still found that male gender was an independent risk marker for 180-day all-cause mortality or rehospitalisation (OR 2.0, p=0.018).

Conclusion: Contrast with other cardiovascular conditions previously reported, among patients with AHF, female gender is associated with better clinical outcome.

P1769

Prevalence prognostic impact of diabetes in heart failure with preserved, mid-range and reduced ejection fraction

SY Se Yong Jang[1]; BE Park[1]; YJ Park[1]; MH Bae[1]; JH Lee[1]; DH Yang[1]; HS Park[1]; Y Cho[1]; SC Chae[1]
[1]*Kyungpook National University Hospital, Daegu, Korea (Republic of)*

On behalf of: KorAHF registry investigators
Funding Acknowledgements: Research of Korea Centers for Disease Control and Prevention

Background Diabetes is common comorbid condition in patients with heart failure and worsens the prognosis of the patients. Prevalence and prognostic impact of diabetes on the heart failure patients with preserved (HFpEF), mid-range (HFmrEF) and reduced ejection fraction (HFrEF) is not well known. This study was aimed to investigate the prevalence and clinical impact of diabetes depending on heart failure subtypes of HFpEF, HFmrEF, and HFrEF.
Methods From Korean acute heart failure registry, 5,116 in-hospital survivors were included in the present study. Prevalence and clinical impact of diabetes were evaluated according to the subgroups divided by ejection fraction (EF) <40%, 40-49%, and ≥50%. Composite event of all-cause mortality and hospitalization for heart failure was analyzed as prognosis using Cox proportional hazard model.
Results Among the study population, 25.7% had HFpEF, 16.5% had HFmrEF, and 57.8% had HFpEF. During 1-year follow-up, 50.1% of composite event were observed. Adverse event rates of each subgroup were 17.6%, 15.9%, and 19.1%, which was not significantly different among the three groups (p=0.089). Prevalence of diabetes in HFpEF, HFmrEF, and HFrEF were 33.8%, 38.8%, and 41.5%, respectively (p<0.001). Diabetes was more frequently observed in patients with lower EF. Diabetes was not significantly associated with worse outcome In HFpEF (hazard ratio [HR] 1.215 [0.996-1.482], p=0.055), whereas diabetes was significantly related to worse outcome in HFmrEF (HR 1.332 [1.032-1.718], p=0.027) and HFrEF (HR 1.368 [1.212-1.543], p<0.001). After multivariable adjustment, diabetes remained as an independent risk factor in patients with HFrEF (HR 1.199 [1.054-1.364], p=0.006). However, the relation was weak in HFpEF (HR 1.11 [0.898-1.372], p=0.335) and HFmrEF (HR 1.128 [0.852-1.492], p=0.401).
Conclusions In patients with heart failure, diabetes was more frequently observed as EF decreased. Diabetes was associated with worse clinical outcome especially in patients with HFrEF increasing adverse event risk by 20%, whereas the association was weaker in HFpEF and HFmrEF.

P1770

Clinical characteristics and long-term outcomes of patients with acute decompensated heart failure with mid-range ejection fraction

M Miyuki Ito[1]; H Wada[1]; T Ibe[1]; Y Ugata[1]; K Sakakura[1]; H Fujita[1]; S Momomura[1]
[1]*Jichi Medical University Saitama Medical Center, Cardiology, Saitama, Japan*

Background/Introduction: Patients with HF have been categorized to HFrEF and HFpEF. There were distinct differences in demography, etiology, comorbidities and response to therapies between HFrEF and HFpEF. In HFrEF, most of previous reports included patients with LVEF <35% to <40%. However, in HFpEF, various cutoffs of LVEF were used in previous studies (LVEF >40% to >50%). Consequently, patients with a LVEF in the range of 40-49% is considered "grey area". Recently, the clinical guidelines categorized patients with LVEF in the range of 40-49% as HF with "mid-range" ejection fraction (HFmrEF).
Purpose: The purpose of this study was to investigate the clinical characteristics and long-term outcomes of HFmrEF patients.
Methods: This was a single-center retrospective observational study. We examined the clinical characteristics and outcomes of consecutive 494 acute decompensated heart failure (ADHF) patients who admitted to our institution between January 2014 and December 2016. They were divided into three groups according to their LVEF: HFrEF (LVEF < 40%), HFmrEF (LVEF 40-49%), and HFpEF (LVEF ≥ 50%). The primary endpoint of this study was the composite of cardiovascular death and HF readmission.
Results: Of this population, 282 (57.1%), 75 (15.2%) and 137 (48.6%) patients were HFrEF, HFmrEF and HFpEF, respectively. Ischemic heart disease was the primary etiology in HFmrEF and HFrEF. At the time of discharge, beta-blockers and renin-angiotensin system inhibitors (RASI) were more frequently prescribed in HFmrEF than HFpEF. The composite outcome of cardiovascular mortality and HF readmission was significantly lower in HFmrEF than HFrEF.
Conclusions: The prevalence of ischemic etiology in HFmrEF was higher than HFpEF. The cardiovascular prognosis of HFmrEF was better compared with HFrEF. Further studies are needed to determine the effectiveness of management of coronary artery disease and cardioprotective medications for HFmrEF.

Association between length of stay and mortality or readmission in patients with acute heart failure

P Sriparn[1]; M Anuntasainont[1]; C Thimphitthaya[1]; P Lalitnithi[1]; S Kittiprachakul[1]; A Trongtorsak[1]; A Ariyachaipanich[1]
[1]*Chulalongkorn University, Bangkok, Thailand*

Background: Length of stay (LOS) in acute heart failure (AHF) varies between patients as it reflexes the counterbalance of optimising patient's condition and avoiding intra-hospital complication. However, Its prognostic significance has not been well studied.
Purpose: We aim to assess whether LOS associates with short and long term all-cause mortality or readmission in AHF patients.
Methods: We conducted a prospective cohort study of 191 consecutive patients who were discharged with admission diagnosis of AHF between July 2017 and March 2018. The patients were categorised into 3 groups by LOS: short, intermediate and long LOS (duration of admission 1-4, 5-10 and ≥ 11 days, respectively). The outcomes were 30 and 180-day all-cause mortality or readmission rate. Pearson's chi-squared test was used to analyse.
Results: Total of 191 patients(mean age 68.4 years, 46.6% female) were included. Patient's baseline characteristics (age, gender, left ventricular ejection fraction, NYHA classification and co-morbidities) were similar in the 3 groups. The 30-day outcome (all-cause mortality or readmission) was not different between short, intermediate and long LOS group (25.8%, 19% and 21%, respectively; p= 0.637). The 180-day outcome was significantly different with the lowest rate of all-cause mortality or readmission in the intermediate LOS group (56.1%, 38.1% and 58.1%; p=0.047)
Conclusion: Compared to intermediate LOS group, short and long LOS groups have greater risk of 180-day all-cause mortality or readmission. As a consequence, the more proper intra-hospital management should be applied to these 2 groups to improve clinical outcome.

Funding Acknowledgements: Fundación IMSS/Novartis México

Background: We conducted a prospective registry of the Acute Heart Failure (AHF) patients in our Hospital during 2018 and compare with the Euro Heart Failure Survey II (n=3580).
Methods: We included 226 patients with AHF. We compared demographic data, comorbidities and underlying diseases, classification of AHF, use of diagnostic tools, in-hospital treatment and medications at discharge.
Results: The mean age in our Centre was 56+/-15.5 years vs 69.9+/-12.5 years in EHFS II. The male proportion was 75% in México vs 61% in Europe. Ischemic heart disease in Europe was 53.6% vs 39% in México, the rate of dilated cardiomyopathy in Mexico was 30.19% vs 19.3% in EHFS II. The clinical profile of AHF in México vs EHFS-II was ADCHF 87% vs 65.4, Pulmonary edema 11% vs 16.2%, Cardiogenic shock 0% vs 3.9%, Hypertensive AHF 7 % vs 11.4%, Right ventricle failure 5% vs 3.2. Clinical tools during hospitalization included (Mexican versus EHFS II): ECG 100% vs 99.9%, Chest X-ray 95% vs 97.7%, Echocardiogram 99% vs 85%, BNP/NT-proBNP 5% vs 16.3%, angiography 29.3% vs 36.5%, MRI 2.3% vs 0.8%, EP 0.9% vs 1.6%. Treatment during the hospitalization included (México vs. EHFS II): Diuretics 95% vs 92.9%, opioids 0% vs 19.4%, Nitrates 26% vs 38.7%, dobutamine 10.2% vs 15%, dopamine 12% vs 11.3%, levosimendan 10% vs 3.0%, amiodarone 6.6% vs 17.5%. The treatment at discharge is presented in Table I.
Discussion: Mexico exhibit a younger population when compared with Europe. The clinical presentation of AHF is similar in both groups, but the use of nitrates and opioids in Mexico is infrequent, the use of inotropes is a common practice in our Centre despite the lack of patients in Cardiogenic shock. The discharge treatment in both compared groups was very similar.

Table I. Medication at discharge (%)

Drug	México (n=226)	EHFS II (n=3580)
Diuretics	91.76	98.1
Betablockers	82.38	61.4
ACEIs	54.51	71.1
ARBs	26.23	10.4
Aldosterone antagonists	77.87	47.5
Nitrates	11.8	32.9
Calcium channel blockers	5.7	14.6
Digoxin	7.55	31.0
Sacubitril/valsartan	4.4	Not reported
Ivabradine	2.2	Not reported

Association of left atrial enlargement with heart failure and cardiovascular events after acute coronary syndromes

PM Paulo Maia Araujo[1]; S Torres[1]; C Resende[1]; A Nunes[1]; C Sousa[1]; M Campelo[1]; F Macedo[1]; MJ Maciel[1]
[1]Sao Joao Hospital, Cardiology, Porto, Portugal

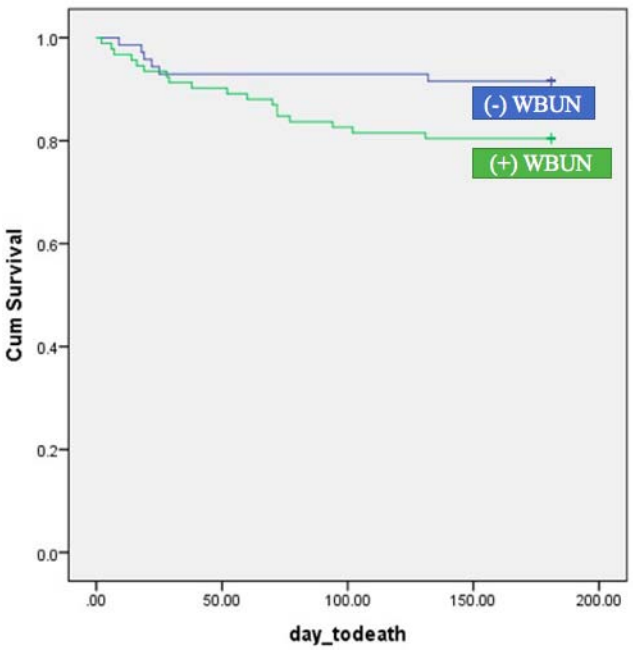
Introduction: Acute coronary syndromes (ACS) are associated with significant morbidity and mortality not only during the acute phase, but also after the event. The occurrence of new major adverse cardiac and cerebrovascular events (MACCE) and heart failure (HF) during follow-up is difficult to predict.
Purpose: Evaluate if the presence of left atrial (LA) enlargement (LAE) in the acute phase of ACS was associated with MACCE and/or HF during follow-up.
Methods: Retrospective evaluation of 92 consecutive pts admitted to our center due to ACS, with a follow up of 2 years. Echocardiographic parameters of diastolic function (performed during the first 48h after admission) and clinical data were evaluated. LAE was defined as a body surface area indexed LA volume (ILAV) > 34 ml/m2. MACCE was defined as the composite of death, ACS, stroke, repeat revascularization (RR) and congestive heart failure requiring hospitalization (CHF) after hospital discharge.
Results: Mean age was 64.6±12.3 years, with a male predominance (73.9%). At the end of follow-up, 44.9% of pts were at NYHA class ≥ 2. These pts had significantly higher ILAV (35.60 vs 29.46 ml/m2; p=0.040) and on univariate analysis, LAE was the only significant predictor of this outcome (OR 4.22; 95% CI 1.67-10.66; p=0.002), while other classic echocardiographic parameters of diastolic function were not (peak E, A and e' wave velocities; E/A and E/e' ratios). During follow-up, MACCE occurred in 18 pts (19.6%): death in 6 (6.5%), ACS in 7 (7.6%), RR in 5 (5.4%) and CHF in 4 (4.3%). LAE was associated with significantly higher risk for MACCE (29.3% vs 6.7%; p=0.006; OR 5.79) and on univariate analysis it was a significant predictor of these events (OR 5.79.; 95% CI 1.50-22.36; p=0.011), with an area under the ROC curve of 0.70 (95% CI 0.56-0.84; p=0.018).
Conclusions: The detection of LAE during the acute phase of ACS was a significant predictor of MACCE and HF during the follow-up, while other parameters of diastolic function weren't capable to do so.

P1775

Prognostic significance of worsening blood urea nitrogen in patients with acute heart failure

P Pakin Lalitnithi[1]; P Sriparn[1]; M Anuntasainont[1]; C Thimphitthaya[1]; S Kittiprachakul[1]; A Trongtorsak[1]; A Ariyachaipanich[1]
[1]King Chulalongkorn Memorial Hospital, Department of Internal Medicine, Bangkok, Thailand

Background: Apart from worsening creatinine (Cr) during hospitalisation with acute heart failure (AHF), Blood urea nitrogen (BUN) is another predictive value of renal impairment which represents the cumulative effect of both kidney function and arterial intravascular volume, including renal perfusion. However, the effect of worsening BUN (WBUN) during hospitalisation on long-term clinical outcome is still less well-established.
Purpose: The aim of this study was to determine the effect of WBUN on 180-day day all-cause mortality after discharge in patient with AHF.
Methods: This was a retrospective cohort of consecutive patients who were diagnosed with acute HF and discharged from an academic tertiary care hospital from July 2017 to March 2018. WBUN was defined by increasing of BUN ≥ 25% from admission value. The 180-day all-cause mortality after discharge was assessed using chi-square, univariate and survival analysis.
Results: Of the 191 patients (52.9% male, mean age 68.5 ±13 years and 35% with left ventricular ejection fraction≥ 40%), the average admission BUN and serum Cr were 31.5 mg/dL and 1.8 mg/dL, respectively. WBUN occurred in 107 patients (56%). The 180-day all-cause mortality rate was higher in WBUN group compared with no WBUN group (19.6% versus 8.5%, p < 0.05). However, worsening renal function (WRF), defined by increased Cr ≥ 0.3 mg/dL or ≥ 25%, was not associated with worse outcome (18.5% versus 12.5%, p > 0.05).



Conclusion: More than half of patients admitted for AHF have WBUN during hospitalisation. This study demonstrates that WBUN, but not WRF, is a prognostic marker on long-term outcome after hospitalised with AHF.

Objective: The purpose of this study was to describe the clinical characteristics and outcomes of the cardiorenal anemia syndrome (CRAS) patients from the Gulf acute heart failure registry (Gulf CARE) stratified by admission diagnosis.

Methods: Data was analyzed from 1,319 consecutive patients admitted to 47 hospitals in 7 Middle Eastern countries with acute heart failure (AHF) from February to November, 2012. CRAS was defined as those AHF patients with eGFR of <60 ml/min and Hb of (<13 g/dL for males or <12 g/dL for females). Analyses were performed using univariate statistics.

Results: The overall mean age of the cohort was 65±14 years, 53% (n=703) were males, 77% (n=1,022) were hypertensives, 67% (n=889) were diabetics and 66% (n=864) had coronary artery disease (CAD). A total of 66% (n=873) had acute decompensated chronic heart failure (ADCHF) while 34% (n=446) has de novo AHF. ADCHF patients were older (66 vs 63 years; p<0.001), associated more with hyperlipidemia (53 vs 41%; p<0.001), CAD (69 vs 58%; p<0.001), hypertension (80 vs 73%; p=0.006), atrial fibrillation (17 vs 8.7%; p<0.001) and lower lower ventricular ejection fraction (36 vs 41%; p<0.001) compared to those with de novo AHF. Those with ADCF were less likely to be associated with mortality at in-hospital (7.8 vs 11.4%; p=0.029) and at 3-month (15.9 vs 20.4%; p=0.042) but not at 12-month follow-up (28.1 vs 27.6%; p=0.852) compared to those with de novo AHF.

Conclusions: CRAS patients in the Middle East were older and associated with significant co-morbidity and increased mortality.

IV	46 (4.2%)	7 (1.3%)	39 (7.2%)	

Results: The overall mean age of the cohort was 65±14 years, 55% (n=649) were males, 78% (n=923) were hypertensives, 67% (n=797) were diabetics, 66% (n=790) had coronary artery disease (CAD) and almost 68% (n=608) had acute decompensated chronic heart failure (ADCHF). A total of 50% (n=601) had LVEF ≤35%. Those patients with LVEF ≤35% were more likely to be associated with males (67 vs 42%; p<0.001), smokers (16 vs 9.9%; p=0.003), CAD (69 vs 64%; p=0.037), in-hospital course of treatment (5.5 vs 2.6%; p=0.010) and ADCHF (75 vs 60%; p<0.001). Those patients with LVEF ≤35% were also more likely to be associated with mortality at in-hospital (10 vs 6.6%; p=0.036), at 3-month (19.5 vs 13.9%; p=0.010) and at 12-month follow-up (30.1 vs 23.9%; p=0.016).
Conclusions: CRAS patients in the Middle East were older and associated with significant co-morbidity. Those with lower LVEF (≤35%) were associated with increased mortality.

P1778
Clinical phenotype and short-term outcome of acute heart failure in patients with mid-range ejection fraction: a prospective cohort study

S Atesler[1]; N Noura Zannad[1]; K Khalife[1]; M Benichou[1]; C Goetz[1]; A Olivier[2]
[1]Regional hospital Center of Metz-Thionville, Cardiology, Metz, France; *[2]University Hospital of Nancy , Nancy, France*

INTRODUCTION: Acute heart failure (AHF) has an unfavourable prognosis in both reduced (HFrEF) and preserved ejection fraction (HFpEF). Current guidelines define heart failure with mid-range ejection fraction (HFmrEF) as a new category to further investigate. Few data are yet available for patients with AHF and mid-range ejection fraction.
PURPOSE : We aimed to define the clinical and biological phenotype, the differences in therapies, the in-hospital management and outcome, and the short-term prognosis of patients hospitalized for AHF with HFmrEF compared to HFrEF and HFpEF.
METHODS: We include prospectively all consecutive patients hospitalized for AHF in our Heart Failure Unit, between February and December 2017. Clinical and biological phenotype, differences in therapies, in-hospital management and outcome of patients with HFmrEF were compared to HFrEF and HFpEF. The primary endpoint was the composite criteria of all- cause death or heart failure related hospitalization 3 months after discharge.
RESULTS: From 245 patients included, 102 (41.6%) had HFrEF, 37 (15.1%) HFmrEF, and 106 (43.3%) HFpEF. HFmrEF resembled HFrEF with more ischemic heart disease (55%), lower body mass index (26.2±5.8 kg/m2) and resembled HFpEF with older subjects (80.0±9.0 years) and more hypertension (70%). We found a decreasing gradient of BNP from HFrEF to HFpEF. First line guideline-directed therapies were similarly increased in all groups. Groups were not significantly different for the primary endpoint with 35.0%, 27.5% and 38.0% for HFrEF, HFmrEF and HFpEF respectively (p=0.49) in univariate analysis and neither for the event-free survival in multivariate analysis (p=0.62). CONCLUSION: HFmrEF patients have a distinct phenotype but a similar adverse short- term prognosis in AHF. Left ventricular ejection fraction solely might be insufficient to assess outcome in AHF. Other variables might be considered.

P1779
Lung injury, a clinical issue among patients with acute heart failure?

IR Lala[1]; DA Darabantiu[1]; A Pop-Moldovan[1]; M Puschita[1]
[1]Vasile Goldis Western University, Cardiology, Arad, Romania

Background: Pulmonary congestion in acute heart failure (AHF) is by far a much more complex phenomenon, beyond that of fluid overload. It has been pointed out the role of inflammation and lung injury that leads to blood-gas barrier dysfunction in cardiogenic pulmonary edema.
Purpose: To evaluate incidence and prognostic implications of lung injury (LI) at admission in AHF patients.
Methods: In this study we have evaluated 114 consecutive patients from our regional heart failure registry, with a primary diagnosis of AHF admitted in the intensive care unit. PaO2/FiO2 ratio was determined to all patients. Patients were divided into two groups: group 1 with a PaO2/FiO2 ratio < 200 mmHg and group 2 with a ratio > 200 mmHg. For statistical analysis we used independent t test for comparison of continuous values, Pearson x^2 test for comparison of categorical values, multivariate logistic regression, survival curves and Cox regression for predictors of in-hospital mortality.
Results: Mean age was 68 ± 58 years and 49% were female regardless of LI development. The percentage of patients with LI was 72%, with a mean of 233±119mmHg. Group 1 was associated with acute pulmonary edema AHF profile (28%, p=0.002) while group 2 was associated with acute decompensated heart failure AHF profile (26%, p=0.001). Patients with cardiogenic shock profile were more frequent seen in group 1 (10% vs 6%, p=0.6) while patients with right heart failure profile were seen more frequent in group 2 (5.3% vs. 4.4%, p=0.5). A PaO2/FiO2 < 200mmHg was correlated with respiratory acidosis (pH=7.3, pCO2=46 mmol/L, p=0.022). Patients with a PaO2/FiO2 < 200 mmHg had a significantly worse survival profile during hospitalization (log-rank test, p<0.045) and Cox proportional hazards modelling showed a crude HR = 1.7 (95%CI [1-3.2], p<0.05) for in-hospital mortality.
Conclusions: There is a high incidence of lung injury within patients admitted for acute heart failure. Patients with acute pulmonary edema are more prone to develop lung injury. A PaO2/FiO2 ratio < 200 mmHg at admission in patients with AHF is responsible for worse in-hospital survival rates. Even though PaO2/FiO2 ratio is used to define acute respiratory distress syndrome among critically ill patients it might also serve as a useful tool in stratifying risk of patients with AHF. Future larger prospective trials are needed.

Complications after implants of cardiac electronic device in acute heart failure

LCSP Luiz Carlos Passos[1]; AGQJ Grimaldi[2]; TM Trindade[2]; TC Silva[2]; WC Neves[2]; AC Guimaraes[2]; EG Lopes[2]; A Seabra[2]; MC Dantas[2]; ILS Santana[2]; DC Monteiro[2]; HM Santos[2]; VO Santos[2]; L Kassia[2]; MV Barreto[2]
[1]Federal University of Bahia, Internal Medicine, Salvador, Brazil; *[2]Ana Nery Hospital, Salvador, Brazil*

On behalf of: EPICO - Estudo para Investigação de Causas Tratáveis e Otimização terapêutica da Insuficiência Cardíaca

BACKGROUND: Acute Heart Failure (AHF) is the most common cause of hospitalization among the elderly in the Unified Health System (SUS) and is associated with high morbidity and mortality rates. In the last decades, Cardiac Resynchronization Therapy (CRT) and Implantable Cardioverter Defibrillators (ICD) are non-pharmacological and adjunctive therapy options that have become increasingly common.The assessment and decision of implantation of cardiac devices may occur in a scheduled outpatient setting or during hospitalization for decompensation of HF.Patients often have a form of severe disease with frequent episodes of AHF and the implant may be related to a good long-term prognosis but may also be related to severe complicationsin the short term.
OBJETIVE: The aim of the study is to describe the complications after implantation of theseelectronic devices of high risk of Acute Heart Failure.
METHODS: A prospective cohort study of patients who were admitted for AHF and implanted some electronic cardiac device (DEIC) from May 2017 at the state center of reference for implantation of devices by the Unified Health System of the state of Bahia.Heart failure (HF) was defined according to the guidelines of the European Society of Cardiology (ESC) and only cases of systolic heart failure, defined as Left Ventricular Ejection Fraction (LVEF) <50% were evaluated. Clinical, laboratory, drug, and other data were collected from medical records.
RESULTS: Were analyzed 65 patients hospitalized to AHF and who needed to perform the implantation of some high cost cardiac electronic device: ICD 78% (51), 6% (4) CRT-P or 15% (10) CRT-D. The mean age was 56 years, 74% (48) males, 15% (10) patients with ischemic heart disease and 46% (30) Chagas' disease. Of these, 37% (24) developed acute renal failure, 6% (4) had hematoma, and 6% (4) had infection. 1.5% (1) developed pneumothorax, 1.5% (1) had electrode displacement followed device explants (4% - 3). The mean time of hospitalization was 15 days and 6.25% (4) patients died in the hospital, and 4.6% (3) patients died within 1 year of discharge.
CONCLUSIONS: These findings suggest that the implantation of these devices during hospitalization for AHF appears to offer additional risks of serious complications such as infection followed by explants and untildeath.

Predictors of in-hospital mortality in patients with acute coronary syndrome in Kosovo

G Gani Bajraktari[1]; E Haliti[1]; A Ahmeti[1]; A Batalli[1]; A Poniku[1]; E Koci[1]; A Ferati[1]; R Leka[1]; E Zhubi[1]; Z Rexhaj[1]; F Zhubi-Bakija[1]; A Leka[1]; F Shatri[1]; H Selmani[1]; S Elezi[1]
[1]University Clinical Centre of Kosova (UCC), Service of Cardiology, Pristina, Kosovo Republic of

Background and Aim: Acute coronary syndrome (ACS) is the major cause of mortality and hospital admissions. The management and outcome of patients with ACS vary in different countries and regions. The in-hospital mortality of these patients declined significantly in developed and developing countries after the introducing of primary percutaneous intervention (PPCI). There are no data regarding mortality and hospital admission of patients with ASC in Kosovo. The objective of this study was to assess possible predictors of in-hospital mortality in patients admitted with ACS.
Methods: This retrospective study included all patients hospitalized for ACS from January 1st, 2014 to December 31st, 2018, at the Clinic of Cardiology of our

University Clinical Center in Kosovo. According to the presenting electrocardiogram, acute myocardial infarction (MI) was categorized as non-ST-segment elevation MI (NSTEMI) and ST-segment elevation MI (STEMI). The in-hospital mortality was defined as the death from the time of the admission till the patient's discharge. **Results:** Among 4667 admitted patients with ACS (mean age 63 ± 12 years, 30% female), according to the final discharged diagnosis, 2982 (64%) patients were identified with STEMI, 1685 (36%) with NSTEMI or unstable angina. Of all ACS patients, 49% underwent diagnostic coronary angiography, 34 0% underwent PPCI, 13 % were referred for coronary artery by-pass graft surgery, and 24 % were transferred to a 24 hours PPCI center. The rest of patients were treated medically. In-hospital mortality in the whole group of patients was 8.4%, whereas in patients that were not transferred to the 24 hours PCI center for PPCI it was 8.9%. The mortality rate was higher in patients that did not underwent reperfusion by PPCI compared to those that underwent (10.6% vs. 4.1%, p<0.001), and even higher in patients that didn't underwent diagnostic coronary arteriography (12.2%). Diabetic patients had higher mortality rate compared to non-diabetic patients (p<0.001), female patients had higher mortality rate compared to male patients (p<0.001) and non-smokers had higher mortality rate compared to smokers (p<0.001). Older age [1.046 (1.025-1.067), p<0.001], low left ventricular ejection fraction [0.962 (0.946-0.978), p<0.001], the presence of STEMI [2.051 (1.295-3.248), p=0.002], high level of creatinine [1.004 (1.002-1.006), p<0.001] and the luck of PPCI intervention [0.338 (0.202-0.566), p<0.001] were independent predictors of in-hospital mortality in ACS patients, in the multivariate analysis. Conclusion: During last five years, the majority of patients with ACS were not treated with PPCI in Kosovo, in whom the in-hospital mortality rate was high. The luck of PPCI intervention, older age, compromised global left ventricular systolic function and renal function are the main predictors of in-hospital mortality in patients with ACS.

P1782

Left ventricular filling pressure as a useful marker of myocardial injury following elective percutaneous coronary intervention

AN Elsheikh[1]; A Elsaid[1]; E Elguindy[1]; A Gafaar[1]
[1]*Tanta University, Cardiology, Tanta, Egypt*

Objectives: We investigated the value of ratio of early transmittal velocity to tissue Doppler mitral annular early diastolic velocity (E/E') in detecting the occurrence of peri-procedural myocardial injury(MI) in patients undergoing elective PCI.
Methods: 62 patients (mean age:56.7±9.7) who undergoing elective PCI and had EF%>50% were recruited prospectively. E/E' ratio was measured immediately before and within 24 hours after PCI.
Results: The cohort consisted of 44(71%) males, 49(27.4%) had ≥ two risk factors for CAD. 30(48.4%) patients had RWMA (WMSI: 0.74±0.29). MI was diagnosed in 39(62.9%) patients, those with predilation showed reduction of E/E' (7.9±3.2 vs 8.9±2.9,P < .001). E/E' correlated negatively with LV EF%(P < .003), positively with CK-MB and cTn level after PCI(P < .0001), NYHA functional class(P < .001), the number of risk factors, and number of vessel diseased and the number of vessels treated with PCI(P < .0001) . Using ROC curve E/E' value ≥6.55 had 68.1% sensitivity and 66.6% specificity to detect MI. Multivariate regression analysis revealed that E/E' and number of stents are predictors of postprocedural MI in elective PCI.
Conclusion: These data suggest that E/E' may be a useful indicator for predicting early MI after successful PCI. Patients with an elevated E/E′ after PCI may need more careful and close follow up.

P1783

Clinical and angiographic Characteristics of coronary artery disease in patients referred to Egyptian cathterization laboratory. A single center study

H Hala Badran[1]; G Soltan[1]; A Shalaby[1]; S Saad[1]
[1]*Menoufiya University, Shebin, Egypt*

Background This Registry collects data from cardiac catheterization laboratories in Our University hospital, as one of Egyptian tertiary centers to provide a perspective on patients referred for diagnostic and/ or percutaneous coronary intervention (PCI) Objectives: This study sought to provide contemporary snapshot of clinical and angiographic characteristics in patients referred to cath lab and disease extent in patients with obstructive CAD.
Methods Data were collected for 12 consecutive months beginning June 2015, and ending June 2016. This report includes 1100 patients undergoing diagnostic cardiac catheterization and /or PCI.
Results: The mean patient age was 57± 8.9 years, 5.4% are below 45 years of age. Men made up 72.6% of the study population, and the proportion of rural area residents was 54.8%. Chronic stable angina was the most common mode of presentation (65.9%). Urgent coronary angiography present in 9.2 % of patients, they referred from CCU with ACS. The most prevalent conventional cardiovascular risk factors were diabetes mellitus (71%), hypertension in 61%, 45.4% had dyslipidemia followed by smoking in 28% and obesity in 20% (an increased body mass index ≥ 30 kg/m2). Radial artery access was used in 1.7% of all referred patients. Angiographically normal coronary arteries were found in 29.5% of patients. 70.5% patients have evident obstructive CAD, 27.4% had prior STEMI. PCI was performed in 11.4% of total population and 16.1% of patients with obstructive CAD 86% using drugs eluting stents and 5.8% were primary. Pre procedural ECHO showed EF mean 57.7±9.1.In obstructive CAD, The most common location of significant atherosclerotic coronary lesions was the left anterior descending artery 64.6% [64.4% were proximal] followed by the right coronary artery in 44% of patients [50% were proximal]. LCX significant obstruction was present in 41% of patients, of them 63% had proximal lesions. Single-vessel disease was identified in 47.1% of patients, two vessel disease was identified in 29.6% and three vessel disease in 23.3% of patients with a positive result of CAG (stenosis > 50%). The mean severity of coronary artery stenosis using gensini score was 19.4±23.2 75.4% in the group with obstructive atherosclerotic coronary disease. By dividing the Gensini score into four quartiles, patients in highest quartile had three or more CV risk factors, older in age, had increased BMI and lower ejection fraction.
Conclusions: In this registry, patients referred to cath lab are predominantly male, diabetes and hypertension were the prevalent risk factors. Single vessel disease and chronic stable angina were the major presentation. The current practice of PCI is essentially elective.

Aim: to evaluate the long-term results of the use of drug-eluting balloon catheters in patients with Left Main (LM) bifurcation stenosis.
Material: the analysis involved 142 patients with true bifurcations of the Left Main. Randomization in 2 main groups: Group I (n=52) included patients, who received kissing- dilatation with traditional NC balloon catheters and Group II (n=52), who had a kissing-dilatation of the main bifurcation artery with a traditional NC balloon catheters, and a side branch - with drug-eluting balloon catheters. In retrospectively, the third (III) control group (n=38) was formed, where the two-stent technique was performed. All patients from main groups had previously performed 'Provisional T' stenting and final 'kissing balloons' dilation technique. Coronary angiography and OCT were performed to evaluate the results of all patients. Inclusion criteria: true LM bifurcation stenoses according to QCA and OCT; SYNTAXscore <32. Primary endpoints: incidence of MACE - death, MI, re-interventions. Secondary endpoints: the incidence of restenosis and late stent thrombosis.
after 24 months the total incidence of MACE were 11.5 vs. 3.8% in groups I and II respectively (p<0.05). When comparing the results in group II and III, the frequency of MACE was 3.8 vs. 13.2%, respectively (p<0.05). Restenosis of the side branch of more than 50% according to QCA was detected in 4 patients (7.7%) from group I and in 1 patients (1.9%) from group II (p<0.05). In patients from group I, the average MLA in the side branch after 24 months was 5.58±1.34 and 4.12±1.21 mm2, respectively (p<0.05), compared with data after PCI; in the main branch - 6.34±1.56 and 5.88±1.14 mm2, respectively (p>0.05). In patients from Group II, the average MLA were, respectively, 5.38±1.24 and 5.12±1.44 mm2 in side branch (p>0.05) and 6.68±1.75 and 6.36±1.22 mm2 in main branch (p>0.05). When comparing the data of MLA in the side branch in groups I and II, there was a significant difference (4.12±1.21 vs. 5.12±1.44 mm2; p<0.05). There were no cases of late thrombosis of the stents.
Conclusion: the use of dug-eluting balloon catheters for the 'Provisional T' stenting in patients with true LM bifurcation stenoses, associated with significantly lower frequency of MACE and side branch restenosis, according to OCT data, compared with patients who used traditional NC balloon catheters for 'kissing- dilatation' and two-stent technique strategy.

P1785

Intraaortic balloon support for myocardial infarction with cardiogenic shock

E Elmir Omerovic[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

Background: Cardiogenic shock (CS) remains the leading cause of in-hospital death in acute myocardial infarction (MI) and is associated with a mortality rate of ˜50%. Intraaortic balloon support (IABP) was class I ESC guideline recommendation for treatment of CS for many years, but this recommendation was changed to class III after the IABP-SHOCK II study. The aim of this large prospective observational

study was to evaluate the impact of IABP on 30-days mortality and in-hospital complications in patients with CS.
Methods: We used data from the Swedish Coronary Angiography and Angioplasty Registry (SCAAR), which contains information about all PCI procedures performed in Sweden (31 hospitals). We included all procedures from 2005 to 2018 in patients with CS due to MI and divided the patients according to whether or not they were treated with IABP. We used instrumental variable analysis to adjust for differences in patient characteristics and hidden bias. Treating hospital was used as a treatment-preference instrumental variable using two-stage least squares regression. Multilevel modeling was used to adjust for clustering of observations in a hierarchical database. In-hospital complication was defined as the occurrence of any of the following events: major bleeding, minor bleeding, extended compression of the access artery, blood transfusion, surgical revision of the access artery, neurologic complication.
Results: In total, 2,991 patients with CS were included in the study. Of these, 737 (25%) were treated with IABP. In the combined cohort, there were 1,554 (52%) deaths 30 days after PCI and 1,239 (41%) cases of in-hospital complications. IABP was not associated with death at 30 days (risk reduction [RR] -1.1 %; 95% confidence interval [CI] -15.7;13.5; P= 0.881). However, IABP was associated with a higher risk of in-hospital complications (RR 35.4%; 95% CI 17.7-53.1; P<0.001). Conclusion: In this observational study, treatment with IABP, was not associated with 30-days mortality in patients with CS. However, the risk of in-hospital complications was substantially higher in patients with CS who were treated with IABP. Our observational study supports class III recommendation by the current ESC guidelines for the use of IABP in CS.

Aim: to evaluate the prognosis of patients with chronic ischemic heart disease, who underwent percutaneous coronary interventions (PCI) and were only on optimal medical therapy (OMT).
Methods: measurement of the fractional flow reserve (FFR) was performed for 432 patients. According to the measurement results, all patients were randomized in 2 groups (1:2): Group I (n=168) – included patients, who had a FFR <0.8 and were followed by PCI; Group II (n=264) – included patients with FFR >0.8 - received OMT and were under monitoring for to 5 years. Inclusion criteria: stable angina II-III FK, post-MI, silent myocardial ischemia. Concomitant diseases: diabetes mellitus (19.2%), multifocal atherosclerosis (21%), hypertension (27%), post-MI (24%), PCI in previously (15%). According to angiography, 44% had a one-vessel disease, 35% had two-vessel diseases, and 21% had a three-vessel disease. Primary endpoints: MACE (death, MI, repeated interventions). Observation periods: 6, 12, 24, 36, 48, 60 months. Long-term results were evaluated by repeated coronary angiography and measurement of FFR.
Results: during 6 and 12 months there were not a single case of MACE in both groups. By the 18th month, 7% of cases conversion from the OMT to the PCI group on the basis of FFR measurements was recorded. By the 24th and 36th months in the OMT, PCI group was performed in 12 and 21% of patients, respectively. By the 48th and 60th month, the number of such patients was 24 and 31%, respectively. Among the total number of performed PCI in Group II, 20% of them were due to unstable angina. Thus, over the entire observation period, 149 patients from group II (56%) had PCI performed. The frequency of MACE in group I to 36 months was 2.4%, and in group II - 18%, respectively (p <0.001). By the end of the observation period, the frequency of MACE in groups I and II was 4.2 and 31%, respectively (p <0.001). Multifactor analysis showed that with SYNTAX score> 28, multifocal atherosclerosis, diabetes mellitus, MACE was significantly more frequent and there was a need to perform PCI in the long-term period.
Conclusions: the prognosis of patients with chronic coronary artery disease undergoing percutaneous coronary intervention, performed using measurement of FFR, is significantly better than in patients who were only on optimal medical therapy.

Background In acute coronary syndrome (ACS) related cardiogenic shock (CS) urgent coronary angiography is essential. The aim was to investigate the association of angiographic results with 90-day mortality in CS patients.
Methods This CardShock (NCT0137486) substudy included 158 patients with ACS aetiology and data on coronary angiography. Survival analysis was conducted with Kaplan-Meier curves and Cox regression analysis.
Results Median age was 67±11 years and 121 (77%) were men. During the 90-day follow-up 66 (42%) patients died. Patients with one-vessel disease (n=49) had lower mortality than patients with two- (n=59) or three-vessel (n=50) disease (25% vs. 48% vs. 52%, p=0.011, Figure A). Successful revascularization (post-procedural TIMI grade 3 flow) was achieved more often in survivors than non-survivors (81% vs. 60%, p=0.019, Figure B). Median symptom-to-balloon time was similar between survivors and non-survivors (335 [210-641] min vs. 340 [190-660] min, p=0.70). In multivariable mortality analysis, the CardShock risk score (HR 1.76, CI 1.45-2.13), multivessel disease (HR 2.24, CI 1.13-4.44) and post-procedural TIMI < 3 (HR 1.85, CI 1.08-3.16) were associated with 90-day mortality.
Conclusion Multivessel disease is associated with worse survival in ACS-related CS. Successful revascularization of the IRA had a positive effect on outcome despite delay from symptom onset.

Aim: to increase the effectiveness of endovascular treatment in patients with ostium coronary artery lesions.
Methods: 150 patients were included in the study. Inclusion criteria: ostium atherosclerotic lesions of LAD or LCx > 75% according to OCT or IVUS; stable angina II-III functional class (CCS); silent myocardial ischemia. The main included 108 patients, who were randomized into 2 groups. In I group (n=54) according to IVUS, atherosclerotic plaque spread from the ostium of LAD and/or LCx to the LMCA, and in group II (n = 54) - the plaque did not spread into the LMCA. In Group I all patients were initially treated with 'Provisional T' stenting of the LMCA, and in Group II - stenting of the ostium LAD or LCx. In retrospectively, the third (III) control group (n=42) was formed, where the stenting of the ostium of LAD or LCx was performed without IVUS.
Results: There were no complications associated with PCI in long-term period results (over a period 30.04±12.04 months). The survival was 100% in all groups. There was no conversion to complete bifurcation stenting. In comparative analysis of Group I and II there were non significant differences of MACE's and restenosis (2.3 and 7.5% respectively; p>0,05). In group III (without IVUS and OCT) where 18 patients with precision stenting and 22 with Provisional T stenting. There were significant difference for frequency of restenosis in this group (9 and 27.7%

respectively; p<0,05). In comparative analysis of Group I and III (n= 22 doing the Provisional T stenting) there were more frequency of restenosis in group III, but this data wasn't significant difference (0 and 9% respectively p>0,05). However, in comparative analysis of Group II and III (doing the precision stenting) there were significant difference of frequency of restenosis and TLR (2.5 and 22.2% respectively; p<0,05). The data of Minimal lumen area (MLA) in long-term period has significant difference in patients with precision ostium stenting compared to MLA data after PCI (LCx 5.38 vs 4.76 mm2; p<0,05 and LAD 6.28 vs 5.88 mm2; p<0,05). And the results of measuring the LAD and LCx after doing the provisional T stenting in long term period and after PCI were not valuable (p<0,05). Conclusion: the use of intravascular imaging methods for the analysis of the ostium lesions of coronary artery allows us to choose the optimal stenting technique and also reliably improve the long-term results of endovascular intervention by reducing the incidence of stent restenosis and MACE.

P1789

SCAD (Spontaneous coronary artery dissection)- United Kingdom (UK) data an observation study of PSCAD (Pregnancy/Post partum associated SCAD) vs. Non PSCAD (Non- Pregnancy/Post partum associated SCAD)

N Natarajan[1]; DA Adlam[1]
[1]Cardiovascular Research Unit of Leicester, Leicester, United Kingdom of Great Britain & Northern Ireland

Funding Acknowledgements: The British Heart Foundation, The NIHR rare disease translational collaboration, The Leicester NIHR Biomedical Research Unit and BeatSCAD

Spontaneous coronary artery dissection (SCAD) is a devastating condition, which affects predominantly young females. It has been associated with Pregnancy and post partum. It is a non-inflammatory, non-atherosclerotic cause of acute myocardial infarction. It can result in significant morbidities such as ventricular arrhythmias, sudden cardiac death and left ventricular systolic dysfunction (LVSD).
The purpose of this study was to compare PSCAD vs. non-PSCAD cohorts to see if there were any substantial differences. UK (United Kingdom) data for SCAD was reviewed from 01/01/2007 to 01/10/2017. Pregnancy and post partum associated SCADs were analysed. Post Partum was defined to be up to 1 year after pregnancy. 24 PSCAD were identified which were randomly matched by age in a 2:1 Ratio. In total 72 SCAD's were selected. 2 patients were withdrawn after the angiograms were reviewed (24 PSCAD and 46 non PSCAD). Data was reviewed using the national registry and SCAD experts reviewed angiograms for all patients.
Mean age for the entire cohort was 35.35. In the PSCAD cohort 62.50% presented as a STEMI (ST elevation Myocardial infarction) with 45.83% having ECG changes in the anterior leads. Compared to non-PSCAD cohort 58.70% presented as a STEMI with 41.30% having ECG changes in the anterior leads. In the PSCAD cohort 33.33% affected the LMS (Left main stem), 20.83% affected the RCA (Right coronary artery), 70.83% affected the LAD (left anterior descending), 29.17% affected LCX (left circumflex artery) and 41.67% affected more than one vessel affected. In 29.17% of cases percutaneous coronary intervention (PCI) was undertaken and 8.33% cases required a coronary artery bypass graft (CABG). In the non-PSCAD group 10.86% affected the LMS, 10.86% affected the RCA, 76.09% affected the LAD, 13.04 % affected LCX and 4.35% affected more than one vessel. 28.26% underwent PCI with 10.87% cases requiring CABG.
Heart failure was reviewed in both cohorts with Echocardiogram or Magnetic resonance imaging (MRI) reviewed at least 3 months after the event. In the PSCAD group 50 % had normal LVSD, 20.83% with mild LVSD, 16.67 with moderate LVSD, 4.17 % with severe LVSD and in 8.33% data was not available. In non-PSCAD group 54.35% had normal LVSD, 19.57% had mild LVSD, 10.87% had moderate, 0 % had severe LVSD and in 15.22% data was not available.
In both sub groups the commonest vessel affected was the LAD. However, the PSCAD group had a higher number of LMS and multi vessel cases of SCAD's. This highlights that this cohort has a more severe form of SCAD. From a heart failure perspective in both subgroups at least half the patients regained normal LV function.

P1790

VEGF-A gene polymorphism and VEGF-A level association with the development of heart failure in patients with ST-elevation myocardial infarction

I Iulia Rodionova[1]; I N Kutya[1]; MP Kopytsya[1]; YJ Samburg[2]; NV Tytarenko[1]; BA Shelest[3]
[1]L.T.Malaya Institute of Therapy, Kharkiv, Ukraine; [2]Kharkiv National Academy of Postgraduate Education, Kharkiv, Ukraine; [3]Kharkiv National Medical University, Kharkiv, Ukraine

The purpose of the study was to assess the predictive value of Vascular endothelial growth factor A (VEGF-A) in associated with in cardiac remodeling and exercise capacity of the VEGF-A gene polymorphism (rs 2010963) with the development of heart failure in patients with ST-Elevation Myocardial Infarction (STEMI) in a 6-month period.
Materials and methods: 91 patients with acute STEMI were examined, 70 (76.9%) males, mean age - 59.21 ± 8.92. The level of the VEGF-A determined by ELISA. VEGF-A gene polymorphism (rs 2010963) assessed by polymerase chain reaction. All patients tested with a 6-minute walking test (6MWT).
Results. Carriers of the genotype GG have a significantly higher level of VEGF-A - 194.10 [115.02-398.86] pg / ml compared to the GC genotype with 148.44 [68.84-221.28] pg / ml, (P = 0.047). The frequency of STEMI was 2.58 times higher in the GC genotype. The 6MWT was 477.35 ± 73.34 m in the GC type, meanwhile, the GG genotype resulted in 545.44 ± 51.09 m (P = 0.014). The ROC analysis determined the cut-off level of VEGF-A ≤ 199.5 pg / ml, as a predictor for left ventricle (LV) remodelling and for poor exercise capacity with a sensitivity of 77.4% and a specificity of 63.3% (AUC 0.654, 95% CI 0.513-0.795, p = 0.032).
Conclusions: The GC genotype in patients with STEMI is associated with more pronounced changes in the LV geometry and poor exercise capacity. The VEGF-A can be suggested as possible predictor for heart failure development in STEMI patients.

P1791

The biomarker gdf 15 in a 5-year prediction of adverse outcomes in patients with acute coronary syndrome

IR Vyshnevska[1]; MP Kopytsya[1]
[1]Government institution"L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine

The search for an optimal biomarker that can significantly predict long-term prognosis in patients with an acute coronary syndrome (ACS) is still going. Growth differentiation factor 15 (GDF 15) is being actively studied.
Purpose: to determine the significance of GDF 15 in the prediction of 5-years adverse outcomes after acute coronary syndrome.
Methods: The study included 70 patients with different forms of ACS. The mean age was 61.8 ± 1.3 years (77% men and 23% women). They were admitted to the hospital from 2012 to 2013 and signed the informed consent. Among them, 54% of the patients with Q-wave myocardial infarction (Q-wave MI), 20% - with non-Q-wave myocardial infarction (non-Q-wave MI), 26% - unstable angina (UA). All patients underwent a baseline investigation which includes: standard electrocardiography, echocardiography, angiography, and determination of marker of myocardial necrosis – cardiac troponin I. In addition to that, the level of GDF 15 determined during the first day of hospitalization. The endpoint considered as all-cause mortality. 20% of patients died during 5-years follow-up. Long-term survival rates were calculated using the Kaplan-Meier method and compared using the log-rank test.
Results: There was a significant difference in GDF 15 serum level between patients who have died and those, who have survived during 5 years after ACS (p=0.0015). The effect of several variables of clinical, instrumental and laboratory status assessed on surviving patients. For the identification of the main risk factors for adverse outcome, we have used logistic regression (LR) method. We have found that GDF 15 (AUC 0.7; p=0.006; 95% CI: 0.552 – 0.814) could independently predict mortality with sensitivity 80% and specificity 60%. GDF-15 < 2350 pg/ml associated with the highest mortality risk. Unadjusted long-term survival is presented as Kaplan-Meier curves, displaying differences in GDF 15 level between patients who survived and those who died (log-rank p = 0.0097 for trend). It was found that the level of GDF 15 significantly predicted the onset of the primary endpoint within 5 years after the ACS (T1 = 12.4 T2 = 8.6; F = 3.36; p = 0.004).
Conclusion: the biomarker GDF 15 is a strong and crucial predictor of 5-years mortality in patients with acute coronary syndrome. The measuring of this biomarker could be used in clinical practice to improve risk stratification during the first 24 hours after the event.

P1792

Role of novel biomarkers of renal injury in patients with st segment elevation myocardial infarction

IR Vyshnevska[1]; MP Kopytsya[1]; YV Hilova[1]; OV Petyunina[1]
[1]Government institution"L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine

Acute deterioration of renal function in patients with ST-segment elevation myocardial infarction (STEMI) is a crucial issue nowadays because it worsens the prognosis. The search for new biomarkers is going on to prevent the acute worsening of kidney functions. One of the promising of biomarker is the soluble ST2 (sST2).
Purpose: to determine the role of soluble ST2 in the prognosis of acute deterioration of renal function in ST-segment elevation myocardial infarction patients.

Methods: 103 STEMI patients with a mean age of 61.85 ± 12.23 years were enrolled to this study (72.8% male and 27.2% female). All patients had to undergo baseline investigations, including the: standard electrocardiography, echocardiography, angiography, determination of marker of myocardial necrosis – cardiac troponin I and level of serum creatinine; the glomerular filtration rate (GFR) was estimated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula. Accordingly, to the result, a group of patients has been selected (n= 59), their creatinine level was determined during the first 24 hours and after 48 hours of admission. The clinical evaluation, N-terminal pro-brain natriuretic peptide (NT-pro BNP) and sST2 serum levels were estimated once during the first day after STEMI.
Results. Receiver operating characteristic curve (ROC) for baseline showed that the optimal cut-off value of sST2 to predict deterioration of renal function was 36 ng/ml, with a sensitivity (Se) and specificity (Spe) of 77% and 60%, respectively (Area under curve (AUC) 0.67; 95% confidence interval (CI) 0.53-0.8; p=0.02). ROC curve for NT-pro BNP showed the cut-off value was equal to 1345 ng/ml (AUC=0.75; 95% CI 0.56-0.94; Se 60%; Spe 95%; p=0.0089). In a multiple regression model, we found sST2 and blood glucose to be the only significant predictors of acute kidney injury during the first 48 hours of investigation (adj. R2 =0.437, P<0.001) among the parameters included in the study such as the biomarker NT-pro BNP, ejection fraction, E/A ratio, end-diastolic volume and hemoglobin level. Conclusion. The study revealed that sST2 predicts acute kidney injury in patients with ST-segment elevation myocardial infarction and could be useful especially in patients who underwent angiography.

P1793

Impact of left anterior descending artery wrapping around the left ventricular apex on cardiac mechanics in patients with normal coronary angiography

H Hala Badran[1]; G Soltan[1]; W Abdou[1]; T Alakshar[1]
[1]*Menoufiya University, Shebin, Egypt*

Background: The anatomic features of left anterior descending (LAD) coronary artery have important clinical significance. An LAD that wraps around the LV apex theoretically supplies a greater amount of myocardium than one that ends at or before the apex.
Objectives: We examined the impact of LAD wrapping on left ventricular longitudinal and circumferential and twist mechanics in patients with normal coronary angiography.
Methods: 71 patients with evidence of normal coronary angiography (Wrapped LAD: n=52,73%) and non wrapped LAD(n=19, 27%) were included in the study. We compared LV longitudinal and circumferential(CS) strain(sys), systolic strain rate(SRsys) early and late diastolic SR (SRe & SRa), LV electromechanical dyssynchrony(TTP-SD) in addition to LV twist and torsion using speckle tracking echocardiography between groups.
Results: No significant difference in age, gender or BSA or EF% between the two groups. LAD wrapped group showed higher LVMI, deceleration time (DT), (P < .0001) global longitudinal SRa (P < .02), CS SRa at the basal segments (P < .02), CS SRsys & SRe and SRa (P < .0001) at the apical segments and apical rotation of septal & anterior segments compared with non wrapped group. LV twist was correlated negatively with LV TTP-SD (r=.25, P < .03), and positively with long. sys (r=.47, P < .0001), CS sys (r=.55, P < .0001), CS SRsys (r=.23, P < .05), CS SRe (r=.55, P < .0001). Using multivariate regression analysis LVMI: OR .922 CI: .860-.990, P < .03, DT; OR: .932, CI: .877-.991, P < .02 and CS SRa at atrial diastole; OR: .000, CI: .000-.271, P < .03, were independent predictors of LAD wrapping around LV apex.
Conclusion: Wrapped LAD is associated with better myocardial relaxation and rotational mechanics in patients with normal coronary angiography. This could explain the worse prognosis in such population when LAD occlusion acutely emerges.

P1794

Clinical significance and dynamics of biomarkers of myocardial remodeling in patients with ST segment elevation myocardial infarction and preserved left ventricular function

T Pecherina[1]; E Zhuravleva[1]; V Kashtalap[1]; O Barbarash[1]
[1]*Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation*

Objective: to determine the clinical significance of markers of myocardial remodeling (NT-proBNP, galectin-3, sST2, MMP-1, 2, 3 and TIMP-1) in patients with ST-segment elevation myocardial infarction and preserved left ventricular function.
Materials and methods: 100 consecutive patients diagnosed with ST segment elevation myocardial infarction and LV ejection fraction ≥40% were included. Echocardiography was performed for all patients on the first day, 10th-12th day of hospitalization and one year later. In all patients on admission to the hospital, on the 10th-12th day and a year later, MI was used to determine serum concentrations of markers: MMP-1, 2 and 3, TIMP-1 , galectin-3; NT-proBNP; soluble protein of the IL-1 receptor family (sST2).
Results: The concentration of MMP-3, determined on the 10th -12th day of the MI, was 1.62 times higher than the values measured on the first day. While the concentration of soluble ST2 receptor, on the contrary, is almost twice as low on the 10th-12th day as measured on the 1st day. Also statistically significant dynamics in the period of hospitalization was determined for galectin-3 (p = 0.0001), MMP-2 (p = 0.0003), NT-proBNP (p = 0.0361). A year later, from the index MI, the value of markers decreased: NT-proBNP - 9.9 times compared with the values of 1-day MI and 2.54 times compared with 12 days from MI; sST2 - 1,9 times in comparison with the values of 1-day MI; galectin-3 - 1,76 times compared with the values of 1-day MI and 1.4 times compared with 12 days from MI; MMP-2 - in 1,3 times in comparison with the values of 1 day of MI and in 1,5 times in comparison with 12th days from MI. The values of MMP-3 and TIMP-1 a year later from the index event increased on the contrary: MPP-3 - 1.7 times compared with the values of 1-day MI; TIMP-1 - in 1,94 times compared with the values of 1-day MI and 2.04 times compared with 12 days from MI. Analyzing the differences in the concentrations of the markers under study, taking into account the presence / absence of signs of DD, draws attention to the fact of large median values in the group of patients with DD (n = 38): galectin-3 at each of the observation points, NT-proBNP by 10-12- day and in a year, MMP-1 - on the 1st and 10-12th day of observation, MMP-2 - at the annual observation stage, MMP-3 - on the 1st and 10-12th days from the MI, TIMP-1 - on the contrary, in the group of patients with DD the concentrations were lower in comparison with patients without DD (n = 62) both on the 1st day and a year later.
Conclusions: It was determined that in the group of patients with ST segment elevation myocardial infarction and preserved LV function in the hospital period and a year later, a statistically significant dynamics of the majority of studied markers: galectin-3, MMP-2, MMP-3, sST2, Nt-proBNP, TIMP-1 , which testify about regular processes of structural and functional remodeling of myocardium of the LV at different stages of observation.

P1795

The influence of gene polymorphism of enos on the course of afterinfarction period

OV Petyunina[1]; MP Kopytsya[1]; AE Berezin[2]; IR Vyshnevska[2]
[1]*Government institution"L.T. Malaya Therapy National institute of the National academy of medical sci, Kharkiv, Ukraine*; [2]*Zaporizhzhya State Medical University, Zaporizhzhya, Ukraine*

Endothelial NO-synthase (eNOS), constitutive enzyme, expresses in endothelial cells, promotes vascular dilatation. Polymorphism T786C of eNOS gene may influence on different clinical aspects of ST-elevation myocardial infarction (STEMI) and afterinfarction course of disease. Vascular endothelial growth factor-A (VEGF-) is one of the factors which influences on eNOS generation.
Purpose. To investigate associations of gene polymorphism 786 of eNOS with clinical and anamnestic data in patients with STEMI, the level of VEGF-, clinical course and prognosis of disease.
Methods. 177 patients with STEMI, 139 (78,5%) – male and 38 (21,5%) - female, at average age (61,73±9,44) years that were admitted to intensive care unit between January 2016 and July 2018 were investigated. Polymerase chain reaction was used to determine allele polymorphism T786C of eNOS gene. Serum level of VEGF by enzyme-linked immunosorbent assay was determined. After a 6-month observation period combined end point (afterinfarction angina, chronic heart failure no less then III functional class, cardiovascular death) were assessed.
Results. STEMI originated in 2,58 times more often in patients-careers of 786CC-genotype of eNOS gene in the presence of diabetes mellitus type 2 (95% OR (1,10-5,88)), in 2,28 times – in smokers (95% OR (1,03-4,88)), in 2,28 times – at age before 55 years (95% OR (1,03-4,88)), in 3,03 times (95% OR ((1,34-6,57)) – in patients with unstable angina before event. Uni- and multivariative regression analysis showed that polymorphism 786 of eNOS gene was independent predictor of unfavorable course of afterinfarction period (afterinfarction angina, chronic heart failure, cardiovascular death) during 6-month observation period (=0,0029). VEGF-level rice was in patients with STEMI – careers of 786-genotype of eNOS gene polymorphism and low level – in patients with minor 786CC-genotype. These data testifies to possible genetic determinant between VEFG-A level and eNOS gene polymorphism.
Conclusion. Observed findings may open new approach to stratify patients for unfavorable duration of afterinfarction recovery.

Complete revascularization on patients presenting with cardiogenic shock: real life data.

I Ines Almeida[1]; H Miranda[1]; H Santos[1]; J Chin[1]; C Sousa[1]; S Almeida[1]; J Tavares[1]
[1]*Hospital N.S. Rosario, Barreiro, Portugal*

On behalf of: Portuguese Registry of Acute Coronary Syndrome - ProACS

Introduction: The CULPRIT-SHOCK trial showed that immediate multivessel percutaneous coronary intervention (PCI) increased the risk of death or severe renal failure at 30 days on patients (P) presenting with cardiogenic shock (CS).
Objective: Evaluation of prognostic impact of complete revascularization (CR) on P admitted with ST segment elevation myocardial infarction (STEMI) in CS and multivessel disease (MVD).
Material and methods: Retrospective analysis of P data admitted due to STEMI and CS and MVD at multicentric registry between 2000-2018. Compared demographic and clinical characteristics of P who were submitted to CR (group 1 – G1) versus who did not (group 2 – G2) and evaluated its prognostic impact.
Results: Admitted 7919 P with STEMI, which 295 (3.7%) on CS. 46.8% of the P on CS had MVD, 69.6% were submitted to CR. G1 P were younger (61±11 vs 73±12 years, p<0.001). The STEMI location was predominantly anterior (80%) in G1 and inferior in G2 (50%). The stablished timings symptoms start - reperfusion therapy and first medical contact - reperfusion were not statistically different between groups. 20% of G1 P did more than one coronarography during hospitalization. The anterior descendent was the artery more frequently involved in both groups (80 vs 89.8%) being the culprit lesion in 47.4% of G1 P and in 27.7% of G2 P, where the most frequently was the right coronary (43.4%, p <0.001). The majority of G1 P (95%) had 2-vessel disease; in G2 53.4% had 2-vessel disease and 46.6% 3-vessel disease (p<0.001). All the G1 P did PCI; in G2, 96.6% did PCI and 3.4% had a hybrid technique (in 2.3% coronary artery bypass grafting planned after hospital discharge). Other interventions during hospitalization were needed, namely non-invasive ventilation (35 vs 21.6%), invasive ventilation (30 vs 34.1%), intra-aortic pump (20 vs 17%) and temporary pacemaker (5 vs 25%), not statistically significant. The stablished endpoints were reinfarction rate (5% between G1 P vs 0%), AHF (70 vs 83%), stroke (5.3 vs 0%) and in hospital death (35 vs 37.5%), not statistically significant.
Conclusion: Although the evaluated endpoints are different and measured at different timings, our results do not appear to follow the trends presented in CULPRIT-SHOCK trial probably as a result of the small sample size and the shorter follow up time.

P1797
Cardiac arrest predictors in cardiogenic shock

H Santos[1]; T Vieira[2]; J Fernandes[2]; R Pinto[3]; T Filipa[3]; AR Ferreira[2]; M Rios[2]; T Honrado[2]
[1]Hospital N.S. Rosario, Cardiology, Barreiro, Portugal; *[2]Sao Joao Hospital, Intensive Care, Porto, Portugal*; *[3]Sao Joao Hospital, Cardiology, Porto, Portugal*

Background: Cardiac arrest (CA) is a defining moment to patient outcome. Cardiogenic shock (CS) is the cardiovascular emergency with more mortality rates, and CA is considerably more frequent in these patients. Combined, CS and CA, are a potentially lethal event.
Purpose: Evaluate the impact of cardiovascular previous history, clinical signs and diagnosis procedures at admission in the prediction of CA in CS patients.
Methods: Single-centre retrospective study, engaging patients hospitalized for CS between 1/01/2014-31/10/2018. Epidemiological, clinical data at admission and diagnosis procedure's results were collected. Chi-square, Fisher and T-student tests were used to compare categorical and continuous variables. Logistic regression was performed to assess CA occurrence based on the cardiovascular history, clinical signs and diagnostic tools at admission.
Results: 218 patients were included, mean age 62.34±13.90 years, with 68% males. Patients that suffer CA (134 patients) were similar regarding age, gender, body mass index, arterial hypertension, dyslipidemia, previous ACS and arterial pressure at admission. Active smoking status was more frequent in CA (47 vs 32.1%, p=0.03), on other hand diabetes (20.1 vs 34.5%, p=0.018) and previous cardiomyopathy (23.1 vs 38.1%, p=0.018) were less prevalent that in non-CA patients. Beta blockers (43.9 vs 23.9%, p=0.002), angiotensin-converting-enzyme inhibitor (50.6 vs 34.6, p=0.021), furosemide (25.6 vs 13.4%, p=0.018) and platelet antiaggregants (41.5 vs 23.1%, p=0.004) are more frequent in non-CA patients. CA patients with CS had at admission lower values of pH (7.21±0.23 vs 7.39±0.10, p=0.009), however, higher lactate levels (6.5±6.45 vs 4.7±4.12, p0.001) and de novo cardiac arrhythmias (23.1 vs 4.8, p0.001). CA patients had less time until angiography performance (3.0±2.5 vs 5.0±4.5 hours, p0.001), but better left ventricular ejection fraction (LVEF) (38.11±13.69 vs 25.43±6.43%, p=0.001). Logistic regression revealed LVEF (odds ratio (OR) 1.04, p=0.001, confidence interval (CI) 1.015-1.064) and de novo arrhythmia (OR 8.248, p=0.008, CI 2.38-28.63) as predictors of CA in CS patients.
Conclusions: LVEF and de novo arrhythmia at admission in CS were significant predictors of CA arrest.

Valvular Heart Disease

Opportunity or futility? TAVI in elderly patients with depressed ejection fraction and severe aortic stenosis.

JM Jose Maria Vietez Florez[1]; G Alonso Salinas[1]; L Salido Tahoces[1]; M Abellas Sequeiros[1]; A Lorente Ros[1]; R Garcia[1]; JL Mestre Barcelo[1]; S Del Prado Diaz[1]; A Pardo[1]; R Hernandez Antolin[1]; JL Zamorano[1]
[1]University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain

Introduction: TAVI has become the election treatment in elderly patients with symptomatic severe aortic stenosis (AS) and medium or high surgical risk. However, whether if TAVI is a good option for this population presenting also reduced left ventricular ejection fraction (LVEF) is still unknown. Is TAVI safe in these patients?
Methods: Patients with severe AS who TAVI was implanted were prospectively assessed between 2010-2018. Patients with reduce LVEF (≤40%) were compared against patients with preserved function. Clinical and echocardiographic characteristics at baseline were recorded. All TAVI complications were collected. During follow up clinical and echocardiographic data, hospitalizations and mortality were recorded. Patients without LVEF quantification previous to TAVI were excluded..
Results: A total of 301 patients were finally included. 85,71% (n=258) has preserved(≥50%) and 7,97% (24) patients have a reduced LVEF (≤40%). 6,31% (19) has a LVEF between 40% and 50%. The average follow-up was 16,55 months. Total mortality was 8,39%, and 35,65% patients had a rehospitalisation.
Patients with reduced LVEF were mostly men (75%), with statically significant higher BNP values (1246 vs. 421, p<0,01), worst right ventricle function (TAPSE 15,01 mm vs. 19,42 mm, p<0.02) and more prevalence of low flow-low gradient AS (mean gradient 28,7 mmHg vs. 43,86 mmHg, p<0,01). There were no other differences in baseline characteristics between both groups (Table 1).
There were no differences in intraprocedure complications neither hospitalization days after TAVI (7,55 vs. 5,44 p=0,11).
During the follow up there were no differences in mortality (8,33% vs. 11,24%, p=0,189), rehospitalisation events (16,67% vs. 32,87%, p=0,155) or in the composed endpoint of admissions or mortality (21.05% vs. 38,96%, p=0,121) between reduced and preserved LVEF group.
Conclusions: TAVI in elderly patients with depressed LVEF (≤40%) is a safe procedure with similar outcomes than patients with preserved LVEF. These data should be confirmed in larger and longer registries.

MitraClip: impact on symptoms and quality of life

J Rigueira[1]; E Infante-Oliveira[1]; R Santos[1]; T Rodrigues[1]; I Aguiar-Ricardo[1]; JR Agostinho[1]; N Cunha[1]; A Nunes-Ferreira[1]; PS Morais[1]; P Antonio[1]; AR Franciso[1]; M Nobre Menezes[1]; P Carrilho-Ferreira[1]; FJ Pinto[1]; P Canas Da Silva[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal

Introduction: In patients with severe mitral regurgitation (MR) and prohibitive surgical risk, percutaneous mitral valve repair seems to be associated with symptomatic and functional improvement.
Aim: To assess the impact on quality of life and symptoms of percutaneous mitral repair in "real world" patients.
Methods: A prospective single-center registry of consecutive patients undergoing percutaneous MR repair with MitraClip from 2013 to 2018. Demographic, clinical (including functional class (NYHA) and Minnesota Quality of Life (QoL) questionnaire) and echocardiographic data were evaluated. Clinical, face-to-face or telephone follow-up with reassessment of functional class and QoL score was performed. For statistical analysis, the chi-square and Student's T tests were used.

Results: 51 procedures (mean age 71.8 ± 13.5 years, 30 men) were performed in patients with symptomatic MR grade III or IV. 14 patients (27.5%) had primary MR and 37 (72.5%) had secondary MR. The procedure success rate per patient was 92.0%. The complication rate was 7.7% (n = 4.2 procedural failures, 1 stroke and 1 vascular complication). During an average follow-up (FUP) of 615 ± 613 days, there were 17 deaths (33.3%). Most patients were in NYHA III functional class (34 patients, 66.7%) or IV (13 patients, 25.5%), with a statistically significant improvement of the functional class in the short-term postoperative period (3.2 ± 0.6 vs 2.0 ± 0.7, p <0.001), which was maintained throughout the FUP period (2.1 ± 1.0 vs. 2.0 ± 0.7, p = 0.329). At the end of the FUP, most patients were in NYHA II (22 patients, 43.1%) or I (9 patients, 17.6%), with only one patient in NYHA IV class. There was also a significant improvement in quality of life, maintained during the long-term FUP (43.7 ± 19.1 vs 22.6 ± 16.6, p <0.001), as measured by the QoL-Minnesota score.
The symptomatic improvement was associated with lower regurgitant volume (69.7 ± 25.8 mL vs 113.3 ± 71.5 mL, p = 0.031) and EROA (0.4 ± 0.2 cm2 vs 0.6 ± 0, 4 cm 2, p = 0.036). No other clinical or echocardiographic predictors of symptomatic improvement were identified.
Conclusion: MitraClip for treatment of severe MR has led to improvement of symptoms and quality of life in real-world patients. As opposed to LVEF, the lower MR severity was a predictor of symptomatic improvement. Thus, it seems important to reaffirm percutaneous repair as a complementary treatment to optimized medical therapy in patients with severe MR and surgical contraindication.

Prognostic impact of MitraClip in patients with left ventricular dysfunction and functional mitral valve regurgitation: a comprehensive meta-analysis of RCTs and adjusted observational studies.

M Maurizio Bertaina[1]; A Galluzzo[1]; F Conrotto[1]; W Grosso Marra[1]; S Frea[1]; G Alunni[1]; G Crimi[2]; C Moretti[1]; A Montefusco[1]; M D'amico[1]; M Rinaldi[1]; F D'ascenzo[1]
[1]Hospital 'Città della Salute e della Scienza di Torino', Cardiology, Turin, Italy; *[2]Policlinic Foundation San Matteo IRCCS, Cardiology, Pavia, Italy*

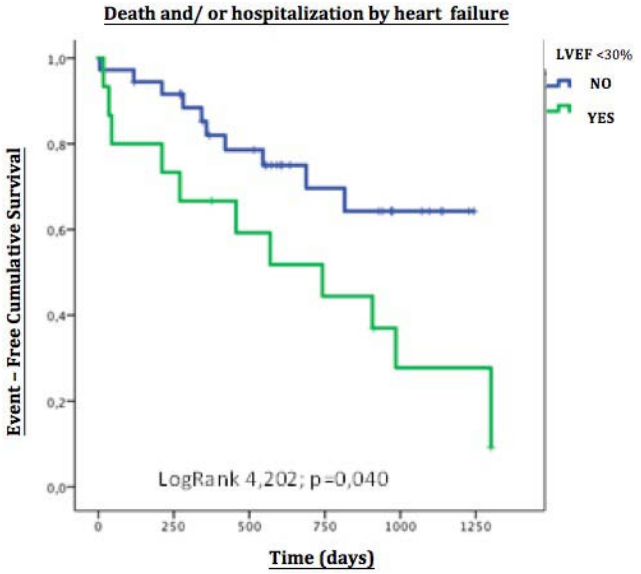
Aims The real prognostic impact of MitraClip in patients with significant functional mitral regurgitation (FMR) and left ventricular (LV) dysfunction remains to be elucidated. Two randomized controlled trials (RCTs) with conflicting results have been recently published.
Methods and Results We conducted a comprehensive meta-analysis of all RCTs and adjusted observational studies to evaluate the clinical impact of percutaneous MR repair when compared to optimal medical therapy (OMT) alone in patients with symptomatic FMR and LV dysfunction. Death from any cause and heart failure rehospitalizations on long term follow-up were the primary endpoints. Cardiac death, one year and short-term death were the secondary ones. 2255 patients (1207 for MitraClip and 1048 for OMT-only) from 8 studies (2 RCTs and 6 observational studies) were included. At a median follow-up of 438 days (IQR 360-625) MitraClip was associated to a significant reduction of all cause death (Odds Ratio [OR] 0.55, 95%CI 0.41-0.73, p<0.001; [ORadj] 0.66, 95%CI 0.49-0.90, p=0.009) and rehospitalization (OR 0.49, 95%CI 0.24-1.00, p=0.05 and ORadj 0.63, 95%CI 0.43-0.94, p=0.02). At one year, only a trend favoring the experimental cohort emerged at adjusted analysis (ORadj 0.73, 95%CI 0.53-1.02, p=0.07). Metaregression suggested that benefit of MitraClip on long term survival persists even accounting for prevalence of implanted CRT, burden of comorbidities, NYHA class, cardiomyopathy etiology and LV function and dimensions.
Conclusions MitraClip for FMR in patients with LV dysfunction is associated to a considerable reduction of death and HF hospitalization on long term follow-up. Further ongoing RCTs are needed to strengthen present results.

P1801

Severe mitral regurgitation:mortality and morbidity predictors after percutaneous mitral valve repair with the mitraClip system

R Santos[1]; E Infante-Oliveira[1]; P Carrilho-Ferreira[1]; M Nobre-Menezes[1]; AR Francisco[1]; J Rigueira[1]; JR Agostinho[1]; I Aguiar-Ricardo[1]; A Nunes-Ferreira[1]; T Rodrigues[1]; N Cunha[1]; P Antonio[1]; PS Morais[1]; FJ Pinto[1]; P Canas Da Silva[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal

Introduction: Percutaneous mitral valve repair with the MitraClip system is an alternative in cases of severe mitral regurgitation (MR) with prohibitive surgical risk. Therefore, it's relevant to analyse factors that impact prognosis after percutaneous valve repair, and select patients that can most benefit from the procedure.
Aims: To identify predictors of bad prognosis after MitraClip implantation.
Methods: Single centre, prospective registry of consecutive patients (pts) submited to percutaneous mitral valve repair with the MitraClip system from 2013 to 2018. Clinical, echocardiographic and demographic parameters were analysed. Follow up was presential or by phone call. For statistical analysis a primary compound endpoint of global mortality and/or admission from cardiac cause was used. Qui-square($\chi 2$) test, T-student test, ROC analysis and Kaplan-Meier survival analysis were applied.
Results: The analysis included 51 procedures (average age was 71,8±13,5 years; 30 were male pts) performed in grade III or IV symptomatic MR pts. 14 pts (27,5%) had primary MR and 37 (72,5%) had secondary MR. Left ventricular ejection fraction (LVEF) averaged 39,0±14,1%. Success rate per patient was 92,0%. Complication rate was 7,7% (n=4; 2 procedure failures, 1 pericardial effusion and 1 vascular complication). 14 admissions from cardiac cause (27,5%) and 17 deaths (33,3%) were verified during an average follow up of 615±13 days. The compound endpoint of global mortality and/or admission from cardiac cause was verified in 43,1% of pts. During the abovementioned follow up, functional class (NYHA) was higher in pts that reached primary endpoint (2,4 ± 0,9 vs 1,7± 0,5; p = 0,045), the same was true for MR grade (grade III/IV 17,7% vs 8,8%, p=0,041) and LVEF was lower in those pts (35,2 ± 12,3% vs 40,9 ± 17,2%; p=0,033). Using ROC analysis a LVEF<30% was identified as the cut-off assotiated with mortality or admission from cardiac cause (AUC = 0,67; Sensitivity= 55,0%; Specificity= 90,0%, PPV 80%, NPV 72%). Pre-procedural NHYA class (OR 7,065 p=0,014), atrial fibrillation (OR 0,039 p=0,039) and immediate complications (OR 720,6 p=0,024) were identified as predictors of the compound endpoint. In the Kaplan-Meier survival analysis a pre-procedural LVEF <30% was associated with the primary endpoint. There were no other identified mortality and/or admission predictors.
Conclusion: Percutaneous mitral valve repair in cases of severe mitral regurgitation showed an elevated success rate with a reduced complication rate. The primary compound endpoint of mortality and/or admission from cardiac cause occurred in patients with higher NHYA functional class, higher mitral regurgitation grade, immediate complications, atrial fibrillation and LVEF <30%.



P1802

Malnutrition in patients undergoing tricuspid valve edge-to-edge repair: incidence, clinical features and prognostic importance

M Unterhuber[1]; C Besler[1]; K-P Rommel[1]; M Von Roeder[1]; T Noack[2]; M Borger[2]; J Ender[3]; H Thiele[1]; P Lurz[1]
[1]Heart Center of Leipzig, Department of Cardiology, Leipzig, Germany; *[2]Heart Center of Leipzig, Department of Cardiac Surgery, Leipzig, Germany*; *[3]Heart Center of Leipzig, Department of Anesthesiology, Leipzig, Germany*

Aims: Transcatheter tricuspid valve edge-to-edge repair (TTVR) is currently evaluated as a treatment option for patients with symptomatic tricuspid regurgitation (TR) at increased surgical risk. These patients often present late in the natural history of the disease with late multiorgan sequelae of right heart failure. The aim of the present study was to assess the incidence and clinical relevance of malnutrition in patients undergoing TTVR.

Methods and Results: 86 consecutive patients (mean age 80±7 years, 45% female, mean STS score for mortality 5.3±5.4, mean Euroscore II 8.3±7.5) with moderate-to-severe TR who were deemed at prohibitive surgical risk by a multidisciplinary heart team decision and underwent TTVR were included in the present analysis. 43 patients (50%) had concomitant mitral clipping. Nutrition status was assessed by Mini Nutritional Assessment (MNA) questionnaires prior to TTVR and after one month of follow-up. Blood samples were drawn at the same time points and analyzed in the local laboratory.

At baseline, MNA displayed that 5 patients (6%) had normal nutrition status, 68 patients (79%) were at risk for malnutrition and 13 patients (15%) were malnourished. Patients with MNA score below median, despite having similar clinical characteristics, had larger inferior vena cava diameter on echocardiography and worse physical role functioning in the Short Form 36 Health Survey as compared to patients with an MNA score above median. TTVR led to a reduction in TR vena contracta (pre: 9.3±2.7 mm, 1 month: 5.5±2.0 mm) and TR effective regurgitant orifice area (pre: 0.6±0.3cm^2, 1 month: 0.3±0.2cm^2). MNA scores improved in 60 patients (70%) following TTVR.

At 1 month, 46 patients (53%) were still at risk of malnutrition and 9 patients (10%) were malnourished. Patients with improved MNA score had superior TR reduction on follow-up and indices of backward failure, such as inferior vena cava diameter, cholinesterase levels and renal function were improved in these patients. No such effect was observed in patients without MNA score increase. NT-proBNP levels were lower in patients with improved MNA score. Only patients with improved nutritional status on follow-up had an increase in quality of life assessments and 6-minute walk distance at 1 month.

Patients with worsened MNA score at 1 month, especially in these with an MNA score ≤8, had a significantly increased risk of death and rehospitalization for heart failure during a median follow-up of 6 months.

Conclusions: This study suggests that a substantial part of elderly patients undergoing TTVR are either at risk for malnutrition or malnourished. Despite an increase in MNA scores following TTVR, poor nutrition status remains a concern and is linked to indices of persistent hemodynamic backward and forward failure. Given the association with functional and prognostic improvement, nutritional status likely deserves further study to improve outcome in this patient population.

P1803

Multiparametric evaluation of percutaneous mitral valve repair (MitraClip) after 6 months

C Vignati[1]; F De Martino[1]; E Salvioni[1]; M Mapelli[1]; V Mantegazza[1]; L Fusini[1]; P Gripari[1]; G Tamborini[1]; M Muratori[1]; S Ghulam Ali[1]; M Pepi[1]; P Agostoni[1]
[1]Cardiology Center Monzino IRCCS, Heart Failure Unit, Milan, Italy

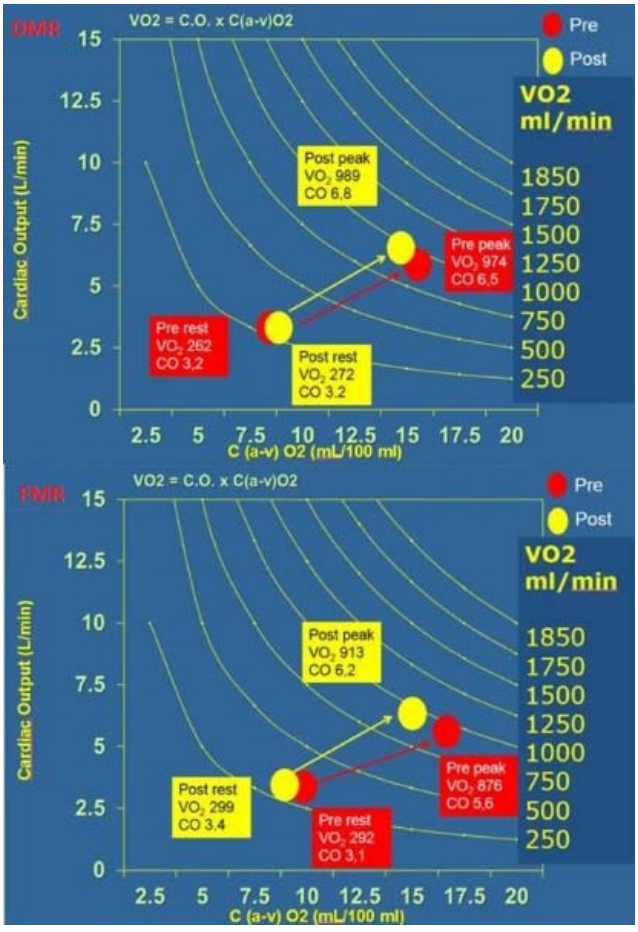
Background. MitraClip (MC) therapy is now established as a secure, feasible treatment option for patients with severe mitral regurgitation (MR) at high surgical risk. The efficacy of the percutaneous approach, especially in patients with functional disease, has been evaluated in a large number of studies, but the endpoints used to establish the success of this procedure over the surgical ones were based on unreliable, less standardizable measures.

Purpose. This study sought to evaluate the efficacy of MC therapy in terms of new functional outcomes, comparing data related to degenerative mitral regurgitation (DMR) and functional mitral regurgitation (FMR).

Methods. Between October 2010 and November 2018, 100 consecutive patients with severe MR and not eligible for surgical mitral valve repair were assessed before MC implant using echocardiogram, BNP assay, cardiopulmonary exercise test (CPX) with non-invasive measurement of cardiac output (CO) with inert gas rebreathing technique, at baseline and after 6 months.

Results. MC implant rate was 95%. Immediate success with reduction of MR to ≤2+ was observed in 80% of cases and 76% after 6 months. In both populations, a significant reduction of MR from baseline was observed (p<0.001). NYHA class showed a significant improvement over six months in both groups. Significant left ventricular (LV) remodeling was observed only in DMR group (LV End-diastolic Volume index was 70±14 mL at baseline, 59±14 mL at 6 months, p<0.001). Systolic pulmonary pressure values were significantly reduced from baseline in both population (PAPs was 44±12 mmHg at baseline, 40±8 mmHg at 6 months, p=0.047 in FMR and 42±12 mmHg at baseline, 38±8 mmHg , p=0.029 in DMR). In DMR LV ejection fraction reduced significantly from 63±9% to 59±8, as expected. CO and stroke volume (SV) increased significantly at rest only in FMR patients (CO 3.1±0.9 L/min at baseline, 3.4±0.9 L/min at 6 months, p=0.006; SV 45±15 mL/min at baseline, 52±14 mL/min at 6 months, p=<0.003), while during exercise in FMR CO improved from 5.6±1.8 L/min to 6.2±1.7, p=0.023 and SV from 56±23 ml/min to 63±21, p=0.007 and AV O2 difference reduced from 17.1±4.3ml/100ml to 15.3±3.9, p=0.019. On the other hand, the population with degenerative disease did not present any improvement. Peak oxygen consumption showed an improving trend, not significant. Heart rate did not show significant changes both at rest and during exercise. No differences were found in BNP levels or VE/VCO2 slope.

Conclusions. MC reduced MR and produced a significant LV reverse remodeling over 6 months in DMR population treated. Functional outcomes, as the implement of CO and SV both at rest and during exercise with an improvement in NYHA class, proved the efficacy of the percutaneous mitral valve repair in patients with FMR.



P1804

The impact of transcatheter aortic valve implantation on aortic elasticity and arterial function

V Vasiliki Gardikioti[1]; D Terentes-Printzios[1]; C Vlachopoulos[1]; K Toutouzas[1]; M Xanthopoulou[1]; M Karmpalioti[1]; G Latsios[1]; E Katsianos[1]; G Siasos[1]; E Vavuranakis[1]; D Tousoulis[1]
[1]Hippokration General Hospital , 1st DEPARTMENT OF CARDIOLOGY, Athens, Greece

Background/Introduction: Aortic stiffness and hemodynamics are established independent predictors of cardiovascular risk. Transcatheter aortic valve implantation (TAVI) is a promising non-surgical technique for the treatment of aortic stenosis.
Purpose: We sought to investigate the effect of TAVI upon aortic vascular function and hemodynamics.
Methods: 67 patients (mean age 80.5±8.1 years, 31 male) with severe symptomatic aortic stenosis scheduled for TAVI were enrolled. Arterial stiffness was assessed by carotid-femoral pulse wave velocity (cfPWV) and brachial-ankle pulse wave velocity (baPWV). Pulse wave analysis of the radial waveform was also performed and the aortic augmentation index corrected for heart rate (AIx@75) was estimated. Measurements were conducted prior to the procedure and at discharge.
Results: Before TAVI, mean transvalvular gradient was 50.1±12.9 mmHg for the population of the study. 24% presented with LVEF<50% and 4 patients with low flow- low gradient severe AS. After the procedure, we observed a statistically significant increase in arterial stiffness indices (7.7±1.5 vs 8.3±1.9 m/s for cfPWV and 1871±535 vs. 2449±646 cm/s for baPWV, with p<0.001 for both variables), and a concomitant decrease in wave reflections as measured by AIx@75 (35±12.1% vs 28.7±8.4%, p<0.001). After TAVI a statistically significant increase in peripheral pulse pressure (72.5±19.4 vs 78±15.8 mmHg, p<0.05) was observed, as well.
Conclusions: Shortly after TAVI the increase in arterial stiffness depicts a "stiffer response" of the vascular system to the acute hemodynamic changes. This could also indicate an "unmasking" of true aortic stiffness as a result of the relief of the LV outflow obstruction. These findings shed light on the short-term hemodynamic effects of the transcatheter aortic valve implantation.

P1805

Clinical impact of new generation of prosthesis in aortic regurgitation after transcatheter aortic valve replacement

M Munoz-Garcia[1]; E Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; AJ Dominguez-Franco[1]; JM Garcia-Pinilla[1]; L Morcillo-Hidalgo[1]; JH Alonso-Briales[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]; E De Teresa-Galvan[1]
[1]University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain

BACKGROUND: The degree of residual AR after TAVR leading to excess mortality remains controversial, and little evidence exists with introduction new generation prosthesis. The aim of this study was to determine the impact of the degree of residual aortic regurgitation (AR) after transcatheter aortic valve replacement (TAVR) on outcomes, with new generation prosthesis.
METHODS: A total of 665 patients undergoing TAVR with balloon-expandable or self-expanding valves were included. The presence and degree of AR were evaluated by transthoracic echocardiography. Was identified two groups, CoreValve devices, (group 1, n=436), and with new generation Sapien 3, Evolut R and Pro prosthesis, (group 2, n=229)
RESULTS: Residual AR after TAVI in group 1 compared with group 2 was classified as none in 48.8% vs. 61.2%, mild in 34.4% vs. 28.2%, moderate in 15.9% vs. 9.7% and severe 1% vs. 0.4%, p.0008, respectively. The presence of moderate to severe AR (≥2) was an independent predictor of mortality at a mean follow-up of 39 ± 28 months compared with none to mild (adjusted hazard ratio [HR]: 1.831, 95% confidence interval [CI]: 1.179 to 2.842; p < 0.007) but there was no increased risk of heart failure (HF) rehospitalizations [HR= 1.183 (95% CI 0.595-2.353), p = 0.631]. The new generation prosthesis was an independent protector factor [HR= 0.243 (95% CI 0.169-0.351), p< 0.001], but not associated HF rehospitalizations [HR= 1.123 (95% CI 0.665-1,895), p = 0.665].
CONCLUSIONS: AR occurred very frequently after TAVR, although with new generation prosthesis improves degree of residual AR and was independent protective factors of mortality.

P1806

Risk willingness and survival in patients with severe aortic stenosis.

Al Hussain[1]; C Brunborg[2]; A Auensen[1]; JO Beitnes[1]; L Gullestad[1]; KIP Pettersen[1]
[1]Oslo University Hospital, Cardiology, Oslo, Norway; [2]Oslo University Hospital, Department of Biostatistics and Epidemiology, Oslo, Norway

Funding Acknowledgements: The Norwegian Health Association and Inger and John Fredriksen to the Department of Cardiology, Rikshospitalet, Norway

Background: Standard Gamble (SG) is a validated tool for assessing patient preferences of treatment. SG derived risk willingness (RW) scores takes into account the notion of risk adhered to the intervention and uncertainty of the outcome, making it well suited to be used in patients with severe aortic stenosis (AS) referred for evaluation of aortic valve replacement (AVR). We anticipated an association between preoperatively assessed risk willingness and survival, but that the association would differ in strength depending on whether patients were operated or not.
Method: Consecutive patients > 18 years with severe AS were preoperatively examined with echocardiography, blood sampling, quality of life questionnaires, functional test, and SG. All patient assessment, including SG was done before and blinded to the treatment decision made by The Heart team. Patients with a Mini Mental Score less than 24 were excluded from this analysis. All-cause mortality data were collected at 5 years after the initial time of decision or intervention. We used the median RW score in the total sample (25%) as a cut of to compare patients with high and low RW.
Results: Overall, 439 patients were included, 365 patients underwent AVR while 74 patients were medically treated (med-treated). Operated patients had a higher RW-score score as compared to med-treated patients; 30% IQR (7-50%) vs. 12.5% IQR (1-40%), respectively, p < 0,005. There was no association between RW and 5-year survival in patients undergoing AVR (Fig. 1), while in the med-treated group ; patients with low risk willingness had higher survival compared to those with high risk willingness , (1229 ±98) vs. (903±111), p=0.035 respectively (days) (Fig. 2). A Cox regression analyses showed that higher RW was associated with increased mortality also when adjusted for gender, NYHA class and NT-proBNP at baseline in the medically treated group.
Conclusion: Patients with severe AS and higher risk willingness are more likely to undergo AVR. The risk willingness is associated with survival only in medically treated patients with severe AS. Patient's risk willingness adds to our knowledge of survival in medically treated patients additionally to established disease markers as NYHA class and NT-proBNP.

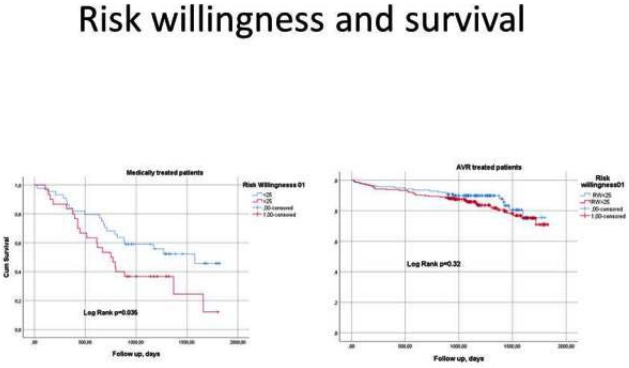


Figure 1. Risk willingness and survival

The register of pericarditis in the university therapeutic clinic: nosological spectrum, approaches to diagnosis and treatment

O V Olga Blagova[1]; AV Nedostup[1]; EA Kogan[1]; GY Sorokin[1]; VP Sedov[1]; ND Sarkisova[1]
[1]I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation

Purpose: to analyze the register of pericarditis in the therapeutic clinic, to evaluate their nosological spectrum, approaches to diagnosis and treatment.
Methods. In 2007-2018, seventy-one patients from 20 to 85 years (52.5±16.1 years), 42 women, were diagnosed with pericarditis. Patients with congestive effusion and isolated hypothyroidism were not included. Diagnostic puncture of the pericardium was carried out in 4 patients, pleural puncture - in 10 patients. Morphological diagnostics included endomyocardial / intraoperative myocardial biopsy (n = 4), thoracoscopic / operative biopsy of the pericardium (n = 5), pleura (n = 5), intrathoracic and supraclavicular lymph nodes (n = 3), lung (n = 1), salivary gland (n = 1), fat (n = 5). Also carried out investigation of viral DNA, the anti-heart antibodies, CRP, ANA, rheumatoid factor, anti-CCP, ANCA, ENA, immunophoresis of proteins, CT, MRI, phthisiatric study, oncological search. The follow-up was 12 [2; 36] months (up to 10 years).

Results. Pericarditis with a large effusion (from 2 cm) was diagnosed in 18 patients, with an average (10-19 mm) in 22, with a small one in 26, and without effusion in 5. The following forms of pericarditis were verified: tuberculosis (14.1%), viral-immune (14.1%, incl. 5.6% with hypertrophic cardiomyopathy) and infectious-immune (36.6%, incl. 26.8% with myocarditis), due to lymphoma and heart tumor (2.8%), sarcoidosis (2.8%), systemic diseases (lupus erythematosus, rheumatoid arthritis, polymyositis, Horton's, Takayasu, Sjogren's diseases, 12.7%, incl. with myocarditis in 56%, virus-positive in two patients), in patients with CHD (after punctures for Dressler's syndrome, bypass surgery and stenting, 4.2%). Pericarditis due to AL-amyloidosis, Loeffler's endocarditis, leukoclastic vasculitis, thrombotic microangiopathy, after ablation, aortic valve replacement, radiation and chemotherapy had one patient each (1.4%). In one case the diagnosis remained unclear. The signs of constriction were diagnosed in 13 patients (18.3%), its leading causes were tuberculosis (38%). The main types of treatment were steroids (n = 23), their combination with cytostatics (n = 12), tuberculostatics (n = 10), acyclovir / ganciclovir (n = 7), hydroxychloroquine (n = 15), colchicine (n = 9), NSAIDs (n = 8), incl. combined treatment in 27 patients. Excellent results (disappearance of effusion, absence of relapses and constriction) were achieved in 51.9% of patients, stable results - in 32.7%, and no result - in 15.4% (in 6 patients pericardectomy was performed). The mortality rate was 12.7% (9 patients) due to heart failure, surgery, PE, tumors. The conclusion. The nature of pericarditis can be established in most patients. Due to low availability of the pericardial puncture the role of other methods of cytological and morphological diagnostics is significantly increased. The predominant forms of pericarditis were tubercular, infectious-immune and pericarditis in systemic immune diseases.

Acute myocarditis: a retrospective study

S Antit[1]; A Bouthouri[1]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*

Background: Acute myocarditis is an inflammation of the heart muscle. Its unpredictable evolution justifies the importance of its early recognition. The clinical polymorphism associated with the lack of sensitivity of conventional diagnostic means make diagnosis a challenge for the clinician. However, the magnetic resonance imaging has been of great interest for the differential diagnosis as well as for the evolutionary follow-up of this pathology.
The purpose of this work was to determine the different clinical, echocardiographic and progressive aspects of acute myocarditis.
Methods: This was a descriptive, retrospective study, including 31 patients hospitalized for acute myocarditis at the cardiology department of our hospital between 2011 and 2017. All patients had an electrocardiogram, troponin bioassay, cardiac echography and cardiac magnetic resonance imaging.
Results: The mean age of our patients was 36.5 ± 13.3 years [17-63] with a clear male predominance (sex ratio = 6.75). Smoking was the most common cardiovascular risk factor (60%). Fifty percent of the population had only two cardiovascular risk factors. The most common clinical picture was acute chest pain (84%) preceded by influenza-like illness (53%). The electrocardiogram was pathological in 97% of cases. Hyperleukocytosis was objectified in 33% of cases. Elevation of C-reactive protein was present in 80% of cases. As for troponins, they were high in 94% of cases. Overall myocardial contractility was conserved in 84% of cases with segmental kinetic disorders in 45%. Cardiac magnetic resonance imaging showed pericardial effusion (10%), spontaneous myocardial hypersignal in triple-reversal-T2 recovery (42%) and which corresponded to the zones of late enhancement. Late contrast enhancement was predominant at the lateral wall (39%), with epicardial involvement occurring in 100% of cases.28 patients had a favorable outcome after a follow-up of 24 months. However, there was only one case of death at 3 months and two cases that progressed to dilated cardiomyopathy.
Conclusion: Acute myocarditis is mainly a disease of the young male subject. It can have very different clinical pictures, posing a major diagnostic problem. In this context, cardiac magnetic resonance imaging is of decisive interest for the differential diagnosis.

P1809

Neutrophil to lymphocyte ratio as a predictor of myocardial injury in patients presenting with myocarditis

S Borges[1]; F Goncalves[1]; JP Guimaraes[1]; JJ Monteiro[1]; C Ferreira[1]; JI Moreira[1]
[1]*Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal*

Background: There is a growing body of evidence highlighting the role of neutrophil to lymphocyte ratio (NLR) as prognostic predictor in several cardiovascular diseases, as a marker of systemic inflammation. Therefore, our aim is to describe the association of NLR and myocardial injury and function in patients with myocarditis;
Methods: Data from patients discharged with the diagnosis of myocarditis, from January of 2008 and October of 2018, in one center, were retrospectively analysed. NLR was defined as the ration of absolute counts of neutrophils and lymphocytes, at admission;
Results: 63 patients were included. Mean age was 39.7 17 years and 89% (58 patients) were men. The NLR values ranged from 1.1 to 14.78 (median 3.48, interquartile range (IQR) 3.06), without significant differences between women and men. In this population, NLR positively correlates with peak troponin values (p= 0.004, r=0.35) and N-terminal pro B-type natriuretic peptide (NT- proBNP) values (p= 0.005, R= 0.35). NLR also positively correlates with other inflammatory makers, such as C-reactive protein (CRP) (p<0.001, r= 0.42), leukocytes (p<0.001, r=0.59) and monocytes (p=0.004, r=0.35). NLR was higher in patients with left ventricular systolic dysfunction (4.45 vs 3.43) but this difference was not statistically significant (p=0.341);
When the patients were divided into NLR>3.48 and NLR<3.48 groups, myocardial injury markers were significantly increased in the higher NLR group (peak troponin 1.53 vs 0.6, p <0.001 and NT- proBNP 654 vs 244, p= 0.044). There is a statistically significant association between higher NLR and need of inotropic support (p=0.024). No differences on in-hospital mortality (p=0.492) between groups were registered.
Conclusion: NLR is a predictor of myocardial injury and inflammation in this group of patients; Despite being nonspecific, it is a readily available marker and it could be a cost-effective predictor and a useful tool to guide the approach in these patients.

P1810

The superimposed myocarditis in arrhythmogenic right ventricular cardiomyopathy: the role in the course of the disease and the results of treatment

Y A Yulia Alexandrovna Lutokhina[1]; OV Blagova[1]; AV Nedostup[1]; SA Alexandrova[2]; EA Mershina[3]; VA Zaidenov[4]; AG Shestak[5]; EV Zaklyazminskaya[5]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*; [2]*Bakoulev Center for Cardiovascular Surgery RAMS, Moscow, Russian Federation*; [3]*Roszdrav Medical Rehabilitation Center, Moscow, Russian Federation*; [4]*City Clinical Hospital No. 52, Moscow, Russian Federation*; [5]*Russian Research Center of Surgery, Petrovsky, Moscow, Russian Federation*

Purpose: to study the role of myocarditis in patients with arrhythmogenic right ventricular cardiomyopathy (ARVC), and to evaluate the results of its treatment.
Methods: 54 patients (38.7±14.1 y., 42.6% men) with ARVC according to Revised Task Force Criteria 2010 were evaluated (34 patients with definite, 18 - with borderline, 2 with possible diagnosis). Follow-up period 21 [6; 60] months. All patients underwent ECG, 24h-Holter monitoring, echocardiography, DNA-diagnostic, blood tests for detection of anti-heart antibodies (AHA) and DNA of viruses. Also were performed cardiac MRI (n=49), signal-averaged ECG (n=18), endomyocardial biopsy (n= 2), autopsy (n=2).
Results: myocarditis was diagnosed in 38 (70.4%) patients, 8 of whom were virus-positive (2 by myocardium, 6 by blood). Immunosuppressive therapy (IST) was conducted in 25 patients and included hydroxychloroquine (n=22, 200 mg/day), steroids (n=7, 16 [8; 24] mg/day), azathioprine (n=2, 150 mg/day). Patients with myocarditis who received and not received IST were compared. Initially, patients receiving IST had a longer term of disease, higher titers of AHA and a larger end diastolic volume of the left ventricle (LV) by MRI. Patients who received IST, had significantly lower mortality in comparison with patients with myocarditis without treatment (4.0 vs 30.8%, p=0.03). Only patients with myocarditis treated with IST demonstrated significant positive dynamics in PVs number (11,7 [2,6; 37] vs 0,8 [0,01; 4.5] thousand/day., p<0.001); nonsustained ventricular tachycardia (VT, 57.9 vs 26.3%, p=0.034); sustained VT (SVT, 31.6 vs 0%, p=0.014); their LV ejection fraction (EF) remained stable (52.1±14.8 vs 52.4±13.5%, p=0.58). In patients with myocarditis without IST, there was a tendency to EF reduction (64,3±8,8 vs 57,2±9,4, p=0,058). Comparison of patients with isolated ARVC and ARVC plus myocarditis revealed no differences in structural and functional parameters (severity of arrhythmias, EF of both ventricles, heart chambers size, functional class of CHF, etc.), in the effectiveness of radiofrequency ablation and in the frequency of adverse outcomes. The absence of differences is regarded as the result of effective IST. However, myocarditis was significantly less common in patients with the most typical form of ARVD (SVT without significant CHF; with mutations in the PKP2 gene) than in patients with latent arrhythmic form (without SVT, with mutations in the DSG, SCN5A, FLNC genes) and with biventricular HF (mutations in DSP, DES genes).
Conclusion: the frequency of superimposed myocarditis in patients with ARVC exceeds 70%. Myocarditis in ARVC could be primary (including viral) or secondary (autoimmune). Regardless to etiology, myocarditis in ARVC should be actively diagnosed and treated, because patients with myocarditis not receiving IST have significantly worse effectiveness of antiarrhythmic therapy and outcomes in comparison with patients with ARVD and myocarditis, received IST.

P1811

Combination immunosuppressive therapy with prednisone and azathioprine for virus-negative inflammatory cardiomyopathy: meta-analysis of all available evidence

PHT Philippe Timmermans[1]; A Barradas-Pires[2]; O Ali[3]; M Henkens[4]; S Heymans[4]; K Negishi[5]

[1]Jessa Hospital, Rehabilitation and Health Centre, Heart Centre, Hasselt, Belgium; *[2]Royal Brompton Hospital, cardiology, London, United Kingdom of Great Britain & Northern Ireland*; *[3]Wayne State University, cardiology, Detroit, United States of America*; *[4]Cardiovascular Research Institute Maastricht (CARIM), Maastricht, Netherlands (The)*; *[5]Menzies Research Institute, Hobart, Australia*

Introduction: Combination immune suppression with prednisolone and azathioprine (IPA) is used to treat heart failure due to chronic non-fulmintant non-viral myocarditis. However, there has been inconsistency in the effects of immunosuppression treatment.

A systematic review and meta-analysis of trials using (IPA) to treat HF refractory to OMT caused by chronic non-fulminant virus negative or "autoimmune" myocarditis was conducted to demonstrate the effect on LV EF and the combined clinical endpoint of cardiovascular mortality and/or HTx-free survival.

Methods and results: All trials with using IPA versus OMT were searched using OVID Medline and ClinicalTrials.gov, following the PRISMA guidelines. Missing clinical outcome data was retrieved after contacting the corresponding authors. All data was reviewed and analysed using and standard meta-analysis methods. A random effect model was used to pool the effect sizes.

A total of 4 trials were identified. Two were published RCT, one was an aborted RCT without publication but randomised and treated 20 patients and one was a published registry with a corresponding control group, resulting in a total of 369 patients.

IPA on top of OMT did not improve LVEF (mean difference 9.9% [95% confidence interval -1.8, 21.7]). Because of the significant heterogeneity (I296.8%, p<0.001) we performed a subanalysis of this result. First, the studies were divided by whether RCT or not, where I2values remained similar (96.9%). Then, they were sub-grouped by whether published or not, which did not reduce I2-values but the pooled estimates of the change in LVEF became significantly positive with 14% [1.4, 26.6].

A trend towards a benefit in the combined endpoint of cardiovascular mortality and/or heart transplantation-free survival was observed with the intervention but did not reach clinical significance (risk ratio 0.34 [0.08, 1.51]). Because of a moderate heterogeneity (I2= 60%), we again performed a subgroup analyses. When categorised by RCT or not, heterogeneity significantly dropped close to low level (32%) with no difference in the pooled RR of the RCTs. Sub-grouping by publication status increased heterogeneity to almost high category (I2=72.9%).

Conclusion: At the moment, there is insufficient evidence supporting functional and prognostic benefits of IPA added to OMT in virus negative inflammatory positive cardiomyopathy.

There is a potential positive effect on both LV EF and the combined endpoint of cardiovascular mortality or HTx-free survival. Significant heterogeneity exist among individual publications regarding diagnosis, dose regime, duration of therapy, study design and quality of the data. More research is needed to elucidate the exact impact of this treatment. Further adequate-powered well-designed prospective RCTs should be warranted to explore the potential effects of adding immunosuppressive therapy to OMT.

INTRODUCTION: Pathophysiology of myocardial damage in patients presenting with acute myocarditis (MCD), which can result in post-myocarditis heart failure, is largely unknown. Although ferritin is an acute phase reactant, there are no data describing the interplay between iron status and inflammation in the context of magnetic resonance indices of MCD in these patients.

PURPOSE: We investigated iron status and inflammatory activation to predict myocardial damage in cardiac magnetic resonance (CMR) in patients with MCD.

METHODS: Consecutive patients hospitalized for MCD (the diagnosis was based on clinical symptoms, elevated myocardial necrosis biomarkers, and excluded coronary artery disease) in a tertiary referral cardiology center in 2017-2018 were enrolled and followed-up after 30 weeks (including CMR). Age- and sex-matched volunteers were considered a control group.

RESULTS: We compared clinical, laboratory and CMR data of 11 patients with MCD (age: 31 [26–34] years; men: 95%; baseline left ventricular ejection fraction [LVEF]; 56±10%) and 13 control subjects. Regarding CMR parameters, patients with MCD vs. controls had lower LVEF (57 (54–59) vs. 60 (58–63)%; p<0.05), longer native T1 [1053 (1038–1073) vs. 1018 (993–1029) ms; p<0.01] and higher T2 ratio [2,08 (1,69–2,5) vs. 1.59 (1,25–1,7); p<0.05]. Median number of left ventricle segments with oedema in MCD was 3 and with late gadolinium enhancement (LGE) – 6. Controls had neither oedema nor LGE segments.In MCD patients we observed myocardial recovery after 30 weeks, defined as a decrease in the number of LV segments with oedema [from 3 (0–4) to 0 (0–0)] and with LGE [from 6 (4–7) to 4 (3–5)], native T1 [from 1053 (1038–1073) to 1030 (1010–1033) ms] and T2 ratio [from 2,1 (1,7–2,5) to 1,6 (1,5–1,7)] (all p<0.05). Importantly, clinical recovery was heterogenous – there was no recovery of LV segments with LGE in about 1/3 of followed-up patients.There was a trend towards higher ferritin related to baseline T2 ratio (R= 0.5, p=0.1), and between the ferritin and baseline number of LV segments with oedema (R= 0.5, p=0.1). In patients with MCD serum ferritin correlated with the area of the major LGE focus after 30 weeks of follow-up (R=0.82, p<0.05). Neither troponin nor N-terminal pro-B type natriuretic peptide correlated with CMR indices of myocardial oedema or necrosis.

CONCLUSIONS: Our data report that clinical parameters which are on the crossroad of immune response and iron metabolism are related to pathophysiology of myocarditis. High circulating ferritin may predict myocardial oedema and fibrosis persisted after 30 weeks of follow-up in patients with MCD.

P1813

Diagnostic value of NT proBNP in patients with myocarditis and preserved left ventricular systolic function

S Borges[1]; F Goncalves[1]; JP Guimaraes[1]; JJ Monteiro[1]; C Ferreira[1]; JI Moreira[1]

[1]Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal

Background: The diagnostic role of N-terminal pro B-type natriuretic peptide (NT-proBNP) in patients with heart failure and left ventricular (LV) dysfunction has been extensively studied. Nevertheless, upper normal NT-proBNP levels can be found in many circumstances without decreased LV ejection fraction (LVEF). The purpose of this study is to evaluate the diagnostic value of BNP in patients with myocarditis and preserved LVEF

Methods: We retrospectively analysed data from patients (pts) admitted in one center, with the diagnosis of myocarditis, from 2008 and 2018;

Results: 63 patients were included. Mean age was 38.8 +/- 16 years and 91% (53) were men. Out of those, 58 (94%) had preserved LVEF (mean 59.9 +/- 4.27%) Average length of stay in hospital was 5 days;

The NT-proBNP values ranged from 24 to 3110 pg/mL (median 482 ng/mL; interquartile range (IQR) = 768). Regarding the group of pts with preserved LVEF, 80% (44pts) had plasma levels of NT-proBNP > 120 ng/mL [upper reference limit]; NT-proBNP positively correlated with peak troponin (p= 0.006, r= 0, 37), leucocyte (p= 0.05, r= 0.25) and neutrophil to lymphocyte ratio (p= 0.003, r= 0.26).

Conclusion: In this population, the majority of the patients with myocarditis did not have significant LV systolic dysfunction, as measured by LVEF; Despite that, most of them presented high levels of BNP at admission. In this subset of patients, in which clinical presentation is highly variable, NT-proBNP measurement may be an important adjuvant in early assessment of myocarditis, regardless LVEF;

P1814

Assessment of left ventricular mechanics before and after surgical myectomy in patients with hypertrophic obstructive cardiomyopathy, using two dimension speckle tracking echocardiography.

H Hala Badran[1]; A Alamin[2]; N Faheem[1]; T Salman[2]; MH Yacoub[3]

[1]Menoufiya University, Shebin, Egypt; *[2]AlAzhar University, Cairo, Egypt*; *[3]Imperial College London, London, United Kingdom of Great Britain & Northern Ireland*

Background: Septal myectomy is the gold standard method to relieve LVOT PG in patients with HOCM. Myocardial mechanics are abnormal in HOCM, demonstrating low longitudinal strain, high circumferential strain, and high apical rotation compared with healthy subjects.

Objectives: The aim of this study was to determine whether functional improvement after myectomy is associated with improved myocardial mechanics.

Methods: A total of 15 patients(60% males and 40% female) with HOCM refractory to medical treatment were subjected to septal myectomy, Clinical data and paired

echocardiographic studies before and within 6monthes after myectomy were analyzed and compared. Myocardial mechanics including longitudinal, circumferential strain, rotation and LV synchronization were assessed using Velocity Vector Imaging.
Results: Symptomatic improvement after myectomy is associated with dramatic reduction of LV outflow gradient 63.13 ± 10.25 to 9.96 ± 2.72mmHg; P < .0001, decreased left atrial volume index (from 37.8 ± 5.6 to 26.4 ± 3.37 cm3/m2; P < 0.05) and decreased E/e´ from (15.2± 2.39 to 9.18 ±1.42, P 0.05). However, longitudinal strain reduced at the myectomy site (basal septum: -7.40± 2.2 vs -5.06 ± 1.75, P < .004), increased in the basal inferior segment and remained unchanged globally (-6.43±6.54 vs -8.70±2.30, P =NS). Meanwhile, circumferential strain decreased from -28.47± 3.35 to -18.26 ± 2.86, P < .05 and LV twist normalized (from 16.52 ± 2.25 to14.02±2.27, P < .05).
Conclusion: Surgical myectomy is associated with different mechanical adaptations and more deterioration of cardiac mechanics despite symptomatic improvement in HOCM.

P1815
Correlations between electrocardiography and echocardiography in hypertrophic cardiomyopathy

S Sidonia Albu[1]; L Mandes[1]; M Rosca[1]; B Popescu[1]; E Apetrei[1]; C Ginghina[1]; R Jurcut[1]
[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, cardiology, Bucharest, Romania

Introduction: In patients with hypertrophic cardiomyopathy (HCM), the electrocardiogram (ECG) represents one of the first line investigation. Despite this fact, the ECG abnormalities may be complex and incomplete recognized in clinical practice. Some of the ECG changes may suggest clues for detecting a specific etiology in HCM or may represent an important diagnostic tool for probands or in relatives.
Purpose: The aim of this study was to determine the relationship between ECG patterns and HCM structural phenotype assessed using echocardiography, as well as to determine the frequency of these parameters.
Methods: We collected data prospectively from consecutive patients with HCM evaluated in our center between October 2015-April 2017. The ECG tracings were analyzed for: cardiac rhythm, P wave anomalies, PR interval, QRS axis and duration, presence and extent of abnormal Q waves, hypertrophy scores, ST-T abnormalities, QTc interval. Conventional echocardiography data included left ventricular (LV) septal and posterior wall thickness, LV maximal wall thickness (MWT), presence of dynamic obstruction, left atrial (LA) and right atrial (RA) anomalies.
Results: The study included 154 patients (57.1% men), mean age 55±14 years. Left atrial enlargement as defined by ECG criteria (64% when considering V1 changes and only 13% of cases when criteria included also changes in unipolar leads) did not correlate with LA dilatation detected by echocardiography (80% patients). In our population, we observed that the mean left atrial volume is greater in patients with atrial fibrillation and furthermore we analized these data in correlation with the type of atrial fibrillation and showed that the left atrial tends to enlarge as AF becomes permanent (from 107±32 ml for paroxystic AF, to 146±72 ml for permanent AF). The interventricular septum was predominantly affected (mean value of 19.5 ± 5mm) when compared with the posterior wall thus reflecting the asymmetrical distribution of hypertrophy. However, no correlation was found between LV maximum wall thickness and the Sokolow Lyon, Cornell or Romhilt-Estes scores. The sensitivity and specificity of Cornell index are higher compared with Romhilt-Estes score, which appears to have, however, a greater positive predictive value. The prevalence of complete AV block seems to be low (3%) and not characteristic for patients with sarcomeric HCM. The giant inverted T waves (>10 mm) were found to predict the presence of apical HCM (p<0.001).
Conclusions: This study demonstrates that normal electrocardiograms are unusual in all subgroups of patients with hypertrophic cardiomyopathy. Not all ECG indices used in clinical practice have similar sensitivity, however using a multiparametric approach usually describes well the severity of structural anomalies.

P1816
Left ventricular longitudinal strain is a predictor of mortality in hypertrophic cardiomyopathy

H Hala Badran[1]; G Soltan[1]; N Faheem[1]; A Yehia[1]; MH Yacoub[2]
[1]Menoufiya University, Shebin, Egypt; *[2]Imperial College London, London, United Kingdom of Great Britain & Northern Ireland*

Background Echocardiographic global longitudinal strain (GLS) is increasingly recognised as a more effective technique than conventional ejection fraction (EF) in detecting subtle changes in left ventricular (LV) function. This study investigated the prognostic value of GLS in patients with hypertrophic cardiomyopathy (HCM).
Methods The study included 313 patients (62% male, mean age 39 ± 19 years) with left ventricular ejection fraction. They were followed for (3.2 ±1.2 years). GLS was calculated using 2-dimensional speckle tracking. Cox proportional hazard models were used to assess the association of measures of LV deformation and all- cause and CV mortality.
Results The mean GLS at baseline was -7.8 ± 4.3%, 64% were symptomatic. There were 24(7.7%) deaths reported that could be attributed to cardiovascular causes. GLS was a significant predictor of all-cause [Hazard Ratio (HR) 1.09 95%; Confidence Interval (CI) 1.02–1.16; p = 0.01] and CV mortality (HR 1.16 95%; CI 1.04–1.30; p = 0.008) following adjustment for relevant clinical variables including (LVMI) and EF. GLS also had greater predictive power for both all- cause and CV mortality. Impaired GLS (>-16%) was associated with a 5.6-fold increased unadjusted risk of CV mortality in patients with preserved EF.
Conclusion: Abnormal GLS is an independent predictor of adverse outcomes in HCM patients. Standardized use of GLS may provide significant incremental value over traditional variables for risk stratification.

Modern strategy in hypertrophic cardiomyopathy treatment: a single European center experience

K Rudenko[1]; V Lazoryshynets[1]; O Krykunov[1]; O Chyzhevska[1]; L Nevmerzhytska[1]; O Trembovetska[1]; P Danchenko[2]
[1]Amosov Institute of Cardiovascular Surgery AMS of Ukraine, Kiev, Ukraine; *[2]National O.O. Bohomolets Medical University, Kiev, Ukraine*

Background. For almost 50 years transaortic septal myectomy has been the standard treatment for patients with hypertrophic obstructive cardiomyopathy (HOCM) and severe symptoms refractory to medical therapy. However, with the beginning of era of alcohol septal ablation (ASA), the number of surgical septal myectomies in Europe and all over the world significantly reduced as it began to be considered less invasive, safer and equally effective procedure. The experience of our Center shows that exceedingly favorable results of the surgical correction not only diminish clinical manifestation of heart failure (HF) but also improve patient's quality of life and reduce the risk of serious complications, including life-threatening ventricular tachyarrhythmias and sudden cardiac death.
Purpose. The cohort randomized study was conducted to establish the effectiveness of surgical extended septal myectomy accompanied by anomalous fibrous chordal attachments resection and papillary muscles (PM) mobilization in symptomatic patients with HOCM and different degrees of HF.
Methods. The research includes 118 consecutive symptomatic patients with HOCM who underwent surgical extended myectomy with anomalous chordal attachments (secondary chordae) resection and mobilization of the anterior and posterior groups of PM. In case of necessity, a plication of the mitral valve leaflet was performed to reduce the length of the oversized structure and thus reduce the risk of post-operative systolic anterior motion (SAM) effect. The following parameters before and after surgical intervention were evaluated: systolic pressure gradient (SPG) on the left ventricle outflow tract (LVOT), mitral regurgitation (MR) degree, NYHA functional class, survival rate and main post-operative complications.
Results. According to the obtained data, SPG on LVOT decreased from 93,6±23,2 mmHg prior the surgery to 19,7±11,4 mmHg after the treatment (p<0,001). 21 (17,8%) patients had moderate degree of MR after the surgery, as before intervention the number of patients having moderate or severe MR degree accounted 101 (85,5%)(p<0,001). Out of 118 patients, 36 (30,5%) of whom have had III-IV NYHA functional class before the procedure, 115 (97,4%) were in functional class I-II at the discharge (p<0,001). No patients with III-IV NYHA functional class were observed. The mortality accounted 1,7% (2 patients). Among 118 patients, one (0,8%) underwent implantable cardioverter-defibrillator (ICD) implantation within sudden cardiac death prophylaxis; 5 (4,2%) patients underwent pacemaker implantation due to complete post-operative AV-block.
Conclusion. Surgical extended septal myectomy remains a gold standard of treatment of patients with HOCM. The presented study showed not only successful results of surgical correction, but most importantly, significant decrease of the HF manifestation in symptomatic patients and improvement of quality of life already in early post-operative period.

The prognostic value of myocardial fibrosis MRI in assessing the risk of progression of heart failure in patients with HCM

O Olesya Shatova[1]; E Zakharova[1]; S Komissarova[1]; E Vankovich[1]; I Haidzel[1]
[1]*Republican Scientific and Practical Centre of Cardiology, heart failure, Minsk, Belarus*

The progression of symptoms of CHF is still a serious complication that determines the outcome in HCM. It should be noted that in most cases in patients with HCM with symptoms of severe CHF, LVEF remains preserved, which requires a search for new diagnostic approaches to assess the systolic function of the myocardium.
Purpose: to assess the prognostic role of myocardial fibrosis volume by gadolinium contrast-enhanced MRI in patients with HCM as a predictor of CHF progression to FC III NYHA, which required hospitalization.
Methods. The study included 124 patients with HCM (79 males and 45 females) aged 18 to 69 years (median age 46 years), median observation 42 months (3.5 years). The clinical end point included the progression of CHF symptoms from I – II FC to NYHA FC III, requiring hospitalization.
Results. Among 124 patients, the progression of CHF symptoms requiring hospitalization was observed in 24 people and occurred in the presence of preserved systolic function (LV EF> 50 %). 12 patients were hospitalized for two years, which indicates the rapid progression of symptoms of heart failure with NYHA FC I-II to FC III. The cumulative 3-year survival rate was 83 % (95% CI 76.5 - 90.1). The one-factor regression analysis was performed to determine the predictors of the progression of CHF symptoms and hospitalizations. As a new marker aimed at identifying patients at risk of adverse events, myocardial fibrosis volume was analyzed by MRI. Kaplan-Meier curve-free survival showed statistically significant differences in groups with a fibrosis volume of less than 20% and more than 20 % (log-rank p <0.001) and amounted to 95.2 % (95% CI 89.9 -100 %) and 32.1 % (95 % CI 17.9 -57.4 %), respectively. All indicators that were statistically significant in univariate regression analysis were included in the multivariate analysis and their threshold values were determined. In a multivariate analysis, independent factors associated with the progression of CHF and related hospitalization were the following characteristics: age> 50 years old (RR 5.9; 95 % CI 2.3–15.1, p <0.001), presence of episodes of AF (RR 5.6 ; 95% CI 2.2 - 14.2, p <0.001) and the volume of myocardial fibrosis by MRI ≥ 20 % (RR 23.3; 95% CI 7.3 - 74.8, p <0.001). The regression analysis identified a group of patients with HCM, potentially having the risk of progression of CHF, which required hospitalization, with age> 50 years, episodes of AF and the amount of fibrosis ≥ 20%.
Conclusion. Myocardial fibrosis index ≥ 20% is associated with the development of adverse events associated with the progression of CHF in HCM and can be used to identify patients at high risk of developing CHF progression with an unfavorable outcome.

Atrial volumes ratio as a predictor of hemodynamic phenotype in patients with pulmonary hypertension

N P D Cunha[1]; R Placido[1]; T Guimaraes[1]; N Cortez-Dias[1]; JR Agostinho[1]; I Aguiar-Ricardo[1]; J Rigueira[1]; R Santos[1]; A Nunes-Ferreira[1]; T Rodrigues[1]; A Mineiro[2]; S Martins[1]; N Lousada[1]; FJ Pinto[1]
[1]*Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal*; [2]*Pulido Valente Hospital/CHULN, Pneumology Department, Lisbon, Portugal*

Introduction: Characterization of the hemodynamic profile in pulmonary hypertension (PH) is crucial for the diagnosis and for deciding the appropriate therapeutic strategy. However, given its invasive nature, it is necessary to develop alternative, non-invasive predictors of the hemodynamic classification. Considering the different patterns of atrial overload due to different PH profiles, we intend to determine the role of the relation between the atrial volumes ratio and the hemodynamic classification.
Results: 174 patients were included, 69.9% females, with a mean age of 68 years old (IQR:24). 60% (N=105) had pre-capilary PH, 14% (N=25) isolated pos-capilary PH and 25% (N=44) combined pos-capilary PH. The ratio RA/LA was higher in patients with pre-capillary PH when compared to patients with combined PH and isolated pos-capillary PH (1.42±0.83 vs 1.18±0.92 vs 0.95±0.42, respectively; p=0,019). A ratio RA/LA of 1.31 allowed to differentiate with reasonable diagnostic accuracy (AUC:0.63, specificity:74%, sensibility:50%, NPV:92%, PPV:64%) the pre-capillary phenotype from others.
Conclusion: The ratio RA/LA assessed by TTE is a useful parameter to distinguish between pre-capillary and post-capillary PH.

Prognostic impact of left ventricle dysfunction in patients with pulmonary hypertension

R Santos[1]; R Placido[1]; T Guimaraes[1]; N Cortez-Dias[1]; JR Agostinho[1]; J Rigueira[1]; I Aguiar-Ricardo[1]; A Nunes-Ferreira[1]; T Rodrigues[1]; N Cunha[1]; NC Andre[1]; A Mineiro[2]; S Martins[1]; N Lousada[1]; FJ Pinto[1]
[1]*Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal*; [2]*Pulido Valente Hospital/CHULN, Pneumology Department, Lisbon, Portugal*

Introduction: Left ventricular (LV) dysfunction is the main cause of pulmonary hypertension (PH) and is associated with a worse prognosis. However, the contributory factor of LV dysfunction in patients with predominantly pre-capillary PH is unclear.

Objective: to assess the prognostic impact of LV dysfunction in patients with PH.
Methods: Retrospective, single-center study of consecutive patients followed in the PH treatment center, with hemodynamic diagnosis of PH, submitted to transthoracic echocardiography at diagnosis.
The concomitant presence of LV dysfunction, classified as isolated diastolic dysfunction, systolic dysfunction or valvulopathy with hemodynamic repercussion was evaluated. The association of this variable with any cause mortality at 5 years was determined using the Kaplan Meier survival analysis and the Cox regression analysis.
Results: 176 patients were included, 69.9% female (N = 123), with a median age of 68 years (IQR: 24). LV dysfunction was identified in 28.4% (N = 49), with the majority (N = 40) presenting with group 2 PH.
The5-year mortality rate from any cause was27.3%.Patients with systolic dysfunction had 50%mortality at 5years, significantly higher than the other groups (p=0,001), being a predictor of mortality in this period (p=0,003).
Conclusion: The presence of left ventricular systolic dysfunction is associated with worse prognosis in PH patients.

On behalf of: RECOPILAR

Hemodynamic of pulmonary arterial hypertension (PAH) has been poorly characterized in Latin America.
The aim of this report was to compare the hemodynamic and clinical profile among subgroups of PAH in Argentina.
Method: From Jul-14 to Oct-16, 399 incident and prevalent patients with PAH were prospectively included by 72 investigators from 23 provinces of Argentina in a collaborative registry. Patients must fulfill all the following inclusion criteria: 1-Age over three months; 2 - mean pulmonary arterial pressure (mPAP) at rest $\geq$ 25 mmHg by right heart catheterization (RHC) and 3 - clinical stability in the absence of hospitalization in last month. The subgroups of PAH were defined as idiopathic, heritable or drugs associated (1), associated with connective tissue disease (2), HIV (3), porto-pulmonary hypertension (4), and congenital heart disease (5).
Results: The proportion of patients in subgroups 1 to 5 was: 1=41.9%, 2=23.8%, 3=5%, 4=4% and 5: 25.3%. The full comparison of clinical characteristics and hemodynamics parameter is shown in Table. Conclusion: In concordance with other international surveys, this Latin American registry showed that despite differences in hemodynamic profile among subgroups in PAH the clinical presentation was similar. These findings suggest that different factors besides hemodynamic may have influence in the severity of the disease.

Prognostic value of baseline and change of NT-proBNP plasma concentrations in pre-capillary pulmonary hypertension

A Vigario[1]; SI Correia[2]; I Furtado[1]; C Maia Cruz[1]; F Goncalves[3]; L Carvalho[3]; M Santos[4]; A Reis[5]
[1]Hospital Center of Porto, Internal Medicine, Porto, Portugal; *[2]Hospital de Braga, Internal Medicine, Braga, Portugal*; *[3]Hospital Center of Porto, Internal Medicine/Pulmonary Vascular Disease Unit, Porto, Portugal*; *[4]Hospital Center of Porto, Cardiology/Pulmonary Vascular Disease Unit, Porto, Portugal*; *[5]Hospital Center of Porto, Pulmonary Vascular Disease Unit, Porto, Portugal*

Introduction /Purpose: NT-proBNP is a validated and widely used biomarker in Pulmonary Hypertension (PH). Little is known about the prognostic value of its change. We aimed to study the prognostic impact of baseline and change of NT-proBNP plasma concentrations after achieving stable pulmonary vasodilator treatment.
Methods: Baseline NT-proBNP refers to NT-proBNP measurement at diagnosis. NT-proBNP delta was calculated as the difference between baseline and 12-month measurement after stable pulmonary vasodilator therapy. Cox proportional hazards models were used to study the relationship between NT-proBNP and death.
Results: We studied retrospectively 116 pre-capillary PH patients with a mean age of 58 years, 70% (n=81) of female gender. Concerning the etiology, the majority of patients were from group 1 (72%, n=83), followed by group 4 (25%, n=29) and group 5 (4%, n=5). Functional class at admission was class III (49%, n=57), class II (27%, n=31), class IV (14%, n=16) and class I (8%, n=9); the mean 6MWD was 300m, and 52%, 35% e 13% of patients were on mono, double and triple vasodilator therapy, respectively. There were 35 (30%) deaths over a mean follow-up time of 5.3±3.5

years. The median and interquartile range of baseline NT-proBNP concentration was 864 [221-2278] ng/mL. The median and interquartile range of 12-month NT-proBNP concentration was 358 [141-1452] ng/mL. The median and interquartile range of NT-proBNP delta was 169 [-22, 854] ng/mL, the median percent of NT-proBNP change was 30%. Baseline and 12-month NT-proBNP were significantly associated to death (p<0.001), however delta NT-proBNP did not (p=0.16).
Conclusion: In contrast to baseline and follow-up plasma concentrations of NT-proBNP, its change did not captured risk of dying. Further studies are needed to explore the correlates of this biomarker changes and its significance in prognostic stratification.

P1823

Correlation between cardiac index and right ventricular systolic function in our patients with pulmonary hypertension.

A Lescano[1]; R Caprini[1]; E Besmalinovich[1]; G Sorasio[1]; AR A Rossi[1]; CM C Musante[1]; MV M Vergara[1]; JF J Farina[1]; C Miranda[1]; R Skena[1]
[1]QUILMES TRINIDAD CLINIC, BUENOS AIRES, Argentina

Pulmonary hypertension (PH) is a multifactorial disease with a high morbidity and mortality. It requires invasive hemodynamic diagnosis, with a value of mean pulmonary pressure (MPP) ≥25 mmHg. In the recommended algorithm studies, doppler echocardiography (DE) is the screening method, by the estimation of systolic pulmonary pressure and right ventricular systolic function (RVSF). The longitudinal excursion of the lateral wall of tricuspid annulus (TAPSE) is an indicator of RVSF, although it was removed from the HP guidelines. By right heart catheterization, the measurement of cardiac index (CI) expresses the right ventricular function and is a mortality marker. The question arises about the correlation between both techniques as indicators of right ventricular function.
Objective: Determine the correlation of TAPSE value and CI in our population with diagnosis of PH.
Methods. The patients derived to the service between March 2012 and January 2018 with a PH diagnosis (PPM ≥ 25 mm Hg or Eisenmenger syndrome), were analyzed. The data recollection included: filiation information, PH group classification, clinical features, direct hemodynamic variables (CCD), functional variables (six minute walk test (6MWT) and functional class) and echocardiographic values, according to recommendations of international guidelines.
Echocardiographic variables were obtained by three experienced operators. It was recorded: RVSF, TAPSE, pulmonary pressure and pericardial effusion (PE) presence. Hemodynamic confirmation has been obtained by a right heart catheterization, with the recollection of quantified pressures (right atrium, systolic, mean, diastolic PP, wedge pressure, CI, pulmonary and systemic vascular resistance). Both studies were performed with a difference <24 hours and physicians did not know echocardiography results. Bioestat 5.0 statistical package was used and linear correlation variables were analyzed.
Outcomes: It s a multicenter, observational, descriptive, consecutive and prospective study that enrolled 114 cases with incidental hemodynamic diagnosis of HP. The average age of the population was 56 years (SD 19), 59 % female. The PH Group (G) was: GI 66%, G II 14%, G III 7%, G IV 8% and GV 5%. With respect to the clinical features we observed: 80% heart failure and 24% syncope. Direct hemodynamic measurements showed average values: systolic PP 74 mmHg, MPP 45 mmHg (SD 15), diastolic PP 31 mmHg , transpulmonary gradient 34, right atrial pressure 9 mm Hg and cardiac index 2.8 (4.6-1.2) l/min/m2. Among the echocardiographic findings we observed an average TAPSE of 17.6mm (30-10). The concordance correlation coefficient resulted in r 0.02 (95% CI 0.20-0.25), with a Pearson p value of 0.8.
Conclusions In our study population with an established diagnosis of PH we observed a bad correlation between TAPSE and CI. This results support the need to use right heart catheterization as a tool to quantify the systolic function of the right ventricle.

P1824

Pulmonary Hipertension. When the experience overcomes the evidence

A Lescano[1]; A Rossi[1]; R Caprini[1]; E Besmalinovich[1]; G Sorasio[2]; C Miranda[1]; M Vergara[1]; C Musante[1]; I Fernandez[1]; F Stroschein[2]; J Farina[2]; R Sckena[2]
[1]QUILMES TRINIDAD CLINIC, BUENOS AIRES, Argentina; *[2]SANTA CLARA RED DE CLINICAS, BUENOS AIRES, Argentina*

Pulmonay Hypertension (PH) guidelines incorporate clinical, functional, hemodynamic and image variables as prognostic indicators. The parameters of right ventricle systolic function (RVSF), as the tricuspid annular plane systolic excursion (TAPSE), have been excluded from the international scores.Objectives: Determinate the value of TAPSE as a prognosic value in our patients with PH.
Methods: Patients (P) with diagnosis of PH (between 2012 and 2018), confirmed by right heart catheterization (mean pulmonary pressure ≥ 25mmHg), were included. The data was recorded: demographic; PH group (G); clinical variables: symptoms and functional class (FC), neurohormonal: brain natriuretic peptide (BNP), hemodynamic parameters: right atrium (RA) pressure and cardiac index (CI); functional: 6 minute walk test distance (6MW), Ed data: RVSF, TAPSE and pericardial effusion (PE). Poor prognosis factors were defined according to PH international guidelines (between moderate/high risk): heart failure history, syncope, advanced FC (III/IV), 6MW <160m, BNP ≥300pg/dl, PE presence, RA ≥14mmHg and CI ≤2,2 l/min/m2. The outcome was follow up Mortality (M) within two years. TAPSE was analyzed as an integral variable and was dichotomized in > 16 mm (A) and ≤ 16 mm (B). We use the STATA 14 program. T test or Chi-squared was applied, according to the variables. The logistic regression model was used to determinate the impact of TAPSE in M, integrate in a multivariate analysis.
Results: Multicentric, analytical, prospective, included 141 P, with a 25% M, 77% female and 57 (± 18) mean age. PH G was: I 68%, II 13%, III 7 % IV 7%, V 5%. Among the prognostic factors, we highlight: advanced FC 50%, syncope 22%, 6MWT ≤160m 16%, RA ≥14 mmHg 18%, IC ≤2,2 26%, BNP ≥ 300 52% and PE in 30%. Within the Ed observed: 79% RVSF deterioration (24% moderate, 18% severe), a mean TAPSE value of 18 mm (± 4,1), with 75% group A and 25% group B distribution. The relationship between M and mean TAPSE probed a significant association: 19,1 mm in the survival A group (CI 95% 18-20) vs 15,8 mm in the B group (CI 95% 14,5-17,1) and a p value: 0,003. Likewise we observe less mortality in the A group (17 vs 47%; p: 0,001). The multivariate analysis shows a correlation between mortality and different variables, such as age, HF, syncope and TAPSE value (p<0.005). When we integrate the groups, we observe that the group B presents a β coefficient of 1,5 (0,5-2,4), with greater variation than the rest of the variables (p=0,001).The OR of the group B was 4,5, with a higher association force than the rest of the variables (age, HF, syncope), and a model adequacy of 76.6%.
Conclusions: In this population with PH diagnosis, a significant relationship between TAPSE value and Mis observed. The dichotomization of TAPSE ≤ 16, associate in an independent way with M. These findings highlight the necessity of designing a great scale study to determinate the prognostic role of that parameter.

SD (standard deviation)

and evolution in patients with PAH in Argentina. Method: From Jul-14 to Oct-16, 399 incident and prevalent patients with PAH were prospectively included by 72 investigators from 23 provinces of Argentina. Patients must fulfill all the following inclusion criteria: 1-Age over three months; 2-mean pulmonary arterial pressure (mPAP) at rest ≥25 mmHg by right heart catheterization (RHC) and 3-clinical stability in the absence of hospitalization in last month. Of these, 257 adults with available body mass index (BMI) data were included in this analysis. Results: The distribution according to BMI was: malnutrition (M, ≤18.4) =11 (4.3%); normal (N, 18.5-24.9) =113 (44%); overweight (OV, 25-29.9) =83 (32.3%); obesity (OB, ≥30) =50 (19.5%). The comparison among groups is shown in the table. Mortality during the follow-up (mean of 24 months) was 20.7%. The area under the curve of BMI to predict mortality was 0.62 and a cutoff point of <24.5 had a sensitivity of 59% and specificity of 62%. Cumulative survival at 36 months according to groups M; N; OV and OB was 76.9, 80.2, 82.1 and 89.6%, respectively (p=NS). Long term survival in non-obese vs. obese groups was 80.8 vs 89.6% (p=NS), and according to the cut-off point, greater or less than 24.5, was 78.6 vs 85.6% (p=NS). Conclusion: Disorders of the nutritional status were identified in more than half of the patients with PAH in Argentina, with a prevalence of obesity in 1 out of 5. Despite the differences in the clinical and hemodynamic profile, the evolution shows a non-significant tendency to lower mortality with high body mass index.

P1826

Post-resuscitation arterial oxygen and carbon dioxide partial pressures abnormalities are not associated to outcomes after out-of-hospital cardiac arrest attributed to acute pulmonary embolism

D David Roque[1]; JS Simoes[1]; DANIEL Faria[1]; JOÃO Ferreira[1]; HF Ferreira[1]; MB Beringuilho[1]; CM Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*

BACKGROUND: Early partial pressures of arterial oxygen (PaO2) and carbon dioxide (PaCO2) after resuscitation from cardiac arrest were found to be related to in-hospital mortality and neurological outcome by some observational studies. Impact of post-resuscitation PaO2 and PaCO2 abnormalities after out-of-hospital cardiac arrest (OHCA) specifically attributed to acute pulmonary embolism (PE) was not explored yet.
PURPOSE: We aimed to know whether post-resuscitation hyperoxaemia, hypoxemia, hypercarbia and hypocarbia are associated with short-term mortality after OHCA attributed to acute PE.
METHODS: Retrospective review of adult patients admitted to a single-centre emergency department (ED), along 3 years, for OHCA attributed to acute PE. We considered OHCA to be attributed to acute PE if (i) computed tomographic pulmonary angiography proved acute PE; (ii) echocardiography documented right ventricular enlargement in clinical settings suspicious for acute PE; and (iii) necropsy confirmed acute PE. Included patients must had sustained recovery of spontaneous circulation (ROSC) ≥1 hour after ED arrival and at least one arterial blood gas (ABG) sample analysis collected within the first 6 hours. In ABG, we identified presence of hyperoxaemia (PaO2 ≥300 mmHg), hypoxemia (PaO2 <60 mmHg), hypercarbia (PaCO2 >50 mmHg) and hypocarbia (PaCO2 <30 mmHg). Outcome was all-cause 7-day mortality. Association between outcome and hyper- or hypoxemia and hyper- or hypocarbia were analysed by $\chi 2$ (chi-square) test.
RESULTS: We included 21 patients admitted for OHCA attributed to acute PE. Mean age was 67.0±18.8 years, and 23.8% were male. All-cause 7-day mortality was 71.4% (n=15). Hyperoxaemia, hypoxemia, hypercarbia, and hypocarbia occurred in 33.3%, 9.5%, 23.8% and 19.0%, respectively. Hyperoxaemia, hypoxemia, hypercarbia and hypocarbia were not associated with all-cause mortality within 7 days (p=0.354, p=1.000, p=.0115 and p= p=1.000, respectively).
CONCLUSIONS: PaO2 and PaCO2 abnormalities were relatively frequent in OHCA attributed to acute PE with sustained ROSC. However, PaO2 and PaCO2 abnormalities were not associated to all-cause 7-day mortality. These results are somewhat unexpected and may be related to small sample size and to inherent limitations of the study retrospective design. Impact of disturbed oxygenation and ventilation following resuscitation for OHCA attributed to acute PE deserves further evaluation.

Hypertension

Purpose: To compare the 24 hours ambulatory central blood pressure (BP) reduction efficacy between losartan combined with fixed dose amlodipine (L/A group) and dose up-titrated hydrochlorothiazide (L/H group) according to office BP.
Methods: We conducted a prospective, randomized, double-blind multicenter trial in 231 hypertensive patients (mean age=59.2±12.2 years). Patients received losartan 50 mg monotherapy for 4 weeks, followed by additional use of amlodipine 5 mg or hydrochlorothiazide 12.5 mg for 20 weeks after randomization. The patients who did not achieve the BP goal after 4 weeks' randomization received an increased dose of 100 mg/5 mg for the L/A group and 100 mg/25 mg for L/H group respectively. The 24 hours ambulatory central BP was measured at baseline and after 20 weeks' treatment.
Results: Brachial office systolic BP reduction was not significantly different between groups (-15.7±14.0 vs. -14.7±15.1 mmHg, p=0.6130), whereas the 24 hours ambulatory central systolic BP was significantly more reduced in the L/A group compared with that in the L/H group after 20 weeks' treatment (-9.37±10.67 vs. -6.28±10.50 mmHg, p=0.0407). The 24 hours ambulatory central systolic BP at the completion of the study and its reduction magnitude were independently associated with reductions in aortic pulse wave velocity (aPWV), pulse pressure, and wave reflection magnitude.
Conclusion: Losartan combined with amlodipine had a more beneficial effect on 24 hours central systolic BP reduction than losartan combined with hydrochlorothiazide and greater reduction in 24 hours aPWV, pulse pressure, and reflection magnitude. The combination of losartan and amlodipine was more favorable in 24 hours ambulatory central hemodynamics beyond BP-lowering efficacy than the combination of losartan and hydrochlorothiazide, regardless of office BP.

P1828

Predictors of blood pressure response to renal revascularization in renal artery stenosis' patients presenting acute cardiac syndromes

DO Geavlete[1]; C Beladan[1]; D Deleanu[1]; MR Zaharia[2]; O Tautu[3]; BA Popescu[1]; C Ginghina[1]; C Chioncel[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania*; [2]*Emergency Clinical Hospital St John, Internal Medicine, Bucharest, Romania*; [3]*University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*

Introduction: Completely different patterns of activation for the renin-angiotensin-aldosteron system depending on the extension of vascular involvement (unilateral or bilateral) were recently demonstrated. These findings may have an impact upon blood pressure (BP) response to renal revascularization.
Purpose: The analysis was aimed to evaluate the response of BP and renal function in patients with significant renal artery stenosis (>70%) presenting acute cardiac syndromes. Methods: 78 hypertensive patients diagnosed with significant uni- and bilateral RAS were prospectively enrolled, subsequently resulting in 3 groups (34-unilateral, 28-bilateral RAS and 16-RAS in solitary kidney). Clinical, biological and echocardiographic parameters were comparatively evaluated between groups at admission and 12 months' after renal stenting. BP evolution and renal function' after stenting were evaluated after one year. Regression logistic analysis - univariate and multivariate (stepwise Likelihood ratio method) was used in order to determine the independent predictors for major outcomes.

Results: No significant differences between groups regarding baseline characteristics (age, gender, stenosis' severity, comorbidities, blood pressure values, biologic and echo parameters) were found. The comparative analysis identified a significant reduction of BP values (systolic, diastolic, medium, pulse pressure) 12 month' after renal stenting (BP variation of 23.6795±19.86 mmHg, 14.86±12.34mmHg, 17.80±13.46 mmHg and 8.81±15.28 mmHg respectively, p<0.001). Controlled BP after revascularization was found in 35.1% of patients and improved BP in 44.6% of the entire series, without significant differences between groups (p>0.05). Cured BP was not identified in the current analysis. The number of antihypertensive classes after renal stenting remained similar (3.51±1.1 vs. 3.41±1.09, p>0.05). Multivariate regression analysis confirmed three independent predictors for BP responder (cured and controlled BP) in the studied population: diabetes, diastolic BP and the severity of residual stenosis. The non-diabetic status predicted a favorable outcome of 8.42 times higher than diabetes (95%CI, 1.71-4.41). The higher diastolic BP (over the median value of 100 mmHg) indicated a greater likelihood of BP responder (95%CI, 0.86-0.97). The accuracy of the combined predictive model as quantified by the area under the receiver-operating characteristics curve was 0.89 (95%CI, 0.81-0.96, p=0.039). Different predictive models emerged for diabetic vs. non-diabetic patients.
Conclusions: The current findings emphasized favorable outcomes in terms of BP control after renal revascularization in patients presenting acute cardiac syndromes, including diabetes associating nephrosclerosis. The extension of vascular involvement did not significantly impact BP outcomes in the studied groups, although different responses in terms of BP evolution (improvement, controlled or stationary) were observed.

P1829

Morning rise in blood pressure according to ambulatory blood pressure monitoring in patients with hypertension and chronic heart failure

VN Larina[1]; EV Fedorova[1]; VP Sidorova[2]
[1]*Pirogov Russian National Research Medical University , Oupatient Medicine, Moscow, Russian Federation*; [2]*Diagnostic Clinical Center No.1, Moscow, Russian Federation*

On behalf of: Olga Kulbachinskaya

The morning rise in blood pressure occurs as a result of activation of neurohormonal systems and is associated with high risk of cardiovascular complications. Objective. Assess profile of the morning blood pressure data on ambulatory blood pressure monitoring (ABPM) in patients with arterial hypertension (AH) and chronic heart failure (CHF). Methods. 128 outpatients were included in the open, one-time study (35.9% M 64.1% F) aged 40 years and older. A general clinical examination, evaluation of the lipid profile, ECG, EchoCG, ABPM, ultrasound duplex scanning of the extracranial regions brachiocephalic arteries of the BCA. Prior to the study treatments, all patients provided written informed consent. The program used is Statistica 10. Results. AH was found in 120 (93,8%) patients (38,3% M/61,7% F) aged 40 to 83 (59,1±7,8) years. LVH according EchoCG was present in 53 (56,4%), thickening of intima-media complex of brachiocephalic artery – in 87 (92,6%), smoking - 21 (17.5%) patients. Co-morbidities were present in 96 (80%) patients: past myocardial infarction – in 5 (4,2%), diabetes mellitus – in 35 (29,2%), CHF – in 59 (49,2%) patients. The median age of patients with CHF was 59,1±9,7 years, without CHF (n=61, 50,8%) – 56,5±9,0 years. Average daily systolic blood pressure (SBP) was increased in 34 (57,7%) patients with CHF and in 26 (42,6%) – without CHF (p=0,145); diastolic blood pressure (DBP) - in 28 (47,5%) and in 23 (37,7%) patients, respectively (p=0,371), average nighttime SBP in 37 (62,7%) and in 20 (40, 9%) patients, respectively (p=0,002); average DBP - in 36 (61%) and in 25 (40,9%), p=0,045), respectively. Insufficient reduction in SBP (non-diper) was in 21 (35.6%) patients with CHF and in 27 (44.3%) - without CHF, respectively; DBP – in 13 (22%) and in 14 (23%) patients, respectively. An overnight increase in SBP (night-picker) was observed in 9 (15.3%) patients with CHF and in 7 (11.5%) - without CHF; DBP – in 7 (11.9%) and in 6 (9 8%) patients, respectively. Morning SBP was 38±17 mm Hg in patients with CHF and 21±14 mm Hg - without CHF (p<0,001), DBP - 31±12 mm Hg and 18±10 mm Hg (p <0.001), respectively. CHF correlated with the value of SBP (r=0,15, p <0,001) and DBP morning rise (r=0,56, p <0,001), regardless of the values of the average daily BP. Morning SBP correlated with LDL cholesterol (r=0,24, p=0,034). Conclusion. The presence of heart failure is associated with an unfavorable profile of morning blood pressure, which can be considered as a target for therapeutic intervention in patients with hypertension and heart failure.

P1830

The role of hyperuricemia in the progression of chronic heart failure in patients with arterial hypertension

G Gaukhar Igimbayeva[1]; CH Abylkanov[1]; K Ibrayeva[1]; K Amanova[1]; B Kanibekova[1]
[1]*Karaganda State University, Cardiology, Karaganda, Kazakhstan*

Background. The relationship between high levels of uric acid and cardiovascular disease has been proposed for many decades, which indicates the need for early detection of hyperuricemia in patients with arterial hypertension for preventive measures to prevent the development of coronary and brain disorders.
Purpose. Identify the relationship between serum uric acid level and the progression of chronic heart failure in patients with arterial hypertension.
Methods. A retrospective study of 841 patients' outpatient cards of the City Polyclinic 1 was carried out. 30.4% were women and 69.6% were men aged 41 to 77 years. Patients were divided into 2 groups depending on the concentration of uric acid. In Group 1 patients' blood uric acid level was within the normal range, or 300–350 μm / l (41.9% of patients); while uric acid among patients from Group 2 was above the normal range, or 500–530 μm / l (58.1% of patients). It was decided to prescribe the drug Allopurinol 100 mg once a day. After completing Allopurinol 3-week course, a biochemical blood test was performed for determining the uric acid level.
Results. According to the study, it was noted that the level of uric acid was reduced in 19% (405-429 μm/l). Also, the study showed that the usage of Allopurinol leads to a gradual decreasing of blood pressure in 12%. The Pearson correlation coefficient of uric acid and the presence of arterial hypertension in men is R^2 = 0.906 and in women, R^2 = 0.9088 (Figure 1). In patients with arterial hypertension with high levels of uric acid, a direct and significant correlation is observed. The findings suggest that the group of patients with a high level of uric acid is a special group in which the risk of developing target organ damage is aggravated by an increase in blood pressure.
Conclusions. The study showed that uric acid has ability to induce mechanisms that contribute to the occurrence and progression of cardiovascular diseases. However, when using the drug Allopurinol in a patient, the level of uric acid and blood pressure decreases, which in turn prevents the progression of chronic heart failure.

Daily monitoring pulse wave velocity and other indicators of arterial stiffness in hypertensive patients comorbid with chronic obstructive pulmonary disease

T Tatiana Aksenova[1]; V Gorbunov[2]; S Tsarenok[2]; P Gromov[2]; S Lukyanov[2]
[1]*Chita State Medical Academy, Chita, Russian Federation*; [2]*Chita State Medical Academy, The hospital within the Russian Railroad Network, Chita, Russian Federation*

Background. More than 40% of chronic obstructive pulmonary disease (COPD) patients have arterial hypertension (AH).Purpose: to investigate the central aortic pressure and arterial stiffness parameters during daily monitoring in patients with comorbidity AH and COPD.
Methods. 62 patients with AH were examined. Patients were divided into 2 groups: group 1, n=32, patients with combination of AH and COPD; group 2, n=30, patients with isolated AH. The groups were similar in age and sex. The ambulatory (daily) monitoring of the peripheral, central aortic pressure and parameters of arterial stiffness were made by BPLab v2.3 with Vasotens technology. For statistical analysis we used Mann-Whitney criteria and Spirmen correlation method.
Results. Aortic SBP and aortic DBP in patients with combination of AH and COPD were higher compared with a group of isolated AH on 6 mmHg (p=0,049), 7mmHg (p=0,0023), respectively. Patients with combination of AH and COPD demonstrated the increase of minimum, medium and maximum PWV compared to isolated hypertension on 14.96% (p = 0.015), 6.98% (p = 0.016) and 11.93% (p = 0.0022), respectively. Ambulatory arterial stiffness index (ASI) in patients with combination of hypertension and COPD was higher compared with a group of isolated AH (p=0,045). Smoking Index was strongly correlated with PWV medium per day (r=0,51; p=0,0037) and PWV maximum per day (r=0,42; p=0,019). Smoking history was strongly correlated with PWV medum per day (r=0,51; p=0,0037), with PWV maximum per day (r=0,54; p=0,0017) and with ASI (r=0,40; p=0,033). The aortic blood pressure profiles were non-dipper on 55,5%, over-dipper on 7,4%, dipper and night-piker on 18,5% respectively in patients with comorbidity AH and COPD.

Conclusions. 1. The basic parameters of arterial stiffness were higher in patients with combination of AH and COPD in comparison with patients with isolated hypertension during the daily monitoring. 2. The relationship of smoking and the indicators of arterial stiffness was revealed in patients with COPD and comorbid hypertension. 3. The nondipper profile was predominant in patients with combination of AH and COPD in the ambulatory monitoring of the central aortic pressure.

Interaction between central hemodynamics and left ventricular geometry in patients with preserved ejection fraction

A Shavarov[1]; GK Kiyakbaev[1]; ZD Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: Arterial stiffness and hemodynamic load can lead to increased left ventricular (LV) hypertrophy and remodeling. Abnormal LV geometry can be associated with excessive wave reflection, increasing late systolic LV wall stress.
Purpose: to assess interaction between blood pressure, arterial hemodynamics and modes of LV geometry in patients (pts) with preserved ejection fraction (EF).
Methods: The study population consisted 309 hypertensive patients (53% men, mean age 61±10 years). Of these, 145 (47%) patients had stable coronary artery disease and 150 (49%) patients experienced recurrent atrial fibrillation. Echocardiography and pulse wave analysis using the SphygmoCor system were performed.
Results: In according with echocardiographic examination four LV phenotypes (phen) were defined: normal LV (phen1, n=63), concentric remodeling (phen2, n=71), concentric LVH (phen3, n=130) and eccentric LVH (phen4, n=45). Mean LV EF was 63±6%. Differences in hemodynamic parameters presented in the table.
Conclusion: Differences in central arterial hemodynamics exist across LV phenotypes in patients with preserved LV EF. Abnormal LV geometry could be related with wave reflection because of augmentation magnitude depends on the time that the reflected wave returns.

Parameters	Phen1	Phen2	Phen3	Phen4	p

Influence of hypertension on QT dispersion and systolic left ventricular function in patients with angina pectoris

V Stoickov[1]; M Deljanin Ilic[1]; M Stoickov[2]; S Saric[2]; D Marinkovic[2]; I Tasic[1]; D Simonovic[2]; I Stoickov[3]
[1]*University of Nis, Medical Faculty, Institute of Cardiology Niska Banja, Nis, Serbia*; [2]*Institute of Cardiology, Niska Banja, Serbia*; [3]*University of Nis, Medical Faculty, Nis, Serbia*

Introduction: QT dispersion (QTd) is a measure of inhomogeneous repolarization of myocardium and is used as an indicator of arrhythmogenicity. According to the values of QTd can identify coronary patients who are at high risk of cardiac death and sudden cardiac death.
Purpose: The aim of this study was to investigate the influence of hypertension on QT dispersion and systolic left ventricular function in patients with angina pectoris.
Methods: The study included 161 patients with angina pectoris (average age 56.8 years), of which 109 were with hypertension, and 52 were without arterial hypertension. There were no significant differences in age and gender between the two groups of patients. In all subjects echocardiographic examination were performed and from standard ECG corrected QT dispersion (QTdc) was calculated.
Results: Patients with angina pectoris and hypertension had significantly higher values of QTdc (58.7 ± 19.6 vs 44.9 ± 17.8 ms; p <0.001) compared to those without arterial hypertension. Also, patients with angina pectoris and hypertension had significantly lower values of left ventricular ejection fraction (58.6 ± 11.5 vs 63.2 ± 12.2%; p <0.025) and significantly higher values of the thickness of the interventricular septum (12.8 ± 1.9 vs 10.7 ± 1.6 mm; p <0.001), left ventricle posterior wall thickness (11.4 ± 1.6 vs 9.3 ± 1.4 mm; p <0.001), left ventricular end-systolic diameter (38.9 ± 6.4 vs 36.1 ± 7.1 mm; p <0.02) and left atrium diameter (41.3 ± 4.7 vs 37.8 ± 5.3 mm; p <0.005) compared to those without hypertension. Patients with angina pectoris and arterial hypertension had higher values of the left ventricular end-diastolic diameter (54.5 ± 5.5 vs 53.8 ± 6.9 mm; p-NS) compared to those without hypertension, but the differences were not statistically significant.
Conclusion: The study demonstrated that patients with angina pectoris and hypertension had significantly higher values of corrected QT dispersion and significantly reduced systolic left ventricular function compared to those without hypertension.

P1834

Evaluation of left ventricle dysfunction and endothelin-1 level in arterial hypertension of renal genesis under influence of therapy

N Nadiia Demikhova[1]; T Mazur[1]; A Demikhov[2]
[1]*Sumy State University, Medical Institute, Sumy, Ukraine*; [2]*Sumy State University, Department of Management, Sumy, Ukraine*

In arterial hypertension (AH) of renal genesis, the contractility of the myocardium of the left ventricle (LV) is often noted. The powerful vasoconstrictive effect of endothelin-1 and an increase in its level in plasma may be indicative of the progression of hypertension and the development of chronic heart failure (CHF).
Purpose: to study the nature of LV dysfunction in patients with AH of renal genesis complicated by CHF and endothelin-1 level, to evaluate the effectiveness of ramipril therapy for LV dysfunction.
Materials and methods. A total of 96 patients with AH of renal genesis complicated by CHF were examined, including 59 men and 37 women aged 59 to 83 years. The duration of the disease AH was 15.9±1.4 years. Clinical signs of CHF FC were 44, FK-40, FK-12 patients (by NYHA). Intracardiac hemodynamics was assessed on the Envisor HD, Phillips. Endothelin-1 was determined by radioimmunoassay. Ramipril was prescribed in a daily dose of 5-10 mg by a course of 18 days.
Results of the study. In the work we confirmed the significant prevalence of LV systolic dysfunction in patients with AH, including in combination with diastolic dysfunction - in 77.94%. For most patients with AH and CHF, the concentric type of LV hypertrophy is characteristic (76.47%). Diastolic LV dysfunction was found in all patients, even with preserved systolic function: early diastolic filling (E) 70.29±3.16 cm/s, isometric relaxation (IVRT) 82.82 ± 4.67 ms, atrial filling rate (A) 55.39±2.97 cm/s, the time of early speed drop (DT) of 228.25±10.67 ms.
Analysis of endothelin-1 in AH complicated by CHF showed that in patients with I FC CHF there was an increase in the activity of factors indicating the presence of endothelial dysfunction in the form of an increase in endothelin-1 content by 2.6 times, which indicates the prevalence of vasopressor mechanisms.
In patients with CHF II FC, the level of endothelin-1 was close to its content in patients without signs of CHF, while in patients with CHF FC it was increased by 71.9%. With CHF IV FC, the content of endothelin-1 was increased by 4.2 times.
Therapy with ramipril leads to a significant decrease in blood pressure (in 70.58%) andcontributes to the normalization of the daily profile of blood pressure. In the process of treatment, a decline in FSV by 15.3% and a FDV of 4.7%, LS volumes (FSV by 13.6%, FDV by 6.2%), an increase in EF by 11.45% (from 52% , 4±0.49 to 58.4±0.78%) and Fs to 8.75% (from 29.7±0.67 to 32.3±0.88%). After treatment, the decrease in the LVMM index from 143.9±5.68 g / m2 to 132.4±5.43 was noted. Cconclusion. Thus, diastolic LV dysfunction and endothelial dysfunction are observed in patients with AH of renal genesis complicated by CHF, which is manifested in an increase in the endothelin-1 content. The inclusion of ramipril in therapy contributes to the normalization of a number of parameters and improvement of LV function in patients with AH of renal genesis.

P1835

Personifying role of natriuretic peptides in patients with essential hypertension

I Gubareva[1]; N Kryukov[1]; E Gubareva[1]
[1]*Samara State Medical University, Internal Medicine Department, Samara, Russian Federation*

The aim of the research: to study NT-proBNP in patients with essential hypertension (EH).
Object and methods of research 420 male patients in age of 30-60 years old were studied, they were divided in 4 groups: group 1 (n=180) – patients with EH without heart failure (HF), group 2 (n=86) – patients with EH and HF, group 3 (n=74) – patients with HF without EH, group 4 (n=80) – the group of control. NT-proBNP (fmol/ml) was measured.
In the prospective part of the study patients of group 1 and 2 (n=60) formed subgroups of 25% (3,8 fmol/ml) and 75% (22,0 fmol/ml) of NT-proBNP percentiles. The results of echocardiography, brachiocephalic trunk ultrasound, heart rate variability were compared in these subgroups at baseline and after 24 months of follow-up.
The results. Patients in group 3 had the highest level of NT-proBNP comparing to the group of control (=0,046), group 1 (=0,037) and group 3
(=0,046). The duration of EH didn't affect the level of NT-proBNP (r=0,186; =0,537). In the group of patients with EH plasma NT-proBNP was lower in patients with grade 2 and 3 of arterial hypertension (AH) comparing to the patients with grade 1 of AH (<0,05). In the group of patients with EH and HF the same pattern wasn't observed (p>0,05). In group 1 NT-proBNP correlated with the grade of AH (r=-0,624; =0,023), in group 2 the same correlation wasn't discovered (r=0,151; =0,294), NT-proBNP interconnected with the functional class of HF (r=0,215; =0,049).
In the prospective part of the study in both groups of patients of subgroup 2 in comparison with group 1, at the beginning of the study, the structural remodeling of myocardium was more pronounced, sympathicotonia prevailed, left ventricle mass index, relative wall thickness index were increasing in the dynamics; however, in patients of the subgroup 1, were more expressed, hypertrophic type of diastolic disorders, dilatation of common carotid artery and thickening of the IMT were progressing. In patients of subgroup 2 dilatation of the right ventricle, the tendency to pseudonormalization of diastolic disorders, thickening of IMT, decreasing of sympathicotonia were observed.
Thus, the results of the study illustrate our assumption about the personifying role of the level of natriuretic peptides in patients with EH: the insufficiency of it in patients with EH is associated with an increase in the degree of AH and the progression of target organ defeat.

P1836

Uncontrolled hypertensives with heart failure with preserved ejection fraction-adherence to therapy

L Livia Popescu[1]; H Balan[1]
[1]*University of Medicine and Pharmacy Carol Davila , Bucharest, Romania*

Background Hypertension is worldwide spread, affects 40.41% of Romanians, and represents the leading cause of death. High blood pressure is associated with left ventricular hypertrophy, diastolic dysfunction and, frequently, evolves to heart failure with preserved ejection fraction. Heart failure with preserved ejection fraction (HFpEF) causes substantial morbidity and mortality and, unfortunately, despite multiple randomized controlled trials, has no disease-specific therapy until now. Suboptimal adherence to therapy is the main impediment in controlling chronic diseases.
Purpose The aim of our study was to assess the adherence to therapy in treated but uncontrolled hypertensives (BP>140/90 mmHg) with HFpEF admitted in an Internal Medicine Department.
Methods We enrolled 64 consecutive treated but uncontrolled hypertensives with HFpEF (satisfying ESC 2016 criteria; left ventricular EF>50%), medium age 65±8 years old, admitted in an Internal Medicine Department. All patients completed the Morisky questionnaire for adherence to treatment.
Results 48 patients (75%) were females, and 16 (25%) males. Morisky score 0 (maximum adherence to therapy) was recorded in only 14.06% of the patients, 39.07% had intermediate adherence (Morisky score 1-2) and 46.87% low adherence (Morisky score 3-4). Adherence to treatment was low in both sexes. Men had a sleight better maximum adherence than women (18.75% vs 12.5%). Women had a sleight lower low adherence to therapy than men (45.85% vs 50%).
Conclusions In-hospital uncontrolled patients with hypertension and heart failure with preserved ejection fraction have a very poor adherence to therapy. Low adherence is present in both sexes. Since adherence to therapy is crucial in controlling chronic diseases, effective strategies to increase adherence to therapy are mandatory in uncontrolled hypertensives with heart failure with preserved ejection fraction.

P1837

Association AG polymorphism of a MTHFR gene in development of an ischemic stroke in patients with an arterial hypertension

A Anna Chernova[1]; S Nikulina[1]; S Tretyakova[1]; A Semenchukov[1]; D Nikulin[1]; I Platunova[1]; O Marylovceva[1]; A Kelemeneva[1]
[1]*Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation*

Introduction . The gene of MTHFR is located on 1 chromosome (1p36.3) and consists of 11 ekzon. The gene of MTHFR codes enzyme a metilentetragidrofolatreduktaza which catalyzes transition of the 5.10-metilentetragidrofolat in 5-metiltetragidrofolat. This reaction represents multistage process which will transform amino acid homocysteine to methionine.
Purpose. Studying of a contribution of rs619203 polymorphism of a gene ROS1 to development of ischemic stroke at patients with an arterial hypertension.
Methods. Examination of 124 patients with an ischemic stroke with an arterial hypertension is conducted. Age median – 60[51; 66.75] years from which there were 75 men, an age median – 57[50; 64.5] years and 49 women, an age median – 63[54; 70] years. Clinical investigation included assessment of neurologic symptoms, a research of the somatic status, control of the ABP, record ECG, an echocardiography, a X-ray analysis, the general and biochemical blood tests, ultrasonic examination of carotid arteries, brain computer tomography. Duration, weight and the sequence of development of the accompanying somatopathies and risk factors were analyzed. The family anamnesis including assessment of existence of disturbances of cerebral circulation in the anamnesis, existence of arterial hypertension, heart diseases (a MI, cardiac arrhythmia, HFA), existence of risk factors was studied.
Results. Frequency of a homozygous genotype of AA on a widespread allele at patients with an ischemic stroke was 81.5%±3.5, a heterozygous genotype of AG – 16.1%±3.3 and a homozygous genotype of GG on a rare allele-2.4%±1.4. In control group 72.9%±4.1 were carriers of a homozygous genotype of AA on a widespread allele, 26.3%±4.1 – carriers of a heterozygous genotype of AG and 0.8%±0.8 – carriers of a homozygous genotype of GG on a rare allele of a gene of MTHFR.
Conclusions. Thus, by results of a research some prevalence of carriers of a homozygous genotype of AA on a widespread allele among patients with an ischemic stroke (81.5%±3.5) in comparison with group of control (72.9%±4.1) is established, but this distinction was statistically not significant. Also it is not established statistically significant distinctions on MTHFR gene alleles.

P1838

Association of polymorphism of 9 chromosome in development of an ischemic stroke in patients with an arterial hypertension

A Anna Chernova[1]; D Nikulin[1]; S Tretyakova[1]; A Semenchukov[1]; O Marilovceva[1]; I Platunova[1]; S Nikulina[1]
[1]*Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation*

Introduction . Rs1333049 is located on a chromosome 9r21.3 in the so-called ANRIL area (area of not coding RNA).
Purpose. To study a role of polymorphic allelic rs1333049 options (a chromosome 9p 21.3) in development of a stroke in patients with cardiovascular pathology.
Methods. Examination of 124 patients with an ischemic stroke with an arterial hypertension is conducted. Age median – 60[51; 66.75] years from which there were 75 men, an age median – 57[50; 64.5] years and 49 women, an age median – 63[54; 70] years. Clinical investigation included assessment of neurologic symptoms, a research of the somatic status, control of the ABP, record ECG, an echocardiography, a X-ray analysis, the general and biochemical blood tests, ultrasonic examination of carotid arteries, brain computer tomography. Duration, weight and the sequence of development of the accompanying somatopathies and risk factors were analyzed. The family anamnesis including assessment of existence of disturbances of cerebral circulation in the anamnesis, existence of arterial hypertension, heart diseases (a MI, cardiac arrhythmia, HFA), existence of risk factors was studied.
Results. Frequency of a homozygous genotype of GG on a widespread allele at patients with an ischemic stroke was 23.1%±3.8, a heterozygous genotype of CG – 47.1%±4.5 and a homozygous genotype of CC in rare alleles-29.8%±4.2. In control group 26.4%±2.0 were carriers of a homozygous genotype of GG on a widespread allele, 54.9%±2.2 – carriers of a heterozygous genotype of CG and 18.7%±1.7 – carriers of homozygous genotype to a rare allele.
Thus, statistically significant prevalence of carriers of a homozygous genotype of CC in rare alleles among patients with an ischemic stroke (29.8%±4.2) in comparison with group of control (18.7%±1.7), p=0.011 and also allele with in group of patients (53.3%±3.2) in comparison with control (46.2%±1.6), p=0.046 is established.
Conclusions. Statistically significant prevalence of a homozygous genotype of the CC in rare allele gene of rs 1333049 of a chromosome 9r21.3 (29.8±4.2) in group of patients with an ischemic stroke in comparison with the faces of control group (18.7±1.7) and an allele C (53.3±3.2) in comparison with group of control is established (46.2±1.6).

P1839
The development of e-health tools to support dietary sodium assessment, behavioural modification and shared decision making in clinical practice

J Joanne Arcand[1]; M Ahmed[2]
[1]*University of Ontario Institute of Technology, Faculty of Health Sciences, Oshawa, Canada*; [2]*University of Toronto, Department of Nutritional Sciences, Toronto, Canada*

Funding Acknowledgements: Canadian Stroke Network, Heart and Stroke Foundation of Canada

Background: Dietary sodium reduction is a recommended therapy for heart failure. However, assessing dietary sodium intake in the clinical setting is challenging. Sodium assessment methods include 24-hour urine collections and self-reported methods such as food recalls and records. These methods are time-consuming, burdensome and do not provide individualized or timely feedback, thereby potentially impeding effective delivery of dietary advice from health care providers and patient-action in behaviour change or adherence.
Purpose: We developed and validated two dietary sodium screening tools: Sodium Calculator (SC) and Sodium Calculator Plus (SCP). The purpose of this abstract is to report the results of iterative user testing during the development phase, and content and face validity by experts and users.
Methods: The SC and SCP are web-based food-frequency questionnaires developed from national survey on foods contributing the most sodium to the Canadian diet. The SCP asks standard portion sizes consumed. To allow for rapid calculations, the SC does not ask about portion size but includes average portion sizes consumed by Canadians in its algorithm. To calculate the amount and sources of sodium in the user's diet, the sodium content of foods and beverages available in the Food Label Information Program 2013/2017 and the Canadian Nutrient File 2010/2015 were used. Nutrition experts conducted face and content validity. University students provided feedback on the SC and SCP in an open-ended survey as part of the iterative testing process.
Results: The SC contains 26 questions on intake frequency and took 5 minutes to complete. The more detailed SCP contains 72 questions and took 10-15 minutes to complete. Nutrition experts made several suggestions about wording, foods included and report formats. They suggested the use of graphs/visual displays to illustrate sodium intake and the inclusion of risk estimates for health impacts of sodium intake. Users (n=118) liked the reported grouping of foods, options for frequency of consumption, concise instructions, and personalized feedback on sodium intakes and felt that SC and SCP both increased awareness of sodium consumption and reading of food labels. However, users indicated some improvements such as clarification of portion sizes, food form (e.g. canned/dry), use of color and larger font and additional examples related to culturally-based diet. These data were used to modify the web-based calculators, as part of the iterative development process.
Conclusion: The SC and SCP provide rapid, detailed, personalized information on dietary sodium. The SC is a rapid screener that is useful in a busy clinical setting. The SCP can provide more detailed assessments and track longitudinal dietary changes. Both tools may be integrated into e-health platforms to support behaviour change and improved health outcomes.

P1840
Cultural factors and power relations influencing willingness to follow self-care recommendation: a qualitative study

O Onome Osokpo[1]
[1]*University of Pennsylvania, Nursing, Philadelphia, United States of America*

Funding Acknowledgements: Ruth L. Kirschstein NRSA Doctoral Fellowship, Research on Vulnerable Women, Children and Families (T32NR007100)

Background: The prevailing power arrangements resulting from patient characteristics, physicians' specialized expertise and the hierarchical structure of the healthcare institutions may disproportionately put older adult immigrants with cardiovascular disease (CVD) at risk for being marginalized and can result in unwillingness to follow self-care recommendations. The power relations between older adult African immigrants and providers and the role that culture plays in health care interactions has, thus far, been largely unexamined.
Purpose: This study aimed to explore how cultural factors influence immigrant older adults' ability to negotiate their care and follow self-care recommendations within the power dynamics of the U.S. health care system.
Method: A qualitative descriptive method with content analysis was used. Purposive sampling techniques were used to enroll 4 community-dwelling older adults who received care at a primary care center in the northeast U.S. Inclusion criteria were: 1) self-identified or pre-identified as a Nigerian immigrant, (2) over 65 years of age, (3) had a confirmed CVD (e.g. hypertension) based on clinical evidence, and (4) able to speak and understand English. Patients with a diagnosis of cognitive impairment that limited their ability to understand questions were excluded from the study. Semi-structured interviews were conducted using an interview guide. A demographic survey was used for data collection. The tape-recorded interviews were transcribed accurately, and data analysis performed using Atlas.ti, version 7.0.
Results: Participants were all female and legal residents of the US. Age: 75 $\pm$ 3.7 years. Years spent in the US: 6$\pm$3.6 years. Findings revealed that social norms and culture play a role in power relations between African-immigrant older adults living with CVD and their providers. Normative thinking, familism and fatalism influenced decisions concerning self-care. Although providers were seen as experts who were competent and caring, patients' beliefs, values, and preferences often were not considered in making self-care recommendations. As a result, participants exercised power either by withholding critical information or outright refusal to follow physicians' recommendations.
Conclusion: These findings have significant implications for treatment for CVD. Taking patient values, beliefs, power and preferences into consideration may improve willingness to follow self-care recommendations.

P1841
How do race, education, and income adequacy affect self-care maintenance in adults with heart failure?

F O Baah[1]; B Carlson[2]; K A Sethares[3]; M Daus[1]; D K Moser[4]; B Riegel[1]
[1]*University of Pennsylvania, Philadelphia, United States of America*; [2]*San Diego State University, San Diego, United States of America*; [3]*University of Massachusetts Dartmouth, North Dartmouth, United States of America*; [4]*University of Kentucky, Lexington, United States of America*

Background: Social determinants (conditions within which people are born, age, work, live and the systems put in place to deal with illness) are known to influence health and adequate self-care maintenance improves heart failure (HF) outcomes, however, the relationship between these two factors is unclear. Self-care maintenance reflects healthy behaviors and adherence to a plan of care to maintain physiological stability and prevent symptoms.
Purpose: This secondary analysis explored main effects of specific social determinants of health (race, education, and income adequacy) on HF self-care maintenance. We focused on self-care maintenance because it is the first construct among the three constructs (maintenance, symptom perception and management) of the situation specific theory of HF self-care, thought to be mastered in succession. The situation specific theory of HF self-care underpinned the study.
Methods: The parent study enrolled 631 adults with HF (any type) who spoke English, without dementia or previous heart transplantation, from five sites in the United States. Institutional Review Board (IRB) approval was obtained at all sites. Participants completed the Self-Care of HF Index (SCHFI) v.7.2 and a demographic survey. Scores on the SCHFI range from 0-100, with higher scores indicating better self-care. We used general linear modeling to determine which SDH variables and levels; race (Whites, Other [Asian/Mixed] or Blacks), education (high school or less, trade school, or college), and income adequacy (more than enough, just enough or not enough) were important in explaining self-care maintenance. Bonferroni correction was used to correct for multiple comparisons (alpha = 0.017 (.05/3)).
Results: The sample was predominantly white (71.5%), male (63.1%), married (54.8%), unemployed/retired (78.5%), and college educated (55.1%) with mean age 64.6$\pm$14.3 years. In model 1 ($F(6, 559) = 2.10$ $p = .05$) which included race, education and income adequacy as predictors, race was a significant determinant of self-care maintenance. In Model 2 ($F(4, 577) = 3.39$, $p < .01$), which included race and education as predictors, race and education were both significant determinants. These models explained only 2.2% and 2.3% of the variance in self-care maintenance respectively. Participants with high school or less education had significantly lower self-care maintenance compared to those with college education. Asians/Mixed (Other) participants also had lower self-care maintenance compared to whites. Although the interaction between race and education was non-significant, 51.2% of Blacks had high school or less education compared to 35.9% of Whites.
Conclusion & Implications: Racial minority groups and patients with high school or less education may be at risk for poor self-care maintenance. Interventions targeting racial minorities and those that compensate for low education may be particularly important in reducing disparities in heart failure outcomes.

P1842
Technology acceptance model for Control VIT: heart failure patient follow-up mobile Application

DM Diana Marcela Achury[1]; RG Gonzalez[1]; AG Garcia[1]; AM Marino[2]; WB Bohorquez[1]; LA Aponte[2]
[1]*Javeriana University, Bogota, Colombia*; [2]*San Ignacio Hospital, Bogota, Colombia*

Introduction Mobile phone based remote monitoring systems for heart failure patients could become simple and affordable tools to improve home management. Research objective: To identify utility and acceptance of Control VIT in heart failure patients.
Method: Pilot observational and descriptive study on 20 heart failure clinic outpatients with reduced ejection fraction, from June to November 2018. For six months, patients used Control VIT Smartphone Application, which contained information to improve selfcare and allowed daily clinical variables registration. Data from the application log was collected in order to identify frequency of use and data submission by patients. At the end of the period of study, a technology acceptance questionnaire was applied to patients. A descriptive analysis with absolute and relative frequency distribution was also performed.
Results: 164 real-time alerts were generated, being weight gain the most frequent one (49 %). 95 % of the patients did not present hospital readmission. Regarding acceptance, 100 % of them acknowledge usefulness in the application. As for the intention and ease of use, 95 % of the patients showed willingness of use without objection or fear.
Conclusion: Control VIT is an efficient tool for prompt complication detection. It can modify pharmacological treatment, avoid disease progression and potential hospitalization. Patient acceptance of the application suggests the need of using it as a complementary follow-up strategy.

P1843
Collaborating with a patient organisation to implement a physical activity intervention

L Klompstra[1]; A Stromberg[2]; L Askenas[3]; J Aidemark[3]; T Jaarsma[1]
[1]Linkoping University, Department of Social and Welfare studies, Linkoping, Sweden; *[2]Linkoping University, Department of Medical and Health Science, Linkoping, Sweden*; *[3]Linnaeus University, Department of Informatics, Vaxjo, Sweden*

Introduction: Physical activity is important for cardiac patients and can reduce morbidity and mortality. Despite these benefits, the majority of cardiac patients are not engaging in enough physical activity, even if they are enrolled in or have completed a structured physical activity program. Patient organisation could play an important role long term adherence to activity recommendations.
Purpose: To explore the potential of using co-design as a method to implement a physical activity intervention in a patient organisation.
Method: Cardiac patients from a patient organisation located in two cities in Sweden worked with a research team to design a tournament of exergaming (video gaming that also is form of physical activity) to stimulate physical activity for their members. There were 4-8 participants from each of the two patient organization in the meetings and 4 researchers from 2 universities. Data on the process of co-design was collected through participative observations of the meetings and the exergaming events.
Results: Patients organised training sessions (and received help from the research team when needed) and a day to exergame together with the neighbouring patient organisation. The implementation of exergaming contained a number of key co-design actions: (1) Engaging patients early; (2) Engaging a patient organisation, bringing the design into an social context; (3) Practical testing element in the design where two exergame platforms were tested by patients of one of the patient organisations; (4) Focus on self-organising, where the patient organisations received the two exergame platforms together with an introduction; (5) Using a competition element, where patients of the two organisations were asked to exergame with/against each other.
Conclusion: Implementation of physical activity interventions by patient organisations is promising. A co-design approach, with both putting physical activity in a social context as including a competition element, can optimize first success and sustainability.

P1844
Ex vivo allograft perfusion for heart transplantation: single centre experience

A Ayan Mukash[1]; RB Kaliyev[1]; ZHA Nurmykhametova[1]; LR Faizov[1]; ZHZ Ashyrov[1]; BK Zhunussov[1]; T Kyttybai[1]; N Utin[1]; G Nadirbekova[1]; YV Pya[1]
[1]National research center for cardiac surgery, Astana, Kazakhstan

Purpose: The Organ Care System (OCS) is the only clinical platform for ex-vivo allograft perfusion. Kazakhstan is the 9th largest country in the world, for donor hearts to be transplanted from distant regions to our Center they often need to be transported up to 2000 km. We reviewed our institutional experience to analyze and describe the outcomes of patients underwent heart transplantation managed with OCS.
Methods: In this study we performed a prospective descriptive analysis of 59 patients underwent heart transplantation from 2012 to 2017. Of this, 47 (80%) cases were preserved using OCS. There are currently two methods for ex vivo preservation of donor hearts: standard cold storage (short distances, < 4 hours) and a system for ex vivo perfusion (long distance < 4 hours and after VAD). Primary and secondary outcomes of interest included cumulative survival, freedom from any-treated rejection (ATR), and non-fatal major cardiac events (NF-MACE).
Results: ex vivo preservation of donor hearts using standard cold storage 12 (20%) cases, distant procurement 35 (60%) cases, after VAD support to HTx 25 (45%) cases. Kaplan–Meier survival estimates for all patients after HTx using OCS heart were 91% after 3 months, 85% after six months and 80% after twelve months. There was no ATR, and NF-MACE.
Conclusions: Severe limitations on donor eligibility, recipients after VAD, optimised myocardial protection and use of a portable ex-vivo organ perfusion platform can enable successful, distantly procured transplantation of hearts. This study can further be followed up by studying the HT outcomes after OCS in subgroups.

P1846
The adherence to pharmacological treatment in patients with chronic heart failure

N Natalia Swiatoniowska[1]; A Szymanska-Chabowska[1]; J Gajek[1]; B Jankowska-Polanska[1]
[1]Wroclaw Medical University, Wroclaw, Poland

Despite the efforts to improve the treatment of heart failure (HF), the number of re-hospitalizations and deaths due to HF are still at high level. The efficacy of the treatment depends on patients' commitment, adherence to recommendations and the ability to self-control. Poor adherence to medications is a common problem among heart failure patients. Inadequate adherence leads to increased HF exacerbations, reduced physical function, and higher risk for hospital admission and death. The aim was to analise the level of adherence of pharmacological treatment and the factors influencing the level of adherence.
Material and methods. 475 patients (including 222 women), of mean age 69.7±7.7, with HF were included into the study. The Revised Heart Failure Compliance Scale was used to assess the compliance. The socio-clinical data were obtained from medical records.
Results. The vast majority of the study group were the patients in NYHA II (62.4%) and NYHA III (28.3%), the mean duration of the disease was 6.2±4.9 years, the number of hospitalizations due to exacerbations in the last year was 2±1.5, and the mean ejection fraction of left ventricle (EF) was 48.6±12.6. The patients were most often treated with diuretics (80.8%), beta blockers (68.2%) and angiotensin converting enzyme inhibitors (ACEI) or angiotensin receptor blockers (ARB) (14.5%). The analysis proved that only 60% of respondents adhered scrupulously to the recommended pharmacological treatment. The rest of the study group were the patients who adhere to recommended therapy often (22.1%), seldom (17.9%) and never 2%. The mean level of adherence was 3.3±0.9 (moderate level). In univariate analysis the predictors negatively influencing the adherence were: female gender (rho=-0.325), age below 65 years (rho=-0.014)), loneliness (rho=-0.559), number of hospitalizations (rho=-0.242) and treatment with diuretics (rho=-0.276). The factors influencing positively the adherence were: EF≥45% (rho=0.020) and treatment with ACEI/ARB (rho=0.34). In multivariate analysis the significant predictors influencing the adherence were: negatively - loneliness (β=-0.205) and number of hospitalizations (β=-0.117), and positively –EF ≥45% (β=0.009).
Conclusion: Almost the half of the patients did not adhere to recommended pharmacological treatment. The loneliness and re-hospitalizations were independent determinants of low level of adherence, and EF≥ 45% was the determinant of high level of adherence.

P1847
Feeling powerless to deal with thirst in heart failure patients: a qualitative study of health care providers

J Ehrlin[1]; T Jaarsma[1]; S Hagelberg Eng[1]; V Diaz[2]; B Gonzalez[2]; N Waldreus[3]; C Rivas[2]; P Velayos[2]; P Martin[2]; M De Antonio[2]; M Domingo[2]; P Moliner[2]; E Santiago-Vacas[2]; J Josep Lupon[2]; A Bayes-Genis[2]
[1]Linkoping University, Linkoping, Sweden; *[2]Germans Trias i Pujol University Hospital, Badalona, Spain*; *[3]Karolinska Institutet, Huddinge, Sweden*

Background: Thirst can be a troublesome symptom in patients with heart failure (HF), and having thirst might decrease patients' quality of life. The pharmacological and non-pharmacological treatment, as well as HF itself can be the reason for an increased thirst in patients. Despite this, there are no evidence-based interventions to reduce thirst distress in patients with HF, and knowledge about thirst and its management by health care providers (HCPs) has scarcely been addressed.
Purpose: The aim of the study was to examine thirst and factors related to thirst in a Spanish cohort of HF outpatients attended in a HF Unit, using information from

HCPs. The goal was to contribute to a better and more personalized care for these patients.
Methods: A qualitative study was performed with purposeful sampling. Data was collected through interviews with 12 HCPs (cardiologists and nurses) working with HF patients, focusing on their experience of thirst in patients with HF, using a structurally developed interview guide. The interviews were recorded and then transcribed. The collected data was analysed using content analysis.
Results: Data on thirst in patients with HF was summarized into 4 categories consisting of a total of 13 subcategories. These categories were 'Thirst is a complex symptom', 'We don't talk about it', 'Thirst is hard to cope with' and 'Nothing helps'. The answers of the HCPs were generally consistent and one statement that permeated the material was that thirst is an important problem that is very difficult for them to solve. Also, the general opinion was that thirst is a complex symptom that is known very little about. Although the HCPs mentioned some practical tips for patients, they also reported that they were not aware of any official guidelines on management of thirst and agreed on that their current advices/treatment methods do not work enough. The HCP also described that they feel powerless in helping patients to deal with thirst. Some culture specific issues were also described.
Conclusions: HCP described that their patients experience thirst as a very complex symptom, causing stress and suffering in patients with HF. The HCPs often feel powerless, trying to help their patients, but realising that their treatment methods/advices are currently insufficient. More knowledge is needed, as well as further research into effective interventions, which might be adapted to specific cultural habits.

P1848

Thirst distress in heart failure outpatients in a Spanish cohort

S Hagelberg Eng[1]; J Ehrlin[1]; B Gonzalez[2]; V Diaz[2]; T Jaarsma[1]; N Waldreus[3]; C Rivas[2]; P Velayos[2]; M Puertas[2]; M Cachero[2]; A Morales[2]; A Ros[2]; P Martin[2]; J Josep Lupon[2]; A Bayes-Genis[2]
[1]Linkoping University, Linkoping, Sweden; *[2]Germans Trias i Pujol University Hospital, Badalona, Spain*; *[3]Karolinska Institutet, Huddinge, Sweden*

Background: Despite studies showing that thirst is a common symptom experienced by heart failure (HF) patients, there is scarce knowledge about its significance in patients from different cultures and climates. The 8-item Thirst Distress Scale for patients with HF (TDS-HF) was recently developed in English, Swedish, Dutch and Japanese to assess how thirst bothers HF patients.
Purpose: To describe thirst distress and associated factors in outpatients at a HF clinic in Spain.
Methods: The TDS-HF (scores 8 to 40) was translated to Spanish and used to quantify the thirst distress perceived by HF outpatients during the preceding three days. Socio-demographic and clinical characteristics were collected and linear regression was performed to identify variables associated with thirst distress.
Results: Three-hundred two HF patients were included (age 67±12 years, 74% male, HF duration 82±75 months, LVEF 42%±14). In total 18% perceived thirst as high or severe. The mean total score obtained was 16.2±9.3 (median 13, Q1-Q3 8-20). The majority of patients perceived mild to moderate thirst distress. Increased thirst distress was associated with female gender, depression, worse NYHA-class, lower serum potassium, higher serum urea, and treatments such as antidepressants and diuretics in the univariable analysis. Serum urea and potassium remained significant in the multivariable analysis, together with the dose of diuretics (Table). Treatment with ARB showed and independent protective effect.
Conclusion: One in five Spanish outpatients patients experienced severe distress of thirst but on average in the total the population seemed mildly to moderately distressed by thirst. Several factors can influence thirst distress in HF patients and might be important targets for thirst relief.

Effects of person-centred telephone-support on fatigue in people living with chronic heart failure: a randomized trail

S Wallstrom[1]; A Fors[1]; L Ali[1]; K Swedberg[2]; I Ekman[1]
[1]Institute of Health and Care Sciences, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; *[2]Department of Molecular and Clinical Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

Funding Acknowledgements: Centre for Person-Centred Care (GPCC), the Swedish Research Council, Research and Development Unit, Region Västra Götaland.

Introduction Fatigue is one of the most commonly and debilitating symptoms reported by people with chronic heart failure (CHF), which hampers functional ability and daily activity. In person-centeredness the starting point is the capabilities, needs and goals, of each patient. In people with CHF person-centeredness has been shown to shorten hospitalisation and lessen uncertainty in illness.
Purpose The aim of this study was to evaluate the effects of a person-centred telephone-support on self-reported fatigue in people with CHF.
Method Patients with CHF were randomized to usual care or a person-centred telephone-support intervention in addition to usual care and followed during 6 months. In the intervention group patients where called by a registered nurse and a person-centred health plan reflecting both perspectives was co-created. The health plan was discussed and evaluated during additional follow-ups by telephone. Fatigue was measured with a validated instrument, the Multidimensional Fatigue Inventory-20 (MFI-20), which consists of five dimensions that also can be summarised to a global score. The questionnaire was distributed to the participants at baseline and 6 months follow up. Between group differences were calculated with the Mann-Whitney U test.
Results In total, 77 participants (38 control, 39 intervention) were included in the study, of which 49 (63.6%) were men and 28 (36.4%) women. Their mean age was 80.5. The analysis shows that the participants in the intervention group reported significantly less fatigue in the General fatigue (p=0.042) and Reduced motivation (p=0.009) dimensions of the MFI-20.
Conclusion The findings indicate that person-centred telephone-support relieves symptom burden in terms of reduced fatigue in people with CHF.

Comparission of between the groups

Psychometric evaluation of the polish version of the council on nutrition (CNAQ) and simplified nutritional (SNAQ) appetite questionnaires in a group of patients with chronic heart failure.

M Marta Wleklik[1]; M Lisiak[1]; C Andreae[2]; I Uchmanowicz[1]
[1]Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland; *[2]Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*

Introduction. The ESC guidelines for the treatment of acute and chronic heart failure indicate the need to monitor and prevent malnutrition. Malnutrition in heart failure (HF) affects up to about 69% of patients and is a negative prognostic factor, increasing the risk of hospitalization and death. Appetite assessment should be performed systematically as part of the provision of multidisciplinary care and

prevention of the negative effects of protein and energy malnutrition, as its reduction is a factor predicting unintentional weight loss. CNAQ and SNAQ are simple and easy tools to identify loss of appetite among the elderly.
Purpose. Evaluation of psychometric properties of CNAQ and SNAQ questionnaires in a group of Polish patients with chronic HF.
Methods. Data for the analysis were collected from 103 patients diagnosed with chronic HF, in NYHA functional classes II-IV–. The inclusion criteria were: age ≥ 65 years, chronic HF confirmed in the medical documentation, written consent for participation in the study. The study used the CNAQ questionnaire and its abbreviated version - SNAQ. In addition, the Mini Nutritional Assessment (MNA) nutritional evaluation questionnaire was used to assess the validity of CNAQ and SNAQ. In order to evaluate the relationship between the scores obtained in individual questions and the general score, item-total correlation was applied based on multi-core correlations, where the permissible rho is > 0.3. The internal consistency of the tool was assessed using the ordinal version of the alpha coefficient, with the value ≥ 0.7 indicating acceptable reliability.
Results. Correlations between each item and the total results of CNAQ (0.47-0.84) and SNAQ (0.78-0.88) were statistically significant p <0.001. Parallel analysis confirmed the univariate structure of both CNAQ and SNAQ, thus confirming the lack of the need to divide the tool into subscales. A statistically significant correlation was found between CNAQ (rs = 0.8, p <0.001) and SNAQ (rs = 0.81, p <0.001), and MNA. Patients in individual NYHA classes differed significantly as regards their CNAQ (p = 0.008) and SNAQ (p = 0.024) scores. NYHA class II patients had significantly higher CNAQ scores than NYHA class IV patients. Cronbach's alpha was 0.88 for CNAQ and 0.86 for SNAQ, which points to their internal consistency.
Conclusion (s). 1. Loss of appetite increases the risk of malnutrition in the group of HF patients studied. 2. CNAQ and SNAQ have positive psychometric properties and can be used to assess appetite among Polish HF patients.

P1851
What HF patients really need.A systematic review and meta-synthesis.

M Martha Kyriakou[1]; C Deaton[2]; A Samara[1]; K Philippou[1]; I Lakatamitou[1]; A Lambrinou[1]
[1]Cyprus University of Technology, Limassol, Cyprus; [2]University of Cambridge, Florence Nightingale Foundation Professor of Clinical Nursing Research Cambridge Institute of Public, Cambridge, United Kingdom of Great Britain & Northern Ireland

Introduction Heart failure (HF) patients frequently have poor health related quality of life (HR-QoL), even when treated with modern evidence-based therapy (Jaarsma et al., 2009).
Support, understanding, receiving comfort and being treated as a whole and unique person are vital for people with HF (Anderson et al., 2012). That is why supportive care may have significant input in HF patients' treatment. Underpinning services may improve their HR-QoL (Cortis and Williams., 2007).
Purpose The purpose of this systematic review and meta-synthesis was to explore HF patients needs from their perspective.
Methods A literature review was conducted using a qualitative methodology. Two of the researchers undertaken the search using the keywords: ("needs" OR "need") AND ("heart failure") AND ("qualitative") in the following databases: PubMed, CINAHL, PsycoINFO, and EBSCO published until the end of February 2018. Pre-defined inclusion and exclusion criteria were set before searching.
A "thematic synthesis" methodology to undertake the current meta-synthesis was used (Thomas and Harden., 2008). This method is a three-step process: 1. Free line by line coding of the findings of the primary studies, 2. the produced free codes have been organized into related areas to build descriptive themes and lastly 3. Analytical themes have been developed (Thomas and Harden, 2008; Barnett Page and Thomas., 2009).
Results Eleven articles were found to fulfill the inclusion criteria which were included in the review and meta-synthesis.
Meta-synthesis extracted five different categories covering patents' needs: Self-management, palliative care, supportive care, social support and continuing person-centered care (CPCC). All themes are correlated together as shown in Figure 1. It begins from the patient itself by recognizing the needs at each time and his ability to self-manage and extends to the "whole 'societal supportive care. On the other hand, meanings are also reversed. The effort of the patient to actively participate in the process of the treatment scheme along to health professionals, may be motivated and empowered by health professionals through the needs and preferences detection, in a continuing basis.
Conclusion A dynamic and interactive continuing care and relationship among patients with HF, their care-givers and health professionals. Giving more emphasis in the human dimension and holistic approach of patients with HF, along with the cardiology medicine development might be the key for the improvement of clinical outcomes and HR-QoL.

P1852
Clinical outcome of cardiac resynchronization therapy patients under a multidisciplinary outpatient clinic model

M Maria Ferreira[1]; P Sarmento[1]; AF Carvalho[1]; F Pousinho[1]; M Oliveira[1]; F Farias[1]; R Ferreira[1]
[1]Hospital de Santa Marta, Cardiologia, Lisbon, Portugal

As the number of implantable electronic cardiac devices increases, a multidisciplinary team following these patients (P) is warranted to provide professionals who clarify doubts, anticipate complications and tends to increase the quality of life and survival of this population. Beyond targeting the technical aspects of the device, the consultation needs to respond to P with co-morbidities and frequently decompensated heart failure (HF).
Aim: to analyze long-term nursing experience in an outpatient clinic for P submitted to cardiac resynchronization therapy (CRT) in a tertiary center.
Methods: The clinical records of P with a CRT who had ≥1 appointments in 2016 and 2017 were analyzed, and demographic data, clinical history and therapeutic compliance were collected.
Results: During a 2-years period, there were 595 appointments in 324 P (average per P - 2; max - 5, min - 1). The mean baseline left ventricular ejection fraction was 26%, with most of the P in class II/III of NYHA. The majority were male (74.7%), with a mean age of 65 (max – 75, min - 45). In 78% were >1 risk factor for cardiovascular diseases. Systemic hypertension was the most common (85%). The most commonly reported symptoms were fatigue (36%), dyspnea (27%), and peripheral edema (23%). Admission to the emergency room occurred in 20% of the P (mean number of unscheduled visits - 2), with 22% having ≥ 2 hospital re-admissions for any cause. The survival rate was 80.2%, with 65% of the deaths classified as cardiac mortality. Regarding therapeutic compliance, 41% of the P do not know how to describe their prescribed therapy and 9% do not fully comply with the recommended medication.
Conclusions: CRT P visits to the emergency room are common, with frequent re-hospitalizations and high mortality rate. Despite a multidisciplinary approach, almost 10% of the P do not comply with medication. These data point out the severity of the clinical situation in these P, reinforcing the need of a proactive HF team.

Polyurethane-based scaffold for cardiac aging studies

F Vozzi[1]; M Cabiati[1]; C Domenici[1]; N Vitale[2]; F Logrand[2]; A Ahluwalia[3]; I Carmagnola[4]; G Ciardelli[4]; S Del Ry[1]; S Sartori[4]
[1]Institute of Clinical Physiology of CNR, Pisa, Italy; [2]2Department of Molecular Biotechnology and Health Sciences, University of Turin, Via Verdi 8, I-1012, torino, Italy; [3]University of Pisa, Pisa, Italy; [4]Politecnico di Torino, Department of Mechanical and Aerospace Engineering,, Turin, Italy

BACKGROUND-AIM: Aging is associated with a progressive decline in numerous physiological processes, leading to an increased risk of health complications and disease.In vitro cardiac tissue engineering, through the use of scaffolds able to favour cell adhesion and survival, is a promising tool for identification of aging-related molecular mechanisms. Aim was to show a new approach focused on tissue-specific architecture and mechanical properties mimicking of young and aged tissue (scaffold) integrated with mechanical stimuli (loading) to generate an in-vitro pathophysiological model of cardiac aging.
METHODS: Young and aged artificial tissues were produced by polyurethane (PUR) and polyurethane-polycaprolactone blend, respectively. The polymer blends were studied to simulate the aged muscle, which is stiffer compare to the young one. Polymer scaffolds were produced by Thermal Induce Phase Separation to obtain oriented fibres texture like cardiac tissues. Scaffolds surface was functionalized with fibronectin. Sprague-Dawley primary neonatal rats cardiomyocytes were seeded on young and aged scaffold and cultured for 7 days. For mechanical tests, scaffolds were placed in SQPR bioreactor and subjected to a cyclic loading stimulus (1Hz) for 24 h. To mimic ischemic pathology, a hypoxia/ reperfusion protocol was applied. Cell viability with CellTiter Blue assay was evaluated. Natriuretic Peptides (NPs) and Endothelin (ET-1) system mRNA expression, to evaluate cardiac phenotype, and Connexin (CX)-43, to confirm cellular interaction by gap junction formation, were measured by Real time-PCR.
RESULTS: Results showed a good viability in static and after mechanical loading stimulation in SQPR. An increased expression of ANP/BNP in parallel to a reduction of CNP mRNA levels in young scaffold with respect to old ones were observed in static condition. An activation of NPR-A and NPR-B was also found. After mechanical stimulation, ANP and BNPtrend significantly decreased in old scaffold with respect to young ones (p<0.0001/p=0.0008, respectively) and, on the contrary, CNP was significantly higher (p=0.011) with a counter-regulation of NPR-B. At the end of hypoxia/reperfusion protocol, an acceptable reduction of 30% in cell viability

was observed. During I/R, only CNP was up regulated in SQPR bioreactor scaffold. ET-1 mRNA was higher in old scaffold while CX43 mRNA decreased. During I/R CX43 mRNA levels resulted significantly higher in SQPR bioreactor scaffold with respect to static conditions (p=0.0028) and plastic surface (p=0.014).
CONCLUSIONS: Our engineered model, thanks to integration of structural properties and mechanical stimuli, furnishes a new approach to study in-vitro cardiac aging.

Lack of macroscopically-evident cardiac regeneration or spontaneous functional recovery in infarcted neonatal pigs

K Konstantinos Malliaras[1]; E Polychronopoulou[1]; ι Poulakida[1]; D Sagris[1]; K Makaritsis[1]
[1]*University of Thessaly, School of Medicine, Larissa, Greece*

Funding Acknowledgements: Co-financed by Greece and the European Union - European Social Fund

Background: Neonatal mice possess an impressive -albeit transient- capacity for spontaneous cardiac regeneration following myocardial injury. Whether such robust cardiac regenerative potential is also present in neonatal large mammals has been under-investigated. Recently, two studies reported that 1-day-old and 2-day-old neonatal pigs exhibit a significant spontaneous cardiac regenerative response post-myocardial infarction (MI), characterized by minimal scarring and recovery of left ventricular (LV) function. According to the aforementioned studies, this regenerative capacity is purportedly lost after the first two days of life.
Purpose: We sought to investigate the regenerative capacity of neonatal porcine hearts post-MI.
Methods: Neonatal farm pigs (n=21) were randomized to undergo MI by permanent ligation of the left anterior descending artery on postnatal day 1 (P1) or postnatal day 3 (P3). Infarcted P1 and P3 pigs were sacrificed either at 1 week or at 7 weeks post-MI. Hearts explanted at 1 week post-MI underwent immunohistochemistry for Ki67 and alpha-sarcomeric actinin to quantify myocyte cell cycle re-entry. Transthoracic echocardiography was performed at 7 weeks post-MI to quantify fractional shortening and systolic thickening of the anterior (infarcted) LV wall and the posterior (non-infarcted) LV wall. Hearts explanted at 7 weeks post-MI underwent staining with triphenyl-tetrazolium chloride and Masson's Trichrome to quantify infarct size, infarct circumference and infarct transmurality.
Results: Fourteen animals successfully completed the protocol. Infarct size was comparable in P1 and P3 animals at 7 weeks post-MI (P1: 9.5±2.2% vs P3: 8.9±3.6% of LV, p=0.797). Infarct circumference (P1: 33.8±7.1% vs P3: 29.8±10.6% of LV, p=0.566) and infarct transmurality (P1: 38.1±4.3% vs P3: 40.4±13.7% of anterior wall, p=0.764) were similar in P1 and P3 animals at 7 weeks post-MI. LV function (as assessed by fractional shortening) was comparable in P1 and P3 animals at 7 weeks post-MI (P1: 25.5±2.9% vs P3: 23.7±4.5%, p=0.662). Furthermore, systolic thickening in the anterior (infarcted) LV wall was depressed to a similar degree in P1 and P3 animals (P1: 31.8±5.3% vs P3: 32.3±8.5%, p=0.914) compared to systolic thickening in the posterior (non-infarcted) wall (P1: 72.5±9.0% vs P3: 69.0±11.4%, p=0.666) at 7 weeks post-MI. P1 animals exhibited significantly increased myocyte cell cycle re-entry compared to P3 animals in the infarct border zone (P1: 4.5±1.3 vs P3: 2.3±0.6 per field of view, p=0.045) at 1 week post-MI.
Conclusions: Contrary to recently-published reports, we did not observe robust cardiac regeneration or spontaneous functional recovery in neonatal infarcted pigs. Both 1-day-old and 3-day-old neonatal pigs exhibited substantial cardiac scarring and significant hypokinesia of the infarcted myocardium post-MI. Additional research is warranted to investigate the cardiac regenerative potential of neonatal large mammals.

P1856
Yes-associated protein (YAP) transcriptional coactivator functions in myocardial infarction

A Angelos Tsipis[1]; AM Athanassiadou[1]; G Agrogiannis[1]; E Petrou[2]; P Athanassiadou[1]; G Athanassopoulos[2]; N Kavantzas[1]
[1]*University of Athens, Department of Pathology, Athens, Greece*; [2]*Onassis Cardiac Surgery Center, Division of Cardiology, Athens, Greece*

Introduction: Myocardial ischemia has been shown to stimulate angiogenesis in many experimental models. Angiogenesis is regulated by local balance between endogenous stimulators and inhibitors of this process. Angiomotin (Amot) is an angiostatin binding protein that promote endothelial cell migration and angiogenesis. Yes-associated protein (YAP) is a protein that acts as a transcriptional regulator and plays an important role in regulating the angiogenic activity. Both factors contribute to apoptotic process. The aim of this study was to investigate the expression of angiomotin, YAP, VEGF and apoptotic proteins in myocytes after myocardial infarction.
Material and methods: We studied myocardial samples of hearts with histologic findings of acute myocardial infarction (group A), old myocardial infraction (group B), and myocardial samples of normal heart (control group). An immunohistochemical method was performed with the use of Angiomotin, YAP, VEGF, Bax, Bcl-2 antibodies.
Results: Angiomotin and YAP expression was intensive at the risk areas of samples with acute myocardial infarction. VEGF is expressed in cardiomyocytes at the risk areas of acute myocardial infarction in 80% of cases. High concordance of Angiomotin,YAP and VEGF expression was detected (76% of cases, p = 0.020). Bcl-2 positive expression was intense at the risk areas in 75% of samples with acute myocardial infarction.
Conclusions: The increased expression of Angiomotin, YAP and antiapoptotic protein bcl-2 at the risk areas of samples with acute myocardial infarction, represents a possible compensatory mechanism of salvaged myocytes and this may be a compensatory mechanism that could be replace damaged myocardium.

P1857
Transcriptional response HIF1a and HSP70 to hypoxic stress in myocardial ischemia

A Angelos Tsipis[1]; AM Athanassiadou[1]; G Agrogiannis[1]; E Petropoulou[2]; P Athanassiadou[1]; G Athanassopoulos[3]; N Kavantzas[3]
[1]*University of Athens, Department of Pathology, Athens, Greece*; [2]*Metropolitan General Hospital, Department of Cardiology, ATHENS, Greece*; [3]*Onassis Cardiac Surgery Center, Division of Cardiology, Athens, Greece*

Introduction: Hypoxia-inducible gene expression via HIF-1α is a compensatory mechanism in the context of acute or subacute myocardial ischemia. HIF1-α is a transcription factor, sensitive to hypoxia and is up-regulated in regions of myocardial ischemia. Under hypoxia, HIF1-α protein rapidly induces the expression of genes that increase the oxygen availability to cells such as the expression of vascular endothelial growth factor (VEGF). The heat shock response is a defense mechanism against cell stress injury and antagonizes protein unfolding or misfolding during stress responses. Heat shock proteins and hypoxia inducible factors regulate the expression of a battery of genes involved in the promotion or inhibition of apoptotic pathway. However, chronic ischemia can lead to progressive heart failure and the chronic activation of these factors is deleterious.
Methods: We studied myocardial samples of hearts with histologic findings of acute myocardial infarction (group A, n=100), old myocardial infraction (group B, n=100) and myocardial samples of normal heart (control group, n=20). An immunohistochemical method was performed with the use of HIF1-α, HSP70, VEGF, Bax, Bcl-2 antibodies, in order to investigate the expression of these proteins in ischemic cardiac disorders.
Results: HIF1-α expression was intensive at the risk areas of samples with acute myocardial infarction. High concordance of HIF1-α and HSP70 expression (90% of cases, p=0,020), HIF1-α and VEGF expression (82% of cases, p = 0.020) was detected. Bcl-2 positive expression was intense at the same risk areas in 85% of samples with acute myocardial infarction. In old myocardial infraction the bcl-2 positive samples demonstrated weak staining as in the control group. Bax staining was weak in 80% of samples with acute myocardial infraction and intensive in 60% of samples with old myocardial infraction.
Conclusions: The role of hypoxia-induced factors in the genesis of heart failure remains unclear. Although experimental data suggest that these changes in gene expression can be either adaptive or maladaptive, depending on context. Increased levels of HSP70 and HIF1-α were associated with intense expression of antiapoptotic Bcl-2 protein in acute myocardial infraction. Decreased levels of HSP70, HIF1-α and intensive expression of proapoptotic bax were found in cases of chronic ischemia. The decreased expression of HSP70 and HIF1-α is associated with the progressive loss of myocytes by apoptosis. The increased expression of HIF1-α, HSP70 and Bcl-2 in acute myocardial infraction represents a possible compensatory mechanism of salvaged myocytes. The prevalence of the apoptotic mechanism or this of compensatory antiapoptotic may influence the progression of heart failure.

P1858
Association rs619203 polymorphism of a ROS1 gene in development of an ischemic stroke in patients with an arterial hypertension

A Anna Chernova[1]; S Nikulina[1]; D Nikulin[1]; I Platunova[1]; O Marylovceva[1]; A Semenchukov[1]; S Tretyakova[1]
[1]*Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation*

Introduction . The gene of ROS1 (rs619203) codes integrated membrane protein I of type. Protein ROS1 has catalytic activity and is a fabric reparation stimulator. It stimulates proliferation of fibroblasts and smooth muscle cells of a vascular wall

and also synthesis of components of connective tissue – glycosaminoglycans and collagen. The specified processes play a key role in an atherosclerosis pathogenesis, and atherosclerosis of cerebral arteries causes an ischemic stroke, and in case of a rupture of the changed vascular wall – a hemorrhagic stroke.
Purpose. Studying of a contribution of rs619203 polymorphism of a gene ROS1 to development of ischemic stroke at patients with an arterial hypertension.
Methods. Examination of 124 patients with an ischemic stroke with an arterial hypertension is conducted. Age median – 60[51; 66.75] years from which there were 75 men, an age median – 57[50; 64.5] years and 49 women, an age median – 63[54; 70] years. Clinical investigation included assessment of neurologic symptoms, a research of the somatic status, control of the ABP, record ECG, an echocardiography, a X-ray analysis, the general and biochemical blood tests, ultrasonic examination of carotid arteries, brain computer tomography. Duration, weight and the sequence of development of the accompanying somatopathies and risk factors were analyzed. The family anamnesis including assessment of existence of disturbances of cerebral circulation in the anamnesis, existence of arterial hypertension, heart diseases (a MI, cardiac arrhythmia, HFA), existence of risk factors was studied.
Results. At 124 patients with an ischemic stroke the following cardiovascular diseases are revealed: at 116 (93.55%) the idiopathic hypertensia of the III level is revealed, atrial fibrillation is diagnosed for 8 persons, that made 6.45%, the ischemic heart disease is documented at 20 patients (16.13%) with an ischemic stroke, chronic cardiac failure at 17 patients (13.71%).
According to results of a research it is established that the frequency of carriers of a homozygous genotype of GG on a widespread allele among patients with ischemic strokes (62.9%±4.3) was statistically significantly higher in comparison with control group (49.3%±2.3, =0.009). Thus, the genotype of GG is risk factor of development of an ischemic stroke, the relation of chances to find GG genotype carrier in group with an ischemic stroke makes 1.459 in comparison with carriers of two other genotypes. Patients had frequencies of genotypes of CC statistically not significantly less with an ischemic stroke (7.3%±2.3), than in group of control (8.0%±1.2, p=0.931).
Conclusions. Communication of polymorphisms of rs1333049 of a chromosome 9r21.3 and ROS1 gene rs619203 with development of an ischemic stroke is shown. Connection between the increased BMI and a heterozygous genotype of CG rs619203 of a gene of ROS1 at patients is established with an ischemic stroke.

P1859

HFWM: - Characterization of a novel closed chest model of ischemic mitral regurgitation in pigs

O Hamza[1]; ATTILA Kiss[1]; AM Kramer[1]; S Trojanek[2]; KE Tillmann[1]; I Goncalves[1]; V Tretter[3]; D Abraham[2]; UK Klein[3]; BK Podesser[1]
[1]Ludwig Boltzmann Cluster for Cardiovascular Research, Center for Biomedical Reasearch, Vienna, Austria; [2]Medical University of Vienna, Anatomy and cell biology, Vienna, Austria; [3]Medical University of Vienna, Anesthesiology Intensive care and Pain management, Vienna, Austria

Background: Development of translational animal models of cardiovascular disease is crucial to understand the disease mechanism and pathophysiology and provide a unique platform to test novel therapies and devices. Surgical treatment of secondary mitral regurgitation remains a subject of controversy and still doesn't show a clear impact on the mortality. In addition, there is unmet need to establish less invasive approaches in patients with secondary mitral regurgitation.
Aims: therefore, the aim of the present study was to establish and characterize a clinically reliable large animal model of mitral valve regurgitation.
Methods: Young female domestic pigs were used (n=12, weight =60 +/- 12kg)). The induction of mitral valve regurgitation was performed by a localized posteromedial papillary muscle (PMPM) myocardial infarction. The PMPM irrigating branches were first identified by selectively injecting contrast media into the circumflex branches and 2ml of pure Ethanol were injected. The evaluation of the mitral valve regurgitation and cardiac function was assessed by echocardiography. After 6 weeks observation period, pigs euthanized and tissue samples from the papillary muscles and the mitral leaflets were taken for further analysis.
Results: Seven pigs survived the 6 weeks follow up period. Ethanol injection resulted in postero-inferior wall and PMPM dyskinesia. Mitral regurgitation jet area significantly increased (jet area at baseline 0.03±0.015 cm^2 vs at 6 weeks 3.22 ± 0.53cm^2). A significant tenting area developed over the follow up period (Tenting area at baseline 0.35 ± 0.21cm^2 vs 2.17 ± 0.63cm^2 at 6weeks; p<0.001). Significant left ventricle enlargement was noticed (End diastolic diameter at baseline: 50,04 ± 4.34mm vs at 6 weeks 62,12 ± 3.92mm; p<0.001) as well as left atrium enlargement (left atrium area at baseline: 7.75 ±0.95cm^2 vs at 6 weeks 17.65 ± 3.2cm^2; p<0.001). These functional changes were accompanied by an increase expression levels of TGFß, MMP9, IL1ß as well as TLR2 and 4 in the posterior mitral valve leaflet while TNC expression was upregulated in the myocardial tissue but not in the valvular tissue.
Conclusion: We established a novel, reproducible and clinically relevant model of ischemic mitral regurgitation in pigs. The functional changes of MVR were associated with a moderate remodeling on valvular level. Collectively, our large animal model gives a platform to test novel pharmacological and device based therapeutic approaches for treatment and reconstructed MVR.

Background: Titin (TTN) is the biggest protein of human proteome responsible for the majority of sarcomeric myofilament mass in cardiomyocytes. It performs structural and signaling functions within the sarcomere and contributes to myofilament development. Truncating variants of TTN (TTNtv) are found in 25-30% of DCM cases, affecting cardiomyocyte metabolism and modifying the course of the disease. Importantly, TTNtv are found in 1-2% of population being linked to cardiac structural phenotype and remodeling. However, their clinical and pathogenic role in non-cardiomyiopathy patients has not been deeply analyzed. Studies assessing the role of TTNtv in patients with ischemic heart disease and cardiac remodeling after infarction (MI) are lacking. There for the aim of our study was to estimate the frequency of TTNtv in patients with postMI remodeling resulted in severe systolic dysfunction (LV EF<30%).
Materials and methods: Using target high-throughput sequencing with long reads (2x300, insert size – 550-600), we analyzed TTN variants in 74 men aged 40-66 y.o. with postMI remodeling and LV EF (Sim)<30%. Q-MI of the anterior LV wall was detected in 78% cases, the rest patients experienced posterior Q-MI. HF with II/III/IV NYHA was detected in 46/41/13% of the cases. Myocardial revascularization (CABG/PCI) was performed in 50% of patients.
Results: We detected 5 TTNtv and disruptive indels resulting in 6.7%. overall prevalence of TTNtv and disruptive indels in patients with postMI cardiosclerosis and low LV EF. One of these variants is SNP with the formation of a premature stop codon (2:179441737 C>A), one of these variants is frameshift deletion (2:179408726 TC>T). Other variants lead to inframe disruptive insertion or deletion (2:179544685 C>CTCT, 2:179436253 TTTA>T, 2:179514941 TTTTCCTCTTCAGGAGCAA>T (rs374976705). In the studied population, titin truncating variants and disruptive indels were associated with symptomatic sustained ventricular tachycardia (VT): sustained VT was detected more often in TTNtv and disruptive indels-positve compared to TTNtv and disruptive indels-negative patients: 40% vs 13% (<0.05), respectively.
Conclusion: our preliminary data demonstrate that TTNtv and disruptive indels can be associated with severe systolic dysfunction in postMI patients and adverse arrhythmic events. Further studies are needed to assess the impact of TTNtv and disruptive indels on disease course in patients with ischemic heart disease.

P1861

HFWM: - Title: Cannabinoid-sensitive receptor GPR55 deficiency impairs wound healing kinetics and aggravates remodelling post myocardial infarction

SL Sarah-Lena Puhl[1]; M Hilby[1]; S Steffens[1]
[1]Ludwig-Maximilians University, Institute for Cardiovascular Prevention (IPEK), Munich, Germany

Introduction: Classical cannabinoid receptors CB1 and CB2 have been shown to impact on left ventricular (LV) wound healing post myocardial infarction (MI). Herein, the role of the cannabinoid-sensitive receptor GPR55 remains fully unknown.
Purpose: We aimed at characterizing the impact of GPR55 on acute inflammation and long-term remodelling post MI.
Methods: Female GPR55+/+ and -/- mice were basally characterized or randomly assigned to MI (ligation of the left coronary artery) or sham-surgery and subsequently analysed based on either acute inflammatory and early wound healing responses (infarct size, leukocyte flow cytometry, chemokine qPCR, fetal genes, fibrosis) at day 1, 3 and 5 post MI (n≥6) or based on structural and functional remodelling (echocardiography and gravimetry) at day 3, 7, 14 and 28 post surgery (n≥7).
Results: In the presence of comparable initial infarct sizes (GPR55+/+ vs. GPR55-/-: 27.8±3.6% vs. 22.0±3.2%) at day 1 after MI, onset of acute inflammation, assessed by cardiac expression levels of interleukin-1β, -6 and CCL2, was delayed in GPR55-/- mice, yet subsequently potentiated and even prolonged until day 5 post MI. This was accompanied by a trend towards increased cardiac leukocyte accumulation and splenic myelopoiesis following the coronary occlusion in GPR55-/- mice. Simultaneously, up-regulation of the MI-triggered reparative, pro-fibrotic factors MerTk, MMP-9, MMP-2, TNFα and collagen I and III was accelerated and potentiated in GPR55-/- mice compared to wild-types.

Regarding remodelling, GPR55 deficiency significantly mitigated early compensatory hypertrophy as determined by re-activation of the fetal genes β-MHC and ANP (β-MHC: 5.93±1.42 vs. 2.85±0.67; ANF: 23.16±7.65 vs. 8.18±2.67) and LV function. Besides, lack of GPR55 aggravated features of maladaptation, such as increased LV diameter and volume, decreased ejection fraction and fractional shortening, thinning of the infarcted anterior wall and infarction expansion into the intraventricular septum post MI.
Conclusion: GPR55 deficiency impairs acute wound healing kinetics, attenuates induction of early compensatory hypertrophy and aggravates dilatation, matrix deposition, scar thinning and infarction expansion after MI. Taken together, our study alludes for the first time in vivo toward a regulatory role of GPR55 during post MI wound healing and LV remodelling.

Background. The clinical use of the chemotherapeutic agent doxorubicin (D) is limited by its cardiotoxicity, which leads to irreversible degenerative cardiomyopathy and heart failure. [βAla14, His15]-galanine (2-15) (G) is a novel pharmacological agonist of galanine receptors GalR1-3 having cardioprotective properties in animal models in vivo.
Purpose. The aim of this work was to study the effect of the peptide G on metabolic and functional disturbances of the heart caused by chronic Dox-induced cardiotoxicity in rats.
Methods. The study followed the "Principles of laboratory animal care" (NIH Publication no. 85-23 revised 1985). G was synthesized by the automatic solid phase method and identified by 1H-NMR spectroscopy and mass spectrometry. Male Wistar rats were divided into four groups and treated for 8 weeks with Dox (D group), Dox and G (D+G group), G (G group) or saline (control). Dox, G and saline were administered intraperitoneally at doses of 2 mg/kg/week, 50 nmol/kg/day and 1 ml/kg/week, respectively. Before treatment and at the end of the study, the animals were weighed and cardiac function was evaluated by echocardiography; the concentration of thiobarbituric acid reactive substances (TBARS) and the activity of creatine kinase-MB (CK-) were determined in blood plasma. Myocardial content of metabolites and mitochondrial respiratory parameters in saponin-permeabilized fibers of the left ventricle (LV) were determined at the end of the experiments.
Results. After an 8-week study, D group exhibited a pronounced cardiac failure, the absence of weight gain and an increase in TBARS concentration and plasma CK-MB activity in plasm. These disorders were accompanied by a decrease in the content of high-energy phosphates in the heart, deterioration of mitochondrial respiration, accumulation of myocardial lactate and glucose, and alterations in myocardial metabolism of glutamic acid, aspartic acid and alanine. Coadministration of G and Dox prevented an increase in CK-MB activity and significantly reduced the plasma TBARS concentration. In D+G group, the myocardial energy state and respiratory control of mitochondria were higher than in D group, there was a decrease of anaerobic glycolysis in the heart and no change in the content of myocardial amino acids as compared to control. Coadministration of G along with G significantly improved the parameters of LV function and caused weight gain in animals of D+G group compared with these indices in D group. No functional or metabolic changes were observed in G group compared with controls.
Conclusion. The results suggest that the peptide G can be used as an adjuvant therapy against Dox-induced cardiotoxicity.

P1864
Impact of glutathione S-transferase M1, T1 and P1 gene polymorphisms on the chronic heart failure

N Jankovic[1]; V Coric[2]; S Suvakov[2]; D Simic[3]
[1]*Clinical center of Serbia, Cardiosurgery, Belgrade, Serbia*; [2]*Institute for Medical Biochemistry, Belgrade, Serbia*; [3]*Clinical Center of Serbia, Clinic for Cardiology, Belgrade, Serbia*

Background: Chronic heart failure (CHF) secondary to ischemic heart disease belongs to oxidative disease. 8-hydroxy-2'-deoxyguanosine (8-OHdG) is a marker of oxidative DNA damage caused by reactive oxygen species (ROS). Members of the glutathione transferase (GST) superfamily catalyze a conjugation of glutathione with a broad range of xenobiotics including reactive oxygen species.
Aim: The aim of this study was to investigate the role of certain GST polymorphisms in the risk of CHF development, as well as the association of different GST variants with the level of 8-OHdG among those patients.Material and methods: The genotypes of GSTM1, GSTT1 and GSTP1 were characterized on DNA isolated from 116 patients with CHF classified according to New York Heart Association classification (NYHA) and 166 healthy controls, all of which completed a structured interview. GST genetic polymorphisms were determined by multiplex PCR or qPCR. Byproducts of DNA oxidative damage (8-OHdG) were determined by ELISA method.
Results: The frequency of GSTT1-null genotype was higher in patients with HF (33%) compared to controls (22%), with an adjusted OR of 3.08 (95% CI: 1.23-7.73; p=0.016). GSTM1 null genotype was found in 58% cases and in 49% controls (p=0.458). GSTP1-variant genotype was found in 53% of cases and in 59% controls (p=0.396). 62% of patients had combined GSTM1-active/GSTP1-referent genotype (OR: 2.68; 95%CI: 0.63-11.38; p=0.180) while 63% of CHF patients had combined GSTT1-active/GSTP1-referent genotype with adjusted OR of 0.68 (95%CI: 0.21-2.17). CHF patients with combined GSTM1-active/GSTT1 active genotype didnt have statistically higher level of 8-OHdG compared to the carriers of GSTM1-null/GSTT1-null genotype (OR: 1.19; 95%CI: 0.31-3.19; p=0.329). Also, patients with combined GSTT1-active/GSTP1-referent genotype didnt have statistically higher level of 8-OHdG compared to the carriers of GSTT1-null/GSTP1-variant genotype (OR: 1.18; 95%CI: 0.31-3.41; p=0.619).
Conclusion: The frequency of GSTM1, GSTT1 and GSTP1 null genotype in present study was similar to what was published previously. GSTT1 null genotype increases the risk of chronic heart failure while GST genotype status did not have influence on the level of 8-OHdG.

Murine Experimental Autoimmune Myocarditis (EAM) is associated with LV hypertrophy but not with reduced LV systolic function

M Moritz Mirna[1]; V Paar[1]; T Kraus[2]; K Sotlar[2]; B Wernly[1]; R Pistulli[3]; M Lichtenauer[1]
[1]*Paracelsus Private Medical University, Clinic of Internal Medicine II, Department of Cardiology, Salzburg, Austria*; [2]*Paracelsus Private Medical University, Department of Pathology, Salzburg, Austria*; [3]*University Medical Center, Department of Cardiology, Münster, Germany*

Funding Acknowledgements: The study was partly financed by a grant from the Paracelsus Medical University (PMU-FFF)

Background: EAM is a common animal model for the investigation of the pathophysiology of myocarditis. Because of diverging echocardiographic findings regarding LV systolic function from previous studies, we performed serial echocardiographic examinations throughout the course of the disease and investigated the dimensions of the murine heart and LV systolic function.
Materials and Methods: EAM was induced in male Balb/c mice by subcutaneous injection of a fragment of the α-myosin heavy chain (MyHC-α 614–629: Ac-SLKLMATLFSTYASAD), as previously published. Transthoracic echocardiography was performed on days 0, 7 and 21 in healthy animals and mice with EAM.
Results: EAM was associated with a reduction in LV systolic function and an increase in LVIDd and LVIDs 7 days post immunization. After 21 days, EAM was associated with LV hypertrophy (1.3-fold increase in septal thickness), but we did not observe a significant difference in LV systolic function when compared to healthy controls.
Conclusion: Our results indicate that EAM leads to an initial dilatation of the LV that is further followed by hypertrophy of the myocardium. Three weeks after the immunization, there was no significant difference in LV systolic function when immunized animals were compared to healthy controls.

Role of innate immune mediators in cardiac damage induced by Doxorubicin in vitro

J Gambardella[1]; A Fiordelisi[1]; M De Rosa[1]; M Ciccarelli[2]; B Trimarco[1]; G Iaccarino[1]; D Sorriento[1]
[1]*Federico II University of Naples, Naples, Italy*; [2]*University of Salerno, Medicine and Surgery, Salerno, Italy*

Background: Even if cardiomyocytes are the most common target of research studies on cardiotoxicity induced by Doxorubicin (DOXO), the contribution of inflammatory cells is of growing interest. Several reports suggest a direct correlation between inflammation and oxidative stress in response to DOXO Purpose: To evaluate the role of inflammation on cardiac damage in response to DOXO. Methods: C57/Bl mice were treated with DOXO (10 mg/Kg) by intraperitoneal injection and histological and biochemical analysis were performed on isolated hearts after 1, 3 and 5

days from treatment. Cytokines production in response to DOXO was evaluated in macrophages culture supernatant by ELISA. In cardiomyoblast (H9C2), mitochondrial mass, TMRE and ROS production were evaluated by cytofluorimetry while LC3 and Caspase levels by western blot. Results: A significant inflammatory infiltrate was observed in mice hearts 5 days after treatment, when a cardiac damage is also present. In order to evaluate whether a crosstalk could exist between macrophages and cardiomyocytes that could affect cardiac outcomes in response to DOXO, we compared two different conditions in H9C2 cells: treatment with culture medium from macrophages (RAW 264.7) exposed to DOXO for 24 hours (M-DOXO) and direct treatment with DOXO (D-DOXO). Both conditions caused an increase of Cleaved caspase-3 levels that was higher in response to M-DOXO. D-DOXO exposure induced an increase of ROS production that was associated with the activation of mitochondrial recovery in terms of increased mitochondrial biogenesis, mitochondrial mass and mitochondrial potential. Conversely, in response to M-DOXO mitochondrial recovery was impaired. Indeed, the increase of mitochondrial biogenesis did not occur and an impaired mitochondrial morphology, showing a prevalence of mitochondrial fission processes, was observed. Moreover, M-DOXO caused a reduction of LC3 mitochondrial levels suggesting alterations of mitophagy, a key player of mitochondrial recovery. Once evaluated the indirect effects of DOXO on cardiac cells through macrophages, we identified the molecules which are secreted by macrophages in response to DOXO that could affect cardiac cell biology. DOXO affected macrophages cytokines production profile, with main alterations of IL-4 and IL-1b expression.
Conclusions: Our data suggest that a crosstalk between inflammatory and cardiac cells could be responsible of cardiac damage in response to DOXO. The identification of inflammatory molecules that could orchestrate the cardiac deleterious effects of DOXO would allow the discovery of new therapeutic targets and/or early markers of anthracycline-induced cardiotoxicity.

Genetics and Histopathology Features of Noncompaction Cardiomyopathy in heart transplant individuals

S Shenghua Liu[1]; Y Xie[1]; H Zhang[1]; Y Wei[1]
[1]*Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, State key Laboratory of Cardiovascular Disease, Beijing, China*

Background: Left ventricular non-compaction cardiomyopathy (LVNC) is a genetic cardiomyopathy with unclear etiology. The clinical symptoms range from asymptomatic to heart failure, arrhythmia, and sudden cardiac death.
Purpose: This study investigated the genetic background and histopathology features of LVNC, and aimed to establish the correlation between genotype-phenotype.
Methods: We recruited 16 LVNC cases who underwent heart transplantation in our hospital. Exome-sequence data, clinical and histopathology features of patients were reviewed and analyzed. Gene-expression profiling of tissue fibrosis was evaluated by quantitative RCR.
Results: This study consisted of 16 LVNC patients, the median age was 21±9.5 years. Of 16 patients, 14 patients harbored sarcomere gene mutations associated with genetic cardiomyopathy. Multiple mutations in TNNT2, MYH7 and MYBPC3 were the major genetic causing of patients. Young patients with TNNT2 mutations had high risk for heart failure and ventricular tachycardia at an early age. Myocardium samples with MYBPC3 and/or MYH7 mutations have hypertrophic cardiomyocytes and disordered morphology of sarcomere. The obvious myocardial interstitial fibrosis was observed in half of samples, as well as young patients who have positive late-Gadolinium enhancement at MRI. By comparison, fibrosis was more associated with the onset-time of symptom, not just age of patients. Genes related with cardiac myofibroblasts activation and extracellular matrix remodeling were dramatically upregulated, whereas the anti-fibrotic factor was corresponded downregulated, which suggested fibrosis of LVNC was a result of accumulative disease progress. Young patients (<18y) with lower LV ejection fraction and multiple mutant genes was more likely to deteriorate rapidly.
Conclusion: In conclusion, LVNC has a complex genetics and histology features. Multiple sarcomere mutations played an important role on etiology of LVNC. Genetic testing is benefit for identifying patients in risk and should be considered in genetic counseling.

Background: Duchenne Muscular Dystrophy (DMD) is an X-linked recessive, progressive muscle wasting disease. Besides skeletal muscle degeneration, increasingly important source of morbidity and mortality is dilated cardiomyopathy leading to heart failure, arrhythmias and vascular dysfunction. There is substantial evidence that Tenascin C (TN-C) plays role in maladaptive left ventricular remodelling and its serum levels were associated with the severity of left ventricular (LV) dysfunction in patients with ischaemic heart disease and heart failure. In addition, recent studies demonstrated that endothelial dysfunction may contribute to the progression of dilated cardiomyopathy. Aims: Our study was aimed to 1) assess the progression of cardiac and vascular (dys)function in mice (3, 6 and 10 months old) with DMD and 2) explore the role of TN-C, as a potential biomarker of the cardiac complications in DMD. Methods: Male mdx and BL/10 mice were used (3, 6 and 10 months old). Echocardiography was performed to assess LV ejection fraction (LVEF) and hemodynamic function was recorded by an invasive method involving the determination of LV systolic pressure (LVSP). Vascular reactivity was performed by wire myography. RT-qPCR was performed to assess the expression of Tnc mRNA and plasma levels of TN-C was measured by ELISA. Results: Mice with DMD showed a moderate and severe endothelial dysfunction at age of 3, 6 and 10 months old in comparison with Wt littermates ($p<0.05$). In addition, LV dilation was observed in DMD mice compared to Wt littermates ($p<0.05$; 6 and 10 months old) and plasma levels of TN-C was positively correlates with LV-end systolic and LV-end diastolic diameter.
Conclusions: Our study first time demonstrated an early and progressive endothelial dysfunction in mice with DMD. In addition, plasma levels of TN-C increased and correlated with LV dimension. Collectively, our data are suggesting that targeting early endothelial dysfunction and TN-C upregulation may be a novel therapeutic approach for preserving cardiovascular function in patients with DMD.

Inhibition of cardiac lymphangiogenesis in imatinib-induced cardiomyopathy

K Urbanek[1]; D Madeddu[2]; S Cavalli[2]; C Frati[2]; A Falco[2]; B Lorusso[2]; D Cappetta[1]; L Berrino[1]; A De Angelis[1]; F Quaini[2]
[1]*University of Campania "Luigi Vanvitelli", Department of Experimental Medicine, Naples, Italy*; [2]*University of Parma, Departments of Medicine and Pathology, Parma, Italy*

Background: Imatinib mesylate (IM) is the backbone for the treatment of chronic myeloid leukemia and gastrointestinal stromal tumors. It inhibits the Abl-tyrosine kinase and PDGFR. Tyrosine kinase inhibitors have been implicated in cardiovascular side effects and the observed fluid retention may result from a defective lymphatic drainage.
Purpose: The possibility that PDGFR-targeting drugs can affect the integrity of cardiac lymphatics was tested in a model of IM-induced heart failure.
Methods: Myocardial samples of two patients who died of heart failure while under IM treatment were analysed. For animal studies, rats were injected with 100mg/kg IM three times a week for 3 weeks. Hemodynamic data were obtained, and the hearts were collected for morphometric, immunofluorescence and electron microscopy analysis.
Results: IM-treated human hearts were characterized by interstitial edema, mitochondrial damage and several features of autophagy. IM treatment reduced survival in the absence of severe myelotoxicity. Slight decrease in systolic blood pressure and altered left ventricular end-diastolic pressure and positive and negative dP/dT were detected. These changes were accompanied by increased theoretical water content and reduced lymphatic vessel density in the myocardium. To determine whether IM affect the process of lymphatic lineage commitment, expression of Prox-1 was evaluated in the population of rat cardiomyocyte-fibroblast-depleted stromal cells with the very low expression of Prox-1. VEGF-C containing lymphatic specific medium induced a 6-fold increase in Prox-1. This effect was blunted by IM.
Conclusions: Inhibition of tyrosine kinase by IM is translated at myocardial level in structural and functional alterations of cardiac lymphatics in the absence of myocardial fibrosis. These data indicate that defective lymphangiogenesis may contribute to tyrosine kinase inhibition-induced cardiovascular events.

Funding Acknowledgements: Marga and Walter Boll foundation

In human heart failure (HF), persistent Na+ current (INaL) is enhanced and may lead to arrhythmias. During HF, Ca/Calmodulin-dependent protein kinase IIδ (CaMKIIδ) and INaL are increased in parallel. CaMKIIδ increases INaL via regulation of sodium channels thereby contributing to arrhythmias through early- and

delayed-afterdepolarizations (EADs and DADs). Genome-wide association studies (GWAS) have described the implication of the neuronal sodium channel isoform NaV1.8 (SCN10A) in cardiac electrophysiology showing modulation in cardiac conduction, such as PR and QRS interval. Our group showed that the expression of the isoform NaV1.8 is significantly upregulated in human HF cardiomyocytes and contributes substantially to the enhanced INaL.
In the present study, we investigated a potential cross-talk of CaMKIIδ and NaV1.8 and its role in cardiac electrophysiology and arrhythmogenesis the heart.
Co-immunoprecipitation experiments revealed an association of CaMKIIδ and Nav1.8 in human homogenates. Furthermore, immunohistochemistry staining in isolated human cardiomyocytes showed a co-localization of CaMKIIδ and NaV1.8 at the intercalated disc and t-tubules. Therefore, we performed electrophysiological experiments to investigate the functional consequence of these findings.
Whole-cell patch clamp experiments were performed in isolated human and murine ventricular cardiomyocytes to measure the contribution of NaV1.8 and CaMKIIδ in INaL generation. We observed a significant reduction in INaL after adding the novel specific NaV1.8 blocker PF-01247324 (orally bioavailable; 1 μmol/L) and a CaMKIIδ inhibitor, autocamtide inhibitory peptide (AIP, 1 μmol/L) in failing human ventricular cardiomyocytes. When PF-01247324 and AIP were administered together a more pronounced decrease in INaL compared to PF-01247324 or AIP alone was recorded, indicating a synergistic effect.
Ca2+-sparks were measured using confocal microscopy with the Ca2+ dye fluo-4 AM. Inhibition of both NaV1.8 and CaMKIIδ lead to a decreased SR-Ca2+ spark frequency (CaSpF) in failing human cardiomyocytes. These findings illustrate that SR Ca2+-leak can be induced by NaV1.8-dependent INaL via Ca2+ overload possibly resulting in arrhythmia.
Additionally, Ca2+ transients were measured using epifluorescence microscopy with the Ca2+ dye fura-2. We did not observe a change in the amplitude of Ca2+ transients after administration of a NaV1.8 blocker in transgenic murine cardiomyocytes suggesting no negative inotropic effect.
Our results demonstrate the significance of both CaMKIIδ and NaV1.8 in INaL generation and their detrimental interaction. This data suggest that increased CaMKIIδ activity plays a substantial role for the activation of NaV1.8-mediated late sodium current.

Background Cardiomyocytes are the main cells affected in the course of myocarditis. They are particularly sensitive to changes in iron homeostasis and reactive oxygen species (ROS). Iron is crucial for the maintenance of optimal energy metabolism, but also plays an important role in inflammation and ROS production. We hypothesize that iron homeostasis might be involved in the pathogenesis of myocarditis.
Purpose The aim of the study was to assess differences in profiles of the expression of key genes involved in iron homeostasis, cardiac remodeling, and protection against ROS in human cardiomyocytes (HCMs) cultured in the presence of sera from patients with acute myocarditis and after 6 weeks of recovery, and also to compare the results with healthy controls.
Methods In HCMs cultured for 48 hours with sera from 11 patients and 7 controls we analyzed expression of light and heavy ferritin chains [FTL, FTH], transferrin receptor 1 [TfR1], galectin 3 [LGALs3], TGFß signaling [TGFß1, TGFß2, TGFß3], glutathione peroxidase [GPX] and superoxide dismutase [SOD1] at the mRNA level using RT-qPCR.
Results We found a significant increase in an expression of TfR1 ($p<0,01$) in HCMs exposed to sera from myocarditis patients, in comparison to those treated with sera from healthy controls. Additionally, elevated expression of TfR1 in cells correlated with serum levels of total iron ($R=-0,52$; $p<0,05$), CRP ($R=0,67$; $p<0,05$), and NT-proBNP ($R=0,55$; $p<0,05$), suggesting increased iron demand in HCMs and its possible relation to inflammation and hemodynamic dysfunction in patients. Moreover, we observed elevated expression of FTH and FTL (both $p<0,01$) and its strong correlation with expression of TfR1 as well as with increased levels of CRP in sera. It could be explained by the double role of ferritin in iron storage and in inflammation.
In the context of remodeling potential HCMs treated with myocarditis sera, in comparison to those treated with sera from healthy controls, displayed augmented expression of galectin 3 ($p<0,01$) and disturbances in TGFß genes. Interestingly, upregulation of galectin 3 was related to changed iron homeostasis, reflected by correlations with TfR1($R=0,77$; $p<0,05$), FTH($R=0,92$; $p<0,05$) and FTL ($R=0,76$; $p<0,05$).
Additionally, HCMs treated with sera from myocarditis patients showed increased expression of ROS defensive genes such as GPX and SOD1 (both $p<0,01$), and also strongly correlated with expression of TfR1, FTH, and FTL. Thus, it is possible that an impairment in iron homeostasis in the course of myocarditis may exaggerate oxidative stress.
A similar pattern of gene expression profile was observed in HCMs treated with sera collected after 6 weeks of clinical recovery, suggesting that the negative impact of sera was preserved.
Conclusions Malfunctioning of cardiomyocytes in myocarditis might be related to derangements in the expression of genes involved in iron homeostasis, cardiac remodeling, and ROS protection

P1875
Mir-146a plasma levels are increased in patients with hypertrophic cardiomyopathy

Introduction: Hypertrophic cardiomyopathy (HCM) is a genetic disease of the myocardium caused by mutations in sarcomeric genes and characterized by hypertrophy and fibrosis. MiRNAs are important posttranscriptional regulators of gene expression with an increasingly recognized role in cardiovascular disease. Among the miRNAs studied so far, miR-146a could be a promising biomarker or therapeutic target for HCM. Besides its role in the inflammatory response resolution, emerging evidence suggests that mir-146a also plays a significant role in cardiac hypertrophy, atherosclerosis and peripartum cardiomyopathy.
Purpose: The aim of this study was to investigate plasma miR-146a levels in hypertrophic cardiomyopathy patients and normal controls.
Materials and methods: miR-146a levels were analysed in plasma samples from 50 patients with hypertrophic cardiomyopathy and 30 normal controls using real time qPCR and specific TaqMan assays. cel-miR-39 was used as external spike-in control. Relative quantitation was performed using the 2-ΔΔCt method. Patients were subjected to standard echocardiographic evaluation. Data regarding myocardial fibrosis assessed using late gadolinium enhancement cardiovascular magnetic resonance (LGE-CMR) were retrieved from patients’ records. Serum Troponin I was used as a marker of myocardial damage. Statistical analysis was performed using SPSS (v25). This research was approved by the appropriate institutional review board, and a written informed consent was obtained from each participant.
Results: miR-146a plasma levels was significantly higher in HCM patients than in healthy controls ($p=0.012$). Interestingly miR-146a was not associated with maximal myocardial wall thickness ($rs=0.098$, $p=0.595$), the extent of myocardial fibrosis (LGE-CMR) ($rs=-0.094$, $p= 0.760$) and serum troponin I levels ($rs=0.097$, $p=0.524$).
Conclusion: Our study indicates that plasma miR-146a is increased in HCM patients. However, the potential role of miR-146a as a genetic modifier in HCM remains to be elucidated.

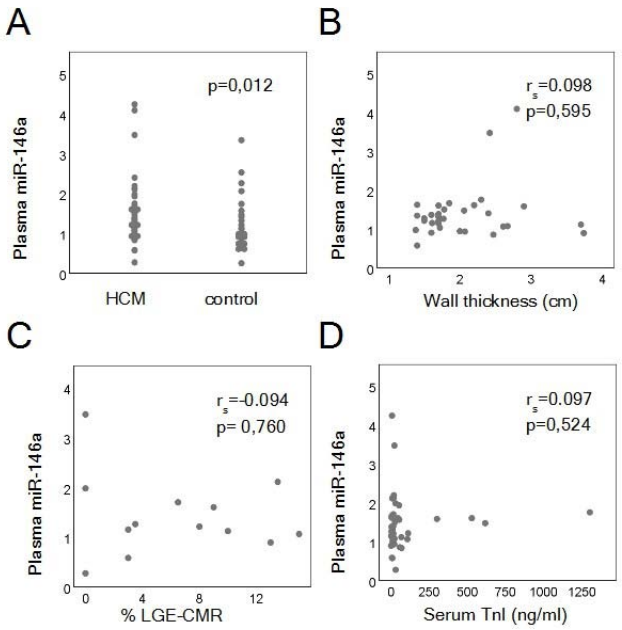

Figure 1: miR-146a serum levels in HCM

Funding Acknowledgements: RFBR:18-015-00198 "Studying of energy cardiac metabolism and cardiomyocyte dedifferentiation in chronic heart failure"

In heart failure (HF) cardiomyocyte remodeling includes: restructuring of the contractile apparatus; changes in energy metabolism. Dedifferentiation represents a key feature of cardiomyocyte remodeling. It is characterized by reactivation of the fetal gene program. Compared to normal myocytes, dedifferentiated cells become more fetal with increased diameter and surface area. Dedifferentiation arises in vivo, in fibrillating atria, ischemic myocardium, and in the border zone of myocardial infarcts. Such dedifferentiated myocytes are not apoptotic and presumably reflect adaptations to abnormal myocardial stress. Re-expression of alpha skeletal actin (alpha SKA) is a marker of cardiomyocyte dedifferentiation but in the same time it is a marker of cardiomyocyte hypertrophy too. Cell dedifferentiation is accompanied by a shift from oxidative phosphorylation to glycolysis. A key regulator of cardiac energy metabolism is transcription factor peroxisome proliferator-activated receptor alpha (PPAR alpha).

The aim of the work to study cardiomyocyte dedifferentiation and hypertrophy in dilated cardiomyopathy (DCM) and HF, the expression of alpha SKA, PPAR alpha and of myosin protein kinase zipper interacting protein kinase (ZIPK) in cardiomyocytes. Endomyocardial biopsies (EMB) were obtained from 28 patients with DCM and HF. Transmission electron microscopy was used to detect cell ultrastructure. The gene expression levels of PPAR alpha, alpha SKA and ZIPK were determined using real time PCR.

Revealed cardiomyocytes have main features of dedifferentiated cardiomyocytes - increased diameter and surface area, sarcomere disorganization, enhanced glycogen content. Gene expression levels of PPAR alpha decreased, gene expression levels of alpha SKA and ZIPK increased in DCM and HF.

PPAR alpha expression level decrease shows shift from oxidative phosphorylation to glycolysis, a transition to dedifferentiated state of cardiomyocytes. Our results demonstrate the reactivation of the fetal gene program, features of fetal heart include the preference of carbohydrates over fatty acids as energy substrate. ZIPK expression level is elevated, perhaps ZIPK is involved in sarcomerogenesis during hypertrophy in HF. The level of alpha SKA may be a useful determinant for the degree of dedifferentiation in HF and an indicator for possible redifferentiation. Since the reactivation of the fetal cardiac gene program is also a characteristic feature of hypertrophic cardiomyocytes during HF, it is possible that the main distinction between hypertrophy and dedifferentiation was made by the presence or absence of glycogen accumulation. We propose that cardiomyocytes detected in our study are dedifferentiated cardiomyocytes. Dedifferentiated cardiomyocytes may take part in cardiac regenerative processes in HF and the understanding of the mechanisms of dedifferentiation, proliferation and redifferentiation of cardiomyocytes is important for heart regeneration and repair.

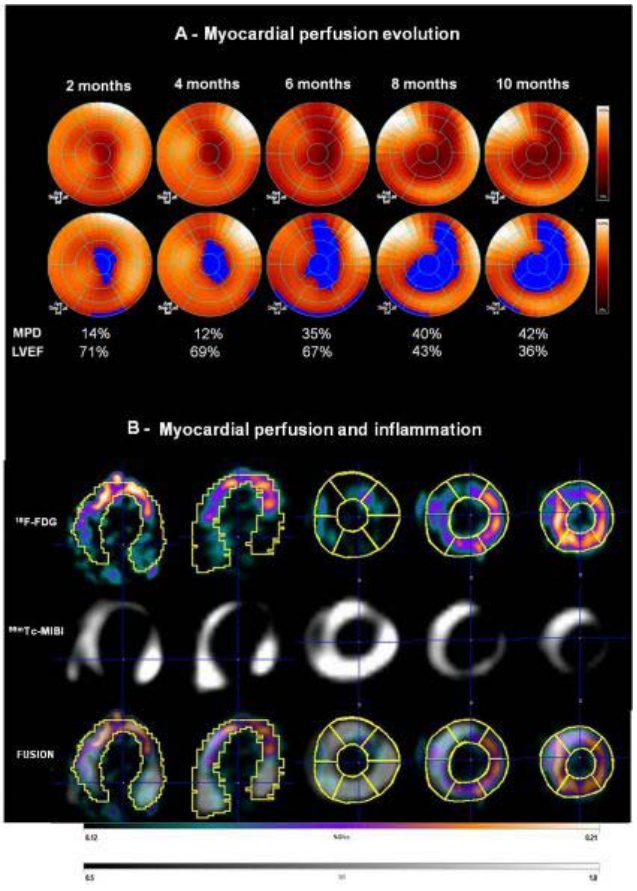
Funding Acknowledgements: São Paulo Research Foundation (FAPESP)

Background: Myocardial perfusion defects (MPD) is a common finding in Chronic Chagas cardiomyopathy (CCC), but it is unclear if the perfusion derangement can precede and correlate with the development of left ventricular (LV) systolic dysfunction and myocardial fibrosis.

Purpose: We investigated the time-course of myocardial perfusion changes and the correlation with the histopathological changes and the progression of LV systolic dysfunction in an experimental model of CCC.

Methods: The study included 40 female Syrian hamsters infected with 3.5x104 trypomastigotes forms of T. cruzi Y-strain and their respective controls (n=10). Surviving animals (22 infected and 10 controls) were submitted to in vivo imaging 2, 4, 6, 8 and 10-months afterwards. Rest high-resolution SPECT imaging using 99mTc-sestamibi was used to assess MPD extension that was analyzed by using polar maps considering the uptake threshold of 50% compared to the maximum pixel uptake value. The left ventricular ejection fraction (LVEF) and the systolic and diastolic diameter (LVSD and LVDD) were assessed by using 2D-echocardiogram. The animals underwent PET imaging using 18F-FDG for assessment of myocardial viability and inflammation. Histological analysis included quantification of myocardial inflammation intensity and fibrosis extension.



Picture

Results: Eight out of 22 (36%) surviving infected animals showed significant LV ejection fraction (LVEF) deterioration after 8-months (%; 60±11 vs 70±3 vs 70±5, p=0.007) and 10-months (%; 54±9 vs 70±3 vs 70±3, p<0.0001) compared to control and infected animals without systolic dysfunction, respectively. However, MPD in infected animals showing LV systolic dysfunction displayed significant progressive deterioration first detected at 6 months after infection. Early stages MPD correlated with the late values of LVEF, LVSD, LVDD and extent of myocardial fibrosis. Moreover, MPD at 6-months correlated with the LVEF decrease from 6 to 10 months after infection (r= 0.56, p=0.0008). MPD in the present experimental model exhibited frequency and topographic similarities with MPD seen in human CCC. Also, MPD correspond to areas with metabolically viable myocardium and correlates topographically with higher 18F-FDG uptake indicating that MPD were associated to myocardial inflammation, which was confirmed by histological assessment.
Conclusions: Rest MPD precedes the development and correlates with the ulterior fibrosis and deterioration of LV systolic dysfunction in experimental CCC. The MPD was topographically associated with increased 18F-FDG uptake, suggesting a correlation between inflammation and the myocardial perfusion derangement. Our findings indicate that MPD may be a surrogated marker for myocardial inflammation in CCC and raise the possibility of using perfusion imaging for risk stratification and monitoring the course of this myocardial disease.

Introduction: During the perinatal adaptation the N2BA titin isoforms are switched for N2B titin isoforms leading to an increase in sarcomeric passive force (Fpassive). We assume that cardiomyocyte development is accompained by a gradual decline in the oxidative sensitivities of titin, and consequently Fpassive becomes more and more resistant against oxidative insults in developing cardiomyocytes. Here we attempted to reveal a hypothetical link between the extents of titin isoform oxidation and small heat shock protein (sHSP) expressions (i.e. HSP27 and αB-crystallin).
Methods: Mechanically isolated and permeabilized left ventricular cardiomyocytes from 0, 7 and 21 day-old and 8 weeks old adult control rats were used. The effects of SH oxidation and carbonylation of titin isoforms were evaluated following in vitro exposures to an oxidative agent, dithiodipyridine (DTDP) or Fenton reagents in cardiomyocytes. Western immunoblot assays were carried out for the semiquantitative determination of oxidized SH-groups or carbonyl-groups of titin isoforms and to monitor sHSPs' expressions. Immunohistochemistry assays were performed to correlate the age-dependent characteristics of titin isoform and sHSPs expressions.
Results: The relative extents of DTDP-evoked SH oxidations and Fenton-evoked carbonylations declined with cardiomyocyte age for both titin isoforms (N2BA(DTDP): 80±1%, 71±1%, 64±1%, cannot detect; N2B(DTDP): 74±1%, 62±2%, 53±2%, 32±2%,; N2BA(Fenton): 2.57±0.06 AU, 2.37±0.04 AU, 1.35±0.03 AU, cannot detect; N2B(Fenton): 2.90±0.10 AU, 2.58±0.04 AU, 1.80±0.04 AU, 1.51±0.03 AU in 0, 7 and 21-day- old rats and adult animals, respectively, P<0.05, n=4-20). The expression levels of sHSPs increased significantly with age (HSP27: 1.04±0.09, 2.14±0.21, 3.04±0.46, 4.83±0.47; αB-crystallin: 1.00±0.12, 1.61±0.17, 3.23±0.58, 4.41±0.70 in 0, 7, 21 day-old and adult rats, respectively, in relative units, P<0.05, n=6). Strong correlations were found between the expression levels of sHSPs and oxidation of titin isoforms. Conclusion: Our data implicate a gradual build-up of a protective mechanism against titin oxidation through the upregulation of HSP27 and αB-crystallin expressions during postnatal cardiomyocyte development.

A novel phospholamban p.Arg14del cardiomyopathy mouse line treated with heart failure medication

T R Eijgenraam[1]; EM Schouten[1]; ACDI Gehlken[1]; MM Dokter[1]; HHW Sillje[1]; RA De Boer[1]
[1]*University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands (The)*

Funding Acknowledgements: CVON-DOSIS grant 2014-40, NWO VIDI grant 917.13.350 and a PLN patient foundation grant

BACKGROUND: Phospholamban (PLN) plays a role in cardiomyocyte calcium handling by acting as a negative regulator of the sarcoplasmic/endoplasmic reticulum Ca2+-ATPase (SERCA). A mutation in the PLN gene leading to the deletion of arginine 14 (R14del) of the PLN protein, is the most frequently identified mutation in patients with dilated cardiomyopathy (DCM) or arrhythmogenic cardiomyopathy (ACM) in the Netherlands. Cardiomyopathy patients that carry the PLN-R14del mutation have a worse prognosis than cardiomyopathy patients that do not carry this mutation, evidenced by more appropriate implantable cardioverter-defibrillator (ICD) discharges and more sudden cardiac death (SCD). There is no specific therapeutic treatment available for these patients other than standard heart failure treatment and heart transplantation.
PURPOSE: The aim of this study is to generate a mouse model of PLN-R14del-induced cardiomyopathy and to screen for treatment options. First treatment consisted of standard heart failure medication including a beta blocker (metoprolol) and a mineralocorticoid receptor antagonist (MRA; eplerenone).
METHODS: The PLN-R14del mutation was introduced into the genome of C57BL/6N mice and backcrossed into C57BL/6J mice. Cardiac function was assessed using echocardiography, electrocardiography (ECG) and histological and molecular analysis. Metoprolol was orally administered as ‘350 mg/kg/day via the drinking water and eplerenone was orally administered as ‘200 mg/kg/day via the chow (n=10-12 per group). All animal studies were performed according to National Institutes of Health (NIH) guidelines and in accordance with national regulations.
RESULTS: Homozygous PLN-R14del mice had increased left ventricular (LV) volume with decreased fractional shortening (FS) in comparison to wild-type littermates. In addition, decreased ECG potentials and prolonged QTc were observed. This resulted in decreased survival with a maximum life span of 2 months. Histological analysis showed severe cardiac fibrosis and aggregation of PLN proteins in the cardiomyocytes. Molecular analysis demonstrated increased levels of genes and proteins associated with cardiac stress, fibrosis and endoplasmic reticulum (ER) stress. Administration of eplerenone significantly decreased LV volume and atrial and pulmonary congestion. In addition, gene expression of B-type natriuretic peptide (BNP) and collagen genes was reduced. However, neither metoprolol nor eplerenone could improve cardiac function or survival of these mice.
CONCLUSION: Homozygous PLN-R14del mice exactly mimic human disease in an accelerated manner. Administration of standard heart failure treatment including metoprolol and eplerenone does not give beneficial effects in these mice. The findings of this study underline the need for better understanding of the pathology of PLN-R14del-induced cardiomyopathy and problem-targeted therapy.

MicroRNAs expression in hypertrophic cardiomyopathy patients.

G A Gayane Shakaryants[1]; M V Kozhevnikova[1]; V Y Kaplunova[1]; E V Privalova[1]; YU N Belenkov[1]; S S Osipova[1]
[1]*I.M. Sechenov First Moscow Medical State University, Moscow, Russian Federation*

Purpose: to analyze the circulation miRNAs expression in patients with hypertrophic cardiomyopathy (HCM) and heart failure (HF).
Methods: Forty three patients with HCM (21 patient with stable course (SC) (men-15; average age 52.6±3.04) and 23 patient with progressive course (PC) (men-15; average age 56.8±2.48) and 43 healthy controls were enrolled to the study. HFpEF was observed in 14 HCM patients. For miRNA profiling the RT-qPCR assay was performed. Based on literature data 3 miRNA associated with hypertrophy and fibrosis were selected for the study: miRNA-29a, miRNA -21, miRNA -133a.
Results: Expressions of these miRNAs were compared in studied groups. There were statistically significant differences of miRNAs expression between HCM patients and control group. Expression of miRNAs were higher in patients with HCM (p<0.005). The ratio of miRNA-21 level in HCM patients to controls (HCM/controls) was 4.806 [4.16; 5.45], miRNA -133a (HCM/controls) - 0.014 [0.010; 0.018], miRNA -29a (HCM/controls) - 0.522 [0.455; 0.590]. There were no significant differences between miRNAs expression in HCM patients with and without HFpEF. There were no significant differences in miRNAs expression between stable course of HCM and progressive course.
Conclusions: 1. Expression of miRNA-21, -133a, -29a were higher in patients with HCM in comparison with control group.
2. There were no significant differences between miRNAs expression in HCM patients with and without HFpEF.
3. There were no significant differences in miRNAs expression between stable course of HCM and progressive course.

Background: Dilated cardiomyopathy (DCM) frequently results in heart failure, a syndrome with an increasingly high prevalence and mortality rate. Recently, we reported changes in expression and structural alterations in Golgi apparatus of patients with DCM. This organelle has been described as a potential source for autophagosomes development, an essential stage of the autophagy mechanism.
Purpose: This study aimed to analyze changes in the expression of autophagy- and phagocytosis-related genes in patients with DCM, especially in relation to left ventricular (LV) dysfunction. Furthermore, we investigated if the gene expression changes were translated into ultrastructural alterations.
Methods: Twenty-three human left ventricle tissue samples were obtained from DCM (n = 13) patients undergoing heart transplantation and control (CNT; n = 10) donors. Diagnosis of DCM was based on clinical history, Doppler echocardiography, and coronary angiography data. Total mRNA levels of heart samples were analyzed by RNA sequencing. Furthermore, transmission electron microscopy of the diseased tissue was carried out by a JEOL TEM system.
Results: The altered expression ($P < 0.05$) of 13 autophagy- and 3 phagocytosis-related genes was observed. The expression changes of the autophagy-related genes NRBP2 and CALCOCO2 were associated with cardiac dysfunction and remodeling ($P < 0.05$). The affected patients had a higher activity of these degradation processes, as evidenced by the greater number of autophagic structures in the DCM tissue ($P < 0.001$). Differences in the ultrastructural distribution were also found between the DCM and CNT tissues.
Conclusions: These results show that in patients with DCM, the altered expression of NRBP2 and CALCOCO2 is related to LV dysfunction and remodeling. Clarification of the molecular mechanisms of cardiac autophagy would help in the future development of therapies to improve LV performance.

Noonan syndrome (NS) belongs to RASopathies and is an autosomal dominant genetic disorder characterized by distinct facial features, short stature, congenital heart defects and developmental delays. However, in many cases it occurs de novo. Pathogenic variants in several RasMAPK pathway genes have been found to contribute to the phenotype, the most prevalent gene (50% of cases) being PTPN11. The rest of the affected individuals harbour mutations in other genes among which the proto-oncogene RAF1 is quite rare (only 3-17% of cases). RAF1 encodes a MAP3K that plays an essential role in cell division, differentiation and apoptosis. Mutations in this gene are associated with Noonan sy. 5 and Leopard sy. 2. Moreover, the majority of patients with RAF1 pathogenic variants manifest cardiac involvements, especially HCM (hypertrophic cardiomyopathy).
The goal of the study was genetic screening for RAF1 mutations in a Hungarian HCM cohort.
We screened 133 HCM patients (81 men, 52 women, average age: 45±15 years) using Next Generation Sequencing. RAF1 gene was also included in the 103 HCM genes panel.
Out of 133 HCM patients included in the study, 2 carried rare pathogenic variants in RAF1 gene that are indicative of NS: p.Ser257Leu in exon 7, and p.Leu633Val in exon 18. The first missense mutation was identified in a 1 year old girl and it's clustered in the CR2 domain of the RAF1 protein known for its regulatory role. Several reports in the literature describe this mutation as highly pathogenic. The second mutation was identified in a newborn boy without a typical manifestation of NS but with a complex cardiac phenotype including severe obstructive hypertrophic cardiomyopathy, pulmonary stenosis and atrial septal defect. Family screening revealed that the mutation occurred de novo, further reinforcing its pathogenicity.
RAF1 pathogenic gene variants are rare cause of typical HCM and may be suspected in syndromic disease or with complex cardiac phenotypes.

A risk prediction score for early-medium term adverse events in patients with infective endocarditis

AR Ana Rita Pereira[1]; A Briosa[1]; I Cruz[1]; A Marques[1]; AL Broa[2]; S Alegria[1]; AC Gomes[1]; AR Almeida[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*; [2]*Hospital Garcia de Orta, Internal Medicine, Almada, Portugal*

Introduction: Host factors and complications have been associated with higher mortality and morbidity rates in infective endocarditis (IE). In 2016, a validated risk score for predicting 6-month mortality was published, based on 2 prospective multinational registries; not including Portugal as a participating country (J Am Heart Assoc. 2016; 5: e2003016).
Objectives: To identify independent predictors of early-medium term adverse events on a Portuguese population with IE and to develop a score system for risk stratification. To assess the predictive value of the 2016 risk score in that population and compare the accuracy of both models.
Methods: Retrospective study including consecutive patients (pts) admitted to a tertiary center with the diagnosis of IE from 2006 to 2017. Clinical, echocardiographic and follow-up data were evaluated. Early-medium term adverse events were a composite of 6-month mortality (including in-hospital death) and reinfection (≤ 6 months from the initial diagnosis). The proposed score was developed from the entire data set using the Cox proportional hazards model. The 2016 validated score, consisting of 14 variables, was applied to each case. Receiver operating characteristic (ROC) curves and area under curve (AUC) were calculated for both scores and used for comparison.
Results: 174 episodes of IE were included in a total of 167 pts (mean age 62.2 ± 16.2 years, 75.3% male). Native valve infection occurred in 73.6%. Aortic valve was the most affected and Staphylococcus aureusthe mainly isolated agent. The adverse events occurred in 41.4% of cases: 6-month mortality rate was 40.2% (n=70, 50 pts died during hospital stay) and reinfection rate 1.2% (n=2). Multivariate Cox regression identified 4 independent predictors (only 1 protector): paravalvular abscess (HR 2.1, 95%CI 1.1-4.2, p = 0.03); heart failure development (HR 1.9, 95%CI 1.2-3.4, p = 0.01); progression to septic shock (HR 3.6, 95%CI 1.9-6.4, p < 0.01); cardiac surgery (HR 0.6, 95%CI 0.3-0.9, p = 0.04). The AUC was 0.74 (95%CI 0.7-0.8, p < 0.01) for the proposed score which performed similarly to the 2016 validated risk score (AUC 0.67, 95%CI 0.6-0.8, p < 0.01).
Conclusions: In this population, IE was associated with a high rate of early-medium term adverse events. Comparing with the 2016 validated score, the proposed model seemed to have at least similarly accuracy for risk stratification of pts with IE and it included only 4 independent predictors, making it easier to apply.

Funding Acknowledgements: FAPESP

Background: There are more than 8 million patients with Chagas' disease around the world. This disease is characterized by intense myocardial fibrosis triggered by a complex cascade of inflammation, oxidative stress and apoptosis. The air pollution is a health problem in urban centers and stimulates the same pathways. We aimed to assess the role of air pollution upon myocardial fibrosis in acute phase of Chagas' cardiomyopathy model. Methods: 100 females Sirius Hamsters were divided into 4 groups: Control (Ct), Control + Pollution (CtP), Chagas (Ch) and Chagas + Pollution (ChP) and analyzed until sixty days of infection. The animals were infected with 105 Tripanossoma cruzi Y strain. Animals were daily exposed to pollution by inhalation of particulate matter produced by burning diesel fuel. The animals were euthanized after 60 days. Morphometric analyses of the interstitial (ICVF) was performed. The evaluation of the inflammation, oxidative stress and apoptosis were studied by gene expression analysis using real-time RT-PCR, ELISA and TUNEL. Results: In the analysis of ICVF, we observed a higher deposition in the LV of the chagasic groups compared to control (p=0.04). Also pollution alone increased myocardial fibrosis in the control exposed to pollution compared to the control group. We observed that the infection did not amplify the deposition of interstitial collagen in the infected groups. Oxidative stress analysis Nox1, MnSOD and iNOS showed higher expression in the Ch and ChP compared to controls, the pollution did not modulate an expression of these genes in infected animals. In the analysis of apoptosis, we observed that the infected groups showed higher expression of the Bcl-2 and Caspase 3 genes in comparison to the controls. The ChP group showed even greater expression than the Ch group suggesting amplification of apoptosis modulated by pollution. In the protein analysis of the inflammatory cytokines on tissue IL-10 and INF-γ we observed increasing of these cytokines in the infected groups. TNF-α also increase, but with no statistical significance. Chagasic group exposed to pollution presents 3 times more apoptotic cells than the chagasic group, demonstrating again a possible modulation of apoptosis by pollution.
Conclusions: We concluded that air pollution amplified apoptosis in a Chagas heart disease model acute phase. However, it was not enough to increase myocardial fibrosis, probably because the strong pathway activation by T. cruzi infection.

Background: Cardiac STAT3 expression decreases with age and is reduced in failing hearts. Male mice with a cardiomyocyte-restricted knockout of STAT3 (αMHC-Cretg/+; STAT3flox/flox, CKO) show age-related heart failure with reduced capillary density associated with diminished Erythropoietin (EPO) production and subsequent reduction of the endothelial differentiation potential of Sca-1+-cardiac progenitor cells (CPC).
Purpose: We hypothesized that reduced cardiomyocyte STAT3 expression impairs the cardiomyocyte secretome and thereby changes the epigenetic priming of CPC.
Methods: Freshly isolated CPC (MACS) from 14 weeks old CKO and WT male mice as well as 2 clonally expanded CPC cell lines were used. Genome-wide methylation profiling was performed on freshly isolated CPC by reduced representation bisulfite sequencing. 3T3-L1 preadipocytes were incubated with conditioned supernatants of HL-1 cardiomyocytes with a lentiviral knockdown of STAT3 (STAT3-KD). Mice (age: 3 months) were injected weekly (i.p.) with NaCl or with a low-dose of an EPO derivative (3 μg/kgBW) for 3 months. Cardiac fat content was analyzed by triglyceride measurement and Oil Red O staining. Using qRT-PCR, immunoblotting and FACS, the expression of (pre-)adipocyte markers was measured.
Results: Clonally expanded CPC could be differentiated in endothelial cells or in adipocytes indicating that both cell types can derive from the same CPC cell. CKO-CPC showed a 2-fold increase in adipocyte formation after 4 weeks in culture (Oil Red O measurement, enhanced mRNA levels of FABP4, CEBPA and OLR1, *P<0.05) compared to WT-CPC. Epigenetic analysis revealed 568 differentially methylated regions between CKO- and WT-CPC. Zfp423, a transcription factor controlling preadipocyte determination, was found to be less methylated in CKO-CPC. QRT-PCR confirmed higher expression of Zfp423 in CKO-CPC compared to WT-CPC. EPO treatment (10 ng/ml) of CKO-CPC cultures reduced Zfp423 expression and adipocyte formation. Cultivation of 3T3-L1 with conditioned media from STAT3-KD HL-1 cardiomyocytes significantly increased adipocyte formation (Oil Red O absorbance, increased mRNA levels of FABP4, AdipoR1 and CEBPA, decreased mRNA levels of Pref-1 and PDGFRα) compared to cultivation with control media, which could also be attenuated by EPO supplementation. Left ventricular fat content and adipocyte number were increased in hearts of 6-month-old CKO mice (2.5-fold compared to WT, *P<0.01), which could be reduced by EPO treatment.
Conclusion: Age-related heart failure in CKO mice is associated with an epigenetic shift in the differentiation potential of CPC from endothelial cells to adipocytes. This is in part caused by diminished EPO secretion by STAT3-deficient cardiomyocytes into the cardiac microenvironment and changes in the epigenetic pattern of adipogenesis related genes. EPO administration could reduce enhanced adipocyte formation in hearts of CKO mice.

P1886

RBM20 missense variant presenting as acute myocarditis and postpartum cardiomyopathy.

A Kiselev[1]; T Vershinina[1]; L Butish[1]; P Fedotov[1]; YU Fomicheva[1]; A Kozyreva[1]; YU Vakhrushev[1]; A Latypov[1]; A Morozov[1]; A Kozyrev[1]; E Vasichkina[1]; T Pervunina[1]; A Kostareva[1]; A Anna Kostareva[1]

Funding Acknowledgements: Russian Scientific foundation grant 18-75-0006

Background: RBM20 is a splicing factor regulating network of several cardiac genes. It has been shown that mutations in RBM20 gene impair nuclear localization of RBM20 protein, that, in turn, causes abandoned alternative splicing of TTN. In addition to effect on TTN RBM20 gene mutations have been shown to affect genes associated with calcium metabolism, such as CAMK2D gene. Pathogenic variants in RBM20 gene have been shown to cause dilated cardiomyopathy. However, the precise spectrum of RBM20-associated clinical phenotypes is not fully described. Here we present a clinical case of familial cardiomyopathy and variable clinical presentations associated with pathogenic variant in RBM20 gene.
Clinical case: 14-years old boy was admitted to the hospital due to progressive signs of heart failure presenting soon after viral infection and a fever. Progressive decrease of ejection fraction (19% Simpson) and chamber dilation accompanied by myocardial injury markers lead to the primary diagnosis of myocarditis. Due to severe refractory pump failure the patient was supplied with LVAD as a bridge to recovery/transplantation. Further diagnostic workup revealed that patient's mother died two months after delivery due to peripartum heart failure, which initiated broad genetic testing. Using high-throughput target exome sequencing a mutation in RBM20 gene was identified. It was previously shown as disease causing variant in patient with dilated cardiomyopathy (RBM20 (Chr10:112581114, rs397516607, NM_001134363.2:c.G2737A :p.Glu913Lys). The variant is located in exon 11, and leads to an amino acid change from a negatively charged and acidic glutamate to a positively charged and basic lysine residue. The result of genetic testing lead to diagnostic reassessment with diagnosis of familial dilated cardiomyopathy and considered implantation of LVAD as a bridge to transplantation.
Conclusions: genetic cardiomyopathy cases may have variable clinical presentation often mimicking myocarditis. Broad genetic workup can be of value in patients presenting as myocarditis or peripartum cardiomyopathy.

P1887

A rare case of Prader-Willi syndrome presenting with heart failure due to dilated cardiomyopathy

A Anna Zlotina[1]; O Melnik[1]; T Vershinina[1]; Y Fomicheva[1]; A Kozyreva[1]; L Butish[1]; T Pervunina[1]; E Vasichkina[1]; A Kostareva[1]
[1]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation

Funding Acknowledgements: supported by Russian Science Foundation (RSF), Grant 17- 75-10125

Background: Prader-Willi syndrome (PWS) represents a rare genetic multiorganic disorder (1:10,000-1:30,000) characterized by severe neonatal hypotonia, specific cranio-facial features, short stature, small extremities, hyperphagia leading to obesity in older children and adults, mental retardation and behavioral problems. Being an obesity-related complication, heart failure is regarded as one of the contributing factors of mortality and reduced life expectancy in adult patients with PWS. Therefore, cardiac abnormalities are not typical for PWS patients at birth and in early childhood.
Purpose: Here we report on a girl who was hospitalized due to dilated cardiomyopathy and heart failure at the age of 1 year (left ventricular end diastolic diameter Z-score 2.0, EF 32% Simpson). Extracardiac presentations mainly included moderate muscular hypotonia, symptomatic epilepsy, some dysmorphic facial features and psychomotor developmental delay. Cardiomyopathies are known to be a part of various congenital syndromes and multisystem diseases, which complicates correct diagnosis of such conditions and appropriate genetic counseling. Here we aimed to determine the genetic basis of the complex clinical phenotype to extend our knowledge on molecular mechanisms underlying the clinical syndromes with dilated cardiomyopathy.

Methods: The investigation was approved by the local ethical committee. Informed consent was obtained from patient's parents. Target sequencing of 108 cardiomyopathy-associated genes was performed to uncover the genetic background of dilated cardiomyopathy followed by molecular-cytogenetic analysis using oligonucleotide array-based comparative genomic hybridization (CGH-array) on a 180K microarray platform with 13 kb median probe spacing.
Results: Target next generation sequencing did not identify any pathogenic, likely pathogenic variant, or variant of unknown significance in a gene segregating with the observed phenotype. High-resolution array-CGH analysis allowed to identify a ~4.8 Mb microdeletion of a 15q11.2-q13.1 locus known as the Prader-Willi/Angelman syndrome critical region. Indeed, 15q microdeletion of the paternal chromosomal copy is the most common genetic cause of Prader-Willi syndrome. A subsequent clinical examination of the patient at the age of 2.5 revealed development of typical features of PWS such as severe hypotonia, global developmental delay, excessive weight gain and hip dysplasia, which supported our genetic finding.
Conclusion: Here we demonstrate a rare case of Prader-Willi syndrome presenting with systolic heart failure due to dilated cardiomyopathy. Our data support the utility of not only next generation sequencing, but also array-CGH screening in patients with heart failure of unknown ethiology and complex clinical phenotype.

P1888

Polymorphisms in the CYP11B2 and AGT genes related to the renin-angiotensin-aldosterone system and their correlation with ischemic and non-ischemic phenotypes in patients with chronic heart failure.

R Ricardo Mourilhe Rocha[1]; G Rodrigues[1]; FN Albuquerque[1]; GS Duque[1]; Y Rollemberg[1]; DC Albuquerque[1]; DA Silva[1]
[1]*State University of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil*

Background: The renin-angiotensin-aldosterone system represents a target for understanding the mechanisms involved in the development of heart failure (HF). Despite the therapeutic advances in this area, HF still represents one of the main causes of mortality. Association studies are commonly used to identify the genetic basis of quantitative traits as well as susceptibility to complex diseases.
Purpose: To determine the allelic and genotypic frequencies distribution of 8 polymorphisms, supposedly deleterious, associated with the production of aldosterone and angiotensinogen in samples of patients with HF. Ancestral information markers of insertion/deletion polymorphisms were also determined in the samples to better identify the ancestralities of the individuals.
Methods: A cross-sectional study of 326 individuals of both genders followed-up at a HF outpatient clinic. They were 220 DNA samples from peripheral blood of patients with HF, 102 with ischemic HF (caucasians= 70; blacks= 16; others= 16), 119 with non-ischemic HF (niHF) (caucasians= 53; blacks= 32; others= 30), and 106 samples from healthy volunteers. The genomic DNA samples were extracted by the salting-out technique and genotyped by the PCS and SnapShot Multipex systems for polymorphisms rs3802228 (UTR-3 region), rs309 (UTR-3), rs72554626 (T498A), rs5317 (F487V), rs146655862 (V129M) and rs5315 (V403E), located in the CYP11B2 gene, which encodes the enzyme aldosterone synthase, in addition to the polymorphisms rs699 (M235T) and rs3789678 (intronic region NM_000029.3) of the angiotensinogen gene. Their allele and genotype frequencies were calculated by the SnapStats Software and compared between the two groups separated by etiology.
Results: The mean age of patients with HF was 64.09±12.67 y.o. and the mean age of the healthy subjects was 42.71±12.68 y.o. The polymorphism rs3802228 demonstrated a possible influence on both HF etiologies when the results were adjusted for age, gender and ethnicity, assuming the co-dominance models (p = 0.013) (genotype frequencies of iHF group were: G/G: 44.9%; G/A: 50%; A/A: 5.1%; and niHF group were: G/G: 30.1%; G/A: 57.3%; A/A: 12.6 %); dominance model (p = 0.014) (genotype frequencies of iHF group were G/G: 44.9%; G/A-A/A: 55.1%; and niHF group were: G/G: 30.1%; G/A: 57.3%; A/A: 12.6%) and recessivity model (p = 0.029) (genotype frequencies of the iHF group were: G/A-A/A: 94.4%; A/A: 5.1%; and niHF group were: G/A-A/A: 87.4%; A/A: 12.6%). The genotypes and alleles of the other polymorphisms studied did not show any significant association with the parameters evaluated in the study population.
Conclusion: these preliminary results suggest a possible link between polymorphism rs3802228, located in the UTR-3 region of the aldosterone synthase gene, and a higher susceptibility to HF, although it has not been possible to identify if this SNP can influence to a higher or lower degree the ischemic and non-ischemic phenotypes of HF.

P1889

Investigation of atrial remodeling induced by exercise training in a rodent model of athletes heart

A Olah[1]; BA Balint[1]; AA Sayour[1]; E Urban[1]; E Virag-Tulassay[1]; M Ruppert[1]; B Merkely[1]; T Radovits[1]

Funding Acknowledgements: National Research, Development and Innovation Office of Hungary (K120277); Scholarship of Ministry of Human Capacities of Hungary (ÚNKP-17-4-I-SE-78)

Introduction Atrial fibrillation and heart failure share common risk factors and frequently coexist as atrial fibrillation leads to impaired myocardial function. Although regular exercise training is associated with cardiovascular benefits, the increased risk of atrial arrhythmias has been observed, with differences in prevalence between genders. While multiple mechanisms are likely, the atrial alterations induced by long-term physical exercise still need to be elucidated.
Purpose We aimed at investigating exercise-induced atrial remodeling in a rat model of athlete's heart and determining sex-specific differences.
Methods Age-matched young adult rats were divided into female exercised (FEx), female control (FCo), male exercised (MEx) and male control (MCo) groups. After exercised animals completed a 12-week-long swim training protocol, echocardiography was used to describe atrial alterations. In vivo electrophysiologic investigation was performed by programmed stimulation with an octapolar catheter inserted into the right atrium and atrial gene expression analysis was carried out. We used two-way ANOVA for statistical evaluation.
Results Post-mortem atrial weight data confirmed marked atrial hypertrophy (atrial weight to tibial length: 18.6±2.7g/cm FEx, 10.3±1.0g/cm FCo, 23.7±2.2g/cm MEx, 15.8±1.9g/cm MCo, pex<0.01), while echocardiography data showed slight atrial dilatation and improved contraction in both exercised groups. Exercise training was associated with bradycardia, P-wave enlargement and prolonged right atrial effective refractory period (RAERP: 45.7±4.3ms FEx, 40.2±5.9ms, FCo, 49.8±4.2ms MEx, 43.1±4.6ms MCo, pex<0.01). Sinus node recovery time (SNRT) did not differ between groups and we could not induce significant number of arrhytmias by programmed stimulation (double extrastimulation, burst pacing) in any groups. We found increased atrial gene expression of antioxidant enzymes (e.g. NADPH oxidase 2, superoxide dismutase 2) in both genders. Despite the marked atrial hypertrophy, no gene expression alteration was found regarding markers that describe pathological remodeling (atrial natriuretic factor), proinflammatoric (tumor necrosis factor-α) and profibrotic [e.g. transforming growth factor-β (TGF-β), matrix metalloproteinase-2 (MMP-2)] processes. While exercise training did not affect on the expression of profibrotic markers, female gender was associated with lower TGF-β and MMP-2 expression. We found altered expression of ion channels participating in atrial depolarization and repolarization.
Conclusions Our data suggests that long-term exercise-induced atrial hypertrophy is not associated with harmful electrical remodeling and no inflammatory or profibrotic response was observed in the atrium of exercised rats.

P1890

Human cardiac precursor cell secreted exosomes improved cardiac function of cardiomyopathic myocytes

YYL Li[1]; W Wen-Pin Chen[1]
[1]*National Taiwan University, Pharmacology Institute, Taipei, Taiwan, Province of China*

Background: The global heart failure is growing and the ominous prognosis is still a socioeconomic burden. Cardiometabolic dysfunction may contribute to the pathogenesis of certain cardiomyopathy and heart failure. The exosomes secreted from human cardiac precursor cell (hCPC-Exo) were reported to have cardioprotective actions. However, it is unclear whether hCPC-Exo can rescue cardiometabolic dysfunction in cardiomyopathic myocytes.
Purpose: This study aimed to examine whether hCPC-Exo could recover cardiometabolism in cardiomyopathic myocytes and to investigate the underlying mechanism.
Methods: Monolayer culture method was used to culture hiPSCs derived from healthy and left ventricular cardiomyopathy patients (LVNC). Cardiomyogenic differentiation of hiPSC was conducted by sequential Wnt modulation (CHIR99021 in the initial day 1-2 and followed by IWP4 in day 3-10). The culture medium in day 3-10 was collected to purify the exosome by ExoQuick-TC. The vesicle size was further measured by Nanosight. The exosomal miRNA profile was characterized by RNA seq. Mitochondrial function of human cardiomyocyte derived from left ventricular non-compaction patient's iPSC (LVNC-hiPSC-CM) was examined by by Agilent seahorse XF24 analyzer.
Results: The significant decrease of oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) was detected in LVNC-hiPSC-CM as compared to those in healthy hiPSC-CM. In the presence of hCPC-Exo (500 ng total exosomal RNA per 104myocytes) for consecutive 7 days, both of OCR and ECAR were prominently increased. The velocity of cell shortening was also increased in hCPC-Exo-treated group. Mirpath analysis shows the possible involvement of the regulated pathways including fatty acid metabolism and glucose metabolism.
Conclusions: The present study demonstrated hCPC-Exo possesses therapeutic potential to improve cardiometabolic dysfunction in LVNC.

A curious case of syncope in an implantable cardioverter defibrillator patient.

J Jan Stassen[1]; D Dilling-Boer[1]; J Vijgen[1]; P JR Timmermans[1]
[1]*Virga Jesse Hospital, Cardiology, Hasselt, Belgium*

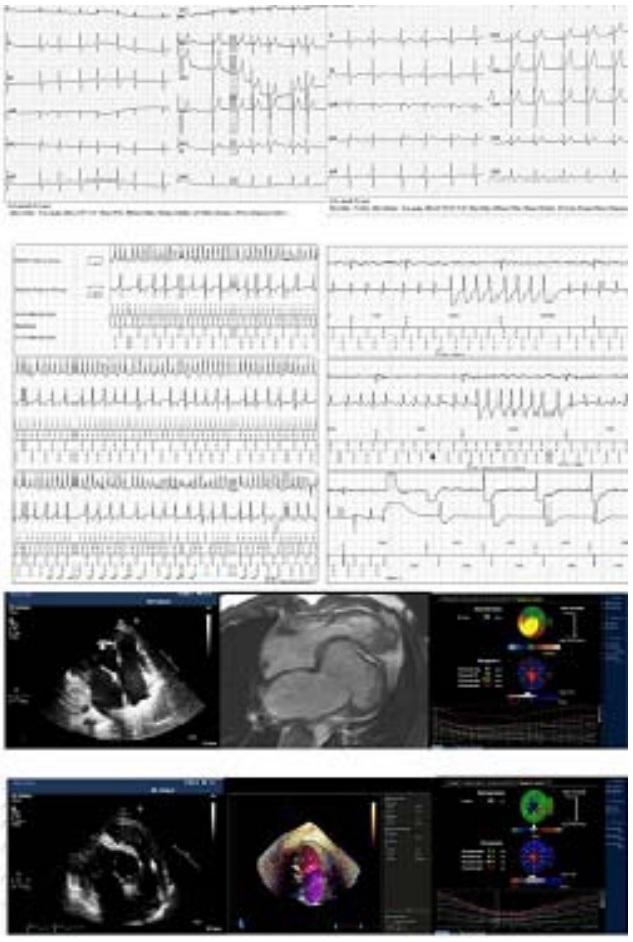
INTRODUCTION: A 68 year old woman presented to the hospital because of multiple syncopal episodes since three weeks. These episodes were almost exclusively after increasing intrathoracic pressure or with sudden changes in body position. Furthermore, she experienced progressive dyspnea and a headache with mild swelling and red appearance of her head since one day.
Her medical history was positive for an out of hospital cardiac arrest due to ventricular fibrillation (VF) for which she received an implantable cardioverter defibrillator (ICD) in 2011. An angiography at that time showed no significant coronary lesions and myocardial fibrosis was excluded using cardiac MRI with gadolinium contrast (LVEDD 101 ml, EF 67%).
On physical examination a sinus rhythm of 70 bpm and oxygen saturation of 90% was noted. Blood pressure was 156/78 mmHg. Auscultation of the lungs revealed mild wheezing and there was some swelling of her head and neck for which methylprednisolone and an anti-histaminic drug were prescribed on the emergency department.ECG showed a sinus rhythm of 76 bpm. There were no ventricular arrhythmias when analyzing her ICD. TTE revealed preserved biventricular systolic function and absence of valvular lesions. A transtricuspid gradient was not measurable.
Blood gas analysis showed a pO2 of 58mmHg, pCO2 33 mmHg, pH 7.47 and elevated blood lactate concentration of 4.7 mmol/l. The patient was brought to the intensive care unit (ICU).COURSE DURING HOSPITALIZATION
At the ICU one episode of syncope, during defecation, was documented. Continuous heart rate monitoring showed an accelerated idioventricular rhythm with desaturation during the syncope. The patient's condition worsened within a day and she was intubated because of respiratory distress.
A CT scan of the thorax was performed and showed no signs of pulmonary embolism. An intraluminal filling defect at the vena cava superior (VCS) was described but interpreted as an artefact by the radiologist.
DIFFERENTIAL DIAGNOSIS: Because of the intraluminal filling defect at the VCS, the diagnosis of vena cava superior syndrome was suspected. A transesophageal echocardiography (TEE) was performed and confirmed an occlusive thrombosis around the ICD lead. Because of the acute onset of symptoms and rapid progression, thrombolysis (alteplase 100mg/2h) was administered. A control TEE showed almost complete resolution of the thrombus. Afterwards, the patient was put on oral anticoagulant therapy with rivaroxaban.
CONCLUSION Superior vena cava syndrome after transvenous ICD implantation is generally an uncommon but serious complication which can lead to syncope, respiratory insufficiency and in extreme cases cardiogenic obstructive shock. Symptoms usually occur early after implantation but may develop at any time, as is shown in this case. In our case, thrombolysis and subsequent oral anticoagulation with a DOAC was successfully used as a treatment.

P1892

Impact of ICD implantation and PVI in patient with Isolated left ventricular apical hypoplasia accompanied by left ventricular noncompaction

VI Skidan[1]; YU Aseeva[1]; HA Bsharat[1]; AA Avyasov[1]; TV Musurivskaya[1]
[1]*Federal Center of Cardiovacular Surgery, Cardiovascular Imaging, Khabarovsk, Russian Federation*

Introduction Isolated left ventricular apical hypoplasia (ILVAH) was first described as congenital heart disease with an unusual restrictive type of cardiomyopathy at CCF, USA in 2004. ILVAH frequently presents with different clinical forms from no symptoms in children to congestive heart failure, pulmonary edema, or atrial fibrillation and malignant tachycardia in adults.
Description: A 32-year-old male patient with exertional dyspnea, anasarca and poorly controlled atrial fibrillation (AF) was admitted to our hospital. The walk distance of 6 MWD was 316 meters. The 24-Hour Holter Monitoring showed atrial fibrillation entire observation period with 8 pauses of 2500-3000 ms in the night.
TTE and TEE revealed a mildly dilated LV with moderately to severely reduced function: LA- 65 ml/m2; RA- 52 ml/m2; LV- 108 ml/m2; LV diameters: basal - 65 mm; mid - 67 mm; longitudinal – 43 mm; RV diameters: basal - 38mm, mid – 30 mm, longitudinal – 96 mm. EDV – 162 ml, LVEF was 32% by 3DECHO and CMR, RV systolic function was abnormal (FAC -29%). There were significant TR and high PASP as an important marker for RV dysfunction and PH.
The TTE and CMR demonstrated all of the phenotypical features of ILVAH: 1) a spherical truncated LV with impaired function; 2) replacement of the LV apex with fatty material contiguous with epicardial fat; 3) anteroapical origin of the papillary muscle network; and 4) an elongated RV. Non-compacted endomyocardial layer and deep myocardial trabeculae, particularly in the mid-cavity of the LV was determined by both methods.
The surgical treatment that was done consistently by implantation of ICD and PVI. After 12 months' follow-up, we registered sinus rhythm, the walk distance of 6 MWD was 650 meters. There was improvement of EFLV and FAC, but LA and RA volumes were the same in comparison with the first exam, TTE data still displayed moderate TR and PH. After the 15 months' follow-up the patient had documented paroxysm of AF in the area of detection of VT 158-210 bpm with a subsequent recovery of the sinus rhythm by "shock" at 23 J. Next day Care Link system recorded the paroxysm of VT 280 bpm, sinus rhythm was restored by ATP.
Conclusion: The early TTE and CMR diagnosis is particularly important due to the difference in the prognosis and treatment of ILVAH from those of other diseases with symptoms similar to this rare entity. This is the first description of rare combination ILVAH and LV noncompaction with successful results of surgical treatment by implantation of ICD device in primary prevention of SCD and pulmonary vein isolation (PVI) for AF treatment.This case also demonstrates the degree to which such patients are highly dependent on atrial contractile function because of altered LV and RV geometry.



15 months follow-up patient with ILVAH

P1893

Atrial and atrioventricular resynchronization therapy bachmanns bundle and his bundle pacing

P Wolff[1]; P Strozik[1]; JM Zawadzki[1]; A Gajek[1]; E Sonntag[1]; D Zysko[2]; A Ciesielski[3]; A Slawuta[4]; J Gajek[5]
[1]*Wroclaw Medical University, Students' Scientific Association, Wroclaw Medical University, Department of Clinical Nursing, Wrocl, Wroclaw, Poland*; [2]*Wroclaw Medical University, Department of Emergency Medicine, Wroclaw, Poland*; [3]*Wroclaw Medical University, Department of Cardiology, Wroclaw, Poland*; [4]*Klodzko County Hospital, Department of Cardiology, Klodzko, Poland*; [5]*Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland*

On behalf of: Students' Scientific Association, Wroclaw Medical University, Department of Clinical Nursing, Wrocław, Poland

GENERAL INFORMATION ON PATIENT:
71 years old male,
HT, DMT2, BMI 38,4 kg/m2
MI 2007, CABG 2012
HF, reduced EF, NYHA class III

BACKGROUND: Recommendations by the ESC guidelines state, that CRT should be used in patients with heart failure and concomitant atrioventricular conduction delay. In patients with a narrow QRS complex, this conventional approach could contributes to worsening of the situation.
So far, biventricular pacing (BiVP) is the investigated and approved method for CRT in patients with LBBB. A novel therapeutic option for this special case is the permanent His-bundle pacing (pHBP). It´s main advantage is the direct access to the His-bundle, propagating it´s activation in a physiological direction compared to BiVP. This way, proximal AV block can be overcome. In combination with pHBP, Bachmann´s bundle pacing can reduce the prolonged interatrial conduction, resulting in electrocardiographic and clinical improvement. Further cardiac remodeling is stopped or even reversed.

PROCEDURE: Due to HFrEF, NYHA class 3, LVEDD of 66mm and EF of 27% we considered the patient as a candidate for CRT-D with pHBP in order to shorten the atrioventricular conduction. The prolonged interatrial conduction of 209 ms made us to use also the Bachmann's bundle pacing. The ECG examples depict the procedure stages and results – Figure 1.
OUTCOMES: To be seen in the Table. Additional ECG shows (A) Baseline ECG, (B) PR duration, (C) P duration, (D) P resynchronization, (E) AV resynchronization, (F) Final ECG

CONCLUSIONS: The effective combination of pHBP with Bachmann´s-bundle pacing, shows remarkable results. In cases like our patient´s, this could be a better primary approach as compared to conventional CRT according to the guidelines.

	Before	After
LVEDD (mm)	66	58
EF (%)	27	40
NYHA (1-4)	3	1

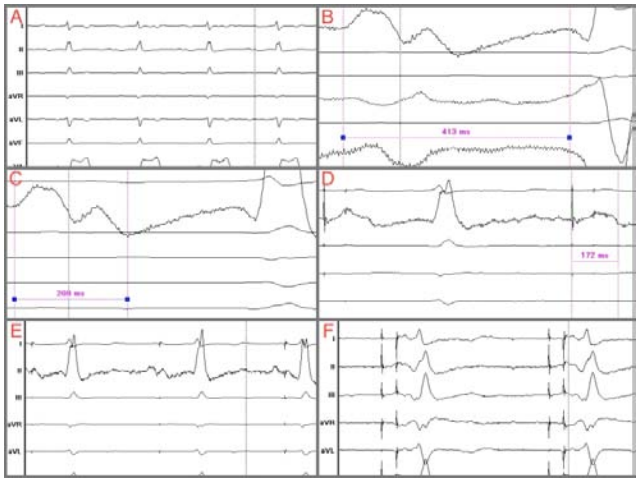
PR (ms)	413	180



P1894
Bundle branch reentrant tachycardia treated with cardiac resynchronization therapy in a patient with dilated cardiomyopathy

P Panagiotis Koudounis[1]; M Agelaki[1]; A Christou[1]; P Manolakou[1]; P Serafeim[1]; D Tagoulis[1]; P Lagadinos[1]; A Papadaki[1]; A Papadopoulos[1]; P Fragkou[2]; T Zografos[1]; I Tsiafoutis[1]; N Bourmpoulis[1]; K Flessa[1]; A Katsivas[1]
[1]*Hellenic Red Cross Hospital, 1rst Department of Cardiology, Athens, Greece*;
[2]*Attikon University Hospital, 4th Department of Internal Medicine, Athens, Greece*

Introduction A 66 – years old woman with known dilated cardiomyopathy and severely reduced ejection fraction presented in our clinic with progressive dyspnea on minimal exertion (NYHA Class III – IV). Physical examination revealed blood pressure 90/70 mmHg, fine crackles over lung basis, a third heart sound, distended jugular veins and mild peripheral pitting oedema.
Drug history included ramipril 5mg od, spironolactone 25 mg od and furosemide 40 mg od. Laboratory results showed only an elevated BNP 850pg/ml.
ECG at presentation demonstrated sinus rhythm with markedly prolonged PR interval, right bundle branch block with left axis deviation and frequent runs of wide complex tachycardia with QRS morphology same as in sinus rhythm.
Echocardiogram reported a dilated left ventricle with diffuse hypokinesia , severely depressed EF=20%, preserved RV function, moderate mitral regurgitation and elevated filling pressures.
We performed an electrophysiological study in order to investigate the nature of the wide complex tachycardia. Baseline intervals in sinus rhythm were: BCL=826ms, AH=76ms, HV=220ms and QRS=176ms. The clinical tachycardia that was reproducibly induced with atrial extrastimulation at 600ms and one extrastimulus at 400ms, had CL=487ms , HV= 300ms and AV dissociation confirming the diagnosis of bundle branch reentrant tachycardia (BBRT).

Picture

Discussion: BBRT is an uncommon form of ventricular tachycardia incorporating both bundle branches into the reentry circuit. It is often seen in patients with cardiomyopathy and conduction defects. The QRS morphology during VT is a typical bundle branch block pattern, usually with LBBB. In addition, the cycle length (CL) of the tachycardia is very short and patients become severely symptomatic in contrast to our findings with extremely long CL of the tachycardia. The diagnosis is based on electrophysiological findings and pacing maneuvers that prove participation of the His- Purkinje system in the tachycardia mechanism. Antiarrhythmics are not helpful, with radiofrequency ablation of right bundle regarded as the first line therapy.
In our patient the ablation imposes a high risk of complications in view of the existing conduction defects. Consequently we decided to proceed at first with a CRT – D implantation that allowed us to optimize medical treatment according to the current guidelines and evaluate the ablation strategy in one month. Patient's follow up revealed no VT episodes and marked symptomatic improvement, supported by device interrogation (report demonstrated increasing thoracic impedance and enhanced patient's activity).
Clinical implication/ conclusion: We describe the first bundle branch re-entrant tachycardia treated with cardiac resynchronization therapy. The rationale is that biventricular pacing can intervene in the tachycardia circuit interrupting the re-entry mechanism. As a result biventricular pacing may serve as an alternative method to ablation treatment.

P1895
Acute myocarditis in a young patient after hypoxic gases exposure

C Margineanu[1]; E L Antohi[1]; R Radu[1]; E Stoica[1]; I-D Kulcsar[1]; O Geavlete[1]; P Platon[1]; C Macarie[1]; O Chioncel[1]
[1]*CC ILIESCU, BUCURESTI, Romania*

Case description: A 26 year old male patient, without prior pathology, in good functional status, was exposed to possibly toxic gases in an underground environment (assumed low fraction of inspired O2). He showed early signs of encephalopathy that completely resolved after 2 weeks (without IRM sequelae). Three days after the incident, while in hospital, he complains of intense chest pain and develops new ST elevation up to 10mm in precordial leads (figure 1).
Clinically he presented with systemic congestive signs but with no signs of hypoperfusion. Blood tests revealed elevated cardiac troponin and transaminases, elevated C reactive protein (up to 33mg/dl), normal blood count.

First echocardiographic evaluation showed severely depressed left ventricular ejection fraction (LVEF), with diffuse hypokinesia and right ventricular (RV) dysfunction. Magnetic resonance imaging revealed late gadolinium enhancement only in the RV wall and the interventricular septum at the RV insertion sites, with normal structure of LV walls.
Although adequate tissue perfusion was maintained, in-hospital evolution was complicated by two episodes of ventricular fibrillation (within first 48 hours), frequent nonsustained and sustained left bundle branch block morphology tachycardia suggesting RV inflow tract origin, which only disappeared after 2 weeks of heart failure medication comprising carvedilol, perindopril (titrated inhospital up to 100mg and 10mg, respectively), spironolactone, furosemide, high doses of Q10 coenzyme. He later evolved well: he regained normal functional status within 2 months, resolution of ST elevation after 1 month, normalisation of cardiac troponin and of echocardiographic LV ejection fraction after 2 weeks, but with persistent RV radial dysfunction at 3 months.
Conclusion: Late onset of myocardial disease after hypoxic insult was only rarely described in the literature. Isolated persistent right ventricular dysfunction while complete resolution of LV dysfunction (functionally and structurally) is also less frequently observed in acute myocardial disease but may carry an immediate dismal prognosis. Although there are no evidence based therapies, use of neurohormonal medication is probably of substantial benefit even in acute setting.
Figure 1. ECG in day 3 after the incident.

Rapid recovery of myocardial dysfunction in an oncologic patient

M Marina Emmanouilidou[1]; A David- Cojocariu[1]; L Jahjah[1]; A Deleporte[2]; P Unger[1]
[1]*CHU Saint Pierre, Brussels, Belgium*; [2]*Institute Jules Bordet , Brussels, Belgium*

On behalf of: Investigation team of Saint-Pierre University Hospital in collaboration of the team of the Institute Jules Bordet

23 year old female, treated for an intestinal mucinous adenocarcinoma of the small bowel with metastatic disease (lymph nodes, hepatic, peritoneal) by Nivolumab 3mg/kg and Ipilimumab 1mg/kg, was admitted to the emergency department, three weeks after the last treatment, with abdominal pain. The abdominal scanner confirmed peritonitis due to tumoral perforation secondary to an eventual response to immunotherapy. A laparotomy was performed for rinsing and drainage. The biopsies taken were negative for neoplastic cells. During a prolonged hospitalization, the patient presented recurrent febrile episodes requiring numerous antibiotic regimens. Subsequently, the patient developed a septic shock with renal and hepatic failure, which was successfully by Linezolide and Piperaciline-Tazobactam. Over the following days the patient developed progressive peripheral edema, anasarca, hypotension and tachycardia. There was a slight elevation of the troponine T (48 ng/l), while the NTproBNP was at 16916 pg/ml. The electrocardiogram showed sinus tachycardia without any other particularities. A cardiac ultrasound was performed, which revealed global hypokinesia with severe left ventricular systolic dysfunction (ejection fraction 30%). The previous echocardiography was unremarkable, showing normal left ventricular ejection fraction (LVEF).
The differential diagnosis of acute heart failure, in this context, includes bacterial or viral myocarditits (but multiples serology came back negative), sepsis, drug cardiotoxicity and ischemia. At this point, the sepsis was controlled, and the patient didn't have any cardio-vascular risk factors or any sign of myocardial ischemia.
Imunotherapy cardiotoxicity was considered among the most probable causes of deterioration of LVEF and some cases of myocarditis due to checkpoint inhibitors, such as Nivolumab and Ipilimumab, in oncologic patients were reported in the literature. The combined immune checkpoint inhibition produces durable antitumor responses in some patients, but it is associated with immune-related adverse events. The cardiotoxicity with the combined regimen of Nivolumab and Ipilimumab is neither frequent nor well-known, but the incidence of drug-induced myocarditis is higher, and in some cases fatal. The patient was treated by corticotherapy (2mg/kg), diuretics, betablockers and angiotensin-coverting enzyme-inhibitors and she experienced a rapid clinical improvement and recovery of myocardial function after five days of treatment. She was discharged two weeks later.
The initial condition of the patient was too fragile to perform cardiac magnetic resonance for myocardial tissue characterization. When renal function recovered and after the administration of the corticoids, the resonance did not show any presence of late gadolinium enhancement and confirmed the improvement of LVEF at 48%. Nevertheless, we retained the diagnosis of myocarditis due to the immunotherapy in the light of the disease evolution.

P1897
Heart failure in a hypertrophic cardiomyopathy phenotype with an unknown genetic mutation: a new aggressive variant?

S Gentile[1]; M Scigliano[1]; C Di Filippo[1]; S Del Pace[1]; R Marcucci[1]
[1]*Careggi University Hospital (AOUC), Florence, Italy*

A 52 years old man presented for progressive dyspnea since six months, atypical chest pain and anasarca. Vital signs were within limits, no fever. Medical history was negative. Familiar history was positive for sudden cardiac death (SCD) (father at 50). Clinical exams were suspect for pulmonary edema; ECG showed atrial fibrillation, low QRS voltages in limb leads and repolarization non-specific alterations. Echocardiogram showed severe biventricular dysfunction (EF 30%), diffuse hypokinesia and concentric hypertrophy of left ventricle (IVS 20 mm, PP 17 mm) with granular and hyperechoic appearance, marked bilateral atrial dilatation, central and moderate mitral regurgitation, restrictive diastolic pattern. At blood tests troponin I was slight increased (1.92ug/L). Treatment with anticoagulants, beta-blockers, ace-inhibitors and intravenous diuretics started promptly. TC-Angiography and coronarography excluded acute events, so patient underwent cardiac MRI that showed severe left ventricle asymmetric hypertrophy and diffuse full thickness late gadolinium enhancement. Suspecting cardiac amyloidosis, serum protein electrophoresis showed a weakly increase in monoclonal IgM lambda component while Bence-Jones proteinuria was negative. Periumbilical fat biopsy was negative. 99m-Tc-diphosphonate myocardial scintigraphy excluded Transthyretin-related amyloidosis, so the main hypotheses were light chains amyloidosis or sarcomere hypertrophic cardiomyopathy (HCM). Therefore myocardial biopsies of right ventricular septum and a genetic counseling were required. Frequent hemodynamically well tolerated episodes of NSTV were recorded. Considering the high risk of SCD, an ICD was implanted. Biopsy showed no amyloid deposition by Congo red staining or other pathological deposits, but minimal and focal subendocardial and interstitial fibrosis and focal myofibrillar disarray, findings compatible with sarcomeric HCM. Genetic test identified an unknown extremely rare variant of sequence 716G>A p. (Cys239Tyr) in heterozygosity in the MYBPC3 gene of uncertain meaning. With medications left ventricular function partially recovered (50% EF) and patient was discharged in good hemodynamic compensation.

DIAGNOSTICAL EXAMS IMAGING

A: Apical four chambers view at US: hypertrophic and hyperechoic left ventricle walls. **B:** Cardiac MRI: lack of parietal edema in T2-weighted scanning sequences. **C:** Diffuse full-thickness late gadolinium enhancement suggesting amyloidosis. **D:** Myocardial scintigraphy with 99m-Tc-diphosphonate negative for transthyretin-related amyloidosis

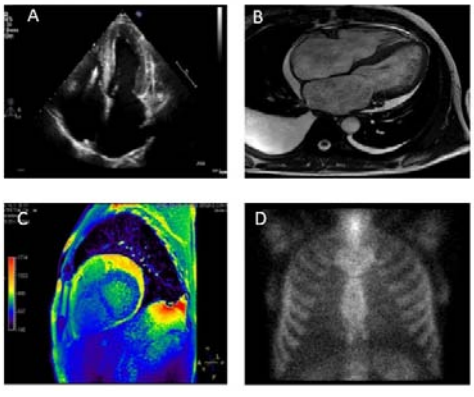

FIGURE 1

This case underlines the importance and complexity of differential diagnosis in hypertrophic ventricular phenotypes. In fact, echocardiography, MRI and electrocardiographic findings were strongly suggestive of cardiac amyloidosis, but our clinical case shows that a sure diagnosis needs myocardial biopsy, as it revealed sarcomere

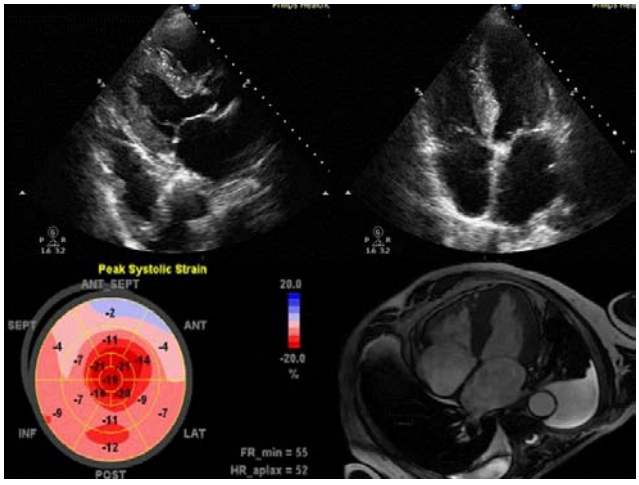
HCM. So, biopsy still remains the gold standard for diagnosis. Myocardial hypertrophy etiology may also impacts on the stratification of the arrhythmic risk and, with other risk factors, consequently helps to identify forms that could benefit from specific therapy or ICD implantation.
This might be the first report of a more aggressive rare hereditary genetic HCM variant with unclear presentation. More cases are needed for further assessments.

P1898

Primary systemic amyloidosis, a rare cause of congestive heart failure

CI Radulescu[1]; A Covaliov[2]; M Alexandrescu[3]; A Jercan[4]; S Badelita[4]
[1]ARES Excellence Center in Interventional Cardiology , Interventional Cardiology, Bucharest, Romania; *[2]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania*; *[3]Monza Cardiovascular Center, Radiology, Bucharest, Romania*; *[4]Fundeni Clinical Institute, Haematology, Bucharest, Romania*

Introduction: Primary systemic amyloidosis (PSA) is a rare condition associated with poor prognosis. Heart failure (HF) and renal failure are major causes of death in these patients.
Case description: This is the case of a 71-year-old man with a history of Grawitz tumor and prostatic adenocarcinoma 3 years prior to the present hospitalisation.
The patient was admitted with signs and symptoms of congestive HF for the last 2 months. Physical examination revealed a heart rate of 100 beats/min with a blood pressure of 95/60 mmHg, peripheral edema and jugular venous distention of 9 cm. The electrocardiogram showed sinus rhythm with first-degree atrioventricular block and right bundle branch block. Initial blood tests asserted mild anemia, an elevated creatinine and severely increased brain natriuretic peptides (BNP of 7586 pg/ml). The echocardiogram performed revealed a pattern of restrictive cardiomyopathy with nondilated, hypertrophic ventricles ("granular sparkling" appearing ventricular septum of 15 mm and hypertrophy of the free wall of the right ventricle), reduced left ventricle (LV) global function with severe diastolic dysfunction and dilatation of both atria; small left pleural effusion was observed. Further analysis using segmental longitudinal strain proved preserved apical strain, raising the suspicion of cardiac amyloidosis. The same findings were confirmed using cardiac magnetic resonance imaging which showed concentric LV thickening with reduced systolic function (a calculated ejection fraction of 44%) and a pattern of restrictive diastolic filling with enlargement of the atria; we should mention a particular thickening of the atrial septum. On delayed postcontrast (gadolinium) images acquired, there was no enhancement of the thickened myocardium. To confirm the diagnosis of amyloidosis, the patient was referred to a haematology departament to continue investigations. Using a serum free-light-chain assay, highly elevated concentrations of kappa isotype light chains were demonstrated. Fine-needle aspiration of abdominal fat was positive for amyloid deposits when stained with Congo red and viewed under polarizing microscopy. Bone marrow biopsy excluded other associated haematologic disorders, confirming the diagnosis of primary systemic amyloidosis. Extended investigations revealed neurologic involvement, hepatic and renal impairment with a decreased glomerular filtration rate and nephrotic range proteinuria. The patient received supporting HF treatment with diuretics and angiotensin-converting enzyme inhibitors and was initiated chemotherapy with high doses of melphalan and dexamethasone. The 6-month evaluation showed mild HF symptoms and no progression of the renal impairment.Conclusion: Even if prognosis in PSA is still poor, chemotherapy substantially improved survival of patients with PSA and cardiac involvement. This case emphasizes the importance of complex cardiac imaging techniques in the diagnosis of rare diseases.



Cardiac Amyloidosis

P1899

Clinical presentation of a novel pathogenic variant in MYBPC3 gene

D Balkute[1]; D Silinskiene[1]; J Simonavicius[1]; V Maneikiene[1]; V Mikstiene[2]; E Preiksaitiene[2]; R Norvilas[3]; J Celutkiene[1]; A Laucevicius[1]
[1]Vilnius University, Clinic of Cardiac and Vascular diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania; *[2]Vilnius University, Institute of Biomedical Sciences, Department of Human and Medical Genetics, Vilnius, Lithuania*; *[3]University Hospital Santariskiu Klinikos, Hematology, Oncology and Transfusion Medicine Center, Vilnius, Lithuania*

Background Mutations in MYBPC3 gene are responsible for up to 30% of familial hypertrophic cardiomyopathy (HC) cases. We present a 29-year-old male patient (Fig. 1; IV.-1) exhibiting NYHA class III symptoms and having a family history of HC (Fig. 1) and sudden deaths. Pathogenic MYBPC3 gene variant NM_000256.3:c.1996A>T, p.(Lys666Ter) was identified to the affected family members. The alteration has not been described previously in the scientific literature.
Family history: The father of the patient (III.-3) died at the age of 40; the uncle of the patient (III-.6) died at the age 21; the father's grandmother (I-.2) suddenly died at the age of 35 (Fig. 1). The causes of the deaths were not determined. The aunt (III.5) (Fig. 1) was diagnosed with stage D heart failure due to HC and received a heart transplant at the age of 50.
Diagnostic work-up: Echocardiography demonstrated severe concentric left ventricular (LV) hypertrophy (interventricular septum at end-diastole 18 mm; LV posterior wall at end-diastole 16 mm; myocardial mass index 140 g/m2; Relative wall thickness 0.8). Systolic anterior motion of the mitral valve with dynamic LV outflow tract obstruction (peak pressure gradient of 70 mmHg during the Valsalva maneuver), midventricular obstruction, severe left atrial dilatation, pseudonormal diastolic function and preserved systolic function were observed. B-type natriuretic peptide at admission was 1310 ng/l. The results of cardiac magnetic resonance imaging were in line with the diagnosis of HC. Fabry disease was excluded. Coronary angiography showed normal coronary arteries. There was no pressure gradient between LV base and aorta detected at rest, whereas pressure gradient of 70 mmHg was identified between LV apex and aorta. Genetic testing revealed MYBPC3 gene variant NM_000256.3:c.1996A>T, p.(Lys666Ter). This variant has been previously identified to the patient's aunt. The alteration causes premature termination of the encoded myosin-binding protein C, resulting in inappropriate binding with cardiac muscle myosin heavy chain in thick filaments and titin in elastic filaments. The truncation of the protein interferes with cardiac contraction and ends up with the development of HC.
Treatment approach: Percutaneous alcohol septal ablation was performed, decreasing the gradient between LV apex and aorta to 30 mmHg. HC sudden cardiac death score revealed high risk of sudden cardiac death (9.6 %), thus an implantable cardioverter-defibrillator was implanted for primary prophylaxis. Metoprolol succinate was up-titrated to 75 mg QD. The treatment successfully reduced heart failure symptoms to NYHA class I.

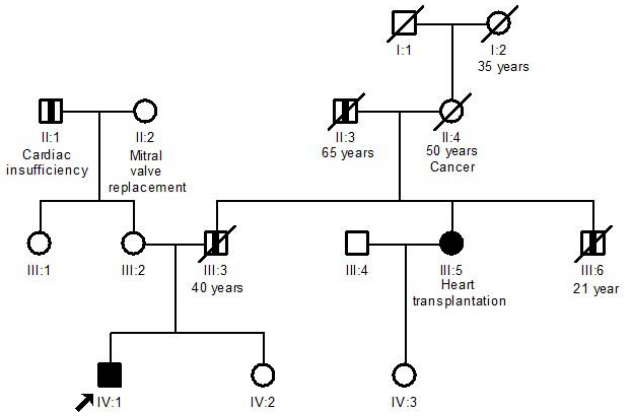


Figure 1

Conclusion Novel pathogenic variant of MYBPC3 gene NM_000256.3:c.1996A>T, p.(Lys666Ter) was related to severe LV hypertrophy, advanced heart failure with preserved ejection fraction and high risk of sudden cardiac death.

P1900

Combination of novel pathogenic variants in sarcomeric proteins genes and GLA gene in relatives with hypertrophic cardiomyopathy

E Sadauskiene[1]; I Eitaviciute[2]; L Venceviciene[1]; J Barysiene[1]; Z Petrulioniene[1]; K Vencevicius[2]
[1]Institutes of Biomedical Sciences and Clinical Medicine, Faculty of medicine, Vilnius University, Vilnius, Lithuania; *[2]Vilnius University, Medicine faculty, Vilnius, Lithuania*

Introduction Hypertrophic cardiomyopathy (HCM) is a primary cardiac muscle disease defined by left ventricular hypertrophy (LVH), in the absence of abnormal loading conditions. Clinical presentation of the disease shows great variability, ranging from little or no cardiovascular symptoms to heart failure (HF) and sudden cardiac death (SCD). Screening of patients with HCM of unknown aetiology reveals a high prevalence (1-12%) of Fabry disease (FD).PurposeOur aim is to demonstrate a confusing case of 4 relatives with HCM phenotype, who were suspected having FD after genetic variant of unknown significance (GVUS) in α-galactosidase A (GLA) gene was identified in 2 of 3 alive patients. As the cause of HCM remains uncertain, it is recommended to perform a sequencing of sarcomere protein genes.MethodsA GVUS in GLA gene c.937G>T (p.Asp313Tyr) was identified in 2 of 4 patients with HCM phenotype. Since clinical features and histological findings consistent with FD were absent, the cause of HCM was still uncertain after evaluation of patients' medical history, physical, laboratory, instrumental examination and histological data, next generation sequencing of sarcomere proteins' genes was performed to three relatives (I-1, II-3, and III-1). Coding sequences of the genes associated with HCM (ACTC1, ACTN2, BRAF, CAV3, CSRP3, GAA, GLA, HRAS, KRAS, MAP2K1, MAP2K2, MYBPC3, MYH6, MYH7, MYL2, MYL3, MYLK2, MYOZ2, NEXN, NRAS, PLN, PRKAG2, PTPN11, RAF1, SOS1, TCAP, TNNC1, TNNI3, TNNT2, and TPM1) were analysed.
Results: We report a case of four patients from one family with HCM phenotype, progressive HF and SCD of the proband's (I-1) older daughter (II-1). Since classical clinical features consistent with FD were absent, renal and endomyocardial biopsies were performed for proband and her daughter (II-3). Histological analysis of proband's renal tissue revealed minimal histological changes which could be consistent with FD. Histological examination of proband's daughter's myocardium showed no histological changes. Next generation sequencing of sarcomere proteins' genes revealed two heterozygous pathological variants in all patients: PLN gene c.26_29dupGCTC (p.Ala11Leufs*10) and MYBPC3 gene c.3530_3531insG (p.Phe1177Leufs*31).ConclusionData of the current case suggests that GLA gene variant c.937G>T p.(Asp313Tyr) is not necessarily associated with FD. Two novel heterozygous pathogenic variants in sarcomeric protein genes which have not been previously reported in the literature – PLN gene c.26_29dupGCTC p.(Ala11Leufs*10) and MYBPC3 gene c.3530_3531insG (p.Phe1177Leufs*31) – determine the development of HCM phenotype. Multiple mutations are related to an earlier presentation of HCM with more severe phenotype and higher risk of sudden cardiac death. Multiple variants in sarcomeric protein genes should be recommended as an additional biomarker in the assessment of SCD.

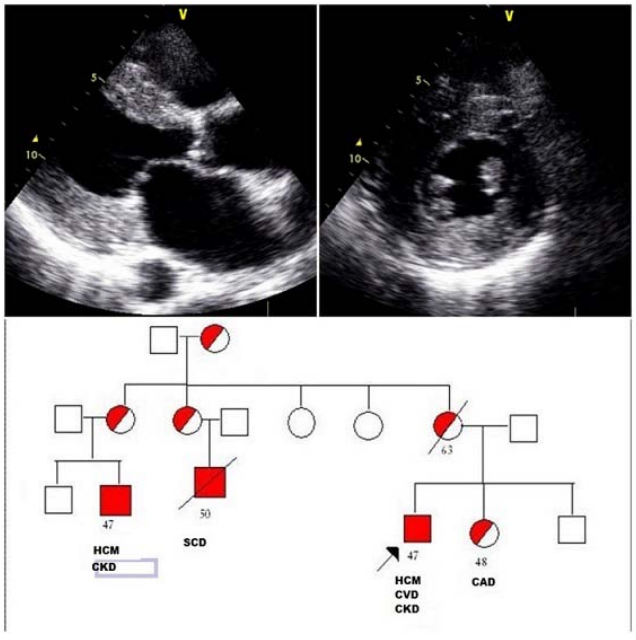
Left ventricular hypertrophy in young man with stroke and end stage renal failure

A Siama[1]; S Giannitsi[1]; T Manolaki[1]; A Athanasios Tsoukas[1]; AJ Manolis[1]
[1]Asclepeion Voulas Hospital, Athens, Greece

Introduction: Fabry disease is an inherited progressive X-linked inborn error of metabolism of the glycosphingolipid pathway due to mutations resulting in a-galactosidase deficiency. The disorder results in intracellular lysosomal storage of globotriaosylceramide, a glycosphingolipid, accumulating in multiple tissues leading to end stage organ impairment, specifically acroparesthesias, skin manifestations, renal failure, neurological and cardiac disease. Hemizygous males are predominantly affected, while heterozygous females are carriers of the disease with a 50% probability per pregnancy of transmitting it to their offspring.
Case presentation: A 47 year old male patient was admitted to the Nephrology Department of our hospital. He presented with symptoms of deteriorating dyspnoea despite intensification of his dialysis sessions. His past medical history was significant for right hemiplegia due to left middle cerebral artery occlusion that occured 3 months ago, arterial hypertension and chronic kidney disease. His electrocardiogram had signs of left ventricular strain. Echocardiography revealed left ventricular end diastolic and end systolic diameters within normal limits accompanied by severe wall hypertrophy (interventricular septum and posterior wall 18 and 17 mm respectively) with a moderately reduced ejection fraction, biatrial enlargement and moderate atrioventricular valve insufficiencies. Restrictive type diastolic dysfunction was demonstrated with an E/E' ratio of 20, indicative of increased filling pressures. Family history revealed a case of sudden death in a male relative living abroad who was diagnosed post mortem with Fabry disease. Subsequently a-galactosidase enzyme blood levels were measured which appeared undetectable. The patient underwent supportive therapy since his disease was advanced at the time of diagnosis with multiorgan failure. Family genetic counselling was adviced and a pedigree was designed which uncovered other affected family members.
Conclusion/Discussion: Early diagnosis is key to Fabry disease management since the disease is controllable after the development of recombinant enzyme replacement therapy. Moreover diagnosis of one patient should prompt targeted genetic family screening to uncover other relatives who may benefit from enzyme substitution and other therapeutic options that improve prognosis.



Advanced fabry disease

P1903

Two cardiomyopathies in one clinical case

M Rabai[1]; L Czopf[1]; L Toth[2]; K Toth[1]; T Habon[1]
[1]*University of Pecs, Medical School, 1st Department of Medicine, Pecs, Hungary*;
[2]*University of Pecs, Medical School, Department of Radiology, Pecs, Hungary*

Introduction: Cardiomyopathies (CMP) are rare, genetically determined, primary diseases of the heart muscle, and are mostly diagnosed in heart failure or after sudden cardiac death.
Case report : A 61-year-old female smoker patient underwent a cardiac examination with symptoms of presyncope, chest pain and weakness. Based on the symptoms, the chest leads detected negative T waves and the extensive apical wall motion abnormalities a coronary angiography was performed showing no alterations on the coronaries. Thus, in accordance with the results of the repeated echocardiography and the cardiac MRI, Tako-tsubo CMP and hypertrophic CMP were suggested as diagnoses.
A year later, the patient was again hospitalized with the above mentioned symptoms. Acute echocardiography showed typical apical ballooning with decreased ejection fraction, asymmetric septal hypertrophy and compensatory hyperkinetic basal segments leading to significantly high outflow tract gradient and systolic anterior motion of the mitral valve (SAM), with grade 3 regurgitation. Troponin kinetics ruled out acute coronary syndrome. NT-proBNP was highly elevated. After the initiation of the heart failure medication, echocardiography showed normalized ejection fraction with no remarkable wall motion abnormalities; the outflow tract obstruction and the SAM phenomenon were no longer demonstrated. While the repeated MRI and echocardiography examinations confirmed hypertrophic CMP without wall motion abnormalities, coronary angiography ruled out the coronary disease. The result of the genetic test is pending.
Conclusions: Based on the symptoms and the morphological alterations we confirmed the diagnosis of Tako-tsubo CMP with preexisting hypertrophic obstructive CMP. The coexisting manifestation of the two disorders, especially the recurrence of the event is extremely rare in the literature. The proper treatment and the connection between the two CMP entities raise further questions.

P1904

Hypertrophic cardiomyopathy and dynamic left ventricular outflow tract obstruction, a possible pathophysiological mechanism of injury in takotsubo cardiomyopathy.

H Zaw[1]; S Samer Fawaz[1]; O Dhillon[1]
[1]*Mid Essex Hospital NHS Trust, Cardiology, Chelmsford, United Kingdom of Great Britain & Northern Ireland*

Background The aetiology of Takotsubo cardiomyopathy (TCM) is unclear and there have been case reports showing underlying features of hypertrophic cardiomyopathy (HCM) with left ventricular outflow tract obstruction is present in some cases of TCM. This has been postulated to be part of pathophysiological mechanism, as catecholamine driven left ventricular outflow tract obstruction, coupled with coronary microvascular spasm may contribute to myocardial stunning and apical ballooning seen in TCM. We report a case of underlying hypertrophic cardiomyopathy masked by Takotsubo cardiomyopathy.
Case
A 63 year old lady with a background of depression was admitted to hospital with severe chest pain that came on following the sudden onset of right calf pain. This was associated with sweating and nausea. She recently returned from America after visiting her son nine days ago. She did not report any recent bereavement. Pulmonary embolism was suspected.
Physical examination was normal. The admission ECG showed deep T wave inversion in anterolateral leads with a raised Troponin-T level of 492.9ng/L. Other blood tests including renal function, full blood count and c-reactive protein were normal, in particular D-Dimer 85 (normal range 0-229). Coronary angiogram showed unobstructed coronary arteries. Transthoracic Echo (TTE) demonstrated mid to apical akinesis of the left ventricle with preservation of basal contraction and an overall ejection fraction of (LVEF) 35-44%, features typical of Takotsubo when in the presence of unobstructed coronary arteries.
A cardiac MRI scan three months later demonstrated normal biventricular function with mild asymmetrical left ventricular hypertrophy with a basal septal bulge and mild chordal SAM suggestive of hypertrophic cardiomyopathy. Late gadolinium showed mild atypical enhancement in the basal to mid inferolateral segments. She did not have systemic hypertension.
Follow up TTE in a years' time revealed normal left ventricular ejection fraction with mild hypertrophy of the basal septum and turbulent flow in the left ventricular outflow tract (LVOT), features consistent with HCM.
Conclusion: There have been previous case reports linking hypertrophic cardiomyopathy and Takotsubo cardiomyopathy, and this case adds to the growing evidence that basal septal hypertrophy and catecholamine driven LVOT obstruction may be part of the pathophysiological mechanism underlying Takotsubo cardiomyopathy. Therefore, we suggest a careful diagnostic approach and consideration of cardiac MRI to identify the concurrence of these two conditions.

P1906

Chicken or egg? A case of tako-tsubo cardiomyopathy and spontaneous coronary dissection

S Siddharth Jogani[1]; P SR Timmermans[1]; P Koopman[1]; P JR Timmermans[1]
[1]*Virga Jesse Hospital, cardiology, Hasselt, Belgium*

Case presentation: A 50-year old woman, with a history of Sudeck atrophy leading to amputation of her left forearm, was transferred to our hospital due to acute onset of chest pain. ECG showed non-specific ST-T alterations in the inferolateral leads. Due to the mild electrocardiographic changes and due to atypical presentation, we performed an urgent transthoracic echocardiography before an angiography. Severe hypokinesia in the apico-lateral segment was seen, compatible with ischemia in the circumflex area. An urgent coronary angiography was performed. This revealed a moderate stenosis in the distal portion of the RCX. Ventriculogram showed severe hypokinesia in the anterior wall and in the apex, as seen in Tako-Tsubo cardiomyopathy. ECG on day three, showed a typical evolution with negative T waves in the precordial leads. The patient was treated with RAAS-inhibition and a beta-blocker.
Course during hospitalization: During her admission, the patient kept on having mild attacks of angina. However, troponin levels were dropping. Transthoracic echocardiography on the third day showed dyskinesia in the basal and mid portions of the inferolateral and inferior wall. On day five, Q-wave formation was seen on ECG, again suggesting ischemia in the RCX or RAC territory. Due to these evolutive signs of ischemia on ECG and TTE, a repeat angiography was performed on the seventh day. We saw a type I spontaneous dissection (SD) of the RCX and a type II SD in the RAC. OCT or IVUS was not attempted, because of the risk of worsening the dissection with subsequent occlusion. Our patient was treated medically with a low dose Aspirin, an ACE-inhibitor, Spironolactone and a Beta-blocker. Echocardiography on the day of discharge (18 days after admission) showed a near to full recovery of the left ventricular function. She is still in ambulatory follow up.
Discussion We present a case of Tako-Tsubo cardiomyopathy associated with spontaneous dissection of the RAC and RCX. Medical therapy with beta-blockers and RAAS-inhibition is the treatment of choice in both diseases, although PCI and CABG are needed in some cases of SD, who have ongoing ischemia. The role of dual antiplatelet therapy for both diseases is not well established.
Conclusion We describe a case of a 50-year old woman presenting with chest pain due to a Tako-Tsubo cardiomyopathy. During hospital stay, persistent evolutive symptoms of angina , ECG changes and regional wall abnormalities on TTE prompted us to perform a repeat angiography. In our case, we treated the patient with optimal medical therapy and a full recovery of systolic function was obtained. Due to the distal location of both the dissections, coronary intervention was not needed. Patients with SD, however, do require PCI or CABG, if the ischemia is ongoing. We conclude that we should be aware of evolutive coronary pathology, requiring intervention, in patients with Tako-Tsubo cardiomyopathy.

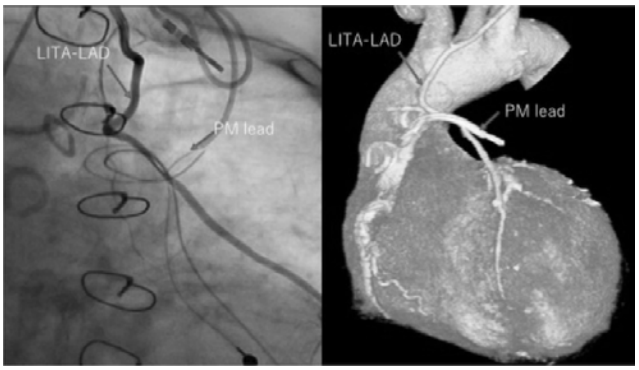
P1907

Implantation of the left ventricular epicardial lead complicated by stenosis of the left internal thoracic artery graft over 7 years

N Nishiyama[1]; C Komiyama[1]; Y Isonaga[1]; H Fujiwara[1]; M Morise[1]; T Yamada[1]; A Haima[1]; Y Tomita[1]; Y Fujimoto[1]; T Kodama[1]
[1]*Toranomon Hospital, Cardiovascular Center, Tokyo, Japan*

The patient is a 64-year-old man with worsening of angina, and suffered from hypertension, diabetes mellitus, dyslipidemia and renal failure requiring dialysis. He originally underwent a coronary-artery bypass grafting (CABG) surgery for triple vessel disease with low ejection fraction (EF) 7 years ago (left internal thoracic artery(LITA)-LAD, saphenous vein graft (SVG)-LCX #14PL, SVG-RCA #4AV). At the same time, the left ventricular (LV) epicardial bipolar lead was implanted for wide QRS with bifascicular block and low EF, in preparation for cardiac resynchronization therapy. After the CABG, he underwent several percutaneous coronary interventions due to occlusion of SVG-LCX #14PL and SVG-RCA #4AV grafts. The coronary angiography (CAG) revealed no significant stenosis of LITA graft until 3 years ago. This time, CAG was performed to evaluate new coronary stenosis due to worsening of angina, it was revealed that the body of theLV epicardial leadwas positioned just beside the LITA, causing 90%stenosis of the LITA. And the intravascular ultrasound reveled that there was compression against the outside of the artery, and the absence of arteriosclerotic changes. The computed tomography showed the LITA was positioned just between theLV epicardial lead and the pulmonary artery.These postoperative anatomical features mightbecome a major contributor

to severe stenosis of the bypass graft. We needed not only ballooning but stenting to achieve good dilatation and flow of the LITA.
Conclusions Although a rare occurrence, an epicardial leadcan be positioned close to the bypass graft and can cause severe stenosis followed by angina several years later.



P1908

A 39-year-old childbearing potential woman in lactation period suffering from STEMI.

IA Mezhiievska[1]; VI Maslovskyi[1]; II Leta[1]; YV Maslovskyi[1]
[1]*National Pirogov Memorial Medical University, Internal medicine #3, Vinnitsa, Ukraine*

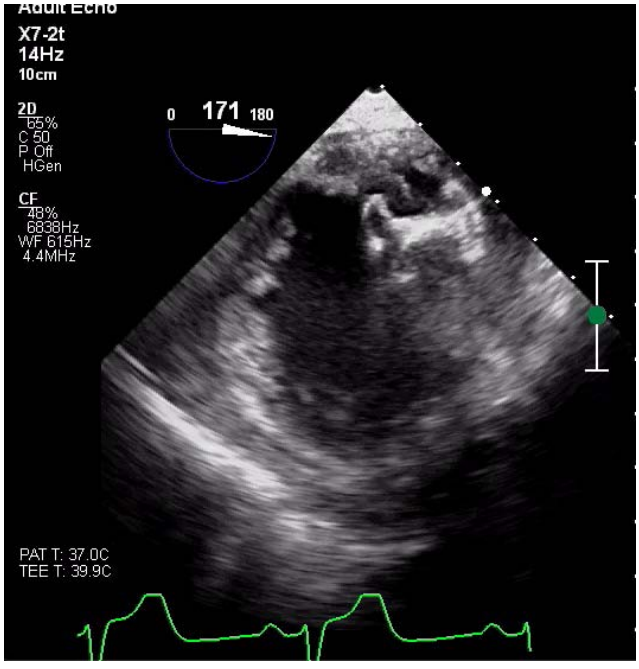
A 39-year-old woman was brought by the ambulance regarding STEMI. She is the mother of two children. At the present time moment, she has been on maternity leave (the lactation period). In 2009, she was diagnosed with diabetes during the first pregnancy. Further, she took sugar-reducing therapy (gliclazide). In 2009 during labor she had acute retinopathy of both eyes. In anamnesis, after the first pregnancy, there was noted an increase in blood pressure of 160/90 mmHg, she didn't take antihypertensive drugs. From 2016, in connection with the second pregnancy she stopped taking any medications. Over the past two days, the patient noted a significant recrudescence of general condition. She suffer from chest pain, which she didn't feel in a state of rest. At about 16.00 she had intensive burning pain in the heart area, pouring sweat. She called the ambulance and was taken to the hospital. In the medical examination, she had a heart rate of 95 beats / min and a BP of 120/80 mmHg. Auscultation of the heart showed normal heart sounds without additional sounds or noises. No signs of congestive heart failure were noted. The respiratory test was not noticeable. Rate of blood sugar at hospitalization was 24.0 mmol / l. Total cholesterol - 8.12 mmol / L, triglycerides - 2.3 mmol / L, LDL - 8 mmol / L, HDL - 0.8 mmol / L, Hb1AC - 8%. At time of admission ECG showed sinus rhythm, ST-elevation I, aVL, V2-V5, ST-depression III, aVF (Fig. 1). Her echocardiography showed hypokinesis of the anterior wall of the left ventricle. Urgent coronary angiography was performed. Acute thrombosis of LAD was detected. She was performed predilatation of LAD with the further stenting with stent system Alex 3.2 × 22 mm / P – 10 Atm. In the distal part, after the dissection followed stenting with stent system Integrity 3.0 × 30 mm P – 9 Atm. Postdilation to 22 Atm. Angiographic results were satisfactory. There were detected no hemodynamically significant coronary artery stenosis, RCA - 10% of distal stenosis. Post-procedure and follow-up: The course of the postoperative period showed no particularities. The patient received treatment: LWMG, Ticagrelor, ASA, Atorvastatin, Carvedilol, Ramipril, Pharmasulin. 72 hrs post procedure, the patient's condition was stabilized, she was asymptomatic and hemodynamically stable, serum urea and creatinine showed normalization dynamic. The patient was discharged in stable condition.
Discussion: Despite the fact that the patient had a high cardiovascular risk due to acute retinopathy after the first pregnancy, she did not receive antihypertensive and other prognosis-modifying therapy. Conclusion. Premenopausal women are believed to have a lower risk of cardiovascular issues than those who are in the postmenopausal period. But in our case, probable decisive factor was diabetes mellitus, non-corrected dyslipidemia, metabolic syndrome and probable toxicosis of the second half of pregnancy.

P1909

Interventricular septal rupture treated by percutaneous device closure

E-L Elena-Laura Antohi[1]; RI Radu[1]; OD Geavlete[1]; I Marinica[1]; D Deleanu[1]; L Predescu[1]; C Macarie[1]; O Chioncel[1]
[1]*Institute of Emergency for Cardiovascular Diseases "Prof. Dr. C.C.Iliescu", Bucharest, Romania*

Case description: A 69 year old female patient was diagnosed with acute anterior ST elevation myocardial infarction and was transferred for rescue PCI after thrombolysis. Her medical history reveals multiple cardiovascular risk factors and chronic kidney disease requiring haemodialysis (having a brachial arteriovenous fistulae). Emergency coronarography showed triple vessel disease and acute thrombotic occlusion of left anterior descendant artery for which percutaneous revascularization was performed. Specific therapy was immediately initiated. The following day the patient complained severe chest pain, without ECG evidence of ischemia, but with hypotension, cold, clammy skin. A new loud systolic murmur was heard and immediate echocardiography revealed new apical septal rupture, 1cm large.The patient evolved with cardiogenic shock and right ventricular dysfunction in the following two days, refractory to mechanical support with intraaortic balloon pump and necessitating increased doses of inotropes. The arteriovenous fistulae was closed to minimise right ventricular load. Given the hemodynamic instability, with rapid development of pulmonary hypertension, percutaneous device closure was chosen. Although small residual shunting was present (but with significant reduced ratio of pulmonary vs. systemic flow), the clinical status improved, and three month later she was proposed for cardiac surgery for definite correction.



Transgastric view of device.

Conclusion: Septal ventricular rupture associated to acute myocardial infarction remains a pathology with severely dismal prognosis. Early percutaneous device closure may be an adequate solution for refractory cardiogenic shock patients in order to avoid prolonged use of mechanical circulatory support.

P1910

Impact of intracoronary injection of bone marrow on CMR derived myocardial strain 12 months after myocardial infarction

M Gastl[1]; J Von Spiczak[2]; A Gotschy[1]; D Suerder[3]; R Corti[4]; S Kozerke[5]; F Ruschitzka[1]; R Manka[1]

[1]University Heart Center, Zurich, Switzerland; *[2]University Hospital Zurich, Institute of Diagnostic and Interventional Radiology, Zurich, Switzerland*; *[3]Cardiocentro Ticino, Department of Cardiology, Lugano, Switzerland*; *[4]Hirslanden Hospital, Cardiology Department, Zurich, Switzerland*; *[5]Swiss Federal Institute of Technology Zurich (ETH Zurich), Institute for Biomedical Engineering, Zurich, Switzerland*

Funding Acknowledgements: German research Foundation (DFG) Research Fellowship (GA 2621/1-1)

Background: The effect of intracoronary injection of bone-marrow unselected mononuclear cells (BM-MNC) after acute myocardial infarction (MI) and its impact on left-ventricular (LV) remodelling and ejection fraction (LVEF) remains controversial. To evaluate the 3-dimensional nature of myocardial function, strain parameters as assessed by cardiovascular magnetic resonance (CMR) imaging or transthoracic echocardiography can be used. They have been claimed to be more sensitive to functional changes of the heart than LVEF.
Purpose: The purpose of the present study was to assess potential changes of global longitudinal (GLS) and global circumferential strain (GCS) in a group of patients treated with BM-MNC after MI.
Methods: In this prospective multicentre study, 113 patients with successfully reperfused ST-segment MI were included. Patients were divided into an open-labelled control (N=42), an early BM-MNC treatment (5-7 days after MI, N=41) and a late BM-MNC treatment group (3-4 weeks, N=30). CMR using a standard ECG-triggered steady state free precession (SSFP) sequence was acquired at baseline and 12 months after MI. GLS and GCS of the LV were obtained using feature tracking software. The primary endpoint was the change of end-systolic GLS and GCS between baseline to 12-months follow-up. GLS and GCS values were noted in percentages [%] with strain being defined as relative deformation and negative values denoting shortening.
Results: The absolute change in GLS between baseline and 12-months follow-up was significant for the early (2.9±6.0%, p=0.006) and late treatment group (2.7±6.1%, p=0.031), but not for controls (0.9±4.0%, p=0.22). Although not statistically significant, baseline GLS of the early and late treatment groups (-11.7±4.1% and -11.8±3.8) was lower compared to the control group (-13.0±4.0%, p=0.427 and p=0.486). 12 months GLS was not different between all groups. Adjusting for different baseline GLS as a covariate, analysis of covariance (ANCOVA) did not reveal a significant change of GLS between the groups (p=0.56).
The absolute change in GCS between baseline and 12-months follow-up was not significant for all groups. Baseline GCS values were not different for controls and treatment groups (-19.4±5.4, -17.4±5.6%, and -19.1±5.7, respectively). LVEF did not show a significant change in any group as well.
Conclusions: In summary, the study found no improvements in myocardial strain due to BM-MNC treatment. Early and late treatment with intracoronary infusion of BM-MNC after MI resulted in significantly improved absolute GLS 12 months after MI. When adjusting for differing baseline values, significant improvement of the BM-MNC treatment groups vanished. Also for GCS and LVEF, no significant changes from baseline to 12-months follow-up were found.

P1911

Paget disease of the bone associated with severe acute reduced heart failure: a case report

EJJ Eduardo Julian Jose Chuquiure[1]; M Balbuena-Madera[2]; C Garcia-Romero[2]; C Silva-Ruz[2]; G Raymundo-Martinez[2]; E Tapia-Lopez[2]; O Fiscal-Lopez[2]

[1]Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico; *[2]Instituto Nacional de Cardiologia Ignacio Chavez, Centro en Insuficiencia Cardiaca, Mexico City, Mexico*

Background: Paget's Disease of the bone (PD) is characterized by a slow progressive skeletal deformity. Heart failure (HF) has not been defined as an initial manifestation of PD, however 4% of the people with PD develop cardiac alterations. We discuss the relevance and poor prognosis of this association in acute severe Heart Failure Reduced Ejection Fraction (HFrEF).
Case Summary: A 73-year-old man without comorbidities history. In a thirty days period, developed rapid onset exertional dyspnea, severe reduction of exercise tolerance, progressive edema and longitudinal asymmetry in lower limbs. Initially the patient was treated with high dose of loop diuretics. He was known in our Institution due to de novo acute Heart Failure in New York Heart Association (NYHA) III functional class. Initial serum NT-proBNP test was elevated significantly (19358 pg/ml). MRI demonstrated dilated cardiomyopathy with Left Ventricular Ejection Fraction was 11%. CT scan angiography didn't evidence ischemic damage as etiology.
Characteristically, X-rays and tomography showed asymmetry of the lower limbs with a longer left lower limb.
Patient fulfilled Paget's disease criteria, which was confirmed by elevated serum alkaline phosphatase. Our therapeutic approach was based and focused in optimizing medical treatment for acute HF symptomatology, according ESC Heart Failure clinical guidelines, in association with vitamin D, due to the decreased glomerular filtration rate we delayed the use of bisphosphonate therapy. After three months follow-up, there was no edema, dyspnea or fatigue, patient had improved to NYHA class I. improvement in NT-proBNP, creatinine, alkaline phosphatase.
Conclusion: We present a case of a man who was diagnosed with de novo acute HFrEF and Paget's Disease. Although PD is a very rare etiology of HF, we suggest that a screening with alkaline phosphatase should be requested in patients above 50 years old with idiopathic dilated cardiomyopathy to define etiology and modify prognosis.

Observed response in Paget causing HFrEF

Lab results	Basal	Follow-upmonths
NT-proBNP (pg/ml)	19358	2390
Alkaline phosphatase (U/L)	309	155
Creatinine (mg/dL)	1.85	1.67
Calcium (mg/dL)	9.37	8.5
Potassium (mmol/L)	4	4.95
Sodium (mmol/L)	140	134
Serum labs (units)

Acute chagas cardiomyopathy in a 40-yo Mexican with very reduced LVEF: a case report

EJJ Eduardo Julian Jose Chuquiure[1]; D Garcia-Romero[2]; M Balbuena-Madera[2]; C Silva-Ruz[2]; G Raymundo-Martinez[2]; L Medina-Paz[2]; E Tapia-Lopez[2]; O Fiscal-Lopez[2]

[1]Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico; *[2]Instituto Nacional de Cardiologia Ignacio Chavez, Centro en Insuficiencia Cardiaca, Mexico City, Mexico*

Chagas cardiomyopathy (CC) is a chronic cardiac complication of Chagas Disease (CD), characteristically generated by the protozoan T. cruzi and transmitted by the kissing Bug (Triatominae) in Latin America. It primarily affects low-income populations and is a major cause of chronic morbidity and mortality. Heart failure (HF) usually appears at least 20 years after the original infection and it has been suggested it is an immune-mediated myocardial injury .
Introduction: A 40-years-old Mexican farmer and handicraftsman male with low incomes, who lives in rural zone arrived to our institution with acute congestive HF symptoms, featuring with NYHA III, medium efforts dyspnea, orthopnea and severe hydric retention. At the physical examination we found an important yugular engorgement, S3 , mitral and tricuspid regurgitation, coarse crackles at both bases, hepatomegaly, jaundice and pretibial oedema. The patient refers he had been bitten by a Triatominae insect several times some previous months ago and reported painless nodule on the right leg. EKG: Showed sinus rhythm, LBBB and both ventricular and auricular dilatation.
MRI showed global dilated cavities, non ischemic intramyocardial enhancement, moderated tricuspid and mitral regurgitation, apical thrombus in both ventricles and severe LV systolic dysfunction (LEVF: 26%). Labs studies showed a NT-proBNP of 19,203 pg/ml and another of >25,000 pg/ml.
Management was based on strict adherence HF-ESC clinical guidelines, to correct heart failure decompensation. The case was reported to the corresponding epidemiology department to obtain antichagasic drug. Three months later he presented clinical improvement and functional class NYHA I.
Conclusions: We present a case of a man who developed HF of rapid clinical deteority and acute Chagas disease, with the referred antecedent of been bitten by the reduviid bug and the documented recent pathognomonic lesion of chagoma in the leg. Although there are anti chagasic drugs available, and our patient improved with this therapy, more studies are needed to recommend the early stages treatment based on clinical benefit and prognosis impact on these patients.

P1913

Hepatitis or heart attack? A rare presentation of acute heart failure

M Madhura Ghosh[1]; Z Khalique[1]; A Vazir[1]
[1]*Royal Brompton Hospital, London, United Kingdom of Great Britain & Northern Ireland*

A 54 year old man with a 4 week history of diarrhoea and no cardiovascular risk factors other than well controlled hypercholesterolaemia, presented to the emergency department following a collapse. Initial examination found hepatomegaly, pulmonary oedema and significant peripheral oedema. Blood tests showed an acute liver injury and a lactate of 6. High sensitivity troponin was only 49.
As part of a work up for hepatitis, he had a CT abdomen which revealed a large left ventricular aneurysm. An urgent echocardiogram demonstrated a dilated and severely impaired left ventricle. There was thinning of the mid-ventricular anterior and septal walls and apical segments. A midventricular inferoseptal ventricular septal defect was noted. These findings were confirmed by cardiovascular magnetic resonance (figure 1). His Qp/Qs was 2.7 indicating significant left-right shunting. The right ventricle was also dilated with severely reduced ejection fraction. Furthermore, laminar thrombus was evident in the early gadolinium images. His constellation of signs and symptoms were attributed to cardiogenic shock secondary to septal rupture due to delayed presentation of myocardial infarction (MI). Consequently he was transferred a high dependency setting for diuresis and inotropic support for optimisation prior to possible surgical intervention. Coronary angiography demonstrated an occluded left anterior descending artery and critical stenosis of the right coronary artery. An intra-aortic balloon pump (IABP) was sited. Multi-disciplinary input from surgical, critical care and heart failure teams discussed the options including percutaneous device closure and suitability and timing of surgical operative repair. A date for surgery was set beyond 21 days of the presumed index event, but unfortunately the patient deteriorated clinically despite escalation of treatment, and a decision was made to palliate.
DIscussion: Whilst ventricular aneurysms and ventricular septal rupture (VSR) are known complications of MI, they are increasingly rare in the era of reperfusion, with rates of 0.17-0.31% of patients. This case is particularly unusual as not only did the patient not have an typical cardiac presentation with chest pain, he also did not have any of the risk factors associated with VSR, such as older age, female sex, chronic kidney disease or prior heart failure. Additionally, this case highlighted the importance of optimal timing of surgical intervention. Mortality is highest (>60%) in those who undergo operative repair within the first 24 hours. Survival rates increase if surgery is deferred beyond 7-21 days and this is attributed to increased stability of the fibroising myocardium, but also survival bias. However, there is a fine balance in deferring surgery against the risk of further clinical deterioration, as seen in this case.

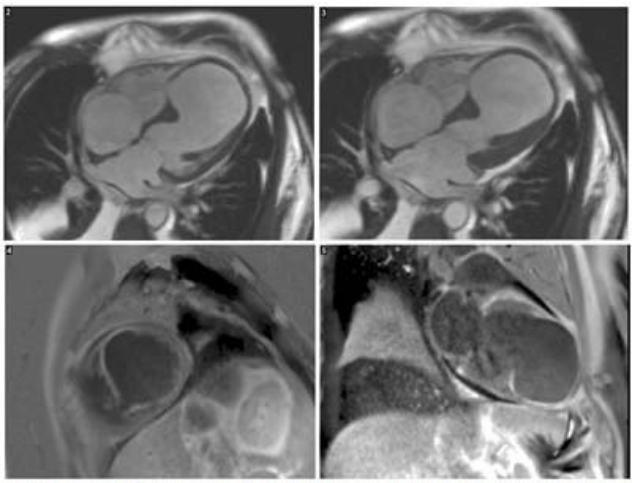

Figure 1: Cardiovascular magnetic resonance imaging of the aneursmal LV with a VSD

Panels 1 and 2 show 4 chamber views in end-diastole and systole respectively. There is thinning of the LAD territory and an aneurysmal apex. Significant left to right shunting is clearly seen. In panels 3 and 4 dark blood late gadolinium images show the transmural infarction (white), with the VSD visible in the short-axis view.

P1914

Ventricular septal defect after acute myocardial infarctation-a clinical case

A Briosa[1]; S Alegria[1]; D Sebaiti[1]; AR Pereira[1]; A Marques[1]; AC Gomes[1]; R Miranda[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Lisbon, Portugal*

Introduction: Post – myocardial infarctation ventricular septal defect (pos-MI VSD) is an increasingly rare complication of myocardial infarctation. It usually develops a few days after a transmural MI involving the septum and is associated with a high mortality rate. Despite the improving outcomes, making the decision of performing surgery is complicated by the severe preoperative condition of the patient and the softness of the necrotic tissues.
Clinical case: 75 years old ex-smoker man with previous relevant history of controlled hypertension, dislipidemia, diabetes, obesity and hyperuricemia. He was medicated with antihypertensive drugs, oral antidiabetics and allopurinol.
He came to medical attention in 2018 with a three-day history of retrosternal chest pain associated with nausea and worsening fatigue At the hospital admission he was conscient, hemodinamically stable and well perfused. His blood pressure was 114/67 mmgH. Cardiac auscultation revealed a harsh holosystolic murmur, which was heard over the entire precordium. The EKG showed sinus rhythm at 110 bpm, ST segment elevation in the anterior wall as well as Q-wave presence in the same derivations. Transthoracic echocardiogram (TTE) revealed a non dilated left ventricule with preserved ejection fraction, apical, septal and anterior wall akinesia and hyperkinesia of the remaining segments It also showed a large and well demarcated anterior interventricular septal defect.
It was admitted subacute anterior myocardial infarctation complicated with ventricular septal defect. Coronary angiography revealed occlusion of the left anterior descending artery. The patient was immediatly transfered to the surgical centre, after the implantation of an intraaortic balloon pump. He was submitted to surgical intervention 15 days after the event, with a succsseful closure of the septal deffect.
The postoperative period was complicated with nosocomial pneumonia and septic shock, requiring aminergic and renal replacement therapy, as well as acute isquemic stroke. 1 month after de surgery, a new TTE revealed a small restrictive interventricular communication. Despite those findings, there was a progressive clinical improvement.
Conclusion: Pos-myocardial infarctation ventricular septal defect is a complication that is still associated to high mortality rate. Closing the shunt and stabilizing the hemodynamic condition of the patient is of paramount importante. However, the optimal time for the intervention remains debatable.

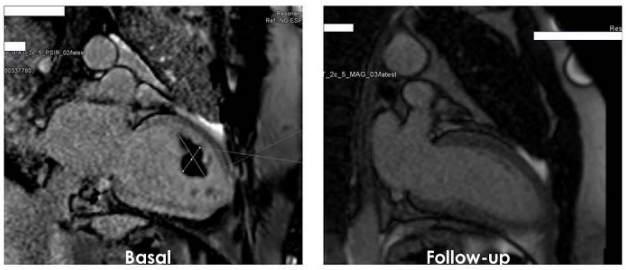
P1917

Striking reduction of a giant intracavitary thrombus in a 46-yo male with heart failure with very reduced ejection fraction due to myocarditis: a case report.

EJJ Eduardo Julian Jose Chuquiure[1]; M Balbuena-Madera[2]; D Garcia-Romero[2]; C Silva-Ruz[2]; E Tapia-Lopez[2]; O Fiscal-Lopez[2]
[1]*Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico*; [2]*Instituto Nacional de Cardiologia Ignacio Chavez, Centro en Insuficiencia Cardiaca, Mexico City, Mexico*

Heart failure (HF) is a pathology associated with high morbidity and mortality. LV regional wall akinesia and dyskinesia results in blood stas. Intraventricular thrombi (IT) are a complication in 25% of patients with myocarditis, and significantly increasing the mortality associated with thrombectomy or heart transplant.
Case Summary: We present the case of a 46-year-old male only with a history of arterial hypertension. Three months ago featured with small efforts dyspnea, paroxysmal nocturnal dyspnea, edema in lower extremities, mild ascites and NYHA IV. At the admission he presented acute HF due to sinus tachycardia, pulmonary congestion and pleural effusion. Laboratory studies presented Troponin I 0.024 ng/ml, NT-pro-BNP 8568 pg/ml, and elevated C-reactive protein (19.64mg/L).
An inicial MRI showed a LVEF of 15%, left ventricle systolic diameter of 55 mm and a diastolic diameter of 63 mm. It also revealed two giant thrombi on LV, one of 52 x 13mm of diameter adhered to the anteroseptal left wall, and a second one of 33 x 21mm with a thin and very mobile pedicle; reported left atrium diameter of 68 x 53 mm (area of 36 cm2); evidenced moderate mitral and tricuspid regurgitation and septal and apical intramyocardial reinforcement, suggesting myocarditis.
Treatment was focused on optimal medical treatment for HF associated with vitamin K inhibitor. We considered the indication of heart transplantation due to the potential surgery risk of the thrombectomy, nevertheless the patient refused. After 45 days he presented improvement of functional class to NYHA I, without signs of hydric retention, marked reduction of NT-pro-BNP to 190 pg/ml. A second MRI was performed, which reported a remarkable improvement of LVEF to 52% and just a single 3.5 x 2mm thrombi attached to the anterior wall; mild mitral regurgitation, with resolution of tricuspid regurgitation. It's important to clarify that no cardioembolism has been reported in the follow up.
Conclusion: The present case demonstrates the great improvement of a young male with giant intracavitary thrombi treated with oral anticoagulation in a short period

of time, with no reported cardioembolism, and no need of thrombectomy or heart transplantation. With the ejemplificación of this case we bring up the possibility of good outcome of a giant intracavitary thrombus in young adults using only anticoagulation therapy, no requiring thrombectomy or heart transplantation. More studies are needed to make recommendations on these patients.



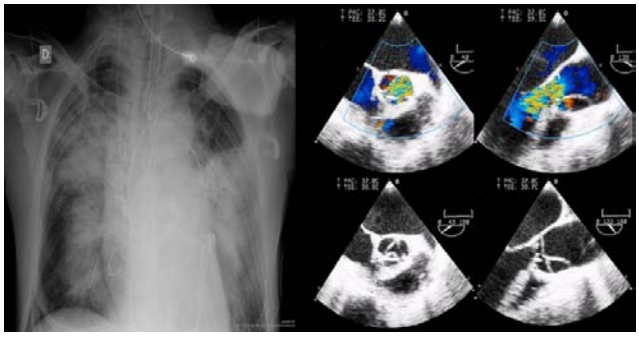
Basal and Post Treatment Cardiac MRI

P1918

A case of complicated acute aortic dissection

A Amaia Arregui Lopez[1]; AEM Ane Elorriaga Madariaga[1]; AAM Abel Andres Morist[1]; IER Irene Maria Elizondo Rua[2]; IBM Idoia Bravo Martinez[1]; GAB Gorka Aurrekoetxea Bajeneta[1]; RSM Jesus Roberto Saez Moreno[1]
[1]Hospital de Basurto, Coronary care unit , Bilbao, Spain; *[2]Donostia University Hospital, San Sebastian, Spain*

Abstract: A 50-year-old male, with a clinical background of allergy to Penicillin, smoker of 10 cigarettes per day and consumer of Cocaine, presented to the emergency department with a 4-day history of increasing shortness of breath with fever and dark expectoration. On arrival, the patient was hemodynamically unstable. The blood pressure was 90/60 mmHg, the pulse 120 bpm, the respiratory rate 32 breaths per minute, and the oxygen saturation 77% while he was breathing ambient air. He had respiratory work and universal crackles on the pulmonary auscultation.
The admission ECG showed an extensive myocardial ischemia with ST segment depression of 3 mm in leads II, III, aVF, V2-V6 and elevation in V1 and aVR. Initial laboratory data revealed a partial acute respiratory failure, data of poor peripheral perfusion (serum creatinine of 1.51 mg/dL, lactate dehydrogenase 54.6 mg/dL), increased markers of myocardial damage (CK 232 U/L, us-Troponine T 3422 ng/L) and inflammatory parameters (C reactive protein 10.04 mg/dL, leucocytes 23.700).



Respiratory failure occurred, so intubation was performed and inotropic agents were initiated. Cultures of blood were extracted and empiric antibiotic therapy with Levofloxacin was administered. Under suspicion of septic shock derived from respiratory tract infection complicated with myocardial ischemia, Cardiology was called. Bedside echocardiography showed severe impairment of left ventricular ejection fraction due to an extensive apical akinesia and a dilated aortic root with severe aortic valve insufficiency. A transesophageal echocardiogram was performed, revealing a proximal aortic dissection with an entry point immediately distal to the aortic valve, with an intimal flap that was interfering in the closure of the aortic valve (in the left coronary cusp) and occluding the ostium of the left common trunk.
The case was accepted for emergent cardiac surgery. Multiple entry points were visualized in the proximal aorta, but dissection did not affect the aortic valve nor the coronary arteries. An aortic valve-preserving technique was performed with re-implantation of the aortic valve into a tubular graft. After surgery, the patient continued to do well and was discharged home after 16 days of admission.
Few cases of acute pulmonary edema originated by aortic dissection complicated with both acute myocardial infarction and severe aortic insufficiency are reported and it results of interest. Differentiating acute aortic dissection with coronary malperfusion from true acute myocardial infarction is challenging and inappropiate treatment may have catastrophic consequences.

P1919

Polyserositis post influenza vaccination, presented as acute heart failure

I Rosenfeld[1]; T Levins[1]; I Nordkin[1]; S Dabbah[2]; M Halabi[2]
[1]Sieff Government Hospital, Department of Cardiology, Safed, Israel; *[2] Bar-Ilan University, The Faculty of Medicine in the Galilee, Safed, Israel*

Background: The dyspnea is a frequent presentation of heart failure. It is a frequent morbidity in elderly age. We describe a patient with heart failure presentation due to presumed diastolic dysfunction, but investigation of the case showed inflamed polyserositis post influenza vaccination.
Case report :A 72 years old men with long history of hypertension, IHD, PVD was admitted to cardiology department complaining of severe dyspnea during the last 2 weeks and dizziness.A one years ago because compliance of mild dyspnea an echo examination was performed and revealed normal LV ejection fraction and mild atrial enlargement.His physical examination was remarkable for signs of dyspnea, BP 130/70 mm Hg, HR 90/min, t 37.0, Sa 93% at room air. ECG revealed normal sinus rhythm without changes from previous recording 1 year ago. At admission BNP was 210pg/ml, normal hs-Troponine, mild leucocytosis and thrombocytosis.
Chest x-ray showed enlarged heart silhouette and left pleural effusion.The acute coronary syndrome was excluded because absence chest pain, normal repeated troponin level and unchanged ECG. The first diagnosis of acute heart failure due to diastolic dysfunction was done and the treatment was started with IV diuretics ,but without improvement in his condition.The diagnostic evaluation of causes for acute heart failure was performed.Blood tests revealed normal for age creatinine level , normal thyroid and liver function tests . Remarkable findings of leucocytosis and high CRP level were suspected for inflammation/infection. Echocardiography examination showed normal LV ejection fraction, mild Left atrial enlargement, moderate to large pericardial effusion without signs of cardiac compression.Although absence clinical and ECG signs of acute pericarditis the treatment with high dose aspirin and colchicine was started for probable pericarditis.The investigation was continued by CT chest and abdomen that showed bilateral moderate to large pleural effusion, large pericardial effusion, mildly enlarged mediastinal lymph nodes.Diagnostic pleurocentesis was performed and revealed exudative pleural effusion.Blood tests for connective tissue disease, cytology and flow cytometry from pleural effusion, blood procalcitonin were all negative.An important anamnestic remark was influenza vaccination 3 weeks ago.A short trial with steroid was done in additional to ASA and colchicine treatment.A patient condition significantly improved , repeated echo revealed mild pericardial effusion and mild pleural effusion on chest x ray.Summary: Although acute heart failure due to diastolic dysfunction is common condition induced dyspnea and pleural effusion, the thorough investigation in this patient revealed polyserositis post influenza vaccination. Hence, rare cause of fluid overload should be considered in differential diagnosis of heart failure.

P1920

Miscellaneous clinical manifestations of an intracardiac tumour

I Irina Cabac-Pogorevici[1]; V Revenco[1]
[1]State University of Medicine and Pharmacy, Cardiology, Chisinau, Moldova (Republic of)

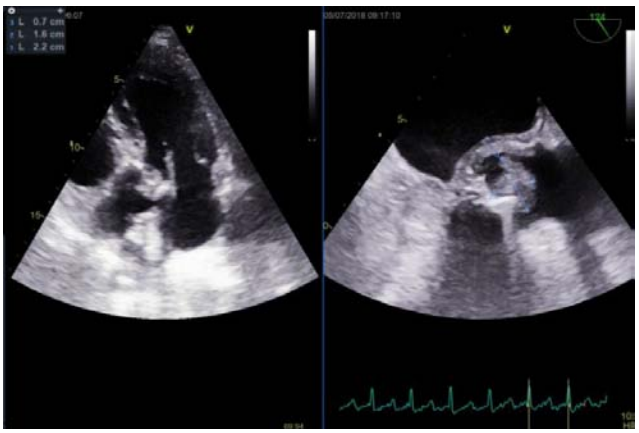
A 60 years old female was admitted to the emergency department presenting signs and symptoms of heart failure, complaining of extreme breathlessness, fatigue, haemoptysis, orthostatic hypotension. The patient didn′t have any medical history besides two physiological pregnancies (35 years ago) and grade I arterial hypertension. Vital signs were stable with a blood pressure of 106/65 mmHg, PR 125 bpm, RR of 19 brpm and subfebrility (37.7 °C). Lungs were clear to auscultation bilaterally with bilateral basal crackles. Cardiovascular exam was notable for a holosystolic murmur at the apex and regularly regular accelerated rhythm. Pulses were intact bilaterally in upper and lower extremities with no edema. Levels of serum electrolytes, glucose, blood urea and creatinine, and complete blood counts were normal, D-dimers were positive, high level of blood lipids and slight hyperglycemia were noted. In the emergency room the patient didn′t respond to conventional diuretic and anticoagulation therapy and presented with worsening of symptoms and alteration of the hemodynamic parameters. Transthoracic echo exam showed normal ejection fraction (EF 58%), moderate mitral regurgitation, moderate to severe tricuspid regurgitation, high probability pulmonary hypertension (PSAP 60 mmHg) and a large mass in the left atrium, attached to interatrial septum, filling the whole chamber with slight protrusion into the anterior mitral valve leaflet and left

ventricle during diastole. It measured 5.6x3.8x5,3 cm (14,8 cm2). A diagnosis of left atrial myxoma was made, the patient was immediately transferred to another hospital and underwent resection of the left atrium myxoma and left atrial wall with pericardial reconstruction. Post-operatively the patient showed significant clinical and haemodynamic improvement, the postoperative echo exam didn't reveal any signs of a cardiac tumour with a normal ejection fraction and mild mitral and tricuspid regurgitation.
Conclusions: Atrial myxomas are the most common primary cardiac tumours in adults, accounting for nearly half of primary cardiac tumours, developing in any of the cardiac cavities, but up to 90% of them are located in the left atrium, mainly adhered to the atrial septum near the fossa ovalis (1). The large spectrum of symptoms and signs as dyspnea, orthopnea, paroxysmal nocturnal dyspnea, pulmonary edema, could easily mislead to several diagnoses, making it difficult for clinicians to consider atrial myxoma (2). Transthotacic echo exam is the cornerstone in the appraisal of the right diagnosis, performing the differential diagnosis and tumour classification according to the tissue appearance. As soon as the suspicion of a myxoma has been raised and the diagnosis by an imaging method was performed expeditious surgery becomes imperative, as the risk of cardiovascular complications is extremely high (3). Generally the results of the surgery are positive, with a low rate of reccurence and a relatively low mortality (4).

P1921
Infective endocarditis complicated with heart failure - when everything goes wrong

S Sergiusz Nowak[1]; W Kula[1]; G Sobieszek[1]; B Olajossy[1]; N Jurzak-Mysliwy[1]; J Sadowski[2]
[1]Military Clinical Hospital of Lublin, Lublin, Poland; *[2]John Paul II Hospital, Krakow, Poland*

A 68-year-old patient, after aortic valve bioprosthesis implantation in 2016 due to severe stenosis, admitted to the Department of Gastrology for the diagnosis of microcytic anemia. Due to persistent fever with unclear etiology associated with elevated inflammatory parameters, the patient underwent transthoracic and



TTE endocarditis

transesophageal echocardiography, where two additional pathological, excessively mobile structures associated with the bioprothesis where confirmed measuring 10x4 mm (from the LVOT side) and 22x16mm (on the aortic side), as well as inflammatory infiltration around the aortic annulus and in the wall of the aortic root. After the Heart Team consultation, the operation of mechanical aortic prosthesis implantation was performed by accessing the median sternotomy. The procedure was complicated with a complete heart block. Due to the efficient escape rhythm, the pacemaker implantation was postponed. The patient was transferred to the Cardiological Rehabilitation Department. In the laboratory tests the aetiological agent was neither produced from blood nor from an explanted aortic prosthesis although in the culture of the anus VRE carriage. Empirical antibiotic therapy with vancomycin, gentamicin and rifampicin has been continued. During the treatment process, maculo-papular rash occured on the entire body. Due to the ineffectiveness of local treatment with steroids and antihistamines, it was decided to replace current antibiotics with ceftazidime. During further hospitalization, increasing markers of severe heart failure with preserved left ventricle ejection fraction: massive edema of the whole body and resting dyspnea. In echocardiography, moderate perivalvular leak, significant tricuspid regurgitation, moderate mitral regurgitation, preserved left ventricle ejection fraction at the level of 50%. In computer tomography: fluid in the pleural cavities and areas of atelectasis in the right lung. In chest x-ray, a high diaphragm on the right side, suspicion of diaphragmatic nerve palsy. Due to the bradyarrhythmia up to 30/min, the patient had temporary right ventricule stimulation through the right internal jugular vein and later on a permanent dual-chamber pacemaker system was implanted. In further hospitalization, clinical improvement was observed. The patient was discharged from the department in NYHA functional class III. For 4 months, she has been on ambulatory surveillance with stable NYHA III symptoms. In transthoracic echocardiography we find, moderate perivalvular leakage, severe tricuspid regurgitation. NT-pro BNP levels by 7000 pg/ml, with exponents of moderately good prognosis in the spirometry test with VO2 peak 1318 ml/min, hundred percent of stimulation during pacemaker control. The patient still has two therapeutic goals. Percutaneous closure of valve-related leak and the tricuspid outlet sealing. The question remains whether to consider both interventions and which order to choose, or perhaps conservative treatment?

P1922
Broken heart syndrome: a challenging diagnosis

AF Cardoso[1]; G Dias[1]; P Von Hafe[1]; B Faria[1]; M Fernandes[1]; F Almeida[1]; I Machado[1]; A Lourenco[1]
[1]Hospital Guimaraes, Guimaraes, Portugal

INTRODUCTION: Takotsubo cardiomyopathy (TC) is a differential diagnosis of myocardial infarction with nonobstructive coronary disease (MINOCA) and is often related to a physical or emotional stress. Although some image features can help to support the diagnosis, the clinical presentation has many similarities with myocardial infarction, making TC a challenging diagnosis.
CASE REPORT: We describe the case of a 75-year-old woman with hypertension, type 2 diabetes mellitus, dyslipidaemia, obesity, depressive syndrome and obstructive sleep apnoea.
She had history of a hospitalization 8 months earlier because of a suspected myocardial infarction with non-ST segment elevation. At that time, she complained of a constrictive chest pain after a vigorous effort. ECG showed a non-specific intraventricular conduction delay with QS from V1-V2 and poor R wave progression. Echocardiography showed hypokinesis of the apical segments of the septum, inferior and inferior-lateral walls; the left ventricular ejection fraction (LVEF) was preserved and a slight hypercontractility of the basal segments was noted. She had troponin elevation (peak 3.5 ng/mL; N<0.045 ng/mL). Coronary angiogram did not show coronary disease and she was discharged with dual antiplatelet therapy.
She was again admitted to our Emergency Room for acute pulmonary oedema, with no complaints of chest pain. The ECG revealed a ST-segment elevation in the anterior precordial leads. An emergent coronary angiogram showed non-obstructive coronary disease. The ventriculography showed akinesia/dyskinesia of the mid/apical segments of all walls. She was admitted with the diagnosis of a probable TC. Transthoracic echocardiogram (poor acoustic window) showed akinesia of all mid-apical segments and a mildly depressed LVEF. During hospitalization peak troponin was 1.9 ng/mL and she developed biphasic T waves in the precordial leads. A revaluation echocardiogram showed improvement of the previous wall motion abnormalities and a preserved LVEF. When exploring the possible triggers, the patient referred that both situations were similar and that she was having sexual intercourse when the symptoms suddenly started. The first event was assumed as a TC and dual antiplatelet therapy was stopped. Because of anxiety over the situation, she had to be referred to a psychiatry appointment.
DISCUSSION: MINOCA should be considered a working diagnosis and the underlying aetiology requires active investigation. Distinction between TC and acute coronary syndrome can be difficult, especially in the presence of atypical features. This case highlights the clinical history as a cornerstone to patients' clinical approach. Also, it points that TC recurrences can have a significant impact in patients' life so, despite their relatively low prevalence, further studies of the mechanisms and therapies for their prevention are essential.

P1923
Tachycardiomyopathy and subclinical hyperthyroidism: when should antithyroid treatment be given? a case report

AL Rodriguez[1]; DP Diaz[1]; SA Prieto[2]; AF Buitrago[1]; Y Yenny R Cardenas[1]
[1]Fundacion Santa Fe de Bogota , Critical Care medicine , Bogota, Colombia; *[2]University of Los Andes, Bogota, Colombia*

Funding Acknowledgements: There was no financial support involved in this clinical case report

Background: Tachycardiomyopathy (TCMP) is a reversible cause of myocardial dysfunction due to increased ventricular workload secondary to chronic or sustained arrhythmias. Thyroid function alterations have been associated with arrhythmias and, in some cases, the appearance of TCMP.
Case Summary: A 42-year-old male with Grave's disease managed with radioiodine therapy and of atrial fibrillation (AF) with prior intact heart function (ejection fraction

(EF) of 65%) managed with Propafenone in a poorly adherent manner, consults for a two-week history of dyspnea, cough, and extremity edema. Physical examination exhibited arrhythmic heart sounds; R3; holosystolic murmur grade II/VI in the mitral; HR: 160 bpm; RR: 16 rpm; AP: 110/80 mmHg; T: 37 C; Jugular engorgement; and grade III edema of lower limbs. The initial ECG displayed AF with rapid ventricular response associated repolarization disturbances on the inferolateral aspects. A chest x-ray showed diffuse infiltrations, upper right lobe consolidation, and cardiomegaly. Rate control medication (metildigoxin 0.1 mg QD, Metoprolol 12.5 mg TIB), diuretics (furosemide 8 mg TIB) and antibiotic (Ceftriaxone 2 g QD) were initiated. Six hours after admission the patient referred palpitations without chest pain and so was started on Warfarin 5mg QD and Propafenone. In the Intensive Care Unit (ICU), subclinical hyperthyroidism was documented (TSH: 0.14 (0.34-5.6), T3L: 2.16 (2.5-3.9), T4L: 0.89 (0.6-1.2) and a transthoracic echocardiogram showed dilated cardiomyopathy, severe compromise of the systolic/diastolic function (EF 29%) and severe mitral/tricuspid insufficiency (IMAGE 1). Since TSH levels were >0.1, no antithyroid medication was started and heart failure management was given with metildigoxin 0,1 mg QD, Metoprolol 50 mg BID, Enalapril 2,5 mg BID, Spironolactone 25 mg QD, and furosemide 10 mg TIB. Still, despite proper management for 7 days, the patient was persistently symptomatic with only a modest decrease in heart rate (120 bpm). Due to the lack of clinical improvement, the case was taken to a board meeting and Methimazole was started 5 mg BID. 3 days later, the patient was euthyroid (TSH: 0.674), heart rate was stable at 90-100 bpm, the edema resolved, there were no overload signs and the patient lost 4 kg. After thyroid control was achieved, heart function improved so the diagnosis of TCMP was made.

Discussion: Clinical and subclinical thyroid disturbances promote and sustain arrhythmias, increased ventricular mass index, TCMP and mortality so both should be treated. The current indications to start treatment are a high prior to cardiovascular risk and TSH <0.1; none of which were present in this patient. Nevertheless, his condition improved once antithyroid treatment was given. There is no clear benefit for correcting subclinical hyperthyroidism when it comes to cardiovascular outcomes, this case supports the idea of treating subclinical hyperthyroidism regardless of TSH levels

An unusual case of myocarditis

I Andrikou[1]; I Leontsinis[1]; E Sfendouraki[1]; C Danelatos[1]; D Syrseloudis[1]; I Skiadas[1]; I Babatseva Vagena[1]; A Androulakis[1]; D Vassilopoulos[1]; C Catherine Avgeropoulou[1]; I Kallikazaros[1]

[1]*Hippokration General Hospital , Cardiology, Athens, Greece*

A 37 year old female presented to the emergency department complaining of fatigue, progressively worsening over one month, following an upper respiratory tract infection. Three years ago, due to Raynaud's sign, episodes of photosensitive facial rash and a previous admission for arthritis affecting her right knee, she had undergone screening which was negative for active connective tissue disease. She has been a smoker.On admission, there were signs of acutely decompensated heart failure consisting of sinus tachycardia (130bpm) with audible S3, bibasal crackles, elevated jugular venous pressure, ascites, oedema, pallor and cold extremities. Her blood pressure was 90/50 mmHg, oxygen saturation 92% on room air and respiratory rate was 32/min. There was no evidence of infection and her temperature was normal. ECG showed sinus rhythm with left anterior hemiblock and no signs of ischemia. Laboratory results revealed thrombocytopenia, abnormal liver function tests, severely reduced eGFR (38 ml/min), raised hs-troponin (3.145 pg/ml) and increased CRP and natriuretic peptides. Echocardiogram demonstrated severely dilated left ventricle with D-shape, global hypokinesia and an estimated LVEF of 15% (GLS=-6%). Right ventricle appeared dilated with reduced systolic performance (RV systolic TDI=7cm/sec). There was increased pulmonary pressure with no significant left sided valvular disease.She was admitted in the ICU for invasive monitoring. She was treated with inotropes (levosimendan and noradrenaline) and diuretics and a gradual improvement of tissue perfusion, dyspnoea and diuresis was noted.

The working diagnosis included myocarditis, viral or connective tissue disease related. After the patient's stabilisation a coronary angiogram was performed and it was negative for CAD. The laboratory work confirmed according to the rheumatology consultation an atypical form of systemic lupus erythematosus (reduced C 3 and C4, positive anti-rib-P). Besides the medical management of heart failure, she received high dose of corticosteroids and chemotherapy (cyclophosmamide). The cardiac MRI confirmed the severely reduced LV function. Additionally, it showed subepicardial and subendocardial fibrosis, especially affecting the antero and inferolateral walls consistent with myocarditis and vasculitis.Two months later her clinical picture was improved, as well as the echo study findings (LVEF 35%, GLS=-11%, RV systolic TDI=10cm/sec). At that time a repeat MRI scan showed moderate improvement in LV function with sustained fibrosis in the above mentioned segments. The latter, in conjuction with episodes of non sustained VT in the 24h ECG, prompted the placement of an ICD pacemaker. The patient has been under the joint care of Cardiology and Rheumatology department.

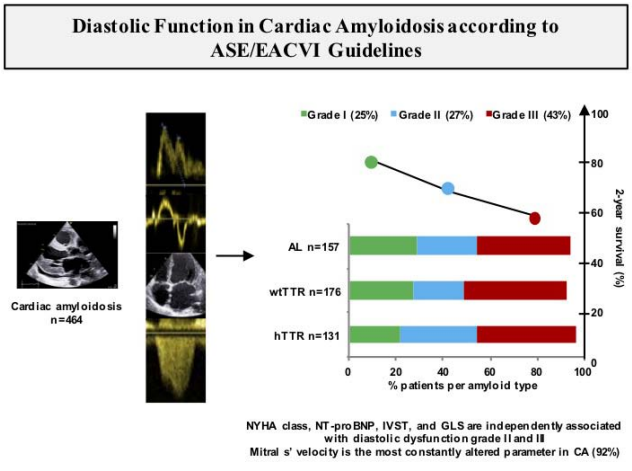
Multiple patterns of left ventricular diastolic function and its determinants in cardiac amyloidosis: an updated evaluation according to ASE/EACVI 2016 guidelines

S Oghina[1]; W Bougouin[2]; M Kharoubi[1]; A Galat[1]; S Guendouz[1]; M Bezard[1]; F Le Bras[1]; JF Deux[1]; E Itti[1]; V Plante-Bordeneuve[1]; A Mokteffi[1]; P Fanen[1]; E Teiger[1]; T Damy[1]; D Bodez[1]
[1]University Hospital Henri Mondor, Creteil, France; *[2]Institut Hospitalier Jacques Cartier, Intensive Care Unit, Massy, France*

Introduction : Cardiac amyloidosis (CA) is an increasingly recognized cause of restrictive cardiomyopathy but its prognosis remains pejorative. Thus, early diagnosis is necessary. The ASE/EACVI guidelines for the evaluation of left ventricular diastolic function (LVDF) have never been applied to CA.
Aim: Assess the pattern and phenotype of LVDF in a large cohort of CA according to these new recommendations, identify the determinants of the diastolic dysfunction, and describe the prognosis of LVDF patterns.
Methods: We conducted a monocentric, observational, retrospective study on patients referred to our expert centre of CA (Henri Mondor Hospital, Creteil, France) between 09/2008 and 06/2017 in 464 patients with a confirmed diagnosis of CA balanced between the three main types. We analysed their diastolic function by standard echocardiography according to the ASE/EACVI 2016 guidelines together with clinical, biological and survival parameters.
Results: 43% had a restrictive mitral pattern (diastolic dysfunction grade III) and 25% had non-elevated LV filling pressures (diastolic dysfunction grade I). No difference was found between the the main type of CA. After multivariate analyses, grades II and III (increase of LV filling pressures) were independently associated with dyspnea, higher NT-proBNP level, cardiac infiltration (intreventricular septal thickness) and systolic dysfunction (global longitudinal strain). Grade I patients had a better prognosis than grades II and III, and showed early impairment of systolic function linked to LV amyloid involvement, especially mitral s' velocity (<8 cm/s).
Conclusion : CA should not be ruled out in patients with mild impairment of diastolic function. It is time to diagnose patients at this early stage associated with less mortality and need for heart transplant, and for which mitral s' velocity is the most constantly impaired parameter.



Diastolic function in CA

High prevalence of cancer in patients with peripartum cardiomyopathy and potential pathophysiological connections

T J Pfeffer[1]; S Schlothauer[1]; S Pietzsch[1]; M Schaufelberger[2]; K Sliwa[3]; C Falk[4]; S Haidari[1]; M Ricke-Hoch[1]; E Stelling[1]; D Berliner[1]; V Abou-Moulig[1]; T Koenig[1]; J Bauersachs[1]; D Hilfiker-Kleiner[1]
[1]Hannover Medical School, Cardiology, Hannover, Germany; *[2]University of Gothenburg, Department of Molecular and Clinical Medicine, Gothenburg, Sweden*; *[3]University of Cape Town, Cape Town, South Africa*; *[4]Hannover Medical School, Institute of Transplant Immunology, IFB-Tx, Hannover, Germany*

Background/Aims: Peripartum cardiomyopathy (PPCM) is a severe heart disease affecting previously heart-healthy women in the last months of pregnancy or in the first postpartum months. PPCM patients have a high chance for cardiac recovery and are at young age at time of diagnosis. Therefore, co-morbidities can occur many years after diagnosis and are of great importance regarding the prognosis of the patients. Here we evaluate the risk of cancer in PPCM patients.
Methods and Results: In a German-Swedish PPCM cohort the prevalence for cancer was more than 10-fold higher (8.5%, 20/235 PPCM patients) than in aged-matched women (cancer prevalence: 0.59%). Cancer occurred in 11 patients prior and in 10 patients after PPCM (n=23 as one patient suffered from cancer before and after PPCM). Two plasma markers associated with cancer, Her2 and sIL-6Rα, were significantly elevated in all PPCM patients (n=47) at diagnosis compared with pregnancy-matched controls (n=23). Ten patients with cancer prior PPCM had obtained cardiotoxic treatments (chemotherapy with Doxorubicine derivatives, Vincristine, Cisplatin and/or radiation) prior PPCM, but did not have left ventricular (LV) dysfunction or heart failure before pregnancy. These patients had a lower chance for full cardiac recovery (LVEF$\geq$50% at 6 months FU) compared to PPCM patients without these treatments (full cardiac recovery after 6 months: 33% vs. 56%). Treatment of juvenile female mice (C57Bl6) with low dose Doxorubicine did not induce LV dysfunction. However, RNAseq of left ventricular tissue revealed persistingly altered expression of 29 genes including HDAC4 and the long non-coding RNA lncpint. No difference in circulating monocytes/macrophages was observed between DOX and control mice. Breeding these mice three weeks later led to high peripartum mortality associated with cardiac inflammation and fibrosis and heart failure. RNAseq revealed the induction of different gene programs by pregnancy in control PP and in Dox treated mice. Among the genes only upregulated in control PP mice were genes involved in sarcomere function and cardioprotection including Mybpc3, Nox4, Nrg1, topoisomerase (DNA) II binding protein 1 and Bcl2. In turn DOX PP mice displayed induction of a pro-inflammatory and pro-fibrotic gene expression program including the upregulation of Adgre1, CCR2, Pecam1 and Timp1, Col3a1, Col4a1.
Conclusion: Our findings suggest a higher prevalence of cancer among PPCM patients compared with age-matched controls. Pregnancy seems to trigger late onset cardiomyopathy after previous cardiotoxic chemo-/radiotherapy. Experimental data suggest that Doxorubicine chemotherapy persistingly alters the epigenetic program and thereby the cardiac response to pregnancy stress.
Therefore, in women with cancer history, especially if chemo-/radiotherapy was applied, heart structure and function should be evaluated before pregnancy and monitoring during pregnancy should be considered.

1927

After initial improvement, left ventricular ejection fraction remains stable in long-term survivors with dilated cardiomyopathy

K Kaspar Broch[1]; A Knutsen[2]; EK Sekne[2]; K Murbraech[3]; AK Andreassen[3]; S Aakhus[4]; L Gullestad[4]
[1]University of Oslo, Rikshospitalet University Hospital, Department of Cardiology, Oslo, Norway; *[2]University of Oslo, Faculty of medicine, Oslo, Norway*; *[3]Oslo University Hospital, Rikshospitalet, Department of cardiology, Oslo, Norway*; *[4]Norwegian University of Science and Technology, Trondheim, Norway*

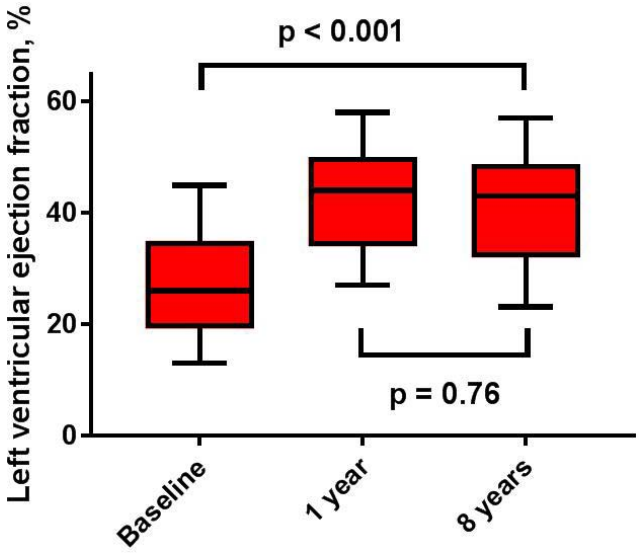
Purpose: Over the last decades, survival in patients with heart failure has improved with the introduction of beta-blockers, inhibitors of the

renin-angiotensin-aldosterone system and implantable devices. We and others have reported a substantial improvement in left ventricular ejection fraction (LVEF) after the initiation of optimal therapy in patients with recent-onset dilated cardiomyopathy (DCM). In a prospective cohort study, we aimed to evaluate whether this initial improvement presaged enduring left ventricular competence or represented a honeymoon phenomenon.

Methods: We included 102 consecutive patients referred to our tertiary care hospital with DCM and an LVEF < 40 %. Patients with significant coronary disease, primary valvular disease, congenital disease, hypertensive cardiomyopathy, myocarditis and specific causes of DCM were excluded. After extensive baseline work-up, follow-up was performed after 1 and 8 years. LVEF was determined by echocardiography.

Results: At baseline, the mean age was 51 ± 14 years. 74 (73%) patients were male. The average duration of symptoms prior to inclusion was 7 (1-13) months, the average LVEF was 26 ± 10 % . The mean New York Heart Association (NYHA) functional class prior to enrolment was 3.2 ± 0.9. At follow-up after 7.8 (IQR 6.3 – 9.0) years, 26 (26%) patients were either dead or had received heart transplants. In long-term survivors, the average LVEF increased from 28 ± 10 % to 42 ± 10 % after one year and remained stable until 7.8 years, (t 41 ± 10 % ; Figure). Circulating levels of NT-proBNP fell substantially from baseline to 1 year (1238 [423-2427] pg/ml vs 320 [121-609] pg/ml, p < 0.001), with no significant difference after that (320 [121-609] pg/ml vs 288 [86 – 919] pg/ml, p = 0.06). Likewise, the average NYHA class improved from 3.2 ± 0.9 prior to inclusion to 1.4 ± 0.6 after one year (p for difference < 0.001), and remained at 1.6 ± 0.6 at 8 years (p for difference from 1 year, 0.10).

Conclusion: After a substantial initial improvement, left ventricular function, natriuretic peptides and functional class remains stable in long-term survivors of dilated cardiomyopathy.



Left ventricular ejection fraction

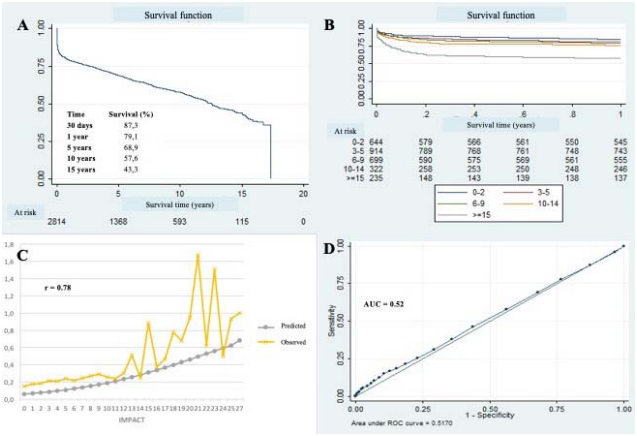
Funding Acknowledgements: CIBERCV

Background: The Index for Mortality Prediction After Cardiac Transplantation (IMPACT)score was derived and validated as a predictor of short and long term mortality after orthotopic heart transplantation (OHT). According to the standards in prediction model research, before implementing a risk score in daily clinical decision making, discrimination ability and impact in clinical practice or prognosis should be evaluated. The primary objective of this work is to externally validate the IMPACT score in the Spanish cohort.

Material and methods: Spanish Heart Transplant Registry data were used to identify adult (>16 years) OHT performed from January 2000 to December 2015. Retransplantation and combined transplantation were excluded from the analysis. Individual values of the IMPACT score were calculated for each patient. Overall 1-year mortality after OHT was assessed and 1-year mortality rates between predefined IMPACT score groups (0-2pts, 3-5pts, 6-9ptos, 10-14ptos, ≥15pts) were compared. Correlation between the observed and expected mortality according to the IMPACT score was evaluated. Finally, discrimination ability was assessed by the area under the ROC curve.

Results: We identified 2,814 OHT. Mean age was 53 ± 12 years, 78% were male and 31% had dilated ischemic cardiomyopathy. Mean value of the IMPACT score was 6.3 ± 4.9 points. Overall 1-year survival rate was 79.1%. Kaplan-Meier 1-year survival rates by IMPACT score groups were 84.6%, 81.3%, 79.4%, 76.4% and 58.3% respectively (Log-Rank test: p <0.001). Correlation between the observed mortality in our series and that expected according to the IMPACT score was good (r=0.78), while its discrimination ability was poor (AUC=0.52).

Conclusions: OHT mortality in Spain is adjusted to that expected by the IMPACT score, so there is good calibration of the predictive model. However, its predictive strength is poor and similar to that determined by chance. On the other hand, there is a lack of studies that compare the IMPACT score with other predictive models and studies that evaluate the impact on clinical practice and outcomes of OHT. In the absence of these studies, we cannot implement the IMPACT score in our daily clinical decision making.



1929

Genetic risk prediction of atrial fibrillation in a contemporary heart failure cohort

M Kloosterman[1]; BT Santema[1]; C Roselli[2]; AL Koekemoer[3]; SPR Romaine[3]; CP Nelson[3]; IC Van Gelder[1]; CSP Lam[1]; P Van Der Harst[1]; IE Sama[1]; DJ Van Veldhuisen[1]; AA Voors[1]; NJ Samani[3]; M Rienstra[1]
[1]University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands (The); *[2]Harvard Medical School, BROAD institute, Boston, United States of America*; *[3]NIHR Biomedical Research Unit in Cardiovascular Disease, Leicester, United Kingdom of Great Britain & Northern Ireland*

Funding Acknowledgements: [CVON2014-11 RECONNECT] [FP7-242209-BIOSTAT-CHF; EudraCT 2010–020808–29].

Background: A genetic basis for atrial fibrillation (AF) is evident in the community, but it remains unclear whether individuals with AF in the context of heart failure share a similar genetic susceptibility.

Purpose: There is an association between AF and common genome-wide susceptibility loci for the arrhythmia in patients with heart failure.

Methods: Associations between an AF genetic risk score (GRS), based on ninety-seven single nucleotide polymorphisms (SNPs) from the latest AF genome wide association study, and AF prevalence was studied in the BIOlogy Study to Tailored Treatment in Chronic Heart Failure (BIOSTAT-CHF). The GRS was calculated by summing the dosage of each AF risk allele (ranging from 0-2) weighted by the natural logarithm of the relative risk for each SNP. Patients were classified into the AF group if they had AF or atrial flutter (AFL) at baseline ECG and/or a prior diagnosis of AF or AFL.

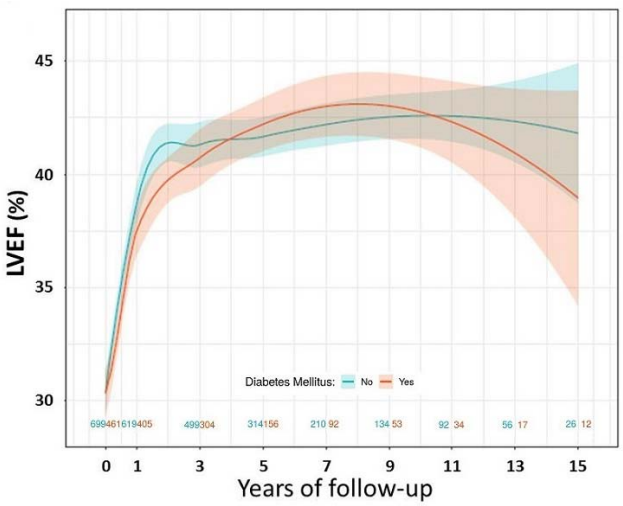
Results: 3759 Caucasian individuals from BIOSTAT-CHF with genetic and rhythm data, of which 1783 in sinus rhythm and 1976 with (a history of) AF, were identified. The GRS was associated with AF after multivariable adjustment for clinical risk factors including; age, sex, BMI, coronary artery disease, hypertension, diabetes and renal disease. The odds ratio for AF was 2.15 per 1-unit in GRS (95% confidence interval (CI) 1.86-2.47, P=4.02x10-26) in the total BIOSTAT cohort. The GRS ranged from 2.12 per 1-unit in GRS (95% CI 1.77-2.55, P=4.58x10-16) to 1.85 per 1-unit in GRS (95% CI 1.27-2.70, P=0.001) in HFrEF (1137 SR, 1125 AF) and HFpEF (223 SR, 307 AF) respectively.
Conclusions: The AF genetic risk score was associated with increased AF risk in heart failure patients, which suggests at least a partial heritable component to the propensity of AF in heart failure. Efforts are warranted to determine the causal mechanisms and extent by which genetic AF susceptibility influences AF risk in patients with heart failure.

1930

Long-term left ventricular ejection fraction trajectory in diabetic patients: is there any difference?

M De Antonio[1]; J Josep Lupon[1]; G Gavidia-Bovadilla[2]; N Alonso[1]; M Domingo[1]; P Moliner[1]; E Santiago-Vacas[1]; E Zamora[1]; J Santesmases[1]; V Diaz[1]; B Gonzalez[1]; C Diez-Quevedo[1]; J Nunez[3]; MI Troya[1]; A Bayes-Genis[1]
[1]*Germans Trias i Pujol University Hospital, Badalona, Spain*; [2]*Technological Center of Catalonia, Department of e-Health, Eurecat, Barcelona, Spain*; [3]*University Hospital Clinic of Valencia, Valencia, Spain*

Background: Advances in heart failure (HF) treatment are responsible for systolic function improvement in patients depressed left ventricular ejection fraction (LVEF). This improvement might be maintained through a decade in survivors. It is known than diabetic mellitus (a pathological situation that usually carries an increased atherosclerotic load and also a low-degree inflammation) entails a worse prognosis in patients. Whether the presence of diabetes mellitus (DM) interferes in the improvement and trajectories of LVEF is not completely elucidated.
Purpose: To prospectively assess very long-term (up to 15 years) LVEF trajectory in diabetic HF patients (form ischemic and non-ischemic aetiology), and to compare these trajectories with those observed in non-diabetic patients.
Methods: Ambulatory patients admitted to a multidisciplinary HF Unit were prospectively evaluated by 2D-echocardiography at baseline and at 1, 3, 5, 7, 9, 11, 13 and 15years of follow-up. Out of 1921 patients, 461 diabetic patients and 699 non-diabetic with LVEF <50% and at least 2 LVEF measurements were included in the study. Statistical analyses of LVEF change along the time were performed by Linear Mixed-Effects (LME) modelling. Locally Weighted Error Sum of Squares (Loess) curves were also plotted for the two pre-specified study subgroups.



Results: LVEF measurements were obtained from 461, 405, 304, 156, 92, 53, 34, 17, and 12 diabetic patients at the predefined time-points, and were compared to those obtained in 699, 619, 499, 314, 210, 134, 92, 56, and 36 non-diabetics. Mean number of echocardiography measurements performed was 3.6 ± 1.7. Although the magnitude of LVEF improvement was similar in diabetic and in non-diabetic patients, Loess curves showed a more pronounced inverted U shape in diabetic patients, with a slower improvement during the first years and a higher decline beyond 9 years of follow-up (Figure). LME analysis showed statistical interaction between diabetes mellitus and the LVEF trajectory along time for the quadratic term of time (p=0.009), justified by the most prominent inverted U shape trajectory curve. Remarkably, the interaction between diabetes and LVEF trajectory was observed only in patients from ischemic aetiology in whom the interaction was significant both for the linear term of time (p=0.004), quadratic term of time (p<0.001), but not in patients from non-ischemic aetiology.
Conclusions: LVEF in diabetic patients with depressed systolic function significantly improved during the first years of management in a HF Clinic, in a similar magnitude that was observed in non-diabetic patients. However LVEF trajectory along a very long-follow-up showed a statistically significant interaction between time and diabetes, showing diabetic patients a more pronounced inverted U shape of LVEF trajectory. This interaction was concentred in patients from ischemic aetiology.

1931

Concentric versus eccentric remodeling in heart failure with reduced ejection fraction: clinical characteristics, pathophysiology and response to treatment

JF Jan Focko Nauta[1]; YM Hummel[1]; W Ouwerkerk[2]; J Tromp[1]; X Jin[2]; CSP Lam[2]; P Van Der Meer[1]; SD Anker[3]; M Metra[4]; K Dickstein[5]; CC Lang[6]; J Bax[7]; DJ Van Veldhuisen[1]; J Van Melle[1]; AA Voors[1]

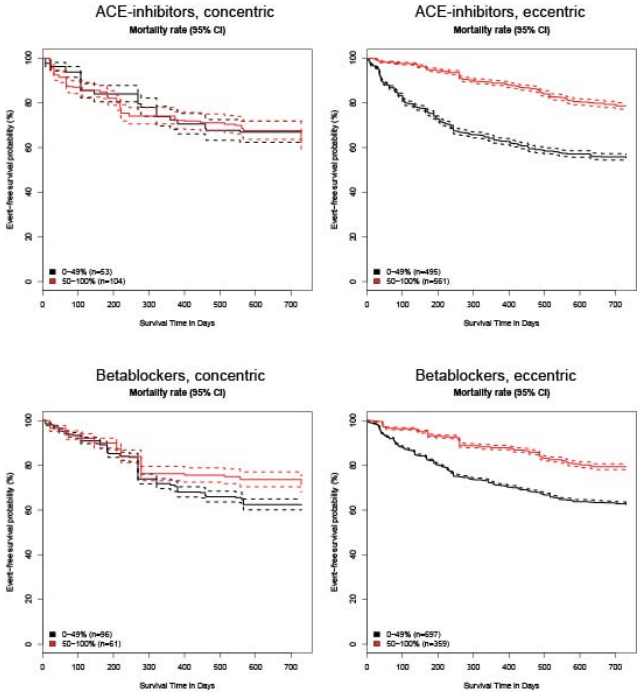
Funding Acknowledgements: This work was supported by a grant from the European Commission (FP7-242209-BIOSTAT-CHF).

Aims: Heart failure (HF) is traditionally classified by left ventricular (LV) ejection fraction (EF), rather than by LV geometry, with effective guideline-directed medical therapies in HF with reduced EF (HFrEF) but not HF with preserved EF (HFpEF). Most patients with HFrEF have eccentric LV hypertrophy, but some have concentric LV hypertrophy. We aimed to compare the clinical characteristics, biomarkers patterns, and response to treatment of patients with HFrEF and eccentric versus concentric LV hypertrophy.



Event-free survival probability

Methods We included 1213 patients with HFrEF (LVEF<40%) from the BIOlogy Study to TAilored Treatment in Chronic Heart Failure (BIOSTAT-CHF) study and classified LV geometry by standard echocardiographic methods. Network analysis of 92 biomarkers was used to investigate pathophysiologic pathways in geometry groups. The response to uptitration of ACE-inhibitors/angiotensin receptor blockers (ACEi/ARBs) and beta-blockers was adjusted for the likelihood of uptitration, based on a previously published model using inversely probability weighing.

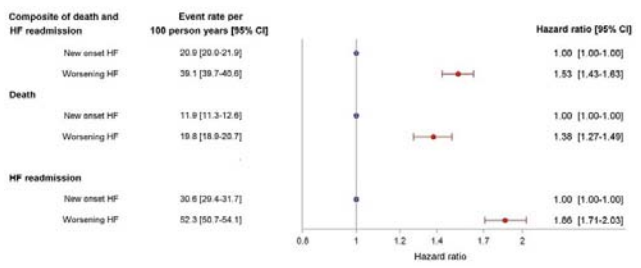
Results Concentric LV hypertrophy was present in 157 (13%) patients with HFrEF, who were on average older, more often female and more likely hypertensive compared to those with eccentric LV hypertrophy. Network analysis revealed that NT-proBNP was the most important hub in eccentric LV hypertrophy, whereas in concentric LV hypertrophy, tumor necrosis factor receptor 1 (TNF-R1), urokinase plasminogen activator surface receptor (U-PAR), paraoxonase (PON3) and P-selectin (SELP) were the most important hubs. Uptitration of ACEi/ARBs and beta-blockers was associated with a mortality benefit in HFrEF with eccentric but not concentric LV hypertrophy (p for interaction ≤0.02).
Conclusion Patients with HFrEF with concentric LV hypertrophy were distinctly different from those with eccentric hypertrophy. Patients with HFrEF and concentric LV hypertrophy resembled patients with HFpEF in their clinical and biomarker profile, as well as (lack of) response to HFrEF therapy.

1932

Risk of readmission and death in patients admitted with new-onset versus worsening heart failure: insights from a nationwide cohort

JH Jawad Haider Butt[1]; EL Fosbol[1]; C Andersson[2]; TA Gerds[3]; JJV Mcmurray[4]; MC Petrie[4]; F Gustafsson[1]; C Madelaire[2]; SL Kristensen[2]; GH Gislason[2]; C Torp-Pedersen[5]; L Kober[1]; M Schou[6]
[1]Rigshospitalet - Copenhagen University Hospital, Department of Cardiology, Copenhagen, Denmark; *[2]Gentofte Hospital - Copenhagen University Hospital, Department of Cardiology, Hellerup, Denmark*; *[3]University of Copenhagen, Department of Biostatistics, Copenhagen, Denmark*; *[4]Cardiovascular Research Centre of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland*; *[5]Aalborg University Hospital, Department of Cardiology and Clinical Epidemiology, Aalborg, Denmark*; *[6]Herlev Hospital, Department of Cardiology, Herlev, Denmark*

Background: There are two distinct group among patients admitted with acute decompensated heart failure (ADHF) – those presenting with new-onset heart failure (HF) and those with worsening of established HF. However, how these groups compare, and their subsequent outcomes, have not been described.
Purpose: To examine the rates of all-cause mortality and HF readmission in patients admitted with ADHF according to HF duration – new-onset HF (defined as a history of HF of 30 days or less) and worsening of established HF (defined as a history of HF of more than 30 days including both in- and outpatient HF contacts).
Methods: In this nationwide observational cohort study, patients aged below 90 years, surviving a hospital admission for HF (defined as an overnight stay and primary discharge diagnosis of HF) between January 1, 2013 and December 31, 2015 and alive at discharge were identified using data from Danish nationwide registries. The rates of outcomes according to HF duration were examined by multivariable Cox regression models.
Results: Of the total 9,617 eligible patients, 4,771 (49.6%) patients were admitted with new-onset HF and 4,846 (50.4%) with worsening of established HF. Compared with patients with new-onset HF, patients with worsening of established HF were characterized by advanced age and a greater burden of cardiovascular and non-cardiovascular comorbidities. Compared with new-onset HF, worsening of established HF was associated with a higher rate of the composite endpoint of death and HF readmission (adjusted hazard ratio [HR] 1.53 [95% confidence interval [CI], 1.46-1.63]), death (HR 1.38 [95% CI, 1.27-1.49]), and HF readmission (HR 1.86 [95% CI, 1.71-2.03]) (Figure). There was a graded relationship between increasing HF duration and rate of these outcomes. In all subgroups (age, sex, ischemic heart disease, atrial fibrillation, diabetes), worsening of established HF was associated with a higher rate of the composite endpoint of death and HF readmission compared with new-onset HF. There was an interaction between atrial fibrillation (AF), HF type, and outcome; in patients with new-onset HF, AF was associated a lower rate of the composite endpoint, as compared with sinus rhythm (HR 0.86 [95% CI, 0.78-0.95]), whereas AF was associated with a higher rate of the composite endpoint in patients with worsening of established HF (HR 1.33 [95% CI, 1.05-1.22]) (P-value for interaction < 0.001).



Adjusted hazard ratios of outcomes

Conclusions: Among patients discharged from hospital with ADHF, worsening of established HF was associated with poorer outcomes compared with new-onset HF. AF was associated with worse outcomes in patients admitted with worsening of established HF, but not in new-onset HF.

1933

18F-Flutemetamol PET/MR imaging of cardiac amyloidosis

M Papathanasiou[1]; L Kessler[2]; C Rischpler[2]; K Herrmann[2]; A Carpinteiro[3]; T Hagenacker[4]; T Rassaf[1]; P Luedike[1]
[1]University Hospital Essen, Department of Cardiology and Angiology, West German Heart and Vascular Center, Essen, Germany; *[2]University Hospital Essen, Department of Nuclear Medicine, Essen, Germany*; *[3]University Hospital of Essen (Ruhr), Department of Hematology, Essen, Germany*; *[4]University Hospital Essen, Department of Neurology, Essen, Germany*

Background: Non-invasive diagnosis of cardiac amyloidosis by means of nuclear imaging is gaining acceptance as an alternative to endomyocardial biopsy. The diagnostic accuracy of bone-tracer scintigraphy for the detection of transthyretin-related cardiac amyloidosis approaches 100%. Positron emission tomography (PET) with amyloid-binding tracers has the advantage of detecting both common types of amyloid deposits. i.e. light-chain (AL) and transthyretin (TTR) with a reported sensitivity of 95% and a specificity of 98% in a recent meta-analysis. Cardiac magnetic resonance (MR) imaging is another established method that provides insight to myocardial structure and performance, especially with the introduction of myocardial T1 mapping. In our study, we describe the first time use of 18F-Flutemetamol PET/MR imaging in a series of patients with diagnosed or suspected cardiac amyloidosis.
Methods: The study included patients with known or suspected cardiac amyloidosis. All study participants underwent PET/MR imaging in a 3 Tesla hybrid system with estimation of tracer-uptake (SUV mean und SUV max of the basal septum), late gadolinium enhancement, T1 global relaxation time and extracellular volume (ECV). Two nuclear specialists blinded for the results of any available biopsies prior PET/MR imaging analyzed the studies.
Results: We included four patients with cardiac amyloidosis (three patients with TTR-Amyloidosis and one with AL-Amyloidosis) and four patients with suspected cardiac amyloidosis and negative histologic results of cardiac biopsy or abdominal fat pad aspirate. The mean age of the amyloidosis patients was 67 (61-77) years and the mean age of patients with suspected amyloidosis was 76 years (67-84). Average myocardial SUV max in the amyloidosis group was 2,24 compared to 1,86 in the comparison group (p=0.15). Average myocardial SUV mean was 1,85 and 1,39, respectively (p=0.07). T1 relaxation time and ECV were higher in amyloidosis patients (1484,7 vs. 1347,9 sec, p=0.07 and 60,6 % vs. 39,4 %, p=0.08, respectively).
Conclusions: 18F-Flutemetamol PET may be an alternative to endomyocardial biopsy and has the potential to outperform scintigraphy due to the specific tracer-affinity to both common types of amyloid deposits. The diagnostic accuracy of PET/MR imaging should be further investigated in larger studies.

Risk of stroke in patients with chronic heart failure and sinus rhythm: clinical prediction model based on the Swedish heart failure (Swede-HF) registry

A Uijl[1]; I Vaartjes[1]; FW Asselbergs[2]; AW Hoes[1]; U Dahlstrom[3]; G Savarese[4]; S Koudstaal[2]; LH Lund[4]
[1]Julius Health Center - Julius Gezondheidscentra, Utrecht, Netherlands (The); *[2]University Medical Center Utrecht, Department of Cardiology, Division Heart & Lungs, Utrecht, Netherlands (The)*; *[3]Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden*; *[4]Karolinska Institute, Department of Medicine, Division of Cardiology, Stockholm, Sweden*

Funding Acknowledgements: This work has received support from the EU/EFPIA Innovative Medicines Initiative 2 Joint Undertaking BigData@Heart grant n° 116074

Background Chronic heart failure (HF) is accompanied by a 2-3 fold increased risk of ischemic stroke, independent of atrial fibrillation (AF), yet anticoagulant therapy has not shown to be effective on a group level in HF patients without AF. Improved risk stratification using readily available clinical information may facilitate the identification of HF patients at higher risk of ischemic stroke.
Purpose To describe the incidence and independent predictors of ischemic stroke in patients with heart failure without atrial fibrillation.
Methods We selected 16,275 HF patients without AF, not receiving anticoagulation from the nationwide Swedish HF (Swede-HF) registry between 2000-2012. A Weibull Hazard Model with backwards selection was used to develop a clinical prediction model for ischemic stroke and/or TIA within 1 year after HF diagnosis.
Results Stroke occurred in 982 (6.0%) patients during a median follow up of 2.35 years [IQR range 0.97 – 4.21 years], amounting to an incidence rate of 21.5/1000 patients-years respectively. Using a Weibull Hazard model with backwards selection, 12 predictors were included in the final multivariable prediction model and the

strongest predictors were: age (hazard ratio (HR) 1.39, 95% confidence interval (95% CI), 1.25 – 1.55 per 10 years), diabetes (HR 1.40, 95% CI 1.12 – 1.74), hypertension (HR 0.79, 95% CI 0.62 – 0.99), peripheral artery disease (HR 1.49, 95% CI 1.12 – 1.98) and previous stroke or TIA (HR 2.16, 95% CI 1.69 – 2.75). The model performance had a c-statistic of 0.689 (95% CI 0.662 – 0.716) (Figure 1a). Based on the prediction model we classified patients based on risk quartiles into highest, high, intermediate and low risk of stroke (Figure 1b). Of note, neither dilated cardiomyopathy, coronary artery disease or HF type (HF with preserved ejection fraction (EF), HF with midrange EF, HF with reduced EF) were independently associated with increased risk of stroke.
Conclusion Using 12 clinically available variables, HF patients with sinus rhythm at high risk of stroke could be identified with moderate accuracy, and the highest risk quartile had stroke rates comparable to HF patients with AF.

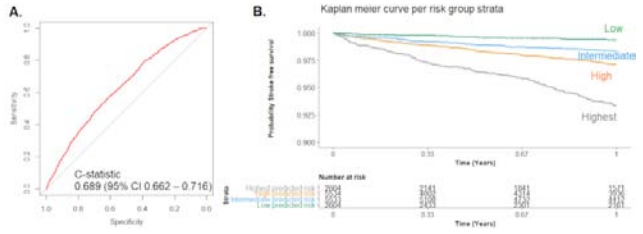

Figure 1

1935

High prevalence of progression of structural and functional abnormalities in a cohort at -risk for heart failure. Report from the STOP HF cohort.

M Ferre-Vallverdu[1]; RB Pharithi[1]; E O'connell[1]; M Ledwidge[1]; J Gallagher[1]; C Watson[1]; K Mcdonald[1]
[1]*St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*

Background: STOP-HF has shown that natriuretic peptide (NP) guided intervention reduces new onset heart failure, ventricular dysfunction and MACE. Patients with BNP level of ≥50pg/mL underwent serial echocardiography studies. Despite the fact that it is well known structural and functional parameters such as LVEF, LAVI, LVH and e' have been shown to be powerful predictors of cardiovascular risk, the value of serial Doppler-echocardiography in this at -risk but stable asymptomatic population is unclear.
Methods: STOP-HF patients with elevated NP who remained asymptomatic and with 3 sequential echocardiography studies were included. Progression was defined as: left ventricular systolic dysfunction (LVSD) progression when LVEF<50% and reduction of >5% from prior study; left ventricular diastolic dysfunction (LVDD) progression when average E/e'>14 and increase of >2 and/or e'<9cm/s with drop of >2cm/s. Left ventricular dysfunction (LVD) progression included LVSD and/or LVDD. We also recorded LAVI progression (LAVI>34ml/m2 with 3.5ml/m2 increased) and LVH progression (>125g/m2 male/>110g/m2 female, with increase of >20g/m2). Baseline characteristics and MACE events during follow-up were recorded.
Results: 211 patients were included (median age 69.2, 46.9% male). Hypertension (77.6%) and diabetes mellitus (38.4%) were the most prevalent comorbidities. 129 (61.1%) patients were considered to have progressed. The common type of progression was LVDD (36.5%, table 1). In the multivariable analysis, the only clinical factor associated with progression was age (OR=1.05, CI95% 1.01-1.1, p=0.02). Neither BNP at baseline or change in BNP predicted progression. Progression was not associated with MACE events but follow-up period was limited and the number of events low.
Conclusion: These sequential Doppler-echocardiographic studies in an asymptomatic at-risk cohort show high prevalence of progression in structural and functional metrics. While no association was shown with clinical events this observation is noteworthy. This coupled with the failure to clearly define a phenotype at risk underlines the need of further studies.

Table 1. Rate of progression.

	YEAR 1-2 (n=211)	YEAR 1-3 (n=211)
LVSD prog.	0 (0%)	2 (0.9%)
LVDD prog.	49 (23.2%)	77 (36.5%)
LVD prog.	49 (23.2%)	79 (37.4%)
LAVI prog.	33 (15.6%)	63 (29.9%)
LVH prog.	9 (4.3%)	22 (10.4%)
LVD/LAVI/LVH prog.	85 (40.3%)	129 (61.1%)

Background: The diagnosis of heart failure with preserved ejection fraction (HFpEF) is challenging. The European Heart Failure Association has proposed a novel diagnostic algorithm, the HFA-PEFF score. The aim of this study is to validate the diagnostic value and establish the potential clinical impact of the HFA-PEFF score.
Purpose: The aim of this study is to validate the diagnostic value and establish the potential clinical impact of the HFA-PEFF score.
Methods and results: The HFA-PEFF score was evaluated in two independent, prospective cohorts from Europe and the U.S.A., respectively, i.e. the Maastricht cohort (228 HFpEF patients and 42 controls, diagnostic validation), and the Chicago cohort (459 HFpEF patients, application). In Maastricht, the HFA-PEFF score categorizes 4% of the total cohort with suspected HFpEF in the low-, 40% in the intermediate-, and 56% in the high-risk category. A high HFA-PEFF score (5-6 points) has proven to be a good 'rule in' for HFpEF with high specificity (93%) and a PPV of 98%. A low HFA-PEFF score (0-1) points can rule out HFpEF with a sensitivity of 99% and NPV of 73%. The diagnostic accuracy of the HFA-PEFF score is 0.89 as determined by the AUC of the ROC-curve. The distribution of the score was similar in HFpEF patients from Chicago. Risk categories were also predictive of HF hospitalization or death in both cohorts.
Conclusion: This study validates and characterizes the HFA-PEFF score in two independent, well phenotyped cohorts in Europe and the U.S.A. We demonstrate that the HFA-PEFF score has a good diagnostic value and can be helpful in clinical practice for screening and risk stratification.

Funding Acknowledgements: Netherlands Heart Foundation, Netherlands Organization for Scientific Research, European Research Council

Background: Detectable cardiac tropoinin-T (cTnT) levels in the plasma indicate ongoing myocardial damage and individuals with higher cTnT have an increased risk of developing heart failure (HF). Data is scarce on sex-specific associations of cTnT and new-onset HF in the general population.
Purpose: To evaluate sex-specific associations of cTnT with incident HF
Methods: Observational study in general population setting; included 8225 community-dwelling individuals from the PREVEND (Prevention of Renal and Vascular ENd-stage Disease) cohort. Mean age=49 years and 50% women. Measurements include baseline cTnT levels and incident HF, and its sub-types. HF cases were identified according to HF guidelines issued by the European Society of Cardiology. Cox proportional-hazards models adjusting for age, classical HF-risk

factors, EKG-assessed left ventricular hypertrophy and NT-proBNP (N-terminal pro-B-type natriuretic peptide) were employed to evaluate the predictive utility of cTnT in men and women separately.
Results: cTnT was a robust predictor of incident HF in the general population, and its predictive utility was greater in women than in men. During a mean follow-up of 12 years, 358 developed HF (36% women). cTnT doubling was associated with a greater risk of developing new-onset HF in women – Pint=0.025, HR-1.60-(1.15-2.14) vs 1.39-(1.12-1.73). Secondary analyses revealed that sex differences were stronger and only present for incident HFrEF (HF with reduced ejection fraction), Pint = 0.003; but not for incident HFpEF (HF with preserved ejection fraction), Pint = 0.988.
Conclusions: cTnT can be particularly useful in predicting new-onset HFrEF in women.

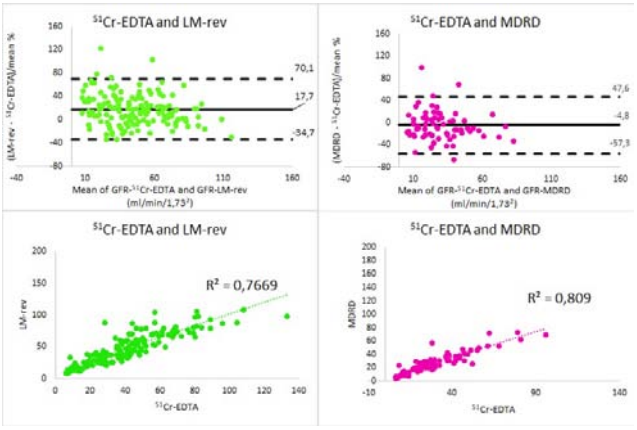
1938

Evaluation of creatinine based methods for estimating glomerular filtration rate in heart failure

A Jonsson[1]; I Viklund[2]; A Jonsson[1]; F Valham[1]; E Berghdal[1]; K Lindmark[1]; H Norberg[2]
[1]Umea University, Department of Public Health and Clinical medicine, Umea, Sweden; *[2]Umea University, Department of Pharmacology and Clinical Neuroscience, Umea, Sweden*

Funding Acknowledgements: This work was supported by the Heart Foundation of Northern Sweden.

Background: Glomerular filtration rate (GFR) is an important factor in management of heart failure. 51CrEDTA based clearance is a method for exact measure of GFR (mGFR) but these and other reference methods are not applicable in large number of patients why estimated GFR (eGFR) is preferred in clinical practice.
Purpose: To validate creatinine-based equations for renal function against 51CrEDTA based clearance in a heart failure population.
Methods: All patients within a predefined catchment area, diagnosed with heart failure, who underwent 51CrEDTA clearance between 2010 and 2018 were included. eGFR were estimated using Cockcroft-Gaults ideal and actual weight (CGIW and CGAW), The Modification of Diet in Renal Disease Study (MDRD), simplified MDRD (sMDRD), The Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI), Lund-Malmö (LM-rev), Full Age Spectrum (FAS) and the Berlin Initiative Study 1 (BIS1). Pearson's correlation and Bland-Altman plots (B&A) were performed. The accuracy were defined as the percentage of patients whose eGFR was within +30% of measured GFR.
Results: 146 patients were included (age 68 +13 years, LVEF <40 % n=53 (36 %)). Mean mGFR were 42 ml/min/1,73 m2 and mean eGFR for all equations were eGFR 30-59 ml/min/1,73m2 except for MDRD with a mean eGFR of 28 ml/min/1,73 m2 due to urea only available for patients with renal impairment. Pearson's correlation coefficient (r) had the highest precision for MDRD (r=0.9), followed by LM-rev (r=0.88) and lowest for CGAW (r=0.81). B&A showed that MDRD had lowest bias (-4,8) followed by LM-rev (17,7). CGAW (29,8) and sMDRD (31,9) had highest bias. Accuracy were under 75% for all equations except MDRD (MDRD 80%, LM-rev 68%, CGIW 63%, BIS1 59%, CKD-EPI 58%, FAS 55%, CGAw 46%, sMDRD 46%).
Conclusions: LM-rev showed the lowest bias and highest precision and accuracy in estimating GFR in our population of patients with chronic heart failure. In patients with renal impairment and heart failure, MDRD was the most accurate method. The most common method, Cockroft-Gault, had the weakest correlation and overestimates renal function the most.



Bland-Altman and Pearson's correlation

Soluble suppression of tumorigenicity-2 in cardiac amyloidosis, hypertrophic and dilated cardiomyopathy

V Castiglione[1]; N Ghionzoli[2]; A Aimo[1]; L Teresi[1]; C Prontera[2]; S Masotti[2]; C Grigoratos[2]; D Genovesi[2]; A Barison[2]; G Todiere[2]; GD Aquaro[2]; C Passino[1]; M Emdin[1]; G Vergaro[2]
[1]Sant'Anna School of Advanced Studies, Institute of Life Sciences, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*

Background: Soluble suppression of tumorigenicity-2 (sST2) is a cardiac biomarker related to inflammation and myocardial tissue remodeling. Although these processes are critically involved in both cardiac amyloidosis and cardiomyopathies, sST2 levels have never been specifically evaluated in these settings.
Purpose: We aimed to assess circulating levels of sST2 in patients with cardiac amyloidosis, hypertrophic cardiomyopathy (HCM) and dilated cardiomyopathy (DCM), as well as their clinical and biohumoral correlates.
Methods: We analysed 339 patients with an established diagnosis of cardiac amyloidosis (n=86, 25%), HCM (n=110, 32%) or DCM (n=144, 43%), undergoing a characterization including sST2, N-terminal fraction of pro-B-type natriuretic peptide (NT-proBNP), and high-sensitivity cardiac troponin T (hs-cTnT).
Results: Median sST2 was higher in cardiac amyloidosis (28 [interquartile interval 19-38] ng/mL) than either HCM (13 [10-19] ng/mL) or DCM (17 [13-22] ng/mL) (p<0.001 for both comparisons). Similar results were found for NT-proBNP and hs-cTnT (Figure). Differences in sST2 between cardiomyopathies were not influenced by gender (p for interaction=0.192), age (p=0.517), glomerular filtration rate (p=0.375) or clinical setting (in- vs. out-patient) (p=0.673). When considering all available patient characteristics at multivariate linear regression analysis, gamma-glutamyl transferase (GGT) (β=0.431 [95% confidence interval - CI 0.127-0.422], p<0.001) emerged as the sole independent predictor of elevated sST2 levels in cardiac amyloidosis. Similarly, in the DCM group, GGT (β=0.206 [95% CI 0.005-0.073], p=0.024) and free triiodothyronine (β=0.193 [95% CI 0.022-0.319], p=0.025) concentrations were associated with increased sST2 levels, independently of other determinants. C-reactive protein (β=0.268 [95% CI 0.001-0.227], p=0.048) was the only independent predictor of sST2 increase in HCM.
Conclusions: Circulating levels of sST2 are higher in cardiac amyloidosis compared to other cardiomyopathies independently from age, gender and renal function. Higher sST2 levels may reflect systemic inflammation and multi-organ involvement.

Fulminant eosinophilic myocarditis: a rare initial presentation of churg-strauss syndrome

P Pedro Lopes[1]; B Rocha[1]; G Cunha[1]; S Ranchordas[1]; C Albuquerque[1]; A Ferreira[1]; J Ferreira[1]; C Aguiar[1]; M Trabulo[1]; S Ramos[1]; JP Neves[1]; M Mendes[1]
[1]*Hospital Santa Cruz, Carnaxide, Portugal*

Case Presentation: A 22-year-old male presented to the emergency room with nausea, vomiting, anorexia and lumbar pain for 5 days. He also had chest pain prior to admission. His past history was notable for asthma and allergic rhinitis. Physical examination was unremarkable, other than a 126bpm regular tachycardia. Laboratory workup showed leukocytosis (24.0x10^9/L), marked eosinophilia (11.7x10^9/L, 48%) and elevated C-reactive protein (19.9mg/dL). Hs-Cardiac troponin T and NT-proBNP were increased, 2500ng/L and 18795pg/mL, respectively. There was inferolateral ST-segment depression on ECG and transthoracic echocardiogram revealed severe left ventricular (LV) systolic dysfunction due to global hypokinesis, a restrictive filling pattern and pericardial thickening. Chest CT revealed bilateral ground-glass lung infiltrates and paranasal CT scan showed cranial sinus opacifications.

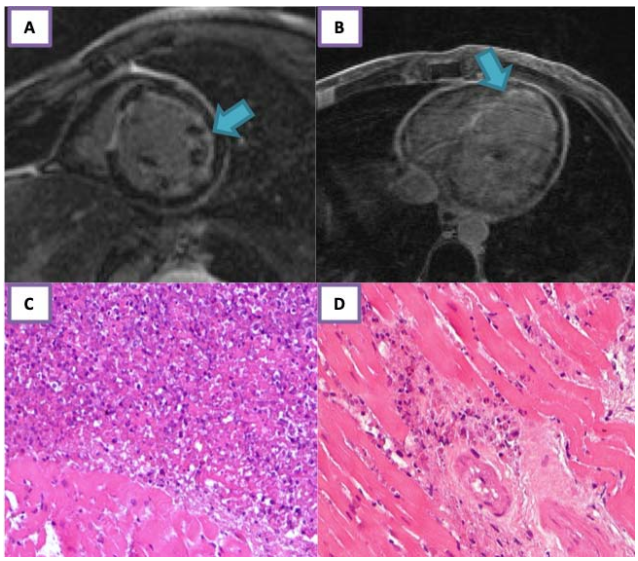

Figure 1

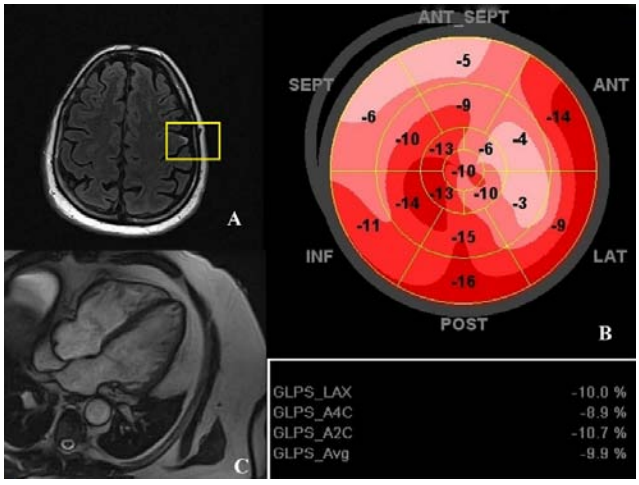
He rapidly progressed to cardiogenic shock in the following hours and was urgently transferred to a Cardiac Intensive Care Unit. Invasive ventilation, empiric antibiotics and IV inotropes were started. However, peripheral veno-arterial extracorporeal membrane oxygenation (ECMO) was required for hemodynamic support just 24h after admission. An endomyocardial biopsy was performed, revealing a necrotizing eosinophilic vasculitis and thrombosis (Figure 1 C and D). On further investigation, cardiotropic viruses, HIV, Aspergillus, Toxoplasma and parasites were negative, as were ANCA antibodies.
Eosinophilic granulomatosis with polyangiitis (EGPA, or Churg-Strauss Syndrome) was considered as the most likely diagnosis, as four out of six criteria were present: (1) asthma; (2) eosinophilia; (3) extravascular eosinophils; and (4) paranasal sinusitis. Thus, IV corticosteroids were started, with significant improvement. ECMO was discontinued after 6 days, while being weaned off of both ventilator and inotropes. Cardiac MRI showed widespread subendocardial late gadolinium enhancement (Figure 1 A and B). Coronary arteries were unremarkable on CT-Angiography. Despite optimal medical treatment, LV ejection fraction plateaued at 34% and a subcutaneous ICD was implanted. After 45 days, the patient was doing well and was discharged home on oral glucocorticoids and twice monthly IV cyclophosphamide pulse treatment.
Conclusion: EGPA is a systemic necrotizing vasculitis often associated with respiratory findings and eosinophilia. We here report a rare case of rapidly progressing vasculitis presenting with fulminant myocardial involvement.

1962

Acute ischemic stroke as the sole manifestation of reversible cardiac dysfunction in a patient with systemic lupus erithematous

AM Alexandra-Maria Chitroceanu[1]; RA Radu[2]; N Patrascu[2]; A I Nicula[2]; D Vinereanu[2]
[1]*University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*;
[2]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*

Introduction . Cardiac dysfunction, a rare but life threatening event in the course of systemic lupus erythematous (SLE), can be related to the inflammation due to the disease itself, even in the absence of coronary artery disease or hypertensive cardiomyopathy. With timely therapy, almost full recovery of cardiac function can be achieved.



Case report . A 46 year-old male was admitted for acute ischemic stroke. His past medical history was consistent with SLE, with biopsy confirming renal involvement 8 years before. He was on treatment with low-dose Prednisone and Azathioprine. He presented with a mild-to-moderate ischemic stroke (score NIHSS=7), mainly with language disturbance. He was treated with intravenous thrombolysis and his symptoms improved markedly in the first 24 hours. He was considered with minor stroke in the left middle cerebral artery territory on repeated head imaging. He did not complain of dyspnoea, or had any signs of acute heart failure. There were no signs of large artery disease. ECG showed no rhythm disturbances, however transthoracic echocardiography (TTE) detected markedly reduced left ventricular (LV) function (LVEF = 30%), moderately dilated LV (90 ml/m2) with global severe hypokinesia. His blood tests were positive for phospholipid antibody syndrome. Thus, his stroke was considered to be either embolic, of cardiac origin (global severe hypokinesia with reduced LVEF), or due to altered coagulation in the context of antiphospholipid antibody syndrome. A myocardial biopsy could not be performed. He was treated with Acenocumarol and conventional treatment for heart failure, without change of

his immunosuppressive treatment. At 3 months follow-up, TTE and cardiac magnetic resonance (CMR) showed an improvement in LVEF to 60%, with moderately dilated LV (89 ml/m2).
Questions, problems. LV failure in SLE may be secondary to myocardial inflammation, or to systemic complications such as hypertension or atherosclerosis. Recently, a stress-related cardiomyopathy syndrome was demonstrate to occur in SLE patients during the course of the disease. In our case, hypertension was unlikely to be the cause, since no significant LV hypertrophy was present on TTE. Due to the minor stroke with rapid improvement after thrombolysis and small ischemic lesion, stroke related stress cardiomyopathy was also unlikely. Since subclinical cardiac involvement is a common finding in SLE, the presumed diagnosis of myocarditis is based on clinical findings of LV dysfunction and imaging. Although TTE cannot diagnose myocarditis with certainty, global hypokinesis, in the absence of other known causes, is strongly suggestive. Moreover, reversible LV function detected on CMR is an argument for myocarditis.
Conclusions. Cardiac dysfunction with low LVEF is a major cause of cardioembolic stroke and extensive cardiologic work-up should be offered to all patients. Lupus myocarditis should be distinguished from stress-related cardiomyopathy syndrome in SLE patients.

1963

Influenza b-induced refractory cardiogenic shock, treated with temporary ecmo support

AH Yamac[1]
[1]*Bezmialem University, Cardiology, Istanbul, Turkey*

A 26-years-old healthy woman without a significant past medical history, presented to the Emergency Room of our center complaining of 5 days of productive cough, diffuse myalgia, and fatigue. Before, she visited several times the family doctor and was prescribed a course of antibiotics for presumed bronchitis.
The patient was found to be hypotensive (90/60 mmHg), tachycardic (115 beats/min) and there were signs of centralisation and peripheral hypoperfusion. Thus an immediate echocardiography was performed revealing a severely impaired left ventricular systolic function with an ejection fraction of 20%.
At the Coronary Care Unit dobutamin, low dose norepinephrin and empiric piperaclillin/tazobactam were started. Hemodynamics were assessed continously and blood gas samples were taken every 2 hours.
Within 8 hours of representation her condition deteriorated, paralleled by increasing lactat values, thus an emergency-ECMO (extracorporeal membrane oxygenator) was implanted.
On the next day she had to be resusciated under ECMO perfusion due to sudden asystole. After 20 minutes of CPR (cardiopulmonary resuscitation) spontaneous circulation returned. She was stabilized with concomitant dobutamin and norepinephrine. Due to renal failure intermittennt hemodialysis was performed using the venous arm of the ECMO. Hemodynamics were monitored via radial artery and Swan Ganz catheter. On day 4 she got extubated and inotropes began to be weaned with regression of the limb ischemia. She patient was awake during these procedures. Meanwhile endotracheal aspiration after CPR returned positive for influenza B by polymerase chain reaction (PCR). Blood, BAL and urine cultures were negative for bacterial growth and empiric antimicrobials were stopped on day 5 and oseltamivir was continued for a total of 7 days. Echocardiography was performed every day, revealing a left ventricular ejection fraction of 45% on day 6. On the next day ECMO was weaned succesfully up to 1 l/min. Thus we decided to withdraw the ECMO support on the same day. The patient was discharged on hospital day 25. Transthoracic echocardiography one month after discharge demonstrated normal LV systolic function with an EF of 60%, normal LV wall thickness, trace mitral regurgitation and no ventricular dilation.
In conclusion, we report this case to draw attention that influenza B, which is usually considered less pathogenic, can unexpectedly be complicated by fulminant myocarditis or cardiomyopathy leading to cardiogenic shock in young adults. Therefore, a multidisciplinary approach including early initiation of antiviral treatment and aggressive cardiac support is essential for a favorable outcome.

1964

Myocarditis in Antisynthetase Syndrome: an infrequent association

C Goena[1]; L Quintas[1]; C Gonzalez De Echevarri[2]; I Lluis[1]; R Garcia[1]; JM Goiri[2]; I Royo[3]; G Ruiz Irastorza[2]
[1]*Mendaro Hospital, Cardiology, Mendaro, Spain*; [2]*Cruces University Hospital, Autoinmune Disease Unit, Barakaldo, Spain*; [3]*Donostia University Hospital, Pneumology, Donostia, Spain*

Introduction: Antisynthetase Syndrome (AS) corresponds to an inflammatory myopathy identified by specific autoantibodies. Myocardial involvement is poorly described. Clinical Case: A previously healthy 65-year-old woman was admitted to ICU after 1 week of fever and dyspnea. Respiratory failure secondary to pulmonary interstitial involvement resolved after 3 weeks of mechanical ventilation and corticosteroids. During the descending pattern of corticosteroids was readmitted for respiratory failure. An autoimmune disorder was suspected due to corticodependence, muscular weakness and the appearance of "mechanic´s hands". Laboratory studies: anti-Jo1 and anti-Ro52 positive. The electromyogram had myopathic patterns and the muscular biopsy had an inflammatory myopathy with intense immunoexpression of HLA in all fibers. After AS diagnosis was made,She underwent treatment with prednisone, cloroquine and cyclophosphamide followed by mycophenolate mofetile. Despite pulmonary radiological improvement, during treatment follow up dyspnea worsened with an increase in Troponin, CK, CK-Mb, Aldolase and NT-proBNP levels. TTE showed non dilated cardiac chambers with LVEF of 45%, inferoposterior wall hypokinesia and moderate MR. Patchy edema and delayed enhancement was evidenced in the cardiac MRI. Despite immunosuppressive therapy and heart failure supportive treatment with ACEi, B-blockers, MRA and loop diuretics the evolution was poor. Serum markers of myocardial damage went down but she had a NYHA III with non sustained polymorphic ventricular tachycardia and TTE showed a clear deterioration: initially it consisted of diastolic dysfunction but it progressed until 4 chamber dilatation,severe MR and severe biventricular dysfunction. Cardiac catheterization excluded coronary artery disease and revealed moderate pulmonary hypertension. Treatment was upgraded with ARNI and an ICD placement. 2 months later she was readmitted in ICU due to an arrhythmic storm (FV). She was not considered for cardiac transplantation owing to age and a mild myositis outbreak despite optimal inmunosupressive treatment and the residual pulmonary damage. Discussion: Understanding the pathophysiologic mechanisms would help with treatment, however, remains speculative. AS antibodies are likely to be associated with muscle and lung inflammation. The effect of antibodies on the heart is unclear. There are no guidelines to aid in the diagnosis of cardiac manifestations. After screening laboratory tests, TTE and especially cardiac MRI are the most useful tools for the diagnosis of myocarditis as the biopsy findings do not alter disease management. Progressive heart failure may result in cardiac complications, such as fatal arrhythmias, despite improvement in skeletal muscle and pulmonary affection.
Conclusions: In the context of AS, the myocarditis diagnosis is important to make as the outcome can be severe. Heart involvement may be a cause of death specially in anti-Ro and anti-Jo positive forms.

1965

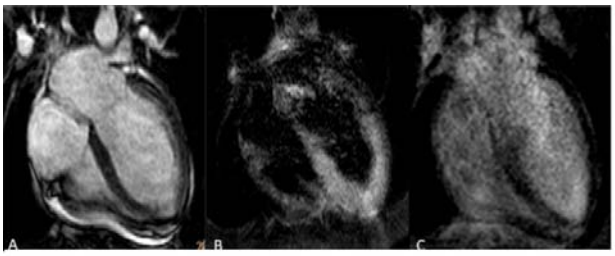
Acute heart failure in young male with body dysmorphic disorder: heroin induced myocarditis.

VE Victor Eduardo Vallejo Garcia[1]; G Barreira De Sousa[1]; S Merchan Gomez[1]; I Toranzo Nieto[1]
[1]*Hospital ClÇðnico Universitario, Cardiology Department, Salamanca, Spain*

Funding Acknowledgements: No financial support was necessary for the completion of this clinical case.

A 23-year-old male, with past medical history of depression, body dysmorphic disorder and usage of illicit drugs, was admitted to the Emergency Department for decreased level of consciousness.
He was comatose, had mild fever and severe respiratory acidosis that required intubation and mechanical ventilation. A gastric pump lavage and activated carbon were administered due to the suspicion of drug overdose. A complete work up was done including normal brain computed tomography, normal lumbar puncture, negative C-reactive protein (CRP) and serology for neurotrophic virus. Blood work results showed markedly elevated high sensitivity troponin T (1082 pg/mL) and NT-proBNP (4194 pg/mL). EKG was unremarkable, with sinus tachycardia and no repolarization abnormalities. A transthoracic echocardiogram (TTE) showed left ventricle (LV) dilation with severely impaired LV ejection fraction (EF) 20%.
The patient's evolution was unfavorable, with progressive cardiogenic shock that required vasoactive support. He was referred to our center to assess mechanical circulatory support. On arrival we repeated complete work up with similar results. Urinary toxic panel was positive for opioids and benzodiazepines. Cardiac MRI (CMRI) and coronary angiography revealed a dilated LV (indexed LV diastolic volume (iLVDV) 144 ml/m2), severely impaired LV EF 25%, global hypokinesis, edema in mid and apical segments, no late gadolinium enhancement and normal coronary arteries. Right heart catheterization revealed pulmonary pressures 30/18/22 and PCWP 18. An endomyocardial biopsy (EB) was executed in the same procedure. Differential diagnoses at this point included myocarditis, illicit drug use or stress-induced cardiomyopathy.
Heart failure (HF) treatment was initiated with a satisfactory evolution, that allowed suspension of vasoactive support and extubation the following days. The Psychiatry department was consulted for symptoms of acute drug withdrawal, and antipsychotic treatment was reinitiated. The patient confessed heroin consumption the night before admission.
Prior to discharge, when HF treatment was optimized, he underwent a new CMRI that showed a normal LV (105 ml/m2 iLVDV) and almost complete normalization of LV

EF (54%). The EB revealed non-specific myocarditis, focal neutrophil infiltrates and negative viral CRP for common viral causes of myocarditis. He was discharged with no HF symptoms, and is currently being treated for substance abuse and previous psychiatric conditions.
In conclusion, drug induced myocarditis is a rare but increasingly recognized cause of HF, with a potentially fulminant course. The underlying mechanisms of heroin toxicity are still unclear. Cardiac dysfunction is generally reversible once consumption has ceased but early initiation of treatment is essential. A holistic and multidisciplinary approach is necessary in order to improve prognosis and avoid new episodes of potentially fatal drug induced cardiovascular toxicity.



A. SSFP Cine sequence showing dilated LV with akinesia of mid and apical segments.
B. T2-STIR sequence showing edema in mid-apical septal and lateral segments.
C. Late gadolinium enhancement sequence that reveals absence of fibrosis or necrosis.

Intra-cardiac aspergilloma in a normally structured heart: a case report

S Soheila Salari[1]
[1]*Shiraz University of Medical Sciences, Kowsar Hospital , cardiology department, Shiraz, Iran (Islamic Republic of)*

Fungal endocarditis is a relatively rare condition which mostly complicates those with intra- cardiac devices whose immune system is compromised. Survival largely depends on timely diagnosis and management which is not frequently achieved.
This case is a 63-year-old diabetic man with two-weeks history of weakness and fatigue. He's undergone coronary artery bypass surgery one year before and had dental procedure (root canal and filling of one tooth) 45 days prior to his current presentation. He was afebrile with relatively stable hemodynamics and a II/VI systolic ejection murmur at left sternal border on auscultation. Transthoracic echocardiography (TTE) showed a mobile mass in left ventricular outflow tract (LVOT) which passed across the aortic valve (AV) in a to and fro movement. Cardiac magnetic resonance (CMR) further confirmed the presence of an 18x20x18 mm mass with suggestive morphologic signs for fungal infection. Amphotericin B was administered at the same day after which distal embolization of the mass to distal abdominal aorta ensued shortly. TTE documented the disappearance of the mass from LVOT and AV. After removed the mass from abdominal aorta and the patient had become unstable and signs of septic shock occurred which ultimately led to his death in 48 hours. The pathology revealed aspergilloma then after.
In such cases CMR can be a very useful tool in rapid diagnosis of any cardiac mass where TTE hardly differentiates thrombus and especially cystic tumors.

1967

Exudative-constrictive pericarditis in association with arthritis: toracoscopic biopsy as the only way to diagnosis and treatment

O V Olga Blagova[1]; IN Alijeva[1]; AV Nedostup[1]; PV Sencichin[1]; EA Kogan[1]; VD Parshin[1]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*

Purpose: to present the problems and modern possibilities of nosological verification of diagnosis and treatment in a patient with resistant exudative-constrictive pericarditis.
Methods: the male patient 31 y. was admitted to the clinic due to exudative pericarditis and arthritis of the left knee joint. His medical history included the association of a disease debut with a respiratory infection, periodic febrile fever with a cough, episodes of syncope and atrial fibrillation, treatment with antibiotics and corticosteroids with a temporary effect. A clinical examination was carried out: blood tests for the genome of cardiotropic viruses and anti-heart antibodies, ENA profile, ANCA, antibodies to DNA, cardiolipin, antinuclear antibodies, rheumatoid factor, thyroid stimulating hormone, EchoCG, chest X-ray and CT, investigations of the sputum (incl. acid-fast mycobacteria by the luminescent microscopy and PCR), skin test with tuberculin antigen, ultrasound examination of the knee, puncture of the pericardium and knee joint with general, bacteriological, virological examination of the fluid and a complex of studies on tuberculosis, thoracoscopic biopsy of the intrathoracic lymph nodes and lung.
Results. No data were received for systemic disease, hypothyroidism, tumor. With CT in both lungs, small areas of fibrosis were identified, a few dense foci up to 5 mm in size, more pronounced on the right; there is no fluid in the pleural cavities, and lymphadenopathy has been identified. Pericardial sheets diffusely thickened. When sputum was sown, the growth of nonspecific microflora was obtained. In EchoCG, LV EDD was 4.0 cm, EF 47%, in the pericardial cavity to 1 liter of fluid with fibrin. Elevated titers of anti-heart antibodies did not allow excluding myocarditis. With puncture, a serous fluid, poor in cells, is obtained, all tests for viruses and tuberculosis are negative. With puncture of the knee joint, exudate was obtained, the ultrasonic picture did not fully correspond to inflammatory arthropathy. To verify the nature of lymphadenopathy (lymphoma? sarcoidosis? tuberculosis?), thoracoscopy was performed. Pleural tubercle was found, a pleural biopsy, a right lung and lymph nodes were performed. Morphological examination showed tuberculosis granulomas with caseous necrosis. When sputum was sown again, the growth of mycobacteria of tuberculosis was obtained. Therapy included pyrazinamide, ethambutol, levofloxacin, prednisolone 20 mg / day. Ponce's disease regressed. Due to the increase of constriction, subtotal pericardectomy with a full clinical effect was performed.
Conclusion. Tuberculosis is one of the real causes of pericarditis with massive effusion and an outcome in constriction in the Moscow therapeutic clinic. The negative results of all laboratory tests for tuberculosis and the absence of an active pulmonary process do not exclude the diagnosis. It is necessary to use invasive morphological diagnosis, including thoracoscopic biopsy.

1968

A mutant Thr95Ile ATTR cardiac amyloidosis with polyneuropathy

K Chun[1]; J Jaewon Oh[1]; K Kim[1]; SM Kang[1]
[1]*Yonsei University College of Medicine, Cardiology Division, Seoul, Korea (Republic of)*

A 72-year-old man was referred for progressive dyspnea and peripheral edema since last year. He had a history of advanced gastric cancer and subsequent radical subtotal gastrectomy with adjuvant chemotherapy (Tegafur/Gemeracil/Oteracil) two years ago. There was no family history of cardiovascular disease. A chest X-ray showed cardiomegaly, and an electrocardiogram showed sinus bradycardia with low QRS voltage in limb leads and left axis deviation. An echocardiogram showed thickened biventricular walls with granular sparkling appearance and biatrial enlargement. Global left ventricular (LV) systolic function was reduced to ejection fraction (EF) 43%, and in diastole, LV showed restrictive filling pattern. Cardiac magnetic resonance (CMR) imaging showed diffuse transmural delayed gadolinium enhancement of LV. A cardiac biopsy revealed deposition of amorphous material in interstitium. However, immunofixation of serum and urine proteins demonstrated no abnormal finding, while Technetium-99m Pyrophosphate (PYP) scan was suggestive of TTR-related amyloidosis (ATTR) with intensely diffuse PYP uptake in myocardium of LV. DNA sequencing of the exon 3 in TTR gene revealed Thr95Ile (c.284C>T) mutation, which is reported as the second case in the world. His LVEF was progressively decreased to 32% in spite of optimal medical treatment for heart failure. He underwent implantable cardioverter-defibrillator implantation for primary prevention. He also suffered from paresthesia in both legs, which was diagnosed as sensori-motor polyneuropathy. Therefore, he is scheduled to be treated with tafamidis, proven to be an effective therapy for ATTR cardiomyopathy and peripheral neuropathy.

1969

Direct confirmation of suspected hereditary ATTR by genetic sequencing

A Alexander Valerievitch Nossikoff[1]; N Koleva[1]; G Lazarova[1]; B Slavchev[1]; T Donova[1]
[1]*University Hospital "Lozenets", Cardiology, Sofia, Bulgaria*

Clinical presentation. 68-year old female was admitted to our institution for diagnostic and therapeutic management. Her only comorbidity was hypertension. She has been complaining of exertional shortness of breath for over 1 year, which has gradually worsened. At the time of admission she was fatigued and short of breath at minimal exertion. On physical examination there was S4-galop and reduced air entry in the left lung base. There was moderate pitting oedema in both lower limbs below the knees. Peripheral pulses were normal. There was no particular family of heart disease. Her daughter had known CKD for which she was followed up.
Clinical investigations and diagnostic process. EKG revealed NSR, low peripheral voltage and and QS in V1-V3. Transthoracic echo revealed biatrial dilation, LVH of 16mm and marked RVH of 9mm. There was a rim of pericardial effusion and small left pleural effusion. GLS was reduced to -12.4% with notable apical sparing and

LV EF was 52.3%(Picture 1). Transmitral PW doppler was pseudonormal, e' was < 5cm/sec. Her labs were normal with no evidence of renal failure or proteinuria. The constellation described above is typical for amyloidosis with cardiac involvement. On direct questioning the patient admitted weight loss of 5kg in the last year, feeling of early satiety and paresthesias in hands and feet for the last 3-4 years. Focussed clinical examination revealed symptoms consistent with bilateral carpal tunnel and reduced sensation in both feet. We referred the patient for genetic sequencing, which confirmed Ser77Phe pathological mutation in the TTR gene. Presence of pathological mutation in symptomatic patients with clinically suspected cardiac amyloid confirms the diagnosis of hereditary ATTR. She was referred to neurology and started on tafamidis treatment for the polyneuropathy as only this indication is reimbursed in our country. Cascade screening was done and her daughter was not carrying the mutation.

Conclusions. Bulgaria is an endemic region for hereditary ATTR. Our cases can be characterised with late onset (frequently in their 60s) and mixed phenotypes (both cardiac and neurological involvement). Peripheral tissue biopsies are rarely positive in hereditary ATTR and CMR cannot distinguish between amyloid types. 99Tc-DPD tracer is not available in our nuclear centers. The slow progression of the disease maked AL-amyloid very unlikely in this particular case. Therefore, we decided to proceed directly to genetic sequencing without performing further tests as the pre-test probability of hereditary ATTR was very high. If genetic testing was negative we would have focussed on exlcuding AL-amyloid by immunofixation electrophoresis and attempting to confirm amyloid deposition by biopsy. In conclusion, local resources do vary and our approach of direct referal for genetic sequencing seems reasonable and effective in cases with high pre-test probability of hereditary ATTR considering the local circumstances.

1970

Rapidly progressive heart failure symptoms in a patient with amyloid cardiomyopathy caused by rare Glu89Lys TTR mutation

M Monika Gawor[1]; M Franaszczyk[2]; P Michalek[3]; M Marczak[4]; J Wnuk[5]; J Grzybowski[1]

[1]Institute of Cardiology, Department of Cardiomyopathies, Warsaw, Poland; *[2]Institute of Cardiology, Department of Medical Biology, Warsaw, Poland*; *[3]Institute of Cardiology, Emergency Room Rapid Diagnosis Department, Warsaw, Poland*; *[4]Institute of Cardiology, CMR Unit, Warsaw, Poland*; *[5]Institute of Cardiology, Department of Nuclear Medicine, Warsaw, Poland*

Transthyretin (TTR) amyloidosis is a systemic disorder caused by mutations in the TTR gene or by the deposition of wild-type TTR protein. The prevalence of different mutations varies according to ethnicity and geographic region. Here we describe the case of patient with TTR amyloidosis caused by a rare Glu89Lys TTR mutation.

A 57-year-old male was referred to our institution for further evaluation because of 3 months history of progressive exertional dyspnoea (NYHA class III at initial presentation) and massive lower-limbs edema. He also suffered from periorbital purpura, weight loss and paresthesias. His family history was unremarkable.

Physical examination revealed bilateral crackles, liver enlargement, and jugular veins distension.

The standard 12-lead ECG demonstrated occult atrial fibrillation of unknown duration, pseudo-infarct pattern, non-specific ST segment and T-wave abnormalities (Fig. 1A). The chest X-ray showed pulmonary congestion and small left sided pleural effusion (Fig. 1B). The baseline level of high-sensitivity cardiac troponin T was 50,4 (normal range 0-14) ng/L and N-terminal pro B-type natriuretic peptide (NT-proBNP) was 2122 (normal range 0-125) pg/mL.

Transthoracic echocardiography (TTE) revealed significant left ventricular (LV) hypertrophy, sparkling echoes, restrictive LV filling pattern and decreased LV ejection fraction (EF 45%). Right ventricle was enlarged with increased wall thickness. Both atria were enlarged and small pericardial effusion was present (Fig. 1C-D).

Cardiac magnetic resonance (CMR) scan confirmed the presence of LV hypertrophy with a maximal wall thickness of 23 mm at interventricular septum. LV systolic function was decreased with EF 42%. The right ventricular function was significantly impaired. Moreover, diffuse subendocardial areas of late gadolinium enhancement were found. Results of CMR suggested cardiac amyloidosis (Fig. 1E-F).

Labial salivary gland as well as gastric biopsy reveled TTR-related amyloid deposits. Bone scintigraphy with DPD tracer confirmed TTR amyloid cardiomyopathy (Fig. 1G). Genetic analysis demonstrated Glu89Lys mutation in the TTR gene. Neurological examination revealed mild symptoms of polyneuropathy. Haematological examination excluded light chain amyloidosis.

Two months after initial presentation patient was stable but with further incease in NT-proBNP and hs-cTnT levels (3513 pg/mL and 68 ng/L respectively). He was referred to the treatment with tafamidis as a bridge to combined heart-liver transplantation.

In conclusion, we present a case of rapidly progressive heart failure in a patient with TTR amyloid cardiomyopathy. Glu89Lys TTR mutation was described previously only in four families and is characterized by early onset and severe phenotype with unusually early heart dysfunction leading to heart and liver transplantation. Our case underlines the diagnostic challange of TTR amyloidosis and the importance of TTR mutation screening for prognostic purposes.

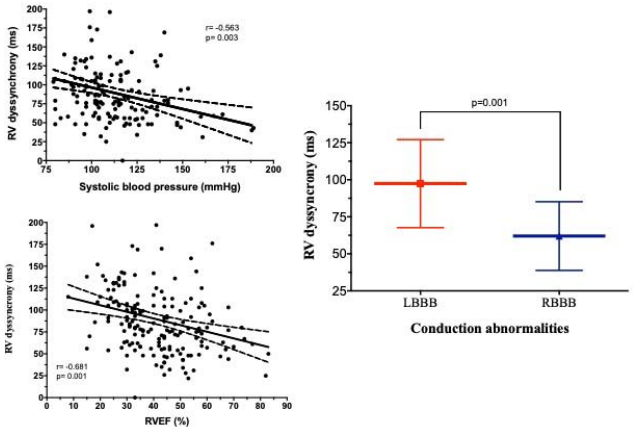
Introduction: Ventricular dyssynchrony compromises myocardial mechanical efficiency. While mechanisms of left ventricular (LV) dyssynchrony are well understood, little is known about the right heart dyssynchrony patterns.Methods:We examined 214 patients with advanced compensated HF (age 56.8±10.5 years, LVEF 29.5±18.0%, 80% males, body mass index 28.9±5.2 kg/m2). Patients underwent right heart catheterisation with thermodilution, followed by a nuclear study. 30 minutes after injection of stannous pyrophosphate (Technestan PYP), erythrocytes were in-vivo labelled by intravenous injection of 740 MBq 99mTc isotope (radiation dose 5-6 mSv). The heart chambers were imaged using D-SPECT camera (Spectrum Dynamics, Israel) with Cadmium-Zinc-Telluride detector. Time-averaged ECG-gated acquisitions were performed. 3D chambers reconstruction was performed using semiautomatic plug-in software (QBS Cedars-Sinai, USA). Right ventricle (RV) was segmented with a pole in the free wall. Interventricular septum was segmented with LV. Standard deviation of peak regional displacements over averaged cardiac cycle (PSD) was used to calculate dyssynchrony and was expressed in milliseconds (ms).



Figure

Results: In the overall population RV end-diastolic volume (EDV) was 260±89 ml and RV ejection fraction (EF) was 41±14%. Peak mechanical contraction occurred at 325±80ms in the LV and at 329±69 ms in the RV (p=0.44). On average, RV and LV had similar degrees of global dyssynchrony (PSD: 89.4±56.3 ms vs 88.9±39.1 ms, p=0.90), but RV differed from LV in the determinants of dyssynchrony. RV dyssynchrony (RV-PSD) increased with the severity of RV dilatation (r=0.065; p=0.05) and dysfunction (r= -0.681; p=0.001). QRS widening had larger effect on LV than on RV dyssynchrony (LV: r=0.13, p=0.001; RV: r=0.02, p=0.71). Left bundle branch block (LBBB) induced more dyssynchrony than right bundle branch block (RBBB) in the RV (LBBB 97.4±29.7 ms vs RBBB 62.0±23.2 ms, p=0.001). RV-PSD inversely correlated with age (r= -1.271; p<0.001) and BMI (r= -1.774; p=0.002), and directly with LV-EDV (r= 0.056; p=0.004) and LVEF (r= -0.507; p=0.002). No correlation was found between RV-PSD and LV-PSD (p=0.382). Regional LV dyssynchrony did not correlate with RV free wall dyssynchrony, with the only exception of the LV inferior wall (p=0.015). RV afterload was not related to RV dyssynchrony. Opposite, transeptal pressure difference (SBP-PAPsystolic) strongly correlated with RV but not with LV dyssynchrony, and this relation was driven by a strong negative correlation between RV-PSD (and RVEF) and systemic blood pressure (r= -0.563; p=0.003).
Conclusions: QRS duration has no significant influence on RV dyssynchrony, that was more pronounced in dilated and dysfunctional RVs. Systemic blood pressure strongly correlates with RV dyssynchrony, indicating the effect of RV-LV systolic interdependence on RV synchrony. Further studies are needed to understand the role of RV synchrony restoration in HF.

1972

Early stages of heart failure in obese patients are associated with natriuretic peptide deficiency and lack of overall neurohormonal activation

F S Gaborit[1]; C Kistorp[2]; T Kumler[1]; C Hassager[3]; N Toender[4]; K Iversen[1]; P Kamstrup[5]; J Faber[6]; L Kober[1]; M Schou[1]

Funding Acknowledgements: Supported by Ministry of Health of the Czech Republic, grant nr. NV18-02-00080.

Background: Obesity is a risk factor for heart failure (HF) with preserved and reduced ejection fraction and it is associated with hemodynamic changes (e.g. increased blood volume) and structural changes in the heart (e.g. hypertrophy and diastolic function). Furthermore, plasma concentrations of amino-terminal pro-B-type natriuretic peptide (NT-proBNP) and mid-regional pro-atrial natriuretic peptide (MR-proANP) are lower in obese patients, but the associations between obesity and neurohormonal activation estimated by midregional-pro-adrenomedullin (MR-proADM) and copeptin in patients with HF is not elucidated.
Purpose: To evaluate the associations between the natriuretic peptide activity (NT-proBNP and MR-proANP), and the neurohormonal response (MR-proADM and copeptin) in non-obese and obese outpatients with and without HF.
Methods: This prospective cohort-study included 392 outpatients without known or suspected HF, ≥60 years, and ≥1 risk-factors for HF (diabetes, chronic kidney disease, cardiovascular disease, atrial fibrillation, hypertension). Patients were categorized as 'non-obese' BMI=18.5-29.9kg/m2 (n=273) or 'obese' BMI≥30kg/m2 (n=119). Physical examination was performed, patients fulfilled the Minnesota Living with HF questionnaire, cardiac biomarkers were analyzed, and echocardiography was performed. Unrecognized HF was diagnosed according to the European Society of Cardiology guidelines, requiring the three following: patient-reported symptoms of HF, clinical signs of HF, and structural or functional changes by echocardiography.
Results: The obese patients were younger, with a higher prevalence of diabetes and chronic kidney disease, but a lower prevalence of atrial fibrillation. A total of 39 (14.3%) non-obese and 26 (21.8%) obese patients were diagnosed with HF. In the obese patients, HF was not associated with higher plasma concentrations of NT-proBNP (P=0.064), MR-proANP (P=0.187), MR-proADM (P=0.168), or copeptin (P=0.669), figure 1A-D. In contrast, plasma concentrations of NT-proBNP (P<0.001), MR-proANP (P<0.001), MR-proADM (P<0.001) and Copeptin (P=0.054) were all higher in patients with HF among the non-obese patients, figure 1A-D. Additionally, obese patients with HF had lower plasma concentrations of NT-proBNP (P=0.012), and MR-proANP (P=0.007) compared to non-obese patients with HF, but plasma concentrations of MR-proADM (P=0.484) and copeptin (P=0.578) were not affected, figure 1A-D.

Conclusions: Patients with HF and obesity have a natriuretic peptide deficiency and a lack of increased plasma concentrations of MR-proADM and copeptin, suggesting that obese patients have a blunted overall neurohormonal response to HF.

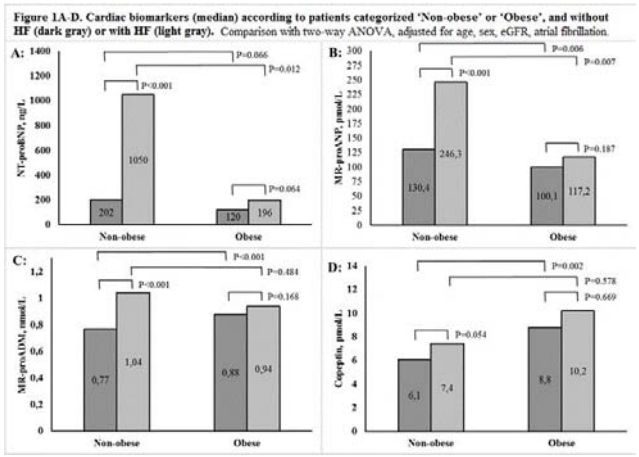

Figure 1A-D.

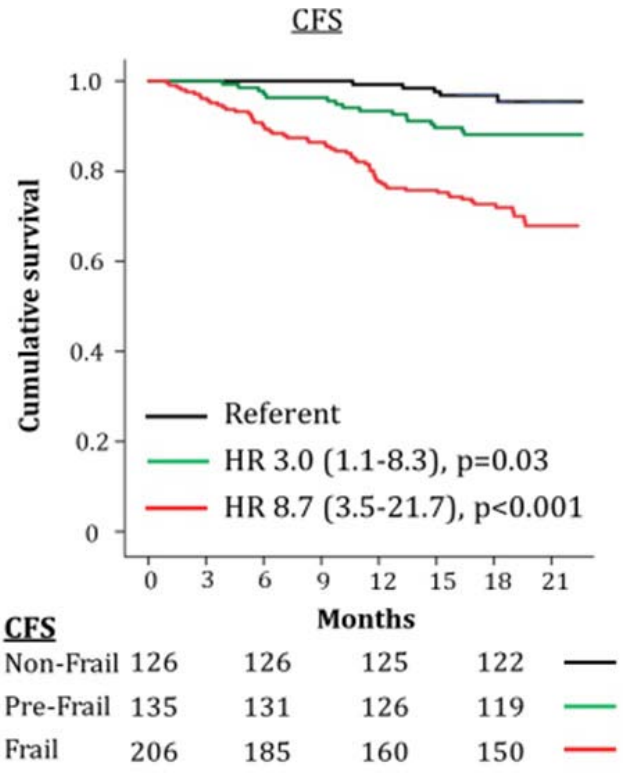
1973

Frailty evaluation in patients with chronic heart failure - A comparison of screening vs assessment tools

S Sze[1]; P Pellicori[2]; J Zhang[3]; J Weston[4]; AL Clark[4]
[1]Cardiovascular Research Unit of Leicester, Leicester, United Kingdom of Great Britain & Northern Ireland; *[2]University of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland*; *[3]Anglia Ruskin University, Cambridge, United Kingdom of Great Britain & Northern Ireland*; *[4]Castle Hill Hospital, Cottingham, United Kingdom of Great Britain & Northern Ireland*

Funding Acknowledgements: Supported by Ministry of Health of the Czech Republic, grant nr. NV18-02-00080.

Background: Frailty is common in patients with chronic heart failure (CHF) and is associated with adverse outcome. Many frailty tools are available, however, there is no consensus as to how to best evaluate frailty in patients with CHF.
Purpose: To report the prevalence of frailty, agreement and prognostic significance amongst 3 frailty assessment tools and 3 screening tools in CHF patients.
Methods: We comprehensively studied frailty using 6 frailty tools. Frailty screening tools include: Clinical frailty scale (CFS); Derby frailty index & Acute frailty network frailty criteria. Frailty assessment tools include: Fried criteria; Edmonton frailty score & Deficit index. Since there is no gold standard in evaluating frailty in CHF patients, for each of the frailty tools, we used the results of the other 5 tools to produce a combined frailty index which we used as a "standard" frailty tool. Subjects were defined as frail if so identified by at least 3 out of 5 tools.
Results: We studied 467 consecutive ambulatory CHF patients (67% male, median age 76 (IQR:69-82) years, median NTproBNP 1156 (IQR:469-2463) ng/L) and 87 controls (79% male, median age 73 (IQR:69-77years).
Prevalence of frailty was much higher in CHF patients than in controls (30-52% vs 2-15%, respectively). Amongst the assessment tools, Fried criteria scored the greatest proportion of CHF patients as frail (52%) while EFS scored the lowest proportion as frail (30%). Amongst the frailty screening tools, DFI scored the greatest proportion of CHF patients as frail (48%) while CFS scored the lowest proportion as frail (44%). Frail patients were older, have worse symptoms, higher NTproBNP and more co-morbidities compared to non-frail patients.
Of the screening tools, CFS had the strongest agreement with assessment tools (kappa coefficient:0.65-0.72, all p<0.001). CFS had the highest sensitivity (87%) and specificity (89%) amongst screening tools and the lowest misclassification rate (12%) amongst all 6 frailty tools in identifying frailty according to the combined frailty index.
During a median follow-up of 559 days (IQR 512-629 days), 82(18%) patients died. 55% (N=45) of frail patients died of non-cardiovascular causes. Worsening frailty was associated with worse outcome. Amongst frailty tools: CFS and Fried criteria increased model performance for mortality prediction most compared with base model (c-statistics:0.78 to 0.80 for both). Patients who were frail according to CFS had a 9 times greater mortality risk than non-frail patients (Figure).
Conclusion: Frailty is common in CHF patients and is associated with worse outcome. CFS is a simple screening tool which identifies a similar group as lengthy assessment tools and has similar prognostic significance.



Figure

1974

Evaluation of malnutrition using 6 screening tools in patients with chronic heart failure.

S Sze[1]; P Pellicori[2]; J Zhang[3]; J Weston[4]; AL Clark[4]
[1]Cardiovascular Research Unit of Leicester, Leicester, United Kingdom of Great Britain & Northern Ireland; *[2]University of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland*; *[3]Anglia Ruskin University, Cambridge, United Kingdom of Great Britain & Northern Ireland*; *[4]Castle Hill Hospital, Cottingham, United Kingdom of Great Britain & Northern Ireland*

Introduction: Malnutrition is common in chronic heart failure (CHF) patients and is associated with adverse outcome. However, there is no standard method of evaluating malnutrition in patients with CHF.
Objectives: To report the prevalence of malnutrition and classification performance of 6 screening tools in patients with CHF.
Methods: We evaluated malnutrition using 3 simple and 3 multidimensional screening tools. Simple screening tools include: Controlling nutritional status index (CONUT), geriatric nutritional risk index (GNRI) & prognostic nutritional index (PNI). Multidimensional screening tools include: malnutrition universal screening tool (MUST), mini nutritional assessment-short form (MNA-SF) & subjective global assessment (SGA). Since there is no "gold-standard" for malnutrition evaluation, for each of the malnutrition tools, we used the results of the other 5 tools to produce a standard combined index. Subjects were 'malnourished' if so identified by ≥ 3/5 tools.
Results: We studied 467 consecutive ambulatory CHF patients (67% male, median age 76 (IQR: 69-82) years, median NTproBNP 1156 (IQR: 469-2463) ng/L) and 87 controls (79% male, median age 73 (IQR: 69-77) years). The prevalence of at least moderate malnutrition ranged between 3-9% in patients vs 0-2% in controls. Amongst the simple tools: CONUT; and amongst the multidimensional tools: MUST score classified the highest proportion of subjects as having at least moderate malnutrition. (Figure 1)
The prevalence of at least moderate malnutrition was similar in CHF patients with reduced vs normal ejection fraction and in patients with atrial fibrillation vs sinus rhythm. Malnourished patients tended to be older, have worse symptoms, higher NTproBNP and more co-morbidities.
Of the simple screening tools, GNRI had the highest, and CONUT score the lowest agreement with multidimensional screening tools in identifying at least moderate malnutrition in patients with CHF. (Kappa coefficients (K) for GNRI: 0.34-0.43; K for CONUT: 0.26-0.36, all p <0.001)

Of all 6 tools, CONUT had the highest sensitivity (80%); MNA-SF and SGA had the highest specificity (99%) and MNA-SF had the lowest misclassification rate (2%) in identifying at least moderate malnutrition in patients with CHF as defined by the combined index.
Conclusion: Malnutrition is common in CHF patients and is associated with increasing age, co-morbidities and HF severity. The prevalence of malnutrition is variable and is dependent on the tool used. The agreement amongst tools was heterogenous, suggesting that they are likely to measure different aspects of malnutrition. Further work is required to compare the prognostic value of malnutrition tools in patients with CHF.

1975
Sex-based differences in heart failure across the ejection fraction spectrum: phenotyping, prognostic and therapeutic implications

D Stolfo[1]; A Uijl[1]; O Vedin[2]; A Stromberg[3]; UL Faxen[1]; G Rosano[4]; G Sinagra[5]; U Dahlstrom[3]; G Savarese[1]
[1]Karolinska Institute, Division of Cardiology, Department of Medicine, Stockholm, Sweden; *[2]Uppsala University, Department of Medical Sciences, Uppsala, Sweden*; *[3]Linkoping University, Department of Medical and Health Sciences and Department of Cardiology, Linkoping, Sweden*; *[4]San Raffaele Pisana Hospital IRCCS, Centre for Clinical and Basic Research, Department of Medical Sciences, Rome, Italy*; *[5]University Hospital "Riuniti", Department of Cardiology, Trieste, Italy*

Background. Females are under-represented in randomized clinical trials (RCTs). Potential sex-related differences in heart failure (HF) might question the generalizability of trials.
Purpose. To assess sex-related differences in a large cohort of unselected patients with HF across the ejection fraction (EF) spectrum.
Methods. The Swedish Heart Failure Registry population was considered. Multivariable Cox regression models were fitted to investigate differences in prognosis and in prognostic predictors across sex and EF.
Results.Of 42,987 patients, 37% were females [55%, 39% and 29% with HF with preserved (HFpEF), mid-range (HFmrEF) and reduced (HFrEF) EF, respectively]. Females were older and more symptomatic, more likely to have hypertension, kidney disease and receive diuretics, but less likely to have diabetes, ischemic heart disease and receive renin-angiotensin-system inhibitors. Crude mortality/HF hospitalization was higher in females in HFpEF and HFmrEF but lower in females in HFrEF. After adjustments, the risk was lower in females in HFrEF (HR:0.81; 95%CI:0.78 to 0.85) and HFmrEF (HR:0.91; 95%CI:0.85 to 0.98), with only a trend in HFpEF (HR:0.94; 95%CI:0.88 to 1.01). Main sex-related differences in outcome predictors concerned diabetes in HFrEF and anemia and heart rate in HFmrEF.
Conclusions. Males and females with HF showed different characteristics across the EF spectrum. Males reported better crude risk of mortality/morbidity in HFpEF and HFmrEF but worse outcome in HFrEF, although, after adjustments, females reported better outcome in all the EF categories, most markedly in HFrEF. The observed sex-related differences highlight the need of an adequate representation of females in HF RCTs to improve generalizability.

1976
Right ventricular to pulmonary artery coupling and risk of recurrent admissions in heart failure with preserved ejection fraction

E Santas[1]; P Palau[2]; M Guazzi[3]; R De La Espriella[1]; M Amiguet[1]; M Soler[1]; J Gonzalez[1]; A Mollar[1]; FJ Chorro[1]; J Nunez[1]
[1]Hospital Clinic Universitari. Universitat de València, Valencia, Spain; *[2]Hospital General de Castellón. Universitat Jaume I, Castellon, Spain*; *[3]IRCCS Policlinico San Donato, San Donato Milanese. University of Milan, Milan, Italy*

Right ventricular (RV) and pulmonary hypertension (PH) are common features in heart failure with preserved ejection fraction (HFpEF). In recent years, tricuspid annular plane systolic excursion (TAPSE) to pulmonary artery systolic pressure (PASP) ratio has emerged as a non-invasive global index of RV-PA coupling. We aimed to evaluate the association between TAPSE/PASP ratio and the readmission burden in patients with HFpEF.
Methods: We prospectively included 1127 consecutive HFpEF patients discharged for acute HF. TAPSE and PASP estimation were obtained by echocardiography through the index admission. Of them, in 367 patients (32.6%) PASP could not be accurately measured, leaving the final sample size to be 760 patients. Negative binomial regression method was used to evaluate the association between TAPSE/PASP ratio and recurrent all-cause and HF-related admissions. Risk estimates were expressed as incidence ratio ratios (IRR).
Results: Mean age of the cohort was 75.6 ± 9.7 years, 68.3% were women, and 46.5% had suffered from previous HF admissions. At a median (interquartile range) follow-up of 2.0 (2.9) years, 352 (46.3%) patients died and 1214 readmissions were registered in 482 patients (63.4%), being 506 of them HF-related. There was a stepwise increase in the rates of all-cause and HF readmission by decreasing TAPSE/PASP ratio. After multivariable adjustment, TAPSE/PASP ratio <0.36 was associated with a higher risk of HF-related recurrent admissions (IRR=1.51; 95% confidence interval (CI), 1.01-2.24; p=0.04), whereas patients in the lowest quintile (TAPSE/PASP<0.28) exhibited the highest risk of both all-cause and HF-related recurrent admissions (IRR=1.40; 95% CI, 1.04-1.87; p=0.025 and IRR=1.85 ;95% CI, 1.22-2.80 ;p=0.004, respectively).
Conclusion: TAPSE/PASP ratio, as a non-invasive index of RV-PA coupling, is able to identify patients with HFpEF at a high risk of recurrent hospitalizations.

1977
Myocardial perfusion mapping in cardiac amyloidosis- Unearthing the spectrum from infiltration to ischaemia

L Liza Chacko[1]; T Kotecha[1]; A Martinez[1]; J Brown[1]; C Little[1]; D Knight[1]; A Steriotis[1]; P Hawkins[1]; J Gillmore[1]; R Rakhit[1]; T Lockie[1]; N Patel[1]; H Xue[2]; P Kellman[2]; M Fontana[1]
[1]University College Hospital, London, United Kingdom of Great Britain & Northern Ireland; *[2]National Institutes of Health, Bethesda, United States of America*

Background: Cardiac involvement is the main driver of outcome in systemic amyloidosis, but the relationship between amyloid deposits and outcomes is not well understood. The simple explanation of physical, mechanical replacement of the interstitium by amyloid material seems insufficient. Preliminary studies support the hypothesis that myocardial ischaemia could contribute to cell damage.
Purpose: To (1) To assess the presence of myocardial ischaemia in patients with cardiac amyloidosis. (2) To compare patients with cardiac amyloidosis to patients assessed on invasive coronary angiography (ICA) to have normal coronary physiology (NCP), microvascular dysfunction (MVD) and triple vessel coronary disease (3VD). (3) To assess correlation of perfusion mapping parameters to markers of disease severity and prognosis.
Methods: 86 patients and 20 healthy volunteers (HV) underwent CMR at 1.5T (Siemens) with standard cine imaging, Phase Sensitive Inversion Recovery Late Gadolinium Enhancement (PSIR-LGE), T1 mapping, T2 mapping, Extracellular Volume (ECV) mapping and adenosine stress with myocardial blood flow (MBF) mapping. Thirty-eight patients also underwent ICA with 3 vessel assessment of Index of Microcirculatory Resistance and Fractional Flow Reserve: 7 had cardiac amyloidosis, 8 had NCP, 15 had MVD and 8 had 3VD.
Results: Cardiac amyloidosis patients had severe reduction in stress myocardial blood flow (stress MBF) and myocardial perfusion reserve (MPR) – (1.22ml/g/min±0.70 and 1.62±0.63 respectively) compared to HV (3.21ml/g/min±0.64,p<0.001 and 4.17±0.78,p<0.001 respectively), NCP (2.66± 0.56, p<0.001 and 2.51±0.43, p=0.036) and MVD (2.10 ±0.31,p<0.001 and 2.29 ± 0.87,p=0.014) with the degree of reduction being similar only to patients with 3VD (1.44±0.54, p=1.000 and 1.64± 0.68, p=1.000) (Figure 1). Rest MBF was also slightly lower in amyloidosis than HV. Cardiac amyloidosis stress MBF (and MPR) inversely correlated with myocardial amyloid burden (measured as extracellular volume, r=-0.715, p<0.001); the transmurality of LGE (no LGE 2.24 ml/min/g, subendocardial LGE 1.16 ml/min/g and transmural LGE 0.81 ml/min/g, p<0.01); systolic dysfunction (EF, r=0.405, p<0.01) and blood biomarkers (NT-proBNP,

r=-0.678, p<0.001 and Troponin T, r=-0.628, p<0.001). There was a correlation between stress MBF and native T1 (r=-0.588, p<0.001) but not with T2 values (p=0.591). Stress MBF and MPR were also early disease markers, being elevated in patients with early cardiac amyloid infiltration (raised ECV, no LGE).
Conclusion: Myocardial ischaemia is common in cardiac amyloidosis – with stress MBF and MPR similar to that of patients with severe three vessel disease. The reduction correlates with the degree of amyloid infiltration and markers of adverse prognosis, highlighting the potential role of myocardial ischaemia as a key mechanism in the pathophysiology of cardiac amyloidosis

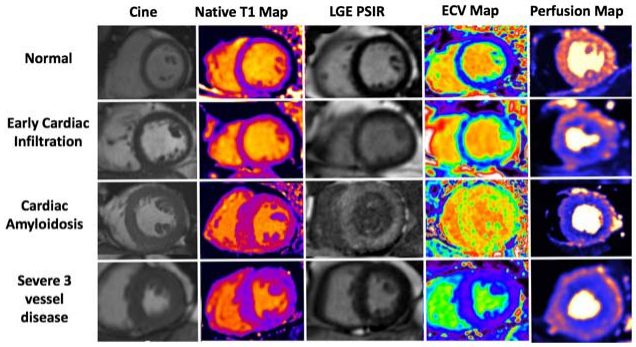

Figure 1. Short axis cine SSFP images in end-diastole, corresponding native T1 mapping, late gadolinium enhancement (LGE) images, ECV Mapping and stress myocardial blood flow mapping in a normal subject, a patient with early cardiac infiltration (raised ECV, no LGE), a patient with cardiac amyloidosis, a patient with severe three vessel coronary disease.

1978

Relationship between diastolic dysfunction and cognitive impairment in patients with CAD and HFpEF

O Nudchenko[1]; I Vivsyanik[1]; L Yakovenko[1]; C Faradzh[1]; M Dolzhenko[1]
[1]*National Medical Academy of Postgraduate Education, Cardiology, Kiev, Ukraine*

Background/Introduction: Cognitive impairment (CI) is a well-known predictor of mortality and readmissions in patients with coronary arteries disease (CAD) and heart failure (HF). Arterial hypertension and reduced left ventricle ejection fraction (LVEF) are known predictors of cognitive function worsening. On the other hand, role of diastolic dysfunction (DD) in the development of CI is less studied.
Purpose. Purpose of the study was to evaluate the relationship between DD, left ventricle filling pressure (LVFP) and CI.
Methods: For 110 patients with established CAD (prior myocardial infarction (MI), unstable angina (UA), percutaneous coronary intervention or coronary arteries bypass grafting) testing of cognitive functioning by validated scales – MMSE, MoCA, FAB – and echocardiography were performed. By results of echocardiography all patients were divided in three groups: I – normal diastolic function; II – impaired relaxation; III – pseudonormalization or restriction.
Results: The average age of patients was 60.1 ± 8.74 years. 71.8% male patients, 28.2% of women. In 64,5% of cases, there was prior MI, and in 35,5% - unstable angina. Mean LVEF in I, II and III group consisted 58,3±5,9%, 52,1±8,2% and 53,1±10,2%, respectively. There are no differences in age, diabetes mellitus prevalence, office blood pressure levels, smoking status, lipids and BNP levels between groups were noted. LVEF was significantly lower and left atrium volume index and left ventricle mass index (LVMI) were significantly higher in II and III group in comparison with I group. Mean score by MMSE scale in I group was 25,45±2,62; II – 24,95±2,69, III– 22,30±3,17. Comparison of groups showed that mean score by MMSE was significantly lower in III group (p1,3<0.00001, p2,3=0.0004). Mean score on the MoCA scale was in the first group 23.58 ± 3.47, in the second group - 22.33 ± 3.72, in the third - 20.07 ± 5.48. Significantly worse values were also noted in III group (p1,3 = 0,003, p2,3 = 0.04). There were no differences in FAB scores between groups. Negative correlation between E/e' ratio – that reflects LVFP – and MMSE, MoCA and FAB scores were noted (r=-0.50, -0,27, -0,24, respectively; p<0,05). Multivariable logistic regression analysis showed that among others (age, LVEF, indexed left atrium volume, LVmi, Hb1Ac, total cholesterol) only E/e' value (OR=1.28, 95% CI 1.11 to 1.47, P=0.0007) –was significantly associated with CI by MMSE score.
Conclusions: In HFpEF patients with grade II-III DD there are significantly lower rates of cognitive function than in patients with normal diastolic function or grade I DD. A negative correlations (r = -0.50, r=-0,27, r=-0,24) between E/e' and MMSE, MoCA and FAB points, respectively, were noted. Multivariable logistic regression analysis showed that E/e' ratio (OR=1.28, 95% CI 1.11 to 1.47, P=0.0007) was the independent predictor of CI by MMSE score.

1979

Outcome of subsequent pregnancies in women with a history of peripartum cardiomyopathy at contemporary.

S Sorel Goland[1]; L Zilberman[1]; I Fugenfirov[1]; E Vaisbuh[1]; J George[1]
[1]*Kaplan Medical Center, Rehovot, Israel*

Background: Women with subsequent pregnancies (SSPs) in patients and history of peripartum cardiomyopathy (PPCM) are at risk of heart failure (HF) recurrence.
Purpose: To describe cardiac and obstetric outcomes of SSP in post-PPCM women.
Methods: Sixty-four women with PPCM are prospectively followed in our pregnancy/heart failure clinic. We identified women with SSP and analyzed their clinical, obstetrical and echocardiographic data.
Results: Among 64 PPCM patients with PPCM treated and followed, 27 had subsequent pregnancies, 8 women had miscarriages or terminations and 19 completed their full-term pregnancy and were included in this study. The mean age was 33±7 years, the mean LV ejection fraction (LVEF) was 53.4±7.4%. Most of the women (n=15, 79%) with SSP had recovered LV function (LVEF ≥50%) prior to SSP. Four patients had reduced LVEF at the time of SSP (ranged 38-43%).
All 19 women delivered healthy babies with mean weight 2870±415 gram. Mean gestational age at delivery was 38±2 weeks. No decline in LVEF was seen during SSP in women with recovered LVEF. In four women with LVEF<50% prior to SSP transient reduction in LVEF was obtained (absolute reduction of 5 to 10% of LVEF) with recovery to the LVEF prior to SSP. All four women were on HF medical treatment. No major adverse events were observed during pregnancy and post-partum.
Conclusions: In our cohort, most of the women with a history of PPCM and SSP had recovered LV function and did not experience a relapse. Those with reduced LVEF at SSP had transient worsening of LV function without clinical complication. No cardiovascular complications were observed and obstetric and neonatal outcomes were favorable. Close follow-up and multidisciplinary management by dedicated cardio/obstetric team are essential to prevent possible complications.

1980

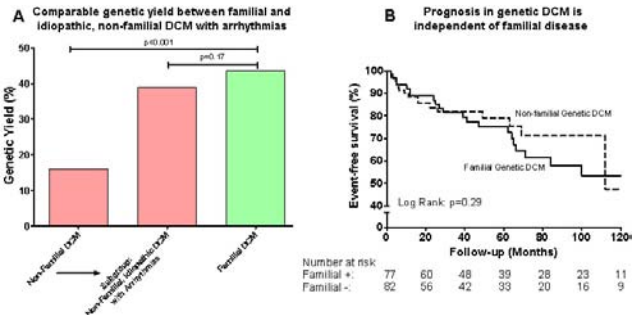
Cardiac arrhythmias at baseline predict a clinically relevant genetic yield in idiopathic non-familial DCM affecting long-term outcome

J A J Verdonschot[1]; MTHM Henkens[1]; AG Raafs[1]; P Wang[2]; JJ Merken[1]; GRF Claes[2]; EK Vanhoutte[2]; A Wijngaard Van Den[2]; IPC Krapels[2]; HG Brunner[2]; MR Hazebroek[1]; SRB Heymans[1]
[1]*Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands (The)*; [2]*Maastricht University Medical Centre (MUMC), Clinical Genetics, Maastricht, Netherlands (The)*

Background: Current guidelines recommend genetic analysis only in dilated cardiomyopathy (DCM) patients with a clear familial history. This increases the diagnostic yield of pathogenic mutations and decreases false-positive variants in non-familial DCM. Moreover, DCM patients with an acquired disease -such as chemotherapy- are not routinely genetically tested. Therefore, the genetic substrate in so-called acquired and/or non-familial DCM remains largely unknown. Which specific clinical variables or diseases could predict the need for genetic screening remain to be determined.
Purpose: To determine the genetic yield, their prediction by underlying clinical variables, and its prognostic value in a large consecutive DCM population.
Methods: This study included 689 DCM patients from the Cardiomyopathy Registry who had full genetic evaluation using a 47 cardiomyopathy-associated gene panel. All patients underwent a complete diagnostic work-up including echocardiography, cardiac MRI, endomyocardial biopsies and holter monitoring. Environmental triggers were predefined as viral, inflammatory, toxic, electrical and systemic auto-immune disease. The combined endpoint constituted of cardiac death, heart transplantation, heart failure rehospitalization or life-threatening arrhythmias with a median follow-up of 4 years.
Results: At least one etiology (genetic and/or environmental) was found in 530 patients (77%) after complete diagnostic workup, of which 159 (23%) had a genetic mutation. One in five of the DCM patients (n=90; 20%) had a combination of a genetic and acquired (environmental) trigger (Figure). All of the acquired triggers had a genetic yield around 20%, indicating no specific subgroup of environmental triggers yields a significant abundance of genetic mutations. Although familial DCM had a significant higher yield of genetic mutations compared to non-familial DCM (43% versus 16%, p<0.001), the prevalence of pathogenic mutations is still 1 in 6. In non-familial DCM patients with arrhythmias at baseline but without environmental trigger, the genetic yield was even 39%, comparable to the yield in familial DCM

(43%; p=0,17). Also, genetic DCM has a worse prognosis compared to non-genetic DCM (Log-Rank=0.008), irrespective of familial history (Log-Rank=0.29).

Conclusions: One in five DCM patients with an acquired trigger and/or absence of familial history has an underlying genetic mutation. Therefore, the finding of one cause for DCM does not exclude a genetic predisposition. Non-familial DCM patients with arrhythmias and no clear etiology have a comparable genetic yield compared to familial DCM. This provides new criteria to select DCM patients who most likely have a genetic mutation, which is important as we show that a genetic substrate has consequences for the prognosis of a patient irrespective of familial disease.



Genetic yield and prognosis of DCM

Poster Session 4

Device Therapy

P1987

Noninvasive diagnostic technique in ventricular tachyarrhythmias assessment in patients with coronary artery disease and secondary prevention indications for ICD implantation

T Atabekov[1]; R Batalov[1]; S Krivolapov[1]; M Khlynin[1]; S Sazonova[1]; A Levintas[1]; A Mishkina[1]; K Zavadovsky[1]; Y Lishmanov[1]; S Popov[1]
[1]State Research Institute of Cardiology of Tomsk, Heart Arrhythmyas Department, Tomsk, Russian Federation

Background. Sudden cardiac death (SCD) remains a serious public health problem. Certainly, coronary heart disease (CAD) is the most common cause leading to SCD. SCD in patients with CAD is caused principally ventricular tachyarrhythmias (VTA). The implantable cardioverter-defibrillator (ICD) is one of the most effective interventions for SCD prevention. However, about 25% patients did not receive an ICD therapy during the first 5-years follow-up. So, it's necessary to find out new predictors of SCD and VTA incidence, which will help to optimize the selection of patients who really need a device implantation.
Purpose. To study the diagnostic value of heart rate variability (HRV) individual parameters analysis, left ventricle ejection fraction (LVEF) assessment and cardiac 123I-methaiodobenzylguanidine (123I-MIBG) scintigraphy in the VTA prediction in patients with CAD and high risk of sudden cardiac death SCD.
Methods. 30 patients (male - 22, female - 8, average age 66,9±8,6 year) with CAD, myocardial infarction and secondary SCD prevention indications were examined. Before ICD implantation, patients underwent echocardiography, HRV individual parameters analysis and cardiac 123I-MIBG scintigraphy. All patients were treated with antiarrhythmic therapy (beta-blockers and amiodarone). All patients were divided into 2 groups according to the incidences VTA events during sixth months' follow-up. The first group consisted of patients with VTA events, second group - without VTA. Data of HRV, LVEF and cardiac 123I-MIBG scintigraphy before ICD implantation were compared.
Results. The 1-st group consisted of 19 (63,3%) patients with VTA events (male - 15, female - 4, age 66,4±9,1 years). The 2-nd group consisted of 11 (36,7%) patients without VTA events (male - 7, female - 4, age 67,7±8,1 years). There were statistically significant differences between patients with and without VTA before ICD implantation in terms of: LVEF - 50,63±9,22% vs. 64,18±7,96% (p=0,001), low frequencies domain - 719,47±437,83 ms vs. 1385,01±889,98 ms (p=0,01), total frequencies domain - 1910,63±882,04 ms vs. 2830,81±1208,61 ms (p=0,04), summed 123I-MIBG score calculation on early (31,68±17,71% vs. 7,36±2,24% (p=0,0005)) and delayed (33,05±18,08 vs. 9,36±3,93% (p=0,0003)), respectively. Conclusion. HRV assessment, as well as LVEF and cardiac sympathetic activity assessment can be used for identification of SCD highest risk group. But cardiac 123I-MIBG scintigraphy is more powerful predictor of VTA events then heart rate variability and left ventricle systolic function assessment in patients with CAD.

P1988

Effect of cardiac resynchronization therapy on right ventricle in adult with congenital heart disease

Y Yanrong Yin[1]; K Dimopoulos[1]; E Shamada[1]; K Lascelles[1]; G Samuel[1]; T Wong[1]; MA Gatzoulis[1]; SV Babu-Narayan[1]; W Li[1]
[1]Royal Brompton Hospital, London, United Kingdom of Great Britain & Northern Ireland

Background: There are published data about the effect of cardiac resynchronization therapy (CRT) on left ventricular function in adult with congenital heart diseases (ACHD)but it's effect on right ventricular (RV) function and remodeling remains insufficiently elucidated.
Purpose: To assess whether CRT is influenced by or affects RV function in ACHD.
Methods: We retrospectively studied all ACHD patients with impaired systemic left ventricle who received CRT in our ACHD centre (2006-2017). Clinical and echocardiographic data were analysed at pre-CRT, early (1.5±0.5 years) and late (4.9±0.6 years) follow-up after CRT.
Results: Forty patients with CRT (median age 48 years, range 22–73 years, 75% male) were followed for 5.6±2.7 years. The underlying anatomy was left-side obstructive lesions (n=17; 42%), right-sided lesions (n=10; 25%), shunt lesions (n=9, 23%) and double outlet right ventricle with ventricular septal defect (n=4, 10%). All patients had previous surgical repair, 21 (53%) were upgraded from RV pacing.
Right ventricular dysfunction (right ventricular fractional area change, RVFAC <35%) before CRT was observed in 26 (65%) patients. At early follow-up, patients with and without RV dysfunction exhibited a similar improvement in NYHA functional class, QRS duration, left ventricular function. The RVFAC was improved ≥5 unit in 62% of patients with RV dysfunction and in 29% of those without RV dysfunction (p=0.047). Magnitude of ΔRVFAC in patients with RV dysfunction was higher than those without RV dysfunction (6.9±6.0% vs. 2.0±6.3%, p=0.020) .
CRT was associated with significant improvement in RV diameters, RVFAC, tricuspid annular plane systolic excursion and tissue Doppler-derived tricuspid lateral annular systolic velocity (S') at early follow-up, but only improvement in S' was sustained at late follow-up (p <0.05).
Eight patients died and 2 had heart transplantation. On univariate Cox regression analysis, RVFAC was independently associated with transplantation and death from all causes. At early follow-up, normalization of RV function was observed in 11 patients (28%) with RV dysfunction at baseline, which invoked favorable clinical outcome. (p=0.034).
Conclusion: Cardiac resynchronization therapy results in RV reverse remodeling, improves RV function and clinic outcomes in ACHD patients with impaired systemic LV. RVFAC was a determinant factor for survival. Improvement in RV function at early follow-up was associated with better outcome.

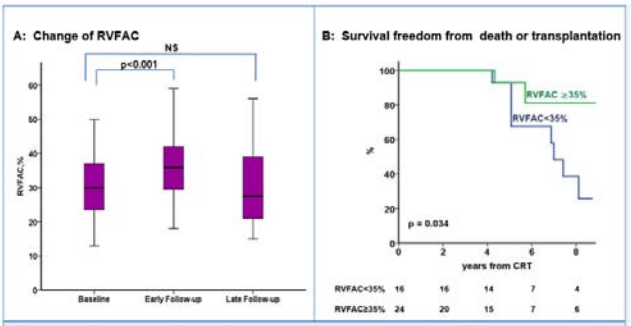


Figure 1 A : There was a significant early but not late improvement in RVFAC. **B:** Kaplan-Meier plots of patients stratified by RVFAC, demonstrating that RVFAC ≥35% at early follow-up was associated with better clinical outcome with respect to freedom from death or heart transplantation. RVFAC = right ventricular fractional area change.

Effect of CRT on RV in ACHD

P1989

ECG predictors of outcome in non-left bundle branch block cardiac resynchronization therapy patients

A M W Antonius Martinus Wilhelmus Van Stipdonk[1]; M Dural[2]; FCWM Salden[1]; I A H Ter Horst[3]; H J G Crijns[3]; F W Prinzen[4]; M Meine[3]; A H Maass[5]; K Vernooy[1]
[1]Maastricht University Medical Centre (MUMC), Cardiology, Maastricht, Netherlands (The); *[2]Eskisehir Osmangazi University, Cardiology, Eskisehir, Turkey*; *[3]University Medical Center Utrecht, Cardiology, Utrecht, Netherlands (The)*; *[4]Cardiovascular Research Institute Maastricht (CARIM), Physiology, Maastricht, Netherlands (The)*; *[5]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The)*

Background: The effectiveness of cardiac resynchronization therapy (CRT) in patients without left bundle branch block (non-LBBB) QRS morphology is limited,

compared to those with LBBB. Still, a substantial part of these patients can benefit from therapy and additional selection criteria are needed to identify these patients.
Purpose: To evaluate the association of additional baseline 12-lead ECG features; with clinical and echocardiographic outcomes in CRT-treated non-LBBB patients.
Methods: Pre-implantation 12-lead ECGs from 790 consecutive non-LBBB CRT patients from 3 implanting centres in the Netherlands, were evaluated for the presence of predefined ECG parameters. QRS morphology (right bundle branch block and intraventricular conduction delay), QRS duration (≥/< 150ms), QRS area (≥/< 109μVs), left ventricular activation time (≥/< 125ms) and the presence of fragmented QRS. The association with the primary endpoint, the combination of left ventricular assist device implantation, cardiac transplantation and all-cause mortality, was evaluated.
Results: There was a significantly lower occurrence of the primary endpoint in non-LBBB patients with QRS area ≥109μVs (p<0.001) and in those without PR prolongation (p<0.001), and without fQRS (p=0.004). (Figure 1)
Conclusion: A larger QRS area is positively associated to all-cause mortality, LVAD implantation and cardiac transplantation. The presence of fragmented QRS is negatively associated with long term clinical outcome in non-LBBB patients. QRS duration, morphology and LVAT however were not associated to the occurrence of long term events in non-LBBB patients treated with CRT. These data may provide additional value for patient selection for CRT in non-LBBB patients and warrant prospective studies.

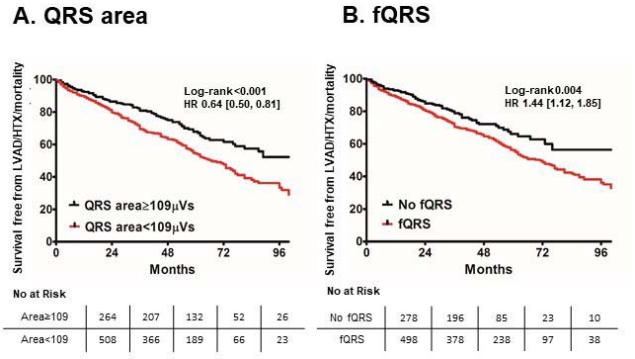

Figure 1.

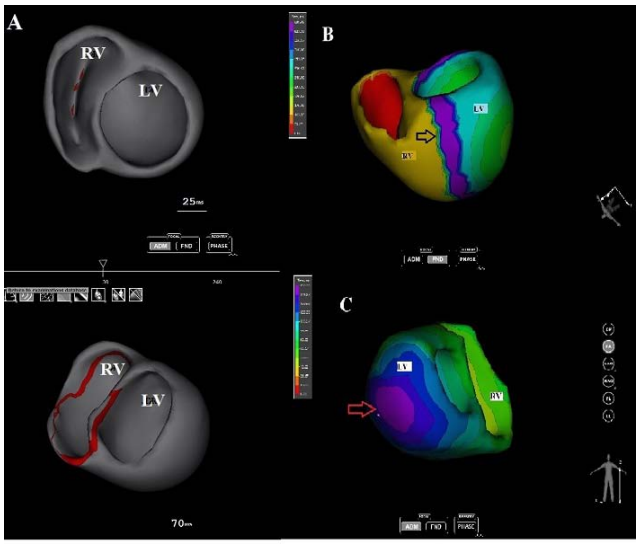
P1990
Definition of myocardial electrical dissynchrony by noninvasive activation mapping in predicting response to cardiac resynchronization therapy
S Kashtanova[1]; M Utsumueva[1]; N Mironova[1]; E Gupalo[1]; S Gaman[1]; M Saidova[1]; S Golitsyn[1]
[1]*National medical research center of cardiology, Moscow, Russian Federation*

Purpose. To assess the ventricular myocardium activation pattern obtained by non-invasive epi- and endocardial mapping (NIEEM), as well as electrocardiographic (ECG) variants of left bundle branch block (LBBB) and to estimate the value of these data for the success of cardiac resynchronization therapy (CRT).
Materials and methods. The study included 53 patients (mean age 60,9±9,9years, 32 males/21 females) with LBBB, QRS duration≥130 ms, left ventricular ejection fraction (LVEF)≤35%, heart failure (HF) NYHA II-IV despite optimal pharmacological therapy during 3 month. All patients had undergone CRT-D implantation. Depending on presence or absence of LBBB ECG-criteria, proposed by Strauss D.G., patients were divided into 2 groups: 1group - strict LBBB, proposed by Strauss D.G. and 2 group – other ECG morphologies of LBBB. NIEEM by the 'Amycard 01C EP Lab' (EP Solutions SA) system with an analysis of epi- and endocardial ventricular electrical activation was performed in all patients. Ventricular electrical uncoupling (VEU) (Fig.A) defined as the difference of duration between the mean LV and RV activation times duration spontaneous rhythm (ms). A line of slow conduction (Fig.B) was recorded if the activation times of adjacent points on either side of this line differed by>50 ms. The zone of late LV activation (Fig.C) was defined as the latest area identified on the isochrones map. Response to CRT was estimated by echo and was defined as decrease in LV end-systolic volume by > 15% after 6 months of follow-up. Results. LBBB ECG-criteria, proposed by Strauss D.G., was detected in 37 patients (70% of all included). According to the results of NIEEM, these patients had more pronounced ventricular electrical uncoupling (=0,022). Most often the line of conduction block was detected in the anteroseptal or posterolateral region of the LV in the "LBBB-Strauss" group. The zone of late LV activation, which is the most optimal position for the LV pacing electrode, was located in the basal and middle segments of the lateral and posterior walls. After 6 months of CRT 34 patients (64%) were included in the "response" group, the remaining 19 patients (36%) formed the "non-response" group according to echo criteria. In the "response" group the morphology of the QRS complex more frequently met the criteria, proposed by Strauss D.G. than other ECG variants of LBBB (30 vs. 4 respectively, p <0,001). Initially, VEU was more pronounced in the "response" group (VEU 55 [51;59] ms in the "response" group vs 35 [14;47] ms in the "non-response" group, p<0,001).
onclusions. LBBB ECG criteria, proposed by Strauss D.G., identify patients with delayed transseptal interventricular conduction due to complete LBBB, what is a good target for CPT. Identification of individual ventricular activation properties may in patients with LBBB help to reveal responders to CRT and to further the response to CRT by improving a patient-specific lead placement and device programming.



Electrical dissynchrony by NIEEM

Chronic Heart Failure - Pathophysiology and Mechanisms

P1991
Exercise unmasks greater arterial stiffness and arterial load in HFpEF patients vs hypertensive controls
L Panah[1]; E Zern[2]; JE Ho[1]; ES Lau[1]; E Liu[1]; T Cunningham[1]; KM Hardin[1]; M Namasivayam[1]; R Malhotra[1]; M Nayor[1]; GD Lewis[1]
[1]*Massachusetts General Hospital, Boston, United States of America*; [2]*Cedars-Sinai Medical Center, Los Angeles, United States of America*

Background: Arterial stiffness is an important contributor to the pathophysiology of heart failure with preserved ejection fraction (HFpEF).
Purpose: We sought to examine rest and exercise measures of arterial stiffness and arterial load among patients with HFpEF compared to hypertensive controls.
Methods: We examined 299 patients with dyspnea on exertion and EF ≥50% who underwent cardiopulmonary exercise testing with invasive hemodynamic monitoring between 2006-2017. Arterial stiffness measures were ascertained using invasive arterial waveforms, and integrated measures of arterial load calculated using simultaneously measured hemodynamics and Fick cardiac output. HFpEF was defined as % predicted peak VO2 < 80% with elevated rest or exercise left heart filling pressures. Hypertensive controls were defined as those with elevated resting blood pressure (>140/90) or taking blood pressure medications with normal left heart filling pressures. We compared measures of arterial stiffness (aortic augmentation pressure [AP] and Augmentation Index [AIx]), pulsatile load (total arterial compliance index [TACI], effective arterial elastance index [Eal], pulse pressure amplification [PPA]), and non-pulsatile load (systemic vascular resistance index [SVRI]) at rest, 30 watts, and peak exercise between HFpEF patients and hypertensive controls in age- and sex-adjusted analyses.
Results: We studied 204 HFpEF patients (age 61 ± 13 years, 57% women) and 95 hypertensive controls (age 55 ± 15 years, 53% women). There was no difference in resting arterial stiffness or load parameters between HFpEF and hypertensive groups in age- and sex-adjusted models (P>0.05 for all, Figure). At 30 watts, measures of pulsatile load were worse among HFpEF patients vs hypertensive controls (P<0.05 for TACI, Eal, PPA). Peak exercise further highlighted differences in arterial stiffness and pulsatile and non-pulsatile load among HFpEF patients vs hypertensive controls

(P<0.05 for AP, AIx, TACI, EaI, PPA, and SVRI). Pulsatile load (TACI) during peak exercise correlated with pulmonary capillary wedge pressure response to exercise in patients with HFpEF, but not in hypertensive controls (age- and sex- adjusted r=0.34, P<0.0001 vs r=0.14, P=0.18).

Conclusions: Patients with HFpEF had similar resting arterial stiffness and load compared with hypertensive controls. By contrast, exercise unmasked worse arterial stiffness, pulsatile, and non-pulsatile load among HFpEF patients vs. controls. Furthermore, exercise arterial load correlated with abnormal left heart filling pressure responses to exercise, suggesting possible contribution of vascular stiffness to the hallmark symptoms of exercise intolerance among patients with HFpEF.

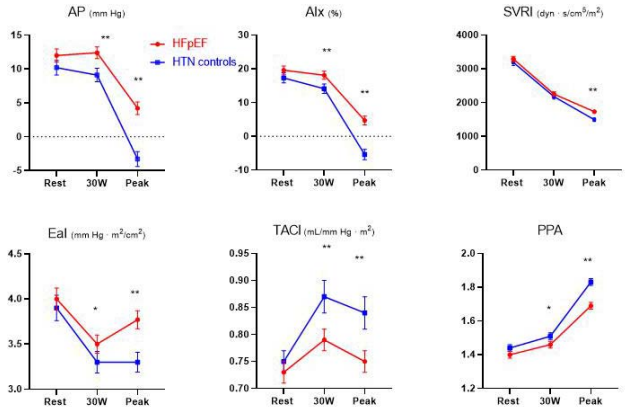


Figure 1. Arterial stiffness and load at rest, 30 watts, and peak exercise in HFpEF vs hypertensive controls, adjusted for age and sex. * denotes P<0.05, ** denotes P<0.01 (AP=aortic augmentation pressure, AIx=augmentation index, SVRI=systemic vascular resistance index, EaI=effective arterial elastance index, TACI=total arterial compliance index, and PPA=pulse pressure amplification)

P1992

Latent class analysis of echocardiographic phenotypes predicts adverse outcomes and treatment response in heart failure with preserved ejection fraction

S Suneet Purohit[1]; PS Jhand[2]; J Lindenfeld[3]; DP Kao[1]

[1]University of Colorado, Aurora, United States of America; *[2]University of Glasgow, BHF Cardiovascular Research Centre, Glasgow, United Kingdom of Great Britain & Northern Ireland*; *[3]Vanderbilt University, Cardiology, Nashville, United States of America*

Introduction Heart failure with preserved ejection fraction (HFpEF) accounts for half of all heart failure cases, but clinical trials in HFpEF have not demonstrated effective therapies. Defining and exploring distinct HFpEF phenotypes may help develop targeted therapies for this condition. We used latent class analysis (LCA) to identify different echocardiographic phenotypes of HFpEF in the Americas cohort of Treatment of Preserved Cardiac Function Heart Failure with an Aldosterone Antagonist trial (TOPCAT).

Echocardiographic Class Phenotypes				
Echo Feature	Class 1(N=172)	Class 2(N=131)	Class 3(N=155)	Class 4(N = 196)
Grade II-III Diastolic Dysfunction ‡	77%	28%	1%	71%
Left Atrial Volume Index < 34 mL/m2 ‡	90%	78%	60%	49%
LV Mass Index ‡	Normal	Mild-Moderately Increased	Normal	Moderate-Severely Increased
LVH Type ‡	Concentric Remodeling	Concentric Hypertrophy	Concentric Remodeling	Concentric Hypertrophy

Purpose Complex HFpEF echocardiographic phenotypes identified using LCA would vary in prognosis and response to spironolactone.

Methods Echocardiograhic phenotype definitions were derived using the maximum likelihood estimation to identify the most common patterns of 7 echocardiographic features. The optimal number of phenotypes was determined using the first minima of the Bayesian Information Criterion and chi squared error statistics. Hazard ratios between echocardiographic phenotypes and treatment response were determined using multivariate Cox proportional hazards models. The primary outcome was a composite of cardiovascular (CV) mortality, aborted cardiac arrest, or heart failure (HF) hospitalization.

Results4 echocardiographic phenotypes were identified with distinct combinations of diastolic dysfunction, structural heart disease, and elevated left atrial pressures (Table). There were significant differences between echocardiographic phenotypes in the primary outcome. There was a significantly increased risk of the primary outcome with use of spironolactone in the Class 1 phenotype (HR 1.97 [1.06-3.64], p = 0.032), while the Class 3 phenotype (HR 0.39 [0.19-0.82], p= 0.01) and class 4 phenotype (HR 0.56 [0.35-0.89], p = 0.015) showed a significantly reduced risk with use of spironolactone (Picture).

ConclusionsUsing LCA, 4 echocardiographic phenotypes were identified and predictive of outcomes and response to spironolactone in HFpEF.

Funding Acknowledgements: Korean circulation society

Background Invasive diastolic stress test (DST) is gold standard for diagnosis of heart failure with preserved ejection fraction (HFpEF) through demonstrating increase of pulmonary capillary wedge pressure (PCWP) during exercise. However bicycle exercise is not available in sizable numbers of cardiology labs. Handgrip exercise has been shown to increase PCWP in HFpEF patients by augmenting afterload. However correlation between handgrip exercise PCWP and bicycle exercise PCWP is not well established in HFpEF patients. Therefore we investigated whether noninvasive handgrip echo could substitute invasive bicycle cath for diagnosis of HFpEF. Method Thirty one patients with undefined dyspnea and EF>50% on echo performed invasive DST. Right heart cath was done with simultaneous echocardiography and expired gas analysis. After resting cath, handgrip exercise with 50% of maximal voluntary power was performed for 3 minutes in supine position. After recovery of resting hemodynamic condition, supine bicycle exercise was performed with graded increments of workload 10 watt for every 3 minutes until patients reached exhaustion. Patients with resting PCWP > 16mmHg or bicycle exercise PCWP > 25mmHg were defined as HFpEF. Results Among 31 patients, 20 patients were revealed as HFpEF and 11 revealed as noncardiac dyspnea (NCD) by invasive bicycle exercise cath. Resting PCWP was higher in HFpEF (15.6±2.6 vs 12.7±2.5 mmHg, p<0.01) and resting E/e' was marginally higher in HFpEF (13.1±3.5 vs 10.6±3.6 mmHg, p=0.07). Handgrip exercise increased PCWP both in HFpEF and NCD but this increase was more marked in HFpEF group (22.4±6.8 vs 17.6±5.4 mmHg, p=0.06). However handgrip exercise did not increase E/e' in both HFpEF and noncardiac dyspnea groups and was not different (HFpEF 14.4±5.2 vs NCD 12.1±4.5, p=0.22). While handgrip E/e' was not correlated with handgrip PCWP

(r2=0.25 p=0.22), handgrip E/e' was correlated with both low grade exercise (20watt) PCWP (r2=0.36 p=0.07) and peak exercise PCWP (r2=0.48, p=0.02). In ROC curve analysis, handgrip E/e' was a marginally significant predictor for detection of invasively proven HFpEF (p = 0.07) and the optimal cutoff value for handgrip E/e' to detect HFpEF was 11 (sensitivity, 0.69; specificity, 0.80), yielding an area under the curve of 0.71 (95% confidence interval, 0.51 to 0.92). Positive predictive value of handgrip E/e' > 11 for diagnosis of HFpEF was 81% and negative predictive value was 62%. Conclusion Handgrip exercise E/e' was correlated with bicycle exercise induced increase of pulmonary capillary wedge pressure (PCWP). Handgrip exercise echo might be used for detecting HFpEF in substitution for bicycle exercise cath.

Characteristics of Worsening Ejection Fraction during Follow-up in Heart Failure Patients with Preserved Ejection Fraction

H Hidenori Yaku[1]; T Kato[1]; T Morimoto[2]; Y Inuzuka[3]; Y Tamaki[4]; E Yamamoto[1]; N Ozasa[1]; T Kimura[1]
[1]Kyoto University Graduate School of Medicine, Department of Cardiovascular Medicine, Kyoto, Japan; *[2]Hyogo College of Medicine, Clinical Epidemiology, Nishinomiya, Japan*; *[3]Shiga Medical Center for Adults, Department of Cardiovascular Medicine, Moriyama, Japan*; *[4]Tenri Hospital, Department of Cardiovascular Medicine, Tenri, Japan*

On behalf of: the KCHF Registry Investigators

Background: Heart failure with preserved ejection fraction (HFpEF) has been recognized as a major and growing public health problem worldwide. However, previous registry data has provided limited information about the changes of ejection fraction in HFpEF patients.
Purpose: The current study sought to clarify characteristics of worsening ejection fraction in HFpEF patients.
Methods: From the consecutive 898 patients hospitalized for acute heart failure (AHF) from October 2014 to March 2016, discharged alive, and performed echocardiography in the acute (during the index hospitalization) and chronic phase (6 months after hospital discharge), we studied 369 patients with HFpEF (baseline EF ≥50%). We classified the HFpEF patients hospitalized for AHF into 2 groups by the change of EF during 6 months after hospital discharge: those with worsening EF in the chronic phase (Group A) and those without worsening EF in the chronic phase (Group B). Worsening EF was defined as EF worsening below 50% compared to baseline EF or the decline of more than 10% in the chronic phase. Clinical predictors of worsening EF during follow-up were identified using multivariate logistic regression analysis.
Results: Group A and B included 56 patients and 313 patients, respectively. Regarding the baseline characteristics, Group A had significantly greater prevalence of patients with prior myocardial infarction (29 vs. 12%, P<0.001), while Group A had significantly lower prevalence of patients with hypertensive heart disease (HHD) as underlying heart disease (21 vs. 42%, P=0.003), and atrial fibrillation (32 vs. 49%, P=0.02). Regarding the clinical presentations, systolic blood pressure and heart rate was lower in Group A than in Group B [143±33 vs. 154±35 mmHg (P=0.04), and 83±30 vs. 91±28 beat/min (P=0.04), respectively], and left ventricular asynergy and left bundle branch block were higher in Group A than in Group B [47 vs. 16% (P<0.001), and 19 vs. 7.1% (P=0.005), respectively]. After adjusting for potential confounders, independent risk factors for worsening EF during follow-up included left ventricular asynergy [odds ratio (OR) 5.71, 95% confidence interval (CI) 2.40–13.6, P<0.001] and HHD (OR 0.33, 95% CI 0.13–0.83, P=0.02).
Conclusions: Worsening EF during follow-up in patients with HFpEF was associated with greater prevalence of left ventricular asynergy, and lower prevalence of HHD as underling heart disease.

P1995

Impact of the geriatric nutritional risk index in non-diabetic patients aged >80 years with heart failure with preserved ejection fraction

Y Mitsuke[1]; H Tsutani[1]; N Ohtsuki[1]
[1]NHO Awara Hospital, Fukui, Japan

Background: Malnutrition has been identified as an important predictor of poor clinical outcomes in patients with heart failure with preserved ejection fraction (HFpEF). The clinical significance of nutritional risk assessment in non-diabetic HFpEF patients aged >80 years is less well defined. Methods: We studied consecutive 112 Japanese HFpEF patients (54 males, older than 80 years of age (85.1 +/- 3.7years) who were hospitalized with HFpEF at the authors' institution. The impact of nutrition, assessed using GNRI on admission was calculated as follows:14.89 × serum albumin (g/dl) + 41.7 × body mass index/22. None had evidence of diabetes mellitus, unstable angina, chronic inflammatory disease, collagen disease, or cancer at the time of evaluation. Patients were followed up for an average of 25.2 months, and 19 of 112 patients had all death. Results: Patients in the low-GNRI group(GNRI<92) had higher cystatin C, interleukin-6, and B-type natriuretic peptide (BNP), noradrenalin, and uric acid compared to those in the high-GNRI(GNRI92) group (P<0.05, respectively). By multivariate Cox proportional hazard analysis, GNRI, IL-6, and cystatin C were significant predictors for all death in those patients.
Conclusions: These findings indicate that the assessment of nutritional status using GNRI may be helpful for risk stratification in those non-diabetic elderly patients with HFpEF.

P1996

Correlation of inflammatory and fibrosis markers with diffuse interstitial fibrosis by T1 myocardial mapping and echocardiography parameters in heart failure with preserved ejection fraction patients

AN Kaburova[1]; OM Drapkina[1]; MS Pokrovskaya[1]; MV Vishnyakova[2]; SM Uydin[3]; SN Koretsky[1]; AS Abramenko[2]; GV Chermensky[2]; BB Shoybonov[1]; AA Fedorovich[1]; LA Matskevich[1]; NV Gomiranova[1]; EV Zyatenkova[1]; IA Efimova[1]; VV Makarov[3]
[1]National Research Center for Preventive Medicine, Moscow, Russian Federation; *[2]M.F. Vladimirsky Moscow Regional Research and Clinical Institute, Moscow, Russian Federation*; *[3]Center for strategic planning and management of medical and biological health risks, Moscow, Russian Federation*

Purpose: The aim of the study was to investigate the association between the serum markers of systemic low-grade inflammation and myocardial fibrosis with the results of transthoracic echocardiography with tissue Doppler imaging and the level of diffuse interstitial myocardial fibrosis calculated by cardiac magnetic resonance T1-mapping in patients with heart failure and preserved ejection fraction (HF-pEF).
Methods: Fifty patients with confirmed HF-pEF (mediana and interquartile range for age 67 [64; 74] years, 52% men, body mass index <35 kg/m2 and no previous history of either acute coronary syndrome or myocardial infarction or diabetes) were enrolled in the study. The patients underwent transthoracic echocardiography with tissue Doppler study, HF-pEF was confirmed according to the recent ESC guidelines (based on E/' ratio, N-terminal pro-B type natriuretic peptide >125 pg/ml and symptoms or signs of HF). The levels of tumor necrosis factor α (TNF-α), transforming growth factor β1 (TGF-β1), procollagen type I C-peptide (PIP) and soluble ST2 were evaluated in patients' serum using enzyme-linked immunosorbent assay. As the last step T1-myocardial mapping was performed to assess native and postcontrast late gadolinium enhancement (LGE) values of T1.
Results: The mean±standart deviation in TGF-β1 was 209,2±61,3 pg/ml, mediana and interquartile range in TNF-α was 55,9 [28,3; 113,7] pg/ml, in PIP was 883,5 [680; 999] pg/ml, in sST2 was 44,75 [26,3; 62,5] pg/ml. The results of T1 mapping adjusted to myocardial segments were: T1 native (base) 1127,8±93 ms, T1 native (middle) 1074,7±53,8 ms, T1 native (apex) 1165,4±151,8 ms; T1 LGE (base), 497±72,5 ms, T1 LGE (middle) 502,8±56,1 ms, T1 LGE (apex) 506±56,2 ms. The analysis revealed significant correlations between TNF-α and e' (r= -0,37); correlation index between PIP and left atrial volume index was 0,29; sST2 correlated with native T1 (base), r=0,29 and diastolic pulmonary artery pressure, r=0,31; TGF-β1 correlated with LGE T1 (apex), r=0,49 and systolic pulmonary artery pressure, r=0,35. All values with p<0,05.
Conclusion: Among the investigated serum markers only sST2 and TGF-β1 significantly correlated with both: T1 myocardial mapping values of diffuse interstitial fibrosis and the parameters of echocardiography in patients with HF-pEF. PIP and TNF-α had no statistically significant correlation with the results of diffuse interstitial fibrosis assessed by T1 myocardial mapping.

P1997

The effects of long-term treatment with sympathetic nervous system blockers on diastolic function in patients with resistant hypertension and heart failure with preserved ejection fraction

A Anna Moiseeva[1]; A Caraus[1]; N Ciobanu[1]; V Moscalu[1]; E Sedaia[1]; A Surev[1]; A Durnea[1]; A Bitca[1]; M Caraus[2]; L Untura[3]
[1]Institute of Cardiology, Chisinau, Moldova (Republic of); *[2]St Spiridon University Hospital, Iasi, Romania*; *[3]The Republican Medical Diagnostic Center, Chisinau, Moldova (Republic of)*

Background The sympathetic nervous system (SNS) plays an important role both in the pathogenesis of resistant hypertension (HTN) and heart failure (HF). The treatment of HF with preserved ejection fraction (HFpEF) and resistant HTN remains a challenge for contemporary cardiology. Moreover, there are insufficient clinical trials demonstrating the efficacy of some remedies in this category of patients.
Purpose Evaluation of diastolic function in patients with resistant HTN and HFpEF under the influence of long-term medication with sympathetic nervous system blockers.
Methods 100 patients with essential HTN gr.3 and HFpEF, without comorbidities, after a 3-week treatment with standardized treatment with Losartan, Amlodipine

and Indapamide and confirmation of their resistance were randomized in two groups, depending on the medication supplemented to the previously administered: group I (M) – selective I1-imidazoline agonist Moxonidine and group II (B) – cardioselective beta-blocker Bisoprolol. All patients were evaluated by transthoracic echocardiography at baseline, six and twelve months follow-up.

Results The authentic improvement in diastolic function parameters occurs from 6 months of continued medication with both SNS blockers with superior potency in the Bisoprolol treatment group, beneficial effect maintained until the end of the surveillance period. The most sensitive parameters have proven to be LAVI and TR velocity (Tab.).

Conclusion Long-term treatment with SNS blockers demonstrated a statistically significant improvement in diastolic function parameters with a superior potency of Bisoprolol in this group of patients.

The relationship between pulse-wave parameters and myocardial fibrosis determined by T1 myocardial mapping in patients with heart failure and preserved ejection fraction

AN Kaburova[1]; OM Drapkina[1]; MS Pokrovskaya[1]; MV Vishnyakova[2]; SM Uydin[3]; SN Koretsky[1]; AS Abramenko[2]; GV Chermensky[2]; BB Shoybonov[1]; AA Fedorovich[1]; LA Matskevich[1]; NV Gomiranova[1]; EV Zyatenkova[1]; IA Efimova[1]; VV Makarov[3]

[1]National Research Center for Preventive Medicine, Moscow, Russian Federation; *[2]M.F. Vladimirsky Moscow Regional Research and Clinical Institute, Moscow, Russian Federation*; *[3]Center for strategic planning and management of medical and biological health risks, Moscow, Russian Federation*

Introduction: Myocardial fibrosis is the pathophysiological hallmark of the diastolic function impairment and the subsequent development of heart failure with preserved ejection fraction (HF-pEF). Major arteries stiffening increases systolic load on the left ventricle contributing to its hypertrophy and leading to increased myocardial oxygen demand, as well as indirectly promoting impaired perfusion. Arterial stiffness and wave reflection effects augment systolic blood pressure and place additional mechanical load on the heart leading to diastolic dysfunction and myocardial fibrosis. Additionally cardiac magnetic resonance T1 myocardial mapping represents the new tool for the accurate assessment of diffuse interstitial fibrosis.Purpose: The research was aimed at investigating the relationship between the results of pulse-wave analysis reflecting vascular stiffness and the diffuse interstitial myocardial fibrosis calculated by T1 myocardial mapping in patients with HF-pEF.

Methods: 50 patients with confirmed HF-pEF (mediana and interquartile range of age 67 [64; 74] years, 52% men, body mass index <35 kg/m2 with no history of acute coronary syndrome, myocardial infarction or diabetes) were enrolled in the study. The patients underwent transthoracic echocardiography with Doppler study, HF-pEF was confirmed according to the recent ESC guidelines (based on E/' ratio, N-terminal pro-B type natriuretic peptide >125 pg/ml and symptoms of HF), 6-minute walk test mean±standart deviation result in patients was 422±23,8m. The following pulse-wave characteristics were measured with novel professional finger photoplethysmographic device AngioScan-01: stiffness index (SI), reflection index (RI), augmentation index adjusted to a heart rate of 75 (AIp75) and ejection duration percent (ED%). As the last step of the study T1-myocardial mapping was performed to assess native and postcontrast late gadolinium enhancement (LGE) values of T1.

Results: The results of pulse-wave analysis were for SI 7,6 [6,8; 8,1], RI 36,3 [21,2; 46,2], AIp75 10,6 [1;17], ED% 32,4±5,9%. The results of T1 mapping adjusted to myocardial segments were: T1 native (base) 1127,8±93 ms, T1 native (middle) 1074,7±53,8 ms, T1 native (apex) 1165,4±151,8 ms, T1 LGE (base), 497±72,5 ms, T1 LGE (middle) 502,8±56,1 ms, T1 LGE (apex) 506±56,2 ms. Among the examined parameters the statistical analysis revealed significant correlations between AIp75 and T1 (base), r=0,37, 1 (apex), r=0,33; as well as the correlation between ED% and T1 LGE (base), r= 0,42. All with p<0,05.

Conclusion: Among the investigated pulse-wave characteristics AIp75 (the elevated values of which reflect the increase in the major arteries stiffness – the process that contributes to elevated central pressure) and ED% (the increase of which denotes the decrease of diastole duration and thus may predict the future myocardial damage) were positively correlated with the results of T1 myocardial mapping (T1 native and T1 LGE).

P1999

Central aortic pressure: the link with markers of inflammation and fibrosis and diastolic function parameters in patients with heart failure and preserved ejection fraction

AN Anastasia Kaburova[1]; OM Drapkina[1]; MS Pokrovskaya[1]; SM Uydin[2]; SN Koretsky[1]; BB Shoybonov[1]; AA Fedorovich[1]; LA Matskevich[1]; NV Gomiranova[1]; EV Zyatenkova[1]; IA Efimova[1]; VV Makarov[2]

[1]National Research Center for Preventive Medicine, Moscow, Russian Federation; *[2]Center for strategic planning and management of medical and biological health risks, Moscow, Russian Federation*

Purpose: The aim of the study was to investigate the association between central aortic pressure (Spa) and serum markers of systemic low-grade inflammation and myocardial fibrosis along with the relationship with Doppler study parameters of diastole in patients with heart failure and preserved ejection fraction (HF-pEF).

Methods: consecutive ambulatory patients with confirmed HF-pEF (n=50, mediana and interquartile range of age 67 [64; 74] years, 52% men, body mass index <35 kg/m2 with no previous history of acute coronary syndrome, myocardial infarction or diabetes) were enrolled in the study. The patients underwent transthoracic echocardiography with Doppler study, HF-pEF was confirmed according to the recent ESC guidelines (based on E/' ratio, N-terminal pro-B type natriuretic peptide >125 pg/ml and symptoms of HF). The levels of tumor necrosis factor α (TNF-α), transforming growth factor β1 (TGF-β1) and procollagen type I C-peptide (PIP) were evaluated in patients' serum using enzyme-linked immunosorbent assay. Central aortic pressure was measured by use of the novel professional finger photoplethysmographic device AngioScan-01.

Results: The mean±standart deviation in TGF-β1 was 209,2±61,3 pg/ml, mediana and interquartile range in TNF-α was 55,9 [28,3; 113,7] pg/ml, in PIP was 883,5 [680; 999] pg/ml. Spa was 118,2±2 mm Hg, e' 5,7±1,1 and E/e' 13,4±0,7 cm/s. Among the investigated serum markers and echocardiographic parameters of diastole the statistical analysis revealed significant correlations between Spa and e' (r= -0,31), TNF-α (r=0,30) and PIP (r=0,32). All values with p<0,05.

Conclusion: Among the examined serum markers central aortic pressure correlated with the levels of PIP and TNF-α, but not TGF-β1. Additionally pressure in aorta showed negative correlation with e' which lowered values reflect the slowed ventricular relaxation in HF-pEF.

Red blood cell distribution width predicts 5-years all cause mortality in patients with preserved ejection fraction heart failure

RN Siliste[1]; R Ciomag[1]; C Homentcovschi[1]; A Trandafir[1]; D Pasoiu[1]; B Herteg[1]; O Mincan[1]; I Savulescu-Fiedler[1]; A Gurgehan[1]; DV Spataru[1]

[1]Coltea Clinical Hospital, Bucharest, Romania

Background: Studies have already validated the prognostic role of red blood cell distribution width (RDW) on outcomes in patients with heart failure as well as other diseaseas. We investigated the association between RDW values at admission and 5- years mortality in patients with decompensated heart failure with preserved ejection fraction (HfpEF).

Material and method: we prospectively followed-up for a period of 5 years, 144 patients with decompensated HFpEF admitted in Cardiology Unit during the period 2012-2013; mean age of the cohort 73.9± 9.36 years, 58% female. At the end of the follow-up, the patients were randomized in 2 groups: survivors vs. non-survivors. Patients with cancer, moderate to severe anemia, COPD, infectious diseases or autoimmune disorders were excluded during the first randomization.

Results: After a median follow-up of 37 months (range 18-60 months), 84 pts. died (58%), non-cardiac mortality accounting for half of this. Non-survivors had higher baseline RDW value (median value 13.9±2.72% vs.12.38±0.61%, p=0.0001), NT-proBNP levels (3885±834pg/ml vs. 2315±78pg/ml, p=0.05), New York Heart Association functional class, presence of atrial fibrillation, the indexed left atrial volume (48.5±15 ml/m2 vs. 45±7.5 ml/m2, p=0.0125) and systolic pulmonary artery pressure (47.3±12 mmHg vs. 38±15.6 mmHg, p=0.03). A multivariate

Cox regression analysis revealed that RDW levels were independently correlated with all-cause and non-cardiac mortality after adjusting for other risk factors, including age, brain natriuretic peptide, echocardiographic parameters. In a receiver-operating curve analysis, a cut-off value of RDW above 14.2% have a 87% sensitivity and 75% specificity to predict the adverse outcome.
Conclusion: The current study demonstrated that besides NTproBNP, functional NYHA class, left atrial size and systolic pulmonary pressure, the RDW levels independently predict poor outcomes in patients with decompensated HFpEF.

P2001
Prognostic value of post-exercise oxygen uptake kinetics in heart failure with preserved ejection fraction

IYU Giverts[1]; MG Poltavskaya[1]; EE Yakubovskaya[1]; MV Serova[1]; DA Andreev[1]; VP Sedov[1]; MD Kuklina[2]; DYU Shchekochikhin[1]; AL Syrkin[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Endocrinology Research Center, Moscow, Russian Federation*

Objectives: Cardiopulmonary exercise testing (CPET) is a well known prognostic tool in chronic heart failure (CHF). Recent data indicate high predictive value of oxygen uptake (VO2) kinetics following exercise test in patients with CHF. The aim of this study was to confirm prognostic significance of VO2 recovery delay (VO2RD) in HF with preserved ejection fraction (HFpEF).
Methods: We retrospectively analyzed the subgroup of 47 patients with HFpEF, NYHA classes II-III (33 male, mean age 64,2±11,7 years) previously included in the prospective observational study. At baseline the patients underwent comprehensive investigation including CPET. VO2RD defined as time from the end of loaded exercise until permanent fall of VO2 below VO2 peak values, was used for estimation of VO2 recovery kinetics. Average follow-up amounted 34 months. Composite end-point of cardiovascular death and hospitalization for HF decompensation was considered a primary analysis variable.
Results: Cardiovascular mortality amounted 23,4% (n=11). Composite end-point was observed in 57,4% of patients (n=27). ROC-analysis demonstrated significant independent predictive value of VO2RD for composite end-point (AUC=0,868; 95%CI=0,726 to 0,953; p<0,0001). Patients were subsequently dichotomized by a VO2RD of 25 seconds used previously as a cut-off point [Bailey CS. JACC Heart Failure 2018]. Kaplan–Meier analysis confirmed prognostic relevance of VO2RD for composite end-point (hazard ratio = 3,3; 95%CI = 1,4- 7,5, Logrank p = 0,0039).
Conclusion: Prolonged post-exercise VO2 recovery delay indicates unfavorable prognosis and may be used as an independent non-invasive marker for risk stratification in chronic heart failure patients with preserved ejection fraction.

Arterial stiffness and the autonomic nervous system function with different phenotypes of heart failure with preserved ejection fraction

N Kurlykina[1]; A Plisuk[1]; R Binyakovskiy[2]; K Galinger[2]; I Orlova[1]
[1]M.V. Lomonosov Moscow State University, Medical Research and Educational Center of M V Lomonosov Moscow State University, Moscow, Russian Federation; *[2]M.V. Lomonosov Moscow State University, Faculty of Fundamental Medicine, Moscow, Russian Federation*

PURPOSE: to study the relationship between arterial stiffness and autonomic nervous system with different phenotypes of heart failure with preserved ejection fraction (HFpEF).
METHODS: This study included 77 patients with arterial hypertension (m-61%, f-39%). 19 of these patients with a verified diagnosis of coronary artery disease (CHD) with HFpEF, the others 58 without CAD. Ejection fraction in patients with CHD and without CHD was significantly different (52±4,3; 65±7,1, p=0,001). These groups were comparable by age (66.5±11.4; 62.9±8.9, p=0.14), body mass index (28.0±3.3; 26.9±3.7, p=0.26), office blood pressure (BP) systolic (133.2±13.9; 140.2±15.0, p=0.08) and diastolic (82.1±7.4; 84.9±7.9, p=0.18). All patients underwent Ambulatory blood pressure monitoring (ABPM) (BPLabVasotens) device. Arterial stiffness was assessed by means of using pulse wave velocity (PWV) measurements using validated Vasotens technology. The assessment of the circadian rhythm of the heart, reflecting the function of the autonomic nervous system was determined by the value of the circadian index (CI).
RESULTS: Within patients with CHD, Central systolic BP and central diastolic blood pressure BP were significantly lower than without CHD (119,0±9,2; 125,7±11,6, p=0,02 and 72,3±7,2; 79,0±8,3, p=0,004, respectively). PWV in the main group was higher than in the control group (11.8±2.7; 9.5±3.4, p=0.007), while in the main group there was more rigid CI (1.12±0.09; 1.21±0.10, p<0.001). Within the patients with HD, a negative relationship between PWV and CI (r=-0.5, p=0.03) was revealed, on the contrary, in patients without HD such a relationship was not revealed (p=0.15).
CONCLUSION: Increased arterial stiffness is associated with an imbalance of the autonomic nervous system, which is detected in patients in HFpEF with CHD, despite more effective treatment of arterial hypertension and dyslipidemia, compared with patients without CHD.

P2003
Galectin-3, AGEs serum levels and endothelial function in post infarction heart failure patients with preserved ejection fraction

O Oksana Sirenko[1]; O Kuryata[1]; A Zabida[1]
[1]Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

The aim of the study to evaluate serum levels of galectin-3, AGEs and endothelial function, cardiac hemodynamics in post infarction chronic heart failure patients with different ejection fraction. Materials and methods. All patients divided into two main groups according to ejection fraction: 1st group - 20 patients have chronic heart failure with preserved ejection fraction, 2nd group -15 patients with chronic heart failure and reduced ejection fraction. Standard laboratory blood tests for erythrocyte sedimentation rate, haematological parameters, lipid profile, glucose, renal function, echocardiographic examination, endothelial function determine were performed for all patients. AGEs and galectin-3 serum levels was determined. Results. Patients with chronic heart failure and reduced ejection fraction and myocardial infarction in anamnesis had significantly increased left ventricle end diastolic volume, left ventricle end systolic volume, left ventricle end diastolic dimension and left ventricle end systolic dimension ($p < 0.05$). AGEs serum level mildly increased in both groups. Galectin-3 level was significantly higher in pts with chronic heart failure and reduced ejection fraction ($p < 0.05$) and was correlated with age (R=0.74, $p < 0.05$), left ventricle end diastolic volume (R=0.57, $p < 0.05$), left ventricle end diastolic dimension (R=0.48, $p < 0.05$), triglycerides level (R=0.45, $p < 0.05$). Most of the patients with chronic heart failure with myocardial infarction in anamnesis had endothelial dysfunction, the FMD % level was significantly higher in patients with preserved ejection fraction ($p < 0.05$). Conclusions. Patients with chronic heart failure and reduced ejection fraction are characterized by significantly higher levels of galectin-3, endothelial dysfunction frequency, cardiac hemodynamics abnormalities.

Dynamics of sST2 and NTproBNP in heart failure with a preserved ejection fraction in acute myocardial infarction

FD Akhmatova[1]; VN Larina[1]; MV Khoreva[1]; IM Doronina[2]
[1]Pirogov Russian National Research Medical University , Moscow, Russian Federation; *[2]City Clinical Hospital 13, Moscow, Russian Federation*

Introduction . Heart failure with preserved ejection fraction (HFpEF) is characterized by an increase in diastolic pressure and an overload of the left atrium. It is important to identificate biomarkers that can be used to control of HFpEF course.
Objective: To study the dynamics of the stimulating growth factor sST2 and the NTproBNP in heart failure with a preserved ejection fraction in acute myocardial infarction (AMI).
Material and methods. The study included 25 patients with AMI, degree of severity of heart failure was to KILLIP I - 43%, KILLIP II - 57%, mediana of age was 52.8 [46; 58] years. The inclusion criteria for the study was the left ventricular ejection fraction (LVEF) over 50%. On the 1st day, the 14th day and 6 months after the onset of myocardial infarction concentration of NTproBNP (pg/ml) and sST2 (ng/ml) in blood serum was determined, and the diastolic size of the left ventricle (LVD, mm), LVEF (%), the size of the left atrium (LA, mm), ratio of peak E and A of transmitral blood flow (E/A) were studied.
Results. LV EF values were normal and did not significantly changed over the entire follow-up period: at 1st - 55.0 [46.0; 63.0]%, on the 14th day – 54.5 [44.3; 58.5]%, after 6 months - 52.0 [45.8; 58.3]%, p> 0.05. The values of LVD also did not differ too: 45.0 [42.0; 49.0] mm, for the 14th day - 45.3 [42.7; 49.0] mm, after 6 months - 45.8 [43.0; 47.0] mm, p > 0.05. The E/A ratio of transmitral blood flow was significantly lower at 1st day AMI, p<0.003. The LA size at 1st day AMI was 36.7 [35.0; 38.0] mm, and 14th day - 36.0 [33.5; 38.4] mm, p>0.05. The LA size was a significant increase after 6 months - 37.9 [35.1; 40.0] mm, p<0.02.
The NTproBNP concentration was higher on 1st day of AMI - 645.4 [197.08; 993.65] pg/ml. It was decreased at 14th day - 164.96 [91.97; 614.76] pg/ml, p=0.05, and after 6 months - 52.55 [16.05; 787.88] pg/ml, p<0.02.
The sST2 serum level was higher on 1st day of AMI: sST2 - 31.86 [27.4; 38.57] ng/ml, and decreased by the 14th day of AMI - 25.99 [20.66; 33,87] ng/ml, p <0.01. After 6 months the level of sST2 concentration significantly increased - 32.39 [28.55; 36.58] ng/ml, p = 0.04.
Conclusions. HFpEF is characterized by an increase in the size of the left atrium and an increase in serum sST2 concentration in the late post infarction period. This allows sST2 to consider as a marker for control the heart failure with a preserved ejection fraction in acute myocardial infarction patients.

The impact of a clinical educational and self-care intervention in patients with heart failure with preserved ejection fraction

H Helena Bolam[1]; PR Kalra[1]; K Guha[1]; GDJ Morton[1]
[1]*Portsmouth Hospitals NHS Trust, Cardiology, Portsmouth, United Kingdom of Great Britain & Northern Ireland*

Background Multidisciplinary team (MDT) care, including education and self-management, improves outcomes in patients with heart failure (HF). Although approximately 50% of patients with HF have preserved ejection fraction (HFpEF), these patients are frequently excluded from MDT services.
Purpose To assess the impact of a clinical educational and self-care intervention on outcomes in patients diagnosed with HFpEF.
Methods Patients with suspected HF are seen in a dedicated HF clinic and receive specialist clinical assessment, echocardiography and diagnosis in a one-stop clinic. Those diagnosed with HF with reduced EF are referred to the MDT. Due to local restrictions, those with HFpEF are usually discharged to their GP. 25 consecutive patients newly diagnosed with HFpEF were offered an additional comprehensive individualised intervention including clinical review, risk factor modification, education and self-management training. Outcomes were knowledge of diagnosis and how to seek help, confidence in self-management, medication changes, and hospitalisations and mortality at 3 months. The intervention group were compared to the 25 consecutive preceding patients who had received usual care.
Results Patients in the intervention group were more likely to have diuretics increased and felt more confident in their ability to self-manage their condition and seek help. There was a non-significant trend towards a reduction in mortality and all-cause hospitalisation at 3 months compared to the standard care group. For both groups combined, after an extended follow-up of 8±5 months, all-cause mortality was 8% and all-cause hospitalisations 26%.
Conclusion Patients newly diagnosed with HFpEF have a poor short-term prognosis with high rates of hospitalisations yet lack access to the MDT. The results suggest that a preventive intervention may improve self-care and patient outcomes. Patients with HFpEF should have access to MDT care. The growing burden of HFPEF means that confirmation in a large study should be an urgent priority.

Characteristic / Outcome	Standard care group n=25	Intervention group n=25	p value	Both groups n=50
Age (Years)	84	83	0.44	84
Gender (%female)	60	68	0.56	64
Hypertension (%)	56	36	0.16	46
Atrial fibrillation (%)	88	76	0.46	82
Mortality n (%)	2 (8)	0 (0)	0.29	2 (4)
Hospitalisation n (%)	4 (16)	2 (8)	0.67	6 (12)
Diuretic increases n (%)	2 (8)	4 (16)	0.67	6 (12)

P2006

The sophisticated echo parameters in diabetic and non-diabetic patients with preserved ejection fraction after STEMI

G Krljanac[1]; D Trifunovic[1]; M Asanin[1]; I Mrdovic[1]; M Djurovic[2]; G Stankovic[1]; L Savic[1]; M Polovina[1]; V Sulovic[2]; L Cucic[2]; J Dudic[2]
[1]*Clinical Centre of Serbia, Cardiology Clinic, Medical Faculty, Belgrade, Serbia*; [2]*Medical Faculty, Belgrade, Serbia*

Coronary heart disease (CHD) and diabetes mellitus (DM) are very often associate diseases. Sophisticated echo parameters as strain and strain rate are powerful predictors of CHD in diabetic patients.
Aim: To compare the parameters of myocardial mechanic of left ventricle and left atrium in diabetic and non-diabetic patients after STEMI and preserved ejection fraction (EF).
Method: Echo examination performed on VIVID 9GE, Echo PAC Ver 202. We analysed conventional echo parameters and parameters of left ventricle myocardial mechanics of systolic and diastolic function, as well as left atrial function. Results: 106 consecutive patients after STEMI treated with primary PCI were analysed by conventional and sophisticated echo parameters. 13/106 diabetic patients were older 61.6±10.5 vs. 56.9±10.3 yr, p=0.126, more female 46.2/31.2%, p=0.282 had impaired LVEF 53.15±3.87 vs. 57.08±4.69, p=0.005 and impaired global longitudinal strain (GLS) in endocardial layers -16.38±2.49 vs. -18.90±2.49 %, p=0.034. However, GLSs in mid layers -14.27±2.43 vs. -16.16±3.33 %, p=0.052 and epicardial layers -12.56±2.38 vs. -14.03±2.99 %, p=0.092 were not significantly different. The parameters of diastolic dysfunction as E/A were different between groups 0.67±0.12 vs. 0.91±0.32, p=0.009. The other parameters of systolic and diastolic function of left ventricle and left atrium were not significantly different between diabetic and non-diabetic patients (table 1).
Conclusion: The conventional echo systolic and diastolic parameters as EF and E/A remain important in diabetic patients with CAD. Still, larger studies are needed to define parameters of myocardial mechanic in these patients.

Table 1. Echo parameters

	Patients with DM (n=13)	Patients withouth DM (n=93)	p

A novel echocardiographic based diagnostic score for identifying heart failure with preserved ejection fraction

J Jasper Tromp[1]; W Ouwerkerk[2]; Y Hummel[3]; PSD Yeo[4]; D Sim[1]; F Jaufeerally[5]; HY Ong[6]; DJ Van Veldhuisen[3]; AM Richards[7]; LH Ling[7]; E Hoendermis[3]; JK Oh[8]; AA Voors[3]; JJV Mcmurray[9]; CSP Lam[1]
[1]*National Heart Centre Singapore, Cardiology, Singapore, Singapore*; [2]*Academic Medical Center of Amsterdam, Amsterdam, Netherlands (The)*; [3]*University Medical Center Groningen, Groningen, Netherlands (The)*; [4]*Tan Tock Seng Hospital, Singapore, Singapore*; [5]*Duke-NUS Graduate Medical School Singapore, Singapore, Singapore*; [6]*Khoo Teck Puat Hospital, Singapore, Singapore*; [7]*National University Heart Centre, Singapore, Singapore*; [8]*Mayo Clinic, Rochester, United States of America*; [9]*University of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland*

Background. Heart failure (HF) with preserved ejection is caused by structural and functional cardiac abnormalities. Therefore, echocardiography is key for the diagnosis of HFpEF. While echo based diagnosis of HF with reduced ejection fraction (HFrEF) is relatively straight forward, the most parsimonious combination of structural and functional abnormalities for diagnosing HFpEF are unclear.
Aims. We aimed to (1) develop a simple echocardiographic diagnostic score; (2) validate the score against invasively measured pulmonary capillary wedge pressure (PCWP); and (3) determine which proportion of patients in two randomized large-scale clinical trials qualified as having HFpEF based on this score.
Methods. Recognizing that hypertensive heart disease is the most common precursor to HFpEF and has overlapping echocardiographic characteristics with HFpEF, we compared echocardiographic features of 233 patients with HFpEF (LVEF ≥50%) to 273 hypertensive controls with normal EF but no HF. An agnostic model was developed using Classification and Regression Tree (CART) analysis. The association of the derived echocardiographic score with invasively measured PCWP was investigated in a separate cohort of 96 patients. An optimal cutoff point to diagnosis HFpEF for the score was chosen based on the highest specificity.
Results. A weighted score based (0-10 points) based on left ventricular ejection fraction (LVEF <60%), posterior wall thickness (>10 mm), E-wave (>0.8 m/s) and left atrial volume index to body surface area (LAVi, >24 ml/m2) had a combined AUC of 0.9 to identify HFpEF from hypertensive controls (Table). The score was significantly associated with PCWP in patients with HFpEF (R^2= 0.23, P= 0.029). An optimal cutoff point of ≥5 for the score was selected. In the TOPCAT Americas and I-Preserve trials, 60% and 33% respectively had ≥5 points and did considerably worse with regard to the primary combined clinical endpoint compared to patients with <5 points in both the TOPCAT Americas (HR 1.59; 95%CI 1.09-2.31) and I-Preserve (1.86; 95%CI 1.19-2.89) trial.
Conclusion. A simple echocardiographic score can distinguish HFpEF from hypertensive controls and is associated with objective measurements of severity and outcomes in HFpEF.

Table

Echocardiographic variable and value	Points
Left ventricular ejection fraction ≥50%, <60%	4
Posterior wall thickness > 10 mm	3
E-wave >0.8 m/s	2
Left atrial volume indexed to body surface area >24 ml/m^2	1

P2008

Influence of cardioversion on left atrial volume and function in patients with heart failure and preserved ejection fraction and atrial fibrillation

MDW Maximilian Von Roeder[1]; S Blazek[1]; KP Rommel[1]; G Goia[1]; C Besler[1]; K Fengler[1]; JA Lurz[2]; G Hindricks[2]; H Thiele[1]; P Lurz[1]
[1]University of Leipzig, Heart Center, Department of Internal Medicine and Cardiology, Leipzig, Germany; *[2]University of Leipzig, Heart Center, Department of Electrophysiology, Leipzig, Germany*

Background: Atrial Fibrillation (AF) is frequent in Heart Failure with Preserved Ejection Fraction (HFpEF) and associated with increased mortality and morbidity. Growing evidence underlines the importance of left atrial (LA) phasic function in HFpEF. Aim of the current study was to investigate acute and chronic changes of LA volume and phasic deformation in patients undergoing cardioversion (CV) for first episode of atrial fibrillation.
Methods: We performed 3-D echocardiography and strain analysis of the LA before CV (baseline, BL), after 25±10 days (post,PO) and after 190±20 days of Follow-up (FU). 3 aspects of atrial deformation were analysed: LA reservoir function, conduit function and booster pump function (at PO and FU) with corresponding volumes from 3-D volume-time curves. Patients were classified as HFpEF according to European Guidelines during the post visit..
Results: 39 patients with sinus rhythm and preserved LV function were available for analysis, including 16 patients with HFpEF. LA maximum volume (LAmax) remained unchanged by cardioversion (BL vs FU 40±11 vs 39±10ml/m^2), but HFpEF patients had higher volumes at all phases of the cardiac cycle at baseline (LAmax 46±10 vs. 35±10 ml/m^2, p=0.001, LAmin 34±11 vs. 24±10ml/m^2, p=0.001) and follow up (LAmax 44 ± 9 vs. 35 ± 8 ml/m^2, p=0.001, LAmin 34±11 vs. 24±10, p=0.001). LA reservoir, conduit and boster pump function were lower at all timepoints in HFpEF (e.g. LAmax strain PO 14.4 ± 4.0 vs 25.2 ± 12.0, p=0.001). In all patients LA conduit function remained unchanged after cardioversion (conduit strain BL vs PO 12.2±7.9 vs 12.5±5.8%, P=ns), but LA booster pump function changed over time: while it was restored immediately post CV in the control group, with no further increase on FU (PO vs FU 11.8±5.5 vs 12.6±8.1, p=ns), it increased in HFpEF over time (PO vs FU 5.7±5.7 vs 8.9±7.0%, P=0.049). This was accompanied by an increase in total LAEF in HFpEF (PO vs FU 32±17 vs 41±16%, p=0.01), while it remained unchanged in controls (PO vs FU 51±17 vs 54±17%, p=0.36).
Conclusion: CV restores booster pump function in all patients, while 3-D derived LA maximum volume and LA conduit function remain unchanged after a median follow up of 190±20 days. Despite the same symptom duration before CV, LA booster pump function needs more time to recover in HFpEF and is an important driver of LA total EF.

P2009

Association of endothelial NO-synthase gene polymorphism with the left ventricle diastolic dysfunction and pulmonary hypertension in patients with heart failure and preserved ejection fraction

KI Cherniaieva[1]; KM Amosova[1]; YV Rudenko[1]; GV Mostbauer[1]; AB Bezrodny[1]; OI Nishkumay[1]; PO Lazarev[1]; OI Rokyta[1]; NV Bereza[1]; NV Shyshkina[1]; KP Lazareva[1]; OV Vasylenko[1]; YA Kovtun[1]; DS Sichinava[1]; ZV Lysak[2]
[1]National O.O. Bohomolets Medical University, Department Internal Medicine, Kiev, Ukraine; *[2]Alexander Hospital of Kiev, Department of cardiac rehabilitation, Kiev, Ukraine*

Introduction . Pulmonary hypertension (PH) develops in 50-80% of patients with left-sided heart failure (HF), regardless to the left ventricle (LV) ejection fraction (EF). Endothelial NO-synthase (eNOS) activity plays important role in the development of PH in patients (pts) with heart failure with preserved ejection fraction (HFpEF). Genetic polymorphisms of eNOS may affect the severity of the left ventricle (LV) diastolic dysfunction (DD) and the elastic properties of systemic arteries in pts with HFpEF.

Purpose. To determine the polymorphism of the eNOS gene 786T>C rs 2070744 and the association of the corresponding genotypes with the severity of LV DD, PH and elastic properties of the arteries in patients with arterial hypertension (AH) and HFpEF.
Methods. We included 69 hemodynamically stable pts with AH and HFpEF (58.1% men, 67.4 ± 10.2 years; NYHA II-III). All patients underwent NT – proBNP evaluation; echocardiography; applanation tonometry; 6-minute walk test (6MWT); endothelium-dependent, flow-mediated vasodilation (FMD); LV myocardium mass index (LVMI), arterial elastance (Ea), ventricular elastance (Ees), their ratio (Ea/Es) and systemic arterial complaence (SAC) were also calculated. Genotyping for eNOS 3 was performed by polymerase chain reaction in the real-time. Genomic DNA samples were isolated from stabilized blood. Patients were divided into 3 groups, according to genotype.
Results. "Wild" homozygous TT genotype was found in 34 (49.3%) pts (TT group), heterozygous TC genotype – in 21 (30.4%) pts (TC group), "mutant" homozygous CC genotype – in 14 (20.3%) pts (CC group). Pts did not differ in gender (19 (55.9%), 12 (60%), 11 (61.1%) men, respectively), age (67.1 ± 8.9, 65.4 ± 10.6, 64.9 ± 10.3 years, respectively), and the prevalence of comorbidities (all p> 0.05). In pts of CC group, compared with TT and TC, there was the worst result of 6MWT (314.3 ± 69.1, 371.8 ± 77.7, 385.7 ± 85.4 m, respectively); higher NT-proBNP level (806.9 ± 369.7, 668.1 ± 317.8, 636.9 ± 433.2 pg/ml, respectively); greater LVMI (187.4 ± 37.1, 182.2 ± 25.7, 195.2 ± 28.5 g/m2 respectively); more pronounced LV DD, according to average e' (4.7 ± 0.6, 5 ± 1.7, 5.3 ± 0.8 sm/sec, respectively) and E/e' ratio (15.9 ± 2.1, 14.5 ± 1.3, 15.1 ± 1.5, respectively); the highest systolic pulmonary artery pressure (50 ± 19.9; 39.6 ± 10.3; 40 ± 19.2 mmHg, respectively); worse elastic properties of arteries according to augmentation index (33,8±4,9, 26,5±4,6, 27,3±5,6%, respectively), pulse wave velocity (13,1±0,7, 12,2±0,8, 12,4±1,1 sm/sec, respectively), SAC (1,1±0,2, 1,6±0,2, 1,55±0,3 ml/mmHg, respectively), Ea (2,3±0,2, 1,9±0,3, 2,1±0,3, respectively) and worse results of the FMD (8,1±2,5,10,1±4,5, 9,8±2,2, respectively, (all p <0.05).
Conclusions. Compared to other polymorphisms, the CC genotype of the NOS3 rs 2070744 gene is associated with more impaired LV diastolic function and systemic arteries elasticity, and greater PH in patients with AH and HFpEF.

P2010

Regional differences in characteristics and correlates of coronary microvascular dysfunction in HFpEF

PURPOSE: In heart failure with preserved ejection fraction (HFpEF) coronary microvascular dysfunction (CMD) is a key feature. However, HFpEF is heterogeneous and phenotypes may differ between countries and regions.
METHODS We compared clinical characteristics and associations with CMD in 202 stable HFpEF patients in US, Singapore, Finland and Sweden in the multi-center PROMIS-HFpEF study. All patients had HFpEF according to current guidelines and no patient had unrevascularized macrovascular coronary artery disease. CMD was defined as coronary flow reserve <2.5. Associations between clinical characteristics and CMD were analysed by multiple logistic regression. The final model included age, sex, smoking, atrial fibrillation/flutter, NT-proBNP and left atrial strain.
RESULTS In Singapore HFpEF patients had the lowest BMI and highest prevalence of hypertension and diabetes, while in Finland and Sweden atrial fibrillation, low atrial strain and high NTproBNP were common (TABLE). In US, patients were younger, more obese with less atrial fibrillation and hypertension. CMD was present in US: 59% (n=30); Singapore: 80% (n=16); Finland 88% (n=35) and Sweden 77% (n=70) (p=0.013). In the final model only smoking was associated with CMD (OR 3.5 (95% CI 1.7-7.2; p <0.001). There was no significant interaction with country in any variable, but LDL and cholesterol were borderline (both p=0.084).

TABLE

Chronic Heart Failure - Epidemiology, Prognosis, Outcome

P2011

Heart rate and rhythm in relation to quality of life in outpatients with heart failure

M Grundtvig[1]; M Laegran[1]; T Volnes-Eriksen[1]
[1]*St Olavs Hospital, Fagenheten, Trondheim, Norway*

Background Studies denote correlation between high heart rate and atrial fibrillation with mortality but less is known about quality of life with these factors in patients with chronic heart failure. This study examined these relationships in a large sample.
Method The Minnesota Living with Heart Failure Questionnaire average score (MLWHFQ score) was examined in relation to heart rate in patients attending specialized hospital outpatient clinics who had sinus rhythm (SR) or atrial fibrillation (AF). The patients were registered at the first visit in our national registry. The difference of the scores between SR and AF were examined by Student t-test and between the rates by one-way Annova.
Results There were 4524 patients. Patients with AF comprised 33% and they were significantly older, had worse renal function, higher NYHA functional class, higher EF, lower s-potassium, lower s-sodium, more stroke, lower systolic blood pressure, less ischemic reason for HF, and used higher doses of diuretics than patients with SR. Patients with AF had significantly worse MLWHFQ scores than patients with SR except for heart rate above 90 bpm. The scores are shown in the table. Higher HR was significantly related to poor quality of life for both rhythms ($p<0.001$). In multivariate Cox proportional hazard regression model after a median 14 months follow-up, the type of rhythm and heart rate were not independent predictors for mortality.
Conclusions Disease specific quality of life measured by MLWHFQ average score was significantly related to heart rhythm (SR vs. AF, $p<0.02$) except for HR>90 bpm ($p=0.9$). Patients had worse quality of life with increasing HR irrespective of rhythm ($p<0.001$).

Table

Heart rate(beats/min)	Sinus rhythm (N=3036)	Atrial fibrillation (N=1488)	p-value fordifferences
< 70	1.65 ± 1.09	1.89 ± 1.09	<0.001
70-79	1.85 ± 1.09	2.05 ± 1.11	0.004
80-89	1.94 ± 1.17	2.15 ± 1.06	0.016
>90	1.94 ± 1.17	2.19 ± 1.07	0.9

Average Minnesota Living with Heart Failure Questionnaire scores ± standard deviation and type of heart rhythm and heart rate at the first visit to the hospital specialized outpatient units.

P2012

Heart failure in Colombia: results form the RECOLFACA registry

CI Clara Ines Saldarriaga[1]; JE Gomez[2]; LE Echeverria[3]
[1]*Cardiovascular Clinic Santa Maria, Universityof Antioquia cardiology department, Medellin, Colombia*; [2]*Valle del Lili Foundation, cardiology, Cali, Colombia*; [3]*Fundacion cardiovascular , Heart failure, Bucaramanga, Colombia*

On behalf of: Heart failure chapter of the Colombian society of cardiology
Funding Acknowledgements: This registry received financial support from NOVARTIS and the Colombian society of cardiology

Background: data about heart failure in Latino America is scarse, the main objective of this registry was to characterize the population of outpatients with heart failure that were followed in 60 Colombian hospitals in order to have a better understanding of the burden of this disease in our country.
Methods: data were collected prospectively, demographic, clinical characteristics and treatment patterns were collected. Univariate analyzes was used with frequencies and proportions for categorical variables and measures of central tendency, positions and dispersion for continuous variables.
Results: 2099 patients were included from September 2016 to September 2018, mean age was 67.59 +/- 13.54 years, 43.46% were female and 72.83% lived in urban areas. 70% had HFrEF , 14.6% had HFmEF and 15.4% had HFpEF.The NYHA was: I: 11.1%, II: 55.7%, III: 27.1%, IV: 4.7%. The most common comorbidities were hypertension (42.5%), malignancy (15.09%), type 2 diabetes (26.11%), hepatic disease (39.7%), coronary artery disease (18.83%), atrial fibrillation (19.93%) and COPD (4.4%). Ischemic cardiomyopathy was the cause of heart failure in 76.2% and Chagas heart disease in 0.8%. 72.5% of the patients were hospitalized once during the last year, 16% twice and 11.5% three or more times. The average length of stay was 11.4 +/- 12.8 days. The percentage of use of medications was: beta blockers: 87.96%, diuretics: 68.29%, MRA: 56.19%, ACE inhibitors: 34.2%, ARB 42.08%, ARNI: 11%. The use of CRT was 10.3% and 5.6% for ICD.
Conclusions: This is a population with a high burden of comorbidities, with an appropriate use of medical therapy but with a lower use CRT and ICD. There is a high number of hospitalizations that represents high costs for our health care system and requires the creation of more multidisciplinary heart failure programs.

Pulmonary arterial hypertension treatment in latin america

SGC Stephania Galindo Coral[1]; JEG Juan Esteban Gomez Mesa[2]
[1]*Valle del Lili Foundation, Cardiology Department and Clinical Research Center, Cali, Colombia*; [2]*Valle del Lili Foundation, Heart Failure/Cardiology department, Cali, Colombia*

On behalf of: CIFACAH investigators
Funding Acknowledgements: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors

Introduction: Pulmonary arterial hypertension (PAH) is a progressive and serious illness that requires structured diagnostic strategies in order to select the best treatment options. Most countries in Latin America (LA) are developing countries

and their social and health characteristics limit access to different medical and interventional procedures, affecting diagnosis and treatment approaches in PAH.
Purpose: This article aims to reveal data about the treatment options for PAH population in LA; This data is necessary to create new lines of cooperation in LA to develop local, national and international strategies and to generate new health policies that meet the specific needs for each country in order to decrease complications related to PAH.
Methods: This is a descriptive observational study conducted in 19 countries in LA. Data was collected since January 2017 to June 2018. A structured questionnaire was sent to each national coordinator of the Council of Heath Failure and Pulmonary Hypertension (CIFACAH) of the Interamerican Society of Cardiology (SIAC). This questionnaire evaluated "availability" (available: yes, no) and "accessibility" (type of access: public/goverment, private, patient, donation or research) to 13 interventions: 10 pharmacological agents and 3 surgical procedures (Pulmonary thromboendarterectomy [PTE], balloon atrial septostomy [BAS]) and lung transplantation).
Results: Sildenafil and bosentan are the only pharmacological agents with public access (ideal coverage) in more than 50% of countries. 58% of countries have access to less than 50% of the interventions, while Argentina, Colombia and Mexico have public access to 80%, 90% and 70% of those interventions (Figure 1). PTE and BAS have public coverage in 52.6% and 57.9% of LA countries, respectively. Lung transplantation centers are located in Argentina, Brazil, Chile, Colombia, Costa Rica, Cuba and Peru.
Conclusion: Access to PAH interventions are unequal among LA countries. 58% of countries have access to less than 50% of interventions in PAH. Some countries do not have different pharmacological or interventional options to treat these population. Only sildenafil and bosentan are available through public access in more than 50% of countries. Limited access to this or other interventions increases disease progression and mortality. This data will help to develop national and international policies that will improve availability and accessibility to these 13 interventions in PAH.

P2014

Prevalence of cardiac and non cardiac comorbidities in heart failure outpatients with preserved, mid ranged, and reduced ejection fraction: a single tertiary university center experience

G Giamouzis[1]; A Xanthopoulos[2]; NA Chroub-Papavaiou[1]; G Karagiannis[3]; A Pantziou[1]; A Douras[4]; A Simou[1]; J Skoularigis[1]; F Triposkiadis[1]
[1]University General Hospital of Larissa, Larissa, Greece; *[2]Cleveland Clinic Foundation, Cleveland, United States of America*; *[3]Harefield Hospital, London, United Kingdom of Great Britain & Northern Ireland*; *[4]General Hospital Volos, Volos, Greece*

Purpose: To assess the prevalence of major cardiac and non-cardiac comorbidities in a contemporary, unselected chronic heart failure (HF) population visiting the HF Clinic of a tertiary University Hospital, stratified by ejection fraction.
Methods-Results: This is a prospective, observational study collecting epidemiological information in ambulatory HF patients from January 2016 to December 2018. Patients were classified according to baseline LVEF into HF with reduced EF [EF <40% (HFrEF)], mid-range EF [EF 40-50% (HFmrEF)] andpreserved EF [EF >50% (HFpEF)]. Major cardiac and non-cardiac co-morbidities were recorded at baseline.
Results: Overall, 1064 patients (mean age 73.4 years, 57.7% men, mean LVEF=43.6%) were recruited in this study [n = 361 (33.9%) HFrEF, n = 247 (23.2%) HFmrEF, and n = 456 (42.9%) HFpEF]. The frequency of comorbidities in the total population is presented in Table. In comparison with HFmrEF and HFpEF subjects, patients with HFrEF were more likely to have a prior myocardial infarction (80.1% vs. 55.1% vs. 9.4%), diabetes (29.1% vs. 21.5% vs. 21.5%), dyslipidemia (50.4% vs. 45.3% vs. 33.8%), anemia (36.6% vs. 30.8% vs. 26.3%) and chronic kidney disease (37.1% vs. 28.7% vs. 20.4%), but less likely to have hypertension (58.7% vs. 66.8% vs. 95.4%) or obesity (19.4% vs. 21.9% vs. 61%). Interestingly, the three groups had similar prevalence of chronic obstructive pulmonary disease and atrial fibrillation.
Conclusion: In a contemporary community population with chronic HF, the HFmrEF group resembled the HFrEF group in more features than the HFpEF group. Non-cardiac co-morbidity rates were similarly high, except for obesity and hypertension which were more prevalent in HFpEF.

Table 1. Frequency of comorbidities in the HF population and stratified by EF phenotype

Comorbidity	Total n=1064	HFpEF n=456	HFmrEF n=247	HFrEF n=361	P
Obesity, n (%)	402 (37.8)	278 (61.0)	54 (21.9)	70 (19.4)	0.000*
Hypertension, n (%)	812 (76.3)	435 (95.4)	165 (66.8)	212 (58.7)	0.000*
Myocardial infarction, n (%)	468 (44.0)	43 (9.4)	136 (55.1)	289 (80.1)	0.000*
COPD, n (%)	155 (14.6)	59 (12.9)	32 (13.0)	64 (17.7)	0.118
Diabetes mellitus, n (%)	256 (24.1)	98 (21.5)	53 (21.5)	105 (29.1)	0.025*
Atrial fibrillation, n (%)	331 (31.1)	147 (32.2)	72 (29.1)	112 (31.0)	0.698
Dyslipidaemia, n (%)	448 (42.1)	154 (33.8)	112 (45.3)	182 (50.4)	0.000*
Anaemia, n (%)	328 (30.8)	120 (26.3)	76 (30.8)	132 (36.6)	0.007*
Chronic kidney disease, n (%)	298 (28.0)	93 (20.4)	71 (28.7)	134 (37.1)	0.000*

* Statistically significant
COPD, chronic obstructive pulmonary disease; EF, ejection fraction; HFmrEF, heart failure with mid-region ejection fraction; HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction

Patients with CHF at low risk after acute decompensation do not need for careful observation and intensive treatment

O Narusov[1]; A Skvortsov[1]; M Muksinova[1]; D Protasova[2]; V Protasov[1]; T Sharf[1]; V Masenko[1]; S Tereshchenko[1]
[1]National Cardiology Research Center, Moscow, Russian Federation; *[2]National Research Center for Preventive Medicine, Moscow, Russian Federation*

Purpose: Assess the need for careful observation and intensive treatment of patients (pts) at low risk after acute decompensation of heart failure (ADHF)
Methods: In the prospective single-center trial were included 100 with class III-IV CHF and left ventricular ejection fraction (LV EF) <40% due to ischemic heart disease, dilated cardiomyopathy, or arterial hypertension. After compensation of HF before discharge they were distributed into groups of low (NT-proBNP <1400 pg/ml, n=30, group LR) or high (NT-proBNP ≥1400 pg/ml, n=70) risk. High risk (HR) pts were randomized into 2 treatment groups: NT-proBNP -control (group 1, n=35) and standard (according to clinical guidelines) therapy (group 2, n=35). Blood sampling to determine the biomarkers concentrations (NT-proBNP, soluble ST2, copeptin, galectin-3, hsTnT and NGAL) were collected at discharge from the hospital, 3 and 6 months after. Pts from groups 1 and 2 attend visits monthly, but LR pts after 3 and 6 months for blood tests only. ombined endpoint (CE) included CV death, HF rehospitalization, resuscitation and worsening heart failure requiring intravenous diuretics.
Results: At the end of the study all pts have been treated by recommended combination, but the mean doses up-titration of iACE/ARB and beta-blockers at the 6 months of treatment were significantly higher in group 1 vs group 2, p<0.05. In groups LR mean doses of iACE and beta-blockers did not change and at 6 months became significantly lower than ones in groups 1 and 2. At discharge median NT-proBNP concentration was 839,2 (508,3;1029,8), 3750.0 (2224.0; 6613.0), 2783.0 (2021.5; 4827.5) pg/ml in groups LR,1 and 2, respectively. After 6 months of treatment, median NT-proBNP concentration significantly decreased in group 1 (Δ%= -53,1%) and in group 2 (Δ%= -11,1%, p=0.024). The same more

pronounced biomarkers activity reduction were found in group 1 for sST2 (Δ%= -37,1% vs -10,4%, p=0,0001) and copeptin concentration (Δ%= -29,9% vs -3,4%, p<0,001). Concentration of galectin-3, hsTnT and NGAL significantly decreased only in group 1. Biomarkers activity changes in LR pts were not found. Minimal rate of CE in HR pts was in group 1 -0,32/pt vs 1,03/pt in group 2 (p=0,002). But the rate of CE in group LR was the same as in group 1 – 0,23/pt (p=0,49).
Conclusion: Patients after ADHF and with discharge concentration of NT-proBNP <1400 pg /ml have the same rate of CE as patients from NT-proBNP-control therapy group. So, patients with CHF at low risk do not need for careful observation and intensive treatment.

P2016

Determinants and prognostic impact of intra-hospital worsening of renal function in acute heart failure

A Andrea Klein[1]; S Muensterer[1]; M Hanke[1]; R Ludwig[1]; M Breunig[1]; C Morbach[1]; V Cejka[1]; M Christa[1]; N Scholz[1]; M Ertl[1]; M Kaspar[1]; G Ertl[1]; S Frantz[2]; C E Angermann[1]; S Stoerk[1]
[1]Comprehensive Heart Failure Center (CHFC), Wurzburg, Germany; *[2]University Hospital of Wurzburg, Wurzburg, Germany*

Funding Acknowledgements: The Federal Ministry of Education and Research (Germany) (grant #01EO1004 & #01EO1504)

Background & Aim: Factors prolonging hospitalization for acute heart failure (AHF), e.g. renal insufficiency (RI) or worsening of renal function (WRF), are ill understood. We analyzed the impact of RI and WRF on intra-hospital course and 12-month outcome.
Methods The AHF Registry at the Comprehensive Heart Failure Center aims to comprehensively phenotype all AHF patients (except cardiogenic shock or high output failure) on a 24/7 basis, and describe in-hospital and post-discharge outcomes. In-hospital WRF was defined as change of baseline serum creatinine (Crea) ≥0.3 mg/dL, and designated as persistent if present at discharge, or transient if not present at discharge. RI was excerpted from medical records. Prognostic impact was analysed using logistic or Cox proportional hazard regression.
Results We report on the first 425 patients consenting to the long-term follow-up study, who were not on chronic hemodialysis. Characteristics at admission were: median age 76 years; 42% women; NYHA class IV/III/II was 52%/40%/5%; 40% had left ventricular ejection fraction ≤40%; mean Crea was 1.3 mg/dl; median NT-proBNP 7700 pg/ml. WRF occurred in 174 patients (41%; Crea 1.6 mg/dl). In n=17 (4%; Crea 1.5 mg/dl), WRF occurred in conjunction with other types of clinical worsening. WRF without concomitant worsening of other condition occurred in 157 patients (36%; Crea 1.7 mg/dl). Baseline Crea in patients without WRF was 1.4 mg/dl (p for difference with isolated WRF <0.001). WRF was transient in n=90 (21%; Crea 1.7 mg/dl), but persisted in n=84 (20%; Crea 1.6 mg/dl; p=ns). The following characteristics were associated with any WRF (odds ratio with 95%CI compared with no-WRF): age per 10 years (1.24; 1.04-1.47), hypertension (2.22; 1.29-3.82), hyperlipidemia (1.80; 1.20-2.70), diabetes mellitus (1.60; 1.07-2.38), coronary artery disease (2.15; 1.44-3.22), RI (2.95; 1.95-4.46), Crea per mg/dl 1.79 (1.32-2.42). WRF was associated with prolonged length of hospital stay: no WRF 9 days (quartiles 6, 13); transient WRF 13 days (9, 19); persistent WRF 13 days (9, 18) (p for no-WRF vs WRF<0.001). Intra-hospital death rate was 1.2% in no-WRF, 4.4% in transient WRF, and 7.1% in persistent WRF. The respective OR for WRF vs no-WRF was 5.0 (95%CI 1.4-18.6; p=0.015), and persisted after adjustment for age and Crea. Age-adjusted 1-year death rate was 23% in patients without WRF, and 31% with WRF (hazard ratio 1.32, 95%CI 0.91-1.92; p=0.15), and was similar for transient and persistent WRF. Of note, age-adjusted RI predicted 12-month death risk (1.89, 95%CI 1.29-2.76).
Discussion Both transient as persistent WRF increase the length of hospitalization by about 50% and raise intra-hospital mortality risk 4- to 6-fold. After discharge, mortality risk seems to be determined mainly by RI per se rather than intra-hospital WRF. Future research should aim to better clarify triggers of in-hospital WRF and develop avoidance strategies.

P2017

Heart failure in very elderly patients (90 years of age and older)

L Liliya Demirevska[1]; M Nedkova[1]; A Chobanov[1]; I Daskalov[1]; T Valova[1]; M Amiorkov[1]
[1]Military Medical Academy, Cardiology, Sofia, Bulgaria

Background: Very elderly patients (≥ 90 years) with heart failure (HF) are rarely included in clinical trials. The aim of this study was to assess clinical characteristics, therapy, and outcomes of very elderly patients after their first HF hospitalization.
Methods and Results: This is a prospective, observational study that included 157 HF patients ≥80 years (mean age 89.2 years, 47% male) hospitalized in our Medical Academy, between January 2016 and December 2017. We used generalized estimating equations to evaluate outcome differences between different age groups within the very elderly cohort (80 to 89 years and ≥ 90), adjusting for comorbidities, demographics, and clustering by treatment facility. Outcomes of interest were pharmacological treatment of HF, mortality during index admission, 30-day and one-year mortality, and 30-day all-cause and HF readmissions. When compared to 80-89 years group, the ≥ 90 years group had less ischaemic heart disease and hypertension; and higher prevalence of atrial fibrillation, conduction abnormalities, chronic kidney disease, and anaemia (p<0.01). Preserved left ventricle ejection fraction (LVEF) was detected in 71% of patients, mid-range LVEF in 18%. When compared to 80 to 89 years group, the patients ≥ 90 years had lower body mass index ((24.9 ± 4.7) vs. (23.5 ± 4.0) kg/m2, p = 0.011), lower systolic blood pressure on admission ((131.5 ± 23.6) vs. (118.3 ± 18.2) mmHg, p = 0.002), higher mortality (29.2% vs. 39.1%, p = 0.003). Multiple logistic regression analysis showed that LVEF < 50% was an independent risk factor for death in the entire cohort. In-hospital, thirty-day, and 1-year mortality were similar (11% in 80-89 years vs. 12% in the ≥ 90 year (p=0.7)), 6% vs 7% (p=0.6), and 18% vs. 20%, respectively (p=0.5). 30-day all-cause readmissions and HF readmissions did not differ between age groups. The most frequently used therapy for HF in patients ≥ 90 years when compared to 80-89 years was beta-blockers (42% vs. 29%, p =0.01) and digitalis (28% vs. 21%, p = 0.02). Non-adherence to medications and to lifestyle recommendations was detected during follow-up in both groups.
Conclusions: The HF patients ≥ 90 years have high mortality and frequent readmission rates. The most frequently prescribed therapy for HF in this age group is beta-blockers and digitalis, which is most likely due to high prevalence of atrial fibrillation in these patients.

P2018

Right ventricular dysfunction in heart failure with preserved ejection fraction: an impact on survival

B Blanka Mahne[1]; S Kariz[1]; R Stopar[1]; T Ravnikar[1]; A Kupresan[1]; N Cernic Suligoj[1]
[1]Izola General Hospital, Department of Cardiology, Izola, Slovenia

Background. Right ventricular (RV) dysfunction and pulmonary hypertension (PH) are common in heart failure with preserved ejection fraction (HFpEF) and are associated with poor outcome.
Purpose. The aim of the study was to investigate the prevalence of RV dysfunction, RV dilatation and PH in patients hospitalized for HFpEF and their impact on survival.
Methods. We retrospectively analyzed medical records of all patients discharged from a regional hospital with the diagnosis of HFpEF (EF ≥ 45%) between January and June 2016. Echocardiographic parameters were analyzed for the presence of RV dilatation (RV diastolic area >25 cm^2, basal RV diameter >41 mm), RV dysfunction (tricuspid annular plane systolic excursion (TAPSE) <17 mm, fractional area change (FAC) < 35%), and pulmonary hypertension (PH) (pulmonary artery systolic pressure (PASP) ≥40 mmHg) and a 2-year mortality was assessed.
Results. 80 patients (mean age 78.6 ± 7,1 years, 60% females) were included in the study. We were able to assess pulmonary pressure in 74 patients, of which 55 (74.3%) had PH. Subjects with PH were further divided into three groups. The first group consisted of 21 subjects with PH, normal RV dimensions and normal RV function. In this group 2 patients died (9.5% mortality). The second group consisted of 18 subjects with PH, dilated RV and normal RV function, of which 7 died (38.9% mortality). The mortality was highest (81.2%) in 16 subjects with PH, RV dilatation and RV dysfunction (third group).
Conclusions. Our data confirm that PH is highly prevalent in HFpEF patients. The progression to RV dilatation and finally to RV dysfunction had an important impact on survival. Accurate assesment of RV function and better understanding of the mechanisms implicated in the development of RV dysfunction and its clinical role in HFpEF may aid to develop novel effective treatment strategies to improve outcomes of this complex disease.

P2019

Comparison of baseline characteristics and outcomes in women versus men referred for advanced heart failure therapies

J K Vishram-Nielsen[1]; T Deis[1]; K Rossing[1]; E Wolsk[1]; AC Alba[2]; HJ Ross[2]; F Gustafsson[1]
[1]Rigshospitalet - Copenhagen University Hospital, Department of Cardiology, the Heart Centre, Copenhagen, Denmark; *[2]Heart Failure / Transplant Program, Toronto General Hospital, University Health Network, Toronto, Canada*

Background: Despite the steady increase in prevalence of patients with end-stage heart failure (HF) who are referred for advanced HF therapies such as ventricular assist device (VAD) or heart transplantation (HTX), sex differences in baseline characteristics and outcomes remain understudied.
Methods We assessed sex differences in baseline characteristics and outcomes in 429 (23% women) consecutive ambulatory adult HF patients, with a left ventricular

ejection fraction <45% who underwent right heart catheterization (RHC) for assessment of advanced HF therapies.
Results At the time of evaluation, women were younger than men (47.9 +13.2 years vs. 51.3 +12.4 years, p=0.02). There were no differences in duration of HF <6 months (62% in women and 60% in men), or time from HF diagnosis to index RHC (median (IQR) 1 (0-5) years in women and 2 (0-7) years in men). Women were less likely to have ischemic cardiomyopathy compared to men (18% vs. 33%, p=0.004). The burden of comorbidities (diabetes mellitus, myocardial infarction, peripheral arterial disease, stroke / transient ischemic attack, venous thromboembolism, sleep apnea, chronic obstructive pulmonary disease, chronic kidney disease, hepatic dysfunction, current / previous malignant disease, depression) was similar, except for atrial fibrillation (18% in women and 36% in men, p=0.0007) and thyroid disease (16% in women and 6% in men, p=0.005). There were no significant differences in NYHA class or physical examination (pulmonary rales, pleural effusion, hepatomegaly, ascites, peripheral hypoperfusion or oedema), except for jugular vein distension (13% in women and 25% in men, p=0.03). Use of contemporary medical HF therapy and CRT/ICD was equal between the sexes. Women had lower RHC pressures (pulmonary capillary wedge (16.9 +7.2 vs. 20.5 +8.4), pulmonary arterial mean (25.5 +9.6 vs. 29.4 +10.2), right ventricular systolic (37.9 +12.7 vs. 43.0 +37.9), and right atrial (9.0 +5.1 vs. 10.5 +6.6), in mmHg, p<0.02 for all), but similar cardiac index compared to men. Peak oxygen uptake was not significantly different (15.3 (9.2-18.6) in women and 12.9 (10.9-16.1) in men, in ml/kg/min, p=0.66). During 1-year follow-up, there were 38 deaths (5% of women and 10% of men, p=0.16), 27 VAD implants (1% of women and 8% of men, p=0.009), and 64 HTXs (24% of women and 13% of men, p=0.01). The time from index RHC to HTX was shorter in women compared to men (81 (51-179) days in women and 174 (110-278) days in men, p=0.003). During total follow-up time (1.5 (0.4-4.3) years), there were 147 deaths (18% of women and 30% of men, p<0.0001), 43 VAD implants (3% of women and 12% of men, p=0.007), and 107 HTXs (31% in women and 23% in men, p=0.15). There were no sex differences in time from index RHC to experiencing an event.
Conclusion At elective evaluation for advanced HF therapies, hemodynamics were less deranged in women. A higher proportion of women received HTX, their waitlist time was shorter, and survival greater.

P2020

The prognosis of patients with chronic heart failure, depending on adherence to observation in a specialized heart failure treatment center

NG Vinogradova[1]; IV Fomin[1]; DS Polyakov[1]
[1]*Privolzhsky Research Medical University, Nizhny Novgorod, Russian Federation*

Introduction: Reducing the risk of overall mortality in patients with chronic heart failure (CHF) depends on effective treatment methods and physical rehabilitation. The main goal today is to increase adherence to the treatment of patients with CHF.
Purpose: To determine the risks of total mortality in patients with CHF during two years of follow-up, depending on adherence to observation in a specialized center for the treatment of chronic heart failure (enter CHF).
Methods: The study included 942 patients with CHF of any etiology over the age of 18, who were discharged from the hospital after the decompensation of CHF. Analyzed the patient's adherence to observation in center CHF: group 1 consisted of 313 patients who continued monitoring at center CHF for two years, group 2 - 382 patients who, after discharge from the hospital, refused observation in center CHF and were observed only in ambulatory department, group 3 - 197 patients who were observed at the center CHF during the first year and then discontinued, and a group of 4−49 patients who were included in the study, refused to follow up, but a year later they began to contact center CHF and were observed throughout the second year. Patients from group 1 visited the cardiologist of center CHF at least 1 time in 3 months regulary. Patients who missed or refused follow-up were under the supervision of a nurse, who made structured phone calls at least once every 3 months. For statistical processing, the program Statistica 7.0 was used.
Results: The average age of patients in groups 1,2,3 and 4 is 69.6+9.9, 71.8+11, 70.1+10.9 and 71.6+8.3 years respectively (p1/2=0.006, other intergroup differences are unreliable). Non-heavy functional class (FC) (I-II) and heavy FC (III-IV) NYHA were found in group 1 in 48.6% and 51.4% of cases respectively, in group 2 - in 41.1% and 58.9%, in group 3 - in 59.6% and 40.4%, and in group 4 in 49% and 51% of cases respectively (p1/2 =0.052, p1/3=0.02, p1/4=0.96, p2/3<0.001, p2/4=0.3, p3/4=0.2). Total mortality after 2 years of follow-up was significantly higher in group 2: 32.4% versus 11.2% in group 1 (OR=3.8, 95% CI 2.5-5.7; p1/2 <0.001), versus 9,1% in group 3 (OR=4.8, 95% CI 2.8-8.1; p2/3<0.001) and against 8.2% in group 4 (OR=5.4, 95% CI 1.9 -15.3; p2/4=0.0005).
Conclusions: Elderly patients initially refused to observe in the center CHF and showed significantly higher mortality. It is necessary to create a system of observation at home for this category of patients. The patients with non-heavy FC NYHA, who initially began observation at the center CHF, subsequently refused to visit. Patients with III-IV FC NYHA were more likely to maintain a high commitment to long-term follow-up at the center CHF, who had a better prognosis of life.

P2021

The importance of changes in prognostic markers during the management of HFrEF : reassessment better predicts the outcomes than the initial evaluation.

M Maxime Faure[1]; F Picard[1]; P Dos Santos[1]
[1]*Hospital Haut Leveque, Heart Failure Unit, Bordeaux-Pessac, France*

Purpose: Risk scores in HFrEF are based on an analysis of numerous prognostic markers at baseline or at one point during the follow-up regardless of the patient's treatment evolution. However, patient's management and therapy response will change their prognosis.
Objectives: To appreciate the changes of prognostic markers throughout management of patients with HFrEF and to compare the prognostic value of these changes with the same markers collected at baseline.
Methods: All patients hospitalized at our institution from 1st May 2011 to 30th April 2015 with LVEF<40% at first visit (M0) with at least a second visit 6 month after (M6) were included and followed for 3 years. Data on pharmacological and non-pharmacological treatment between MO and M6 were collected. Usual prognostic markers such as EF, LVEDD, NYHA class, BNP, heart rate, 6 MWD, GFR, haemoglobin, mitral regurgitation grade, RV systolic function (S') were studied. The primary outcome was a composite of death, heart transplantation, need of mechanical circulatory support or hospitalization for heart failure.
Results: Among the 328 patients included at M0, 81% were men, mean age was 57 years, 42% had ischaemic cardiomyopathy and 39% were in NYHA class I or II. The average BNP was 584pg/mL (IQR 211-777) and LVEF was 28±7%. The exposure to specific heart failure therapy was significantly higher at M6 when compared with M0: 96% at M6 versus 55% at M0, (p<0.001) for beta-blockers, 94% versus 65% (p<0.001) for ACEI/ARB and 86% versus 43% for ARM (p<0.001). Moreover, the target doses of these treatments were greater at 6 months than at baseline: 61±34% of target dose (TD) versus 28±35% for beta-blocker (p<0.001), 63±35% TD versus 35±37% TD for ACEI/ARB (p<0.001), 65±35%TD versus 27±37%TD (p<0.001) for MRA. Same findings were seen for non-pharmacological therapies: use of cardiac rehabilitation (63% at M6 versus 12% at M0, p<0.001), ICD implantation (49% versus 27%, p<0.001) and CRT (29% versus 19%, p=0.003) were greater at 6 months than at baseline. The primary outcome occurred in 20% of the patients at one year and in 35% at three years. During follow-up, there were significant changes on prognostic markers like NYHA class (86% in class I-II at M6 versus 39% at M0, p<0.001), BNP (394ng/mL (IQR 63-441) at M6 versus 584pg/mL (IQR 211-777) at M0, p<0.001) and LVEF (35±12% at M6 versus 28±7% at M0, p<0.001). On multivariate analysis, better predictors of outcomes were: BNP level at M6 (HR 6,25; IC 95% 3,13-12,51; p<0,001), NYHA at M6 (HR 3,76; IC 95% 2,06-6,86; p<0,001), GFR at M6 (HR 2,28; IC 95% 1,33-3,89; p=0,003), RV systolic function (S' wave) at M6 (HR 2,28; IC 95% 1,23-4,24; p=0,009) and HR at M0 (HR 1,3; IC 95% 1,04-1,62; p=0,021).
Conclusion: Prognostic markers measurements after treatment optimization during six months are more associated with long-term mortality/morbidity when compared with the same markers collected at the beginning of the management in patients with HFrEF.

P2022

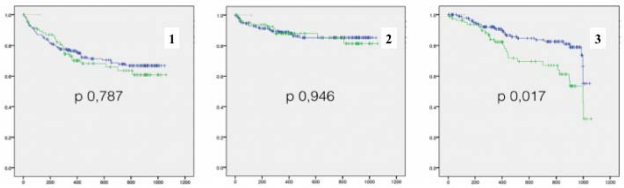
Follow-up of patients with heart failure and right ventricular dysfunction: clinical profile and prognosis.

CN Carlos Nicolas Perez Garcia[1]; D Enriquez Vazquez[1]; T Luque Diaz[1]; A Travieso Gonzalez[1]; M Ferrandez Escarabajal[1]; C Olmos[1]; D Vivas Balcones[1]; I Vilacosta[1]
[1]*Hospital Clinic San Carlos, Instituto Cardiovascular Clínico San Carlos, Madrid, Spain*

Introduction: the role of the right ventricle in the pathophysiology of heart failure (HF) and its clinical and prognostic implications in case of dysfunction, have aroused a growing interest in recent years.
Purpose: the aim of this study is to compare the clinical profile and prognosis of patients with heart failure and right ventricle dysfunction (RVD) and those with preserved right function.
Methods: patients admitted to a Cardiology ward in a tertiary hospital were collected prospectively and consecutively during 12 months with diagnosis of HF and right ventricular dysfunction, comparing with those with equal diagnosis without dysfunction, with subsequent follow-up.
Results: 321 patients were included, 93 patients with RVD (28.97%) and a mean TAPSE of 14.2 mm. There was a greater proportion of males (63.4%, p 0.04) with a worse cardiovascular risk profile (more HBP, DM, dyslipidemia, CKD, and AF, without reaching the statistical significance).
A greater proportion was associated with depressed LVEF (63.4% vs 46.5%, p 0.01), with higher average PASP figures (48 vs 41mmHg, p <0.001). The mean NT-proBNP figures at discharge were significantly higher (7776 pg / ml vs. 3539 pg / ml, p 0.01). Regarding the treatment, patients with RVD took more diuretic at admission (71% vs 48.5%, p 0.001) as well as RMAs (33.35% vs 18.5%, p = 0.01) and digoxin (18.3%,

vs 5.7 p 0.002). At discharge, more beta-blockers were used (77.4% vs 69.8%), diuretic (82% vs 69.4%), RMAs (40.7% vs 24.5%) and digoxin (16.1% vs 7.1%) reaching significance only in the last group (p 0.04). The consumption of ACEIs / ARBs was similar, close to 60% in both groups. The rate of ICD implantation was higher (18.3% vs 5.4%, p 0.001), but not that of CRT, with a higher percentage being derived to heart failure units at discharge (44.1% vs. 19.8%; p <0.001). In terms of follow-up, there were no differences in terms of mortality from all causes (1) or from HF (2), although a greater number of readmissions was described at 6 months by HF (3) (figure 1, 29.9 vs 15.4%, p 0.017).

Conclusion: the patient with HF and DVD tends to present a worse cardiovascular risk profile and greater concomitant left ventricular dysfunction. Regarding treatment, it was related to an increased use of diuretics, RMA and digoxin, greater implantation of ICD and greater referral to HF units at discharge. Although no differences in mortality were detected in our series, readmissions for HF were higher in this subgroup.



P2023

Risks of death from decompensation and cardiovascular causes in patients with chronic heart failure, depending on adherence to observation in a specialized center.

NG Nadezhda Vinogradova[1]; IV Fomin[1]; DS Polyakov[1]
[1]*Privolzhsky Research Medical University, Nizhny Novgorod, Russian Federation*

Specialized centers for treatment chronic heart failure (center CHF) contribute to reducing the risk of death from decompensation of heart failure (DHF) and cardiovascular cases (CVC). The analysis of the work first in Russia center CHF is presented in this work.

Purpose: to determine the risks of death from CVC and DHF in patients with chronic heart failure (CHF) during two years of follow-up, depending on the adherence to observation of center CHF.

Methods: 942 patients with CHF of any etiology older than 18 years old who were discharged from the hospital after DHF were included to the study. For two years, the patient's adherence to observation in center CHF was investigated. 4 groups were created: group 1, n=313, observation at center CHF for two years, and group 2, n=382, were observed at the other clinics, group 3, n=197, only the first year at center CHF was observed, and group 4, n = 49, the 1st year was observed in the other clinics and the 2nd year in center CHF. Observation of a cardiologist at the center CHF at least 1 time in 3 months. In cases of refusal from supervision, the control was carried out by a nurse who did structured telephone calls 1 time in 3 months. For statistical processing, the program Statistica 7.0 was used.

Results: The mean age of patients in groups 1,3,4 did not differ significantly. Significant differences were found between groups 1 and 2 (69.6+9.9 and 71.8+11 years, p1/2=0.006). Patients with III-IV FC NYHA initially in groups 1, 2, 3, and 4 met in 51.4%, 58.9%, 40.4%, and 51% of cases respectively (p1/2=0.052, p1/3=0,02, p1/4=0.96, p2/3<0.001, p2/4=0.3, p3/4=0.2). Death from CVC for 2 years of follow-up was significantly higher in group 2 versus 1 (8.1% and 1.3% of cases, OR=6.8, 95% CI 2.4-19.5; p1/2<0.001), also in group 2 versus 3 (3%), OR=2.8, 95% CI 1.1–6.8; p2/3=0.02. When comparing groups 1 and 4 (6.1%), death from CVC was higher in group 4, OR=5.0, 95% CI 1.1-23.2; p1/4=0.02. When comparing other groups there are no significant differences (p1/3=0.2, p2/4=0.6, p3/4=0.3).

The risks of death from DHF over the 2 years of follow-up were significantly higher in group 2 (16.4%) compared with all groups: group 1 (6.4%), OR=2.9, 95% CI 1.7-4, 9; p1/2<0.001; group 3 (5.1%), OR=3.7, 95% CI 1.8-7.3; p1/3<0.001; group 4 (2%), OR=9.5, 95% CI 1.3-69.7; p1/4=0.008. When comparing other groups, no significant differences were obtained (p1/3=0.5, p1/4=0.2, p3/4=0.4).

Conclusions: In groups 1, 2, and 4 baseline prevailed patients with severe CHF. The patients in group 3 were not committed to follow-up after 1 year but retained lower risks of death of CVC and DHF in comparison with patients who did not attend the center CHF. The highest risks of death from CVC and DHF were obtained in patients who were not observed in the center CHF after discharge from the hospital. Prolonged regular follow-up in specialized center CHF reduces the risk of death from CVC and DHF.

Conflict of interest: not declared.

P2024

Comorbidity burden can discriminate chronic heart failure with preserved and reduced but not with mid-range ejection fraction

G Gregory Giamouzis[1]; A Xanthopoulos[2]; NA Chroub-Papavaiou[1]; G Karagiannis[3]; A Pantziou[1]; A Douras[4]; A Simou[1]; J Skoularigis[1]; F Triposkiadis[1]
[1]*University General Hospital of Larissa, Larissa, Greece*; [2]*Cleveland Clinic Foundation, Cleveland, United States of America*; [3]*Harefield Hospital, London, United Kingdom of Great Britain & Northern Ireland*; [4]*General Hospital Volos, Volos, Greece*

Introduction: The 2016 ESC guidelines formally introduced a new classification whereby three types of HF patient are distinguished based on LVEF, comprising those with HF with reduced (HFrEF), mid-range (HFmrEF), and preserved EF (HFpEF). Whether or not comorbidity burden can define the new HFmrEF phenotype has never been explored.

Purpose: To evaluate the discriminative ability of comorbidity burden in the traditional vs. the newly introduced phenotype models.

Methodology: All consecutive ambulatory HF patients visiting the HF Clinic of a Tertiary University Center were examined for major cardiac and non-cardiac comorbidities and classified according to baseline LVEF into HFrEF (EF <40%), HFmrEF (EF=40–49%), and HFpEF (EF ≥50%). The discriminative ability of comorbidities to predict the Echo-based HF phenotype was then evaluated.

Results: 1140 HF patients were included in this prospective study, 500 (43.9%) with HFpEF, 259 (22.7%) with HFmrEF, and 381 (33.4%) with HFrEF. In comparison with HFpEF subjects, patients with HFrEF were more commonly younger, male, with prior myocardial infarction, chronic kidney disease, and anemia but less likely to have hypertension or obesity (Table 1). The prevalence of the respective comorbidities for the HFmrEF group most of the times resembled that of the HFrEF group. When the traditional model was used for classification the discriminative ability of comorbidities was very good in the total population (82,4% correct classifications) as well as for both HFpEF (87.6%) and HFrEF (78.4%). When HFmrEF was introduced, the discriminative ability dropped significantly for the total population (66.2%), due to the very poor discrimination of patients with HFmrEF (17.4%), even though it remained very good for HFpEF (86.8%) and modest for HFrEF (72.3%) patients respectively.

Conclusion: The discriminative ability of comorbidity burden is very good with regards to HFpEF and HFrEF but very poor when HFmrEF is introduced.

	HFpEF n=500(43.9%)	HFmrEF n=259 (22.7%)	HFrEF n=381 (33.4%)	P
Age (years)	72.8±11.4	71.2±14.4	70.4±11.6	0.015

Recovered ejection fraction in alcoholic cardiomyopathy: is alcohol abstinence the only predictive factor?

I Ines Pereira Oliveira[1]; A Leal Neto[1]; D Seabra[1]; A Andrade[1]; J Azevedo[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Penafiel, Portugal*

Introduction: Alcoholic cardiomyopathy (AC) is a presumptive diagnosis when other etiologies are excluded and there are excessive drinking habits. Since it is a toxic cardiomyopathy, recovery of left ventricular systolic function (EFrec) after cessation of consumption would be expected. However, the degree of ejection fraction (EF) improvement varies, possibly in the dependence of other factors not completely understood.

Purpose: Characterize a cohort of patients (pts) with AC admitted in a Heart Failure (HF) Clinic (HFC) and analyse the potential contributing factors to EF recovery.

Methods: Unicentric, retrospective analysis of AC pts followed in a HFC since 3/2011. Divided in two initial groups according to EFrec (defined as an EF increase > 10% with respect to the initial value) and then evaluated regarding alcoholic habits maintenance – four groups were obtained: G1 (abstinent pts with EFrec), G2 (non-abstinent pts with EFrec), G3 (abstinent pts with non-EFre) and G4 (non-abstinent pts with non-EFrec). Clinical, demographic, analytical, electrical, echocardiographic characteristics and major cardiac events – HF hospitalization (HFH) and mortality were analysed.

Results: Included 75 pts, mainly men (95%), with a mean age of 53.3 ± 11.2 years. Among the 35 pts who recovered EF, 70% ceased alcohol consumption (25 pts – G1). 10 pts had EFrec without becoming abstinent. Regarding non-EFrec (40 pts), 18 pts ceased alcohol consumption (G3) and 22 pts maintained their habits (G4). Considering cardiovascular risk factors, no significant differences in body mass index, hypertension, diabetes, dyslipidaemia or tabagism were identified between groups. Atrial fibrillation (AF) was more prevalent in G3 than in other groups (72.2% vs 33.3%, p=0.003); QRS mean duration was more significant in G4 in contrast to other groups (139ms vs 123ms, p=0.030). No statistically significant differences were documented in terms of NYHA functional class and HF hospital admissions.
Conclusion: In this cohort, most of the pts who recovered EF had ceased alcohol ingestion. However, some pts who ceased drinking habits did not show EF improvement; in this group, a higher prevalence of AF was observed. Despite the small size of the subgroups included in this study, the data obtained suggest that other factors may be implicated in EF recovery, such as rhythm disturbances as AF.

P2026

Prevalence of palliative care needs in patients with heart failure

CI Clara Ines Saldarriaga[1]; LF Arenas Ochoa[2]; L Montoya Trejos[2]; MC Zapata[2]; AM Restrepo Siegert[1]; F Toro[3]; AM Agudelo[1]; JS Diaz Betancur[4]; N Gonzalez Jaramillo[1]; JJ Vargas Gomez[2]; MA Lemos[3]; A Krikorian[2]
[1]Cardiovascular Clinic Santa Maria, Universityof Antioquia cardiology department, Medellin, Colombia; *[2]Pontificia Bolivariana University, Paliative care, medellin, Colombia*; *[3]Universidad Eafit, Pshychology program, medellin, Colombia*; *[4]Clinica las Americas, Cardiology - heart failure clinic , medellin, Colombia*

Background: The implementation of Palliative Care (PC) is heart failure is still limited, particularly in developing countries. The objective of this study was to identify the prevalence of PC needs and to describe the symptom burden and quality of life in a cohort of patients with heart failure (HF) followed in two HF clinics in our city.
Methods: Descriptive, cross-sectional study using a comparative and correlational design. Assessment of PC needs was conducted using NECPAL CCOMS-ICO, an instrument that helps to recognize needs of palliative care for different diseases. Symptom burden and quality of life were assessed using the Edmonton Symptom Assessment Scale (ESAS), The SF-12 Health Survey and the Kansas City Cardiomyopathy Questionnaire (KCCQ). Descriptive, correlational and comparative analyses were conducted using non-parametrical statistical tests.
Results: 136 patients were included; mean age was 66,43 +/- 14.55 years. 53,7% were male. 75.7% had HF with reduced ejection fraction, NYHA classification was: I (34,6%), II (45,6%) III (19,9%), NYHA IV (0%). 42.6% were classified as candidates for PC according to NECPAL CCOMS. The PC candidates were older, with average age of 71,6 Vs 62,4 (p<0,0001) and higher burden of symptoms according to ESAS (p =0,002). There was not difference in ejection fraction mean 33% Vs 33,2%. Main symptoms were pain, dyspnea and affective symptoms. KCCQ and SF-12 showed worse scores in different dimensions: physical function median 59,16 Vs 83,33 (p<0,001) and social function median 50 Vs 87,5 (p<0,0001), quality of life median 58,33 Vs 79,15 (p=0,004). SF-12 subscales showed total physical score median 37,25 Vs 62,5 (p<0,001) and general health median 25 Vs 50 (p=0,023). ESAS scores for emotional symptoms were inversely correlated with scores SF- 12.
Conclusion: More than 40% of patients attended in these heart failure programs were potential candidates for PC. Those patients presented more symptom burden and lower quality of life. Patients with heart failure should be assessed and treated by cardiologist along with palliative care team.

P2027

Short-term mortality in final stage heart failure patients.

MA Munoz[1]; JM Jose Maria Verdu[1]; E Calero[1]; JL Del Val[1]; R Abellana[1]; M Casademunt[1]; J Duran[2]; E Casajuana[1]; S Alonso[1]; P Furio[1]; N Torralba[1]
[1]Primary Care Research Institute (IDIAP), Barcelona, Spain; *[2]Primary Care Research Institute (IDIAP), Clinica Sant Antoni. Barcelona, Barcelona, Spain*

On behalf of: GRECAP
Funding Acknowledgements: Departament de Salut de la Generalitat de Catalunya

Purpose: This study is aimed at analyzing the impact of the main factors contributing to short and long-term mortality in patients at final stages of HF.
Methods: It is a multicenter cohort study including 1148 HF patients attending 279 primary care centers, and followed for one-year after reaching New York Heart Association (NYHA) IV.
The primary outcome was all-cause mortality. Multivariate logistic regression models were performed at 1, 3, 6, and 12 months.
Results: Mean age of patients was 82 (SD 9) years and women represented 61.7%. A total of 135 (11.8%) and 397 (34.6%) patients died three months and one year after inclusion, respectively. Male gender, age, and decreased body mass index were associated with higher mortality from three months onwards. In addition, low systolic blood pressure levels, severe reduction in glomerular filtration, malignancy, and higher doses of loop diuretics were related to higher mortality from 6 to 12 months.
The most important risk factor over the whole period was presenting a body mass index lower than 20kg/m2 (three months OR 3.06, 95% CI: 1.58-5.92; six months OR 4.42, 95% CI: 2.08-9.38; and 12 months OR 3.68, 95% CI: 1.76-7.69).
Conclusions: male, age, and decreased body mass index determined higher short-term mortality in NYHA IV. In addition, low systolic blood pressure, reduced glomerular filtration, malignancy, and higher doses of loop diuretics contribute to increasing the risk of mortality at medium and long-term.

P2028

Gender-related differences in chronic heart failure: is there anything else to learn?

G Russo[1]; F Rea[2]; G Barbati[3]; K Stellato[1]; A Cherubini[1]; A Scagnetto[3]; A Iorio[4]; G Corrao[2]; A Di Lenarda[1]
[1]Cardiovascular Center A.S.U.I.Ts, Trieste, Italy; *[2]University of Milan-Bicocca, National Centre for Healthcare Research & Pharmacoepidemiology, Milan, Italy*; *[3]University of Trieste, Biostatistics Unit, Department of Medical Sciences, Trieste, Italy*; *[4]Hospital Riuniti of Bergamo, Bergamo, Italy*

Background: Heart failure (HF) is a disease characterized by steep morbidity and mortality rates posing a challenge for the sustainability of our healthcare systems. Literature shows that sex-specific differences do exist even though women are less represented in clinical trials.
Purpose: Aim of this study was to evaluate clinical sex-based differences among real life outpatients suffering from chronic HF and to evaluate whether these differences might impact therapy and outcomes.
Results: 2528 HF patients were studied (mean age 76, 42% female) between 2009 and 2015. Women were older than men, less obese and with less cardiovascular disease such as hypertensive and ischemic heart disease, diabetes, peripheral disease, and atrial fibrillation. Furthermore, they had a lower renal function and lower values of haemoglobin. Female gender had less frequent HFrEF and HFmrEF, but more frequent HFpEF. There were no differences in terms of HF therapy, except for a slightly high prescription of ß-blockers in HFrEF and a higher prescription of MRAs in the female group with HFmEF and HFpEF. No differences in therapy adherence between sex and inside the three LVEF groups were described. Age, anemia, chronic kidney disease, cancer, chronic obstructive pulmonary disease and BMI were independent prognostic factors for survival in female.
Conclusions: Outpatient women with HF were older and with fewer cardiovascular co-morbidities than men, even if they had a worse renal function and they were more anaemic. Age and comorbidities but not LVEF were independent prognostic factors for death.

P2029

Do elderly patients with chronic heart failure have special clinical profile? Data from Russian National Heart Failure Registry 2012.

EM Seredenina[1]; IA Orlova[1]; EN Borisov[1]; V YU Mareev[1]
[1]M.V. Lomonosov Moscow State University, Medical Research and Education Center , Moscow, Russian Federation

Background: Heart failure (HF) is the leading cause of hospitalization for those over the age of 65 and represents a significant clinical and economic burden. At this point, it is necessary to study the characteristics of elderly HF patients to optimize care.
The purpose of the study was to analyze the clinical profile of elderly patients with HF in real clinical practice in Russia.
Methods: we performed a sub analysis of data from Russian National Heart Failure Register 2012. The patients were divided into two groups: <65 year age and ≥ 65 year age.
Results: this analysis included 2055 patients with HF: 1003 patients ≥ 65 years and 1052 patients <65 years. There were more women in the ≥ 65 year age-group (64.1% vs 32.0%; p<0.001). Among elderly patients had fewer smokers (4.1% vs 18.0%; p<0.001). HFpEF patients significantly prevailed in the elderly group. Among younger patients most had HFrEF and HFmrEF (HFpEF 58.6% vs 43.0%, HFmrEF 25.1% vs 29.5%, HFrEF 16.3% vs 27.6%; p<0.001). The frequency of myocardial infarction in elderly patients was slightly lower than in younger (40.5% vs 47.0%; p=0.004). The prevalence of hypertension (95.0% vs 88.3%; p<0.001) and atrial fibrillation (44,3% vs 30,4%; p<0.001) in the elderly was higher. The prevalence of diabetes in both groups was not significantly different. Elderly patients had a lower functional status according to the results of the 6-minute walk distance test (HFrEF 288.3 m vs 333.8 m, HFmrEF 256.1 m vs 297.2 m, HFpEF 221.4 m vs 271.2 m; p<0.001). The frequency of prescribing RAAS blockers and beta-blockers was not significantly different in both groups. However, elderly HFrEF patients were less likely to receive mineralocorticoid receptor antagonists (45.4% vs 60.5%; p=0.0023).

Conclusion: Elderly patients with HF demonstrate a different clinical profile compared with younger patients. The number of women was higher in the age group of ≥ 65 years. Elderly HF patients had a higher left ventricular ejection fraction (LVEF), lower prevalence of previous myocardial infarction and smoking. There are was a higher prevalence of hypertension and atrial fibrillation in the age group of ≥ 65 years. Elderly patients with comparable LVEF and therapy had a lower functional status.

Chronic Heart Failure - Treatment

P2030

Real life heart failure, a heterogeneous population benefiting from a specialized multidisciplinary programme

I Egidio Sousa[1]; I Lopes Da Costa[2]; I Nabais[3]; F Pulido Adragao[4]; P Moniz[1]; S Quintao[1]; L Fernandes[1]; C Osana[1]; L Campos[1]; I Araujo[1]; C Fonseca[1]
[1]Hospital de Sao Francisco Xavier, Lisbon, Portugal; [2]Hospital de São José, Lisbon, Portugal; [3]Hospital de Cascais, Lisbon, Portugal; [4]Centro Hospitalar do Algarve EPE, Portimão, Portugal

Introduction: Heart failure(HF) is a public health problem, affecting a diversified population, growing in prevalence despite therapy and prevention advances. Most Cardiology departments' registries describe predominantly HF with reduced ejection fraction(HFrEF), while Internal Medicine(IM) mainly reports HF with preserved ejection fraction(HFpEF).
Purpose: To evaluate demographics, clinical characteristics and acute management(AM) of a non-selected population hospitalized in an Acute Heart Failure Unit with a multidisciplinary team.
Methods: Retrospective study of consecutive hospitalizations due to decompensated HF over one year.
Results: Of 181 hospitalizations, 55.2% were men, mean age 76 years. Most patients(77.3%) were admitted from the emergency room and 12.1% were admitted from our Day Hospital(DH). 50.8% had non-HErEF (HEpEF 44.2% and HF with mid-range ejection fraction(HFmrEF) 6.6%) and 49.2% HErEF. The most frequent etiologies were hypertensive(48.6%), ischemic(44.2%) and valvular(26%). 93% patients had chronic HF. Most decompensation were due to arrhythmias(26%), infection(24.9%), medication non-adherence (24.9%). Patients were admitted in NYHA classes III (35.4%) or IV (64.6%), and at discharge the majority (70.7%) were in class II. Most were on B profile(95.6%) requiring IV diuretics; of these 14.4% evolved to C profile requiring inotropics, 9.4% of which on levosimendan. Mean stay: 8,1days, mortality 6%. Population had high multimorbidity, the most common: arterial hypertension (75.6%), atrial fibrillation (6.2%), chronic Kidney disease (56.4%), diabetes (42.5%). After discharge, 87.7% were referred to DH, 76,5% HF consultation and 45.7% other speciality evaluation (22.2% Pneumology, 16% Cardiology, 4.3% Nephrology, Endocrinology and IM). Readmission at 30 days was 12.5% (52.4% due to decompensated HF) and mortality 5.3% (45.4% due to HF).
Conclusion: results support epidemiologic data, where HErEF tend to be as prevalent as non-HErEF. Despite differences, AM tends to be similar as most patients are congestive at admission. All groups had similar number of comorbidities, requiring multidisciplinary approach. A specialized and structured HF Program allows integrated care, with systematic and differentiated approach, reflected on our short hospital stay and mortality, inferior to national and international data.

	HFrEF	HFmrEF	HFpEF
Population	89 (49.2%)	12 (6.6%)	80 (44.2%)
Male	60 (67.4%)	7 (58.3%)	33 (41.3%)
Number of comorbidities (average)	5.3	4.8	5.6

New approaches in personalized diagnose of patients with symptomatic obstructive hypertrophic cardiomyopathy optimize the type of treatment decision-making.

YF Yulia Frolova[1]
[1]Petrovsky National Russian Research Center of Surgery, Cardio Surgery of Heart Failure, Moscow, Russian Federation

Background. Obstructive form of hypertrophic cardiomyopathy (HCM) is still the most common inherited myocardial disease characterized by clinical and genetic heterogeneity. Treatment diversity of HCM, including surgical approaches, is available nowdays, but personalized decision-making is still a challenge.
Aim. To review the clinical and diagnostic indications, genetic testing, outcome and 9-years follow up due to optimize surgical decision-making for the HCM patients (pts) with obstructive form.
Material and methods. From 2009 to 2018, 91 symptomatic HCM with obstructive form patients (49 (53,8%) male, the mean age was 47,4±14,8 years) had been operated. 64% pts had III – IV FC NYHA (functional class, New York Heart Association). The average follow-up period after operation was 7 years. Equal clinical, instrumental, biochemical, and genetic investigations were performed for all patients. Histopathological study was carried out for myocardial and valve samplings.
Results: According to the researches, all pts were distinguished in 2 main morphological phenotypes -group I (46 pts, 52%) had predominant hypertrophy of the basal segment of the interventricular septum and group II (42 pts, 48%) had diffuse generalized HCM (diffuse hypertrophy of the septum and free wall, increased number of the hypertrophic papillary muscles displaced to the apex, and significant mitral valve insufficiency). In 25 pts from group I underwent open-heart surgery was performed, and in 21 pts - septal alcohol ablation. Cardioverter-defibrillator (ICD) was implanted for pts with a high risk of sudden cardiac death (SCD). All these pts underwent expanded myoectomy, and parietal resection of the enlarged papillary muscles and left ventricular trabeculae. Chordal sparing mitral valve replacement was performed for 28 of them. All operated pts showed significant cardiac function improvement. During follow-up period in 5 pts was observed ICD chocks, and 2 pts died suddenly due to ventricular tachycardia. Total mutation detection rate was 40% in whole HCM cohort but vary significantly between groups II and I. Histopathological study had revealed mitral valve dysplasia in all studied samples. in
Conclusion: To optimize surgical decision-making for the HCM patients the multidisciplinary approach is needed. Genetic background and fibrosis level may contribute in the SCD risk assessment.

P2033

Reassuring community heart failure care in the absence of specialist involvement; but some gaps indicate need for continued specialist team input

R B Pharithi[1]; M Ferre-Vallverdu[1]; C Walsh[1]; L Fennell[1]; J Gallagher[1]; R Fawsitt[1]; M Ledwidge[1]; K Mcdonald[1]
[1]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland

Introduction: Adherence to guideline-recommended therapy in heart failure (HF) management among patients receiving cardiology care remains a concern. Given that the majority of HF patients do not receive regular specialist input, this concern is likely heightened in patients exclusively managed in the primary care setting. Aim of this study was to evaluate the community care gaps in HF population who are not under active cardiology management.
Methods and study setting: Irish Data from 15 family practitioner services have been interrogated. Patients with confirmed HF diagnoses and no contact with secondary care services for ≥1 year were assessed. Quality of care for HF-PEF patient was based on 5 items: self-care education, flu vaccination, clinic BP control <140/ 90mmHg, appropriate use of oral anticoagulants and avoidance of inappropriate medicines (1 point per item if strategy adhered to; max score 5). For HF-REF (LVEF<45%) in addition to above metrics a point was given for use of ACEi/ARB/ARNi, Beta-blocker and/or MRA, and Appropriate device therapy (HF-REF; Total Score 9).
Results: 220 patients (77±9 years; 56% male) included. 70% were documented HF- PEF phenotype and mean care score was 3.76 ± 0.55. The most obvious gap in management was self-care education provided(in ≤ 2% of patients); Other management strategies were achieved in > 85% of patients. In the HF-REF cohort, the mean score was 6.51 ± 1.23 with self-care again being poor (22.6%). In addition, there was a deficit in MRA prescription (21% of patients); whereas >80% had ACEi/ARB/ARNi and BB. 66% had Appropriate device therapy. Target doses achieved; 66% for ACEi/ARB/ARNi, 88% for BB and 92% for MRA.
Conclusions: Data from a HF population exclusively managed in primary care demonstrated an overall acceptable standard of management. Failure to educate patients/family in self-care strategies is a prevalent gap across both phenotypes. Notable under-utilisation of MRA among HF-REF patients might reflect the lack of awareness of the value of the intervention. This last observation underscores the need for continuing contact between primary and secondary care teams to ensure heart failure care management reflects current guidelines.

Heart Failure Management in Community

	Total (n=220)	HF-PEF (n=155)	HF-REF (n=62)	p-value
Self-care education	17 (7.7%)	3 (1.9%)	14 (22.6%)	<0.001
BP control	190 (86.8%)	132 (85.2%)	56 (91.8%)	ns
Flu vaccination	209 (95.4%)	150 (96.8%)	56 (91.8%)	ns
Appropiate use OAC	210 (95.9%)	149 (96.1%)	58 (95.1%)	ns
Use of inappropiate medicines	10 (4.6%)	6 (3.9%)	4 (6.6%)	ns

Factors influencing guideline-led prescribing to heart failure patients in an Egyptian critical care setting

S El Hadidi[1]; N Bazan[2]; E Darwesh[3]; S Byrne[1]; M Bermingham[1]

[1]University College Cork, School of Pharmacy, Cork, Ireland; *[2]Cairo University, Clinical Pharmacy Department, Critical Care Medicine Department, Cairo, Egypt*; *[3]Future University in Egypt , Faculty of Pharmaceutical Sciences and Pharmaceutical Industries, Cairo, Egypt*

Funding Acknowledgements: the research was funded through a collaboration between University College Cork and Future University in Egypt

Introduction: Heart Failure represents a crucial issue for the healthcare systems in the Middle East and North Africa due to its considerable human and economic burden. Guideline-led prescribing improves HF patient outcomes, however little is known about the factors influencing guideline-led prescribing to HF patients in Egypt.

Purpose: To assess the knowledge and behaviours of medical doctors towards prescribing to HF patients and to investigate potential barriers and facilitators to HF guideline-led prescribing in an Egyptian setting.

Methods: An 11-item survey was disseminated in hardcopy and electronically to all medical doctors (n=62) at the Critical Care Medicine Department, Cairo University Hospitals, Egypt from July – November 2018. Doctors were classified as Associate Staff (Bachelor of Medicine holders) or Staff (postgraduate degree holders). Ten survey items were rated on a 5-point Likert scale. Likert questions were anchored, as appropriate, by very familiar/completely unfamiliar or always/never. Comparisons between groups were made using $\chi 2$ test or Fischer's Exact test.

Results: Thirty-four doctors responded (54.3% response rate), of whom 15 (44.2%) were Staff. Overall, 82% of respondents reported that they use international clinical guidelines to inform prescribing practice (100% Staff vs. 66.7% Associate Staff, p =0.027). Staff were more familiar with ESC Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure 2016 than associate staff (66.7% vs. 36.8%, p=0.012). Most respondents (76.5%) stated that they always/often comply with prescribing guidelines. Medication choice is discussed with the patient always/often by 44.1% of respondents, however, Staff were more likely to do so than Associate Staff (86.7% vs. 26.3%, p=0.036). Over 85% of prescribers always/often considered patients' renal function and serum potassium when prescribing a loop diuretic or a renin-angiotensin system inhibitor and >75% of prescribers always/often considered heart rate, blood pressure and pulmonary function when prescribing beta-blockers. The most frequently cited barriers to guideline-led prescribing were the absence of local guidelines (79.4%); the cost of medication to patients (76.5%); and absence of Egyptian national guidelines (67.6%). Associate Staff reported workload as a barrier to guideline-led prescribing more often than Staff did (52.3% vs. 13.3%, p=0.026). Two-thirds of respondents supported greater involvement of clinical pharmacists to improve guideline-led prescribing to HF patients in this setting.

Conclusion: Familiarity with international HF guidelines was high however experienced Staff were more likely to be familiar with and to implement prescribing guidelines than less experienced Associate Staff. Availability of local or national HF prescribing guidelines and greater involvement of clinical pharmacists provide opportunities to deliver optimised HF care in Egypt.

P2035

Meta-analysis on MitraClip implantation for functional mitral regurgitation

M Noutsias[1]; M Matiakis[1]; M Ali[1]; E Abate[1]; H Melnyk[1]; B Bigalke[2]; AG Rigopoulos[1]

[1]University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany; *[2]Charite - Campus Benjamin Franklin, Berlin, Germany*

In patients with heart failure reduced left ventricular ejection fraction (HFrEF), moderate-to-severe or severe functional mitral regurgitation (FMR) may is associated with high rate of hospitalizations for heart failure and with increased mortality. Transcatheter mitral valve repair (TMVR) by MitraClip® implantation may effectively reduce severe MR; however, the long-term clinical effects of this procedure are not well defined.

Aims: We analyzed outcomes for rehospitalization and survival in heart failure patients with moderate-to-severe or severe functional mitral regurgitation (FMR) treated by either medical treatment (MT) only versus transcatheter mitral valve repair (TMVR) by MitraClip® implantation + MT by meta-analysis.

Methods & Results: By systematic search of bibliographic databases, we evaluated publications comparing heart failure patients with FMR treated by MT only versus treatment by MT combined with TMVR (by Mitraclip® implantation). Studies with a minimum of 25 enrolled patients and a follow/up period of at least 12 months were deemed eligible for this meta-analysis. We identified n=8 studies enrolling 2,960 HFrEF patients, divided into two study arms: MTVR by MitraClip® implantation and MT (n=1,692), versus FMR patients receiving MT only (n=1,268). At 12 months, there was a significant reduction in all-cause mortality favoring TMVR+MT (OR: 0.67; CI 95% 0.55-0.81), as well as a reduction of unplanned rehospitalizations (OR: 0.64; 95%; CI 0.54-0.77), compared with the MT only patients. At 24 months, there was a significant reduction of all-cause mortality in the TMVR+MT patient group (OR: 0.50; CI: 95%: 0.38-0.66; p<0.001). TMVR+MT was associated with significantly lower rates of unplanned re-admissions for heart failure compared with MT only at 12 months (OR: 0.69; 95% CI: 0.53-0.89; p<0.001) and at 24 months (OR: 0.53; 95% CI: 0.39-0.71; p<0.001).

Conclusions: This meta-analysis on n=2,960 patients with moderate-to-severe or severe FMR reveals that TMVR+MT, as compared with MT alone, is associated with a significant reduction of rehospitalizations and improvement of survival. These data imply additional evidence for TMVR by Mitraclip® in eligible heart failure patients with relevant FMR, which might be important for an update of the corresponding guidelines.

First-in-human VisONE heart failure study implant experience and study design: asymptomatic diaphragmatic stimulation for chronic heart failure

M Zuber[1]; R Young[2]; A Mcmonnachie[2]; T Shaburishvili[3]; K Rudenko[4]; V Demyanchuk[5]; A Jorbenadze[3]; R Buriak[4]; B Todurov[5]; M Mirro[6]; N Nikitin[7]; P Erne[8]; J Cleland[2]

[1]University Heart Center, Zurich, Switzerland; *[2]University of Glasgow, Robertson Centre for Biostatistics, Glasgow, United Kingdom of Great Britain & Northern Ireland*; *[3]Heart and Vascular Clinic, Tbilisi, Georgia*; *[4]Amosov Institute of Cardiovascular Surgery AMS of Ukraine, Kiev, Ukraine*; *[5]Heart Institute of the Ministry of Healthcare of Ukraine, Kiev, Ukraine*; *[6]Indiana University, Fort Wayne, United States of America*; *[7]Clinical Accelerator, Douglas, United Kingdom of Great Britain & Northern Ireland*; *[8]Universita della Svizzera Italiana, Faculty of Biomedical Sciences, Lugano, Switzerland*

Funding Acknowledgements: SHK Foundation; Viscardia, Inc.

Background Asymptomatic Diaphragmatic Stimulation (ADS) is a novel device-based heart failure (HF) therapy under investigation. Prior studies have shown that diaphragmatic contractions gaited to the cardiac cycle transiently lower intrathoracic pressure thereby affecting cardiovascular preload, venous return, right atrial pressure, right ventricular end diastolic volume, pulmonary artery flow and stroke volume. An early feasibility study to deliver ADS to the diaphragm via a superior thoracic approach in post-CABG patients demonstrated chronic ADS decreased LV volumes after 3 weeks in moderate symptomatic HF patients with reduced ejection fraction (HFrEF) incremental to optimal care.

Purpose: To prospectively evaluate the benefits and risks of chronically delivering ADS in patients with HFrEF and preserved ventricular synchrony, using a novel dedicated implantable system containing an algorithm for delivering ADS pulses gaited with sensed cardiac activity, via a new laparoscopic inferior approach, on chronic measures of HF function in an observational pilot study (NCT03484780).

Methods Medical refractory patients with symptomatic HFrEF (EF $\leq$ 35%) with no evidence of arrhythmias or ventricular dyssynchrony were screened to undergo laparoscopic implantation of the VisONE ADS system comprised of a pulse generator and two bipolar sutureless active fixation leads affixed to the inferior left and right hemispheres of the diaphragm. Exclusion criteria included severe primary pulmonary disease, known intra-abdominal infections and contraindications to laparoscopy. Therapy was programmed to deliver cardiac-gaited diaphragmatic stimulation at asymptomatic outputs. Patients will be followed at pre-specified times (1, 3, 6 and 12-months) using efficacy measures of haemodynamic, echocardiographic, HF status, and diaphragmatic function in conjunction with standard safety measures including adverse events.

Results: Nineteen patients were screened and 15 men (61 $\pm$ 7 years, EF 28 $\pm$ 5%, NYHA class II/III (2.5 $\pm$ 0.5), 87% prior myocardial infarction) were enrolled and successfully implanted with the VisONE system. The time from implant to

hospital discharge was 3.3 ± 2.4 days. For all patients an effective asymptomatic diaphragmatic pacing threshold was confirmed using palpitation and patient perception. All patients were discharged with ADS therapy turned on without therapy-related complications.
Conclusions Early pilot data suggests a dedicated ADS system implanted using a minimally invasive laparoscopic procedure can be performed successfully with short in-hospital stays. In addition, all implanted patients were free of device-related symptoms at discharge. Results from upcoming monitoring visits will further elucidate the risks and benefits of chronic ADS therapy.

Heart failure patient's journey: clinical practices and attitudes regarding the diagnosis and management of heart failure

M Boehm[1]; I Kindermann[1]
[1]*Internal Medicine Clinic III, Saarland University Clinic, Saarland University, Homburg, Saar, Germany*

Funding Acknowledgements: SERVIER

Background. Multiple studies have identified gaps and challenges in current heart failure (HF) care. A better understanding of the patient journey could be useful for tailoring educational interventions to address knowledge and practice gaps in the long-term management in HF. This survey assessed the attitudes and perceptions of the different health care professionals (HCPs) involved in HF patient management at different steps of the HF patient's journey.
Method. A total of 25 intensive care unit (ICU) cardiologists, 34 non–ICU cardiologists, and 25 primary care physicians (PCPs) from France, Germany, Spain, the UK, and Russia were interviewed between March and April 2018.
Results: Cardiologists and primary care physicians reported that HF was diagnosed in 70% of patients in the hospital following an acute decompensation or an ischemic event and in 30% of patients in an outpatient setting. Up to 30% of patients diagnosed in the hospital seemed to be referred to the hospital by an office-based physician. A majority of HF patients get to the hospital in an ambulance or emergency truck.
PCPs are generally seen within 1 week after discharge / diagnosis. Cardiologists are generally seen within 1 month for severe patients or up to 3 months for most patients. Up to 10% of patients may not come back for follow-up consultations.
Physicians estimate that approximately 30% to 40% of patients diagnosed with HFREF decompensate and they are readmitted to the hospital within weeks or months after diagnosis. The main reasons for decompensation declared involved respiratory infections, difficulties to see and monitor patients as frequently as needed, difficulties to continue the titration process in an outpatient setting, difficulties to provide appropriate and comprehensive patient education, lack of patient compliance, and failure to identify early signs of decompensation.
Conclusion. These results identify multiple gaps over the spectrum of HF care, including, treatment, diagnosis (difficult access to echocardiography), treatment planning (underuse of recommended agents and subtherapeutic dosing), treatment monitoring and adjustment (lack of adherence to recommendations), and long-term management (difficulties to provide appropriate and comprehensive patient education). These data may help identify current areas of potential improvement in the management of patients with HF.

On behalf of: Universidade Luterana do Brasil Heart Failure Study Group

Background - Heart failure clinics add multidisciplinary resources in order to obtain an integrated patient care to heart failure outpatient. The level of patient satisfaction can be acquired by using service quality scores as the SERVQUAL method. Purpose - The study aims to compare the SERVQUAL service quality scores of an heart failure outpatient clinic to a general cardiology clinic. Methods - A cross-sectional analysis was performed to obtain quality indices by the SERVQUAL questionnaire of outpatients heart failure clinic and in outpatients from a general cardiology clinic attended at the same University general hospital in southern Brazil, from February to September 2018. The SERVQUAL scale consider domains of tangibility, reliability, assurance, responsibility and empathy. The gap analysis between the health care quality domains was calculated by the difference between the delivery and expectation means by statistical T test analysis. A positive gap score was related to service satisfaction. Results - The total population sample included 224 patients, 74 are from the heart failure clinic and 150 from the general cardiology outpatient clinic. The total average of the SERVQUAL gap questionnaire mean was positive in the heart failure clinic and negative in the general cardiology outpatient clinic and were statically different (0,03 x -0.32, P<0,001).Conclusion - We observed significant better quality health care scores of heart failure outpatients clinic in comparison of a general cardiology clinic using the SERVQUAL tool.

P2040
Consultant-led multidisciplinary community heart failure service improves the delivery of guideline directed medical therapy and reduces hospital admissions, re-admissions and length of stay.

T Tahir Nazir[1]; MAHMUD Naffati[2]
[1]*University of Manchester, Manchester, United Kingdom of Great Britain & Northern Ireland*; [2]*Liverpool Heart and Chest Hospital, Liverpool, United Kingdom of Great Britain & Northern Ireland*

Introduction: Heart failure (HF) epidemic is estimated to affect 26 million people worldwide, with nearly a million patients living in the United Kingdom alone. Guideline directed medical therapy improves survival and quality of life in HF patients. Long-term adherence with medical therapy declines after discharge from hospital and under-treatment with evidence-based pharmacotherapy is an important problem in community dwelling HF patients.
Objectives: This observational study aims to assess the impact of a cardiologist led community HF service (comprising consultant, HF specialist nurses and allied health professionals) on the delivery of / adherence to first line treatments for HF patients, their unplanned hospital admission / readmission rates and length of stay.
Methods: Retrospective data analysis of 700 consecutive patients treated by our community heart failure service was included in this study. Data were collected from medical records, prescriptions, hospital episode statistics (HES) database and national audit office socio-economic database for the north-west of England.

Results: Baseline study characteristics: Mean Age (79 years +/- 8), Gender (Male =65%, Female=35%), ECG rhythm (Sinus Rhythm=65% , AF=35%), NYHA class (I -10%, II &III -88% , IV – 2%), Aetiology of HF (IHD 52%, Idiopathic cardiomyopathy 16%, Valve disease 12%, Hypertension 10%, Other 20%), Heart Rate (<80/minute -85%) and Blood Pressure (135/80 mmHg – 66%).
Of the study cohort, 85% were taking first line HF treatment as recommended by the NICE UK guidelines (beta blocker 85%, ACE inhibitors 65%, MRA 65%). This is well above the regional average (60%). Of the patients taking beta-blockers, most were on cardio-selective drugs (Bisoprolol, Nebivolol ,Carvedilol); and >50% were on the target dose. Clear explanations were documented in medical records for the patients not on a first line drug or below target dose.
For the study period (2017); HF related unplanned hospital admission rate for our local community was 310 (per 100,000 population) and re-admission rates 38 (per 100,000 population) were much lower than the northwest average 600 and 72.5 per 100,000 population, respectively. Average Length of stay for HF related hospital admission in the study population was 5.07 days (compared to regional average of 9 days).
Conclusions: Our study shows that a consultant-led community HF service significantly improves delivery of guideline directed therapy by offering expertise and skill-set required to maintain patients on appropriate dosages of first line medications required to achieve target heart rate and blood pressure; and as a result lower admission and re-admission rates. Large scale studies and national audits must include community dwelling HF patients to get a better snapshot of how this increasingly complex medical problem is managed in the real world after hospital discharge.

P2041
Self-care management intervention in heart failure

SG Sofia Gerward[1]; DS Daniel Sahlin[1]
[1]*Skane University Hospital, Lund, Sweden*

Background In elderly heart failure (HF) patients there is little experience regarding evaluation of digital self-care management interventions. Previous digital interventions studies in HF has a mean age of 62-65 years.
Purpose: Evaluate a novel home-based self-care intervention in an elderly HF population.
Methods HF patients were enrolled at five general practitioners and two hospitals and randomized 1:1 to intervention (IG) or control group (CG). The intervention group received a tablet computer with education and symptom monitoring, wirelessly connected to a weight scale and incorporating a titration module for loop-diuretics. Baseline data was collected at randomization and the number of days lost to HF-hospitalizations was analysed using negative binomial regression. Patients will be followed up after eight months, and this is an interim analysis of data after three months.
Results: One hundred patients were randomized to IG, n=50 and CG, n=50. The groups were well balanced at randomization, except for a higher diastolic blood pressure in the CG. The mean age was 79±9, 59 % were male. Five percent were NYHA-class I, 64 % NYHA-class II and 31 % NYHA-class III. There were no significant differences in terms of pharmacological treatment, self-care behaviour or quality of life. A total of 88 HF-related in-hospital days were registered (61 days in the CG group and 27 in the IG). The unadjusted risk ratio between IG and CG was 0.44 (CI: 0.24-0.81) for HF-related in-hospital days. The log rank test for time to event was significant with p-value 0.046. There was no group difference in number of admissions.
Conclusions This interim analysis indicates a significant reduction of in-hospital days due to HF by 56 % in this elderly HF population.

P2042
OPTIMIZE Heart Failure Care Program in Mexico. Impact on early and mid term Heart Failure readmissions

JA Magana-Serrano[1]; JA Cigarroa-Lopez[1]; R Cantero-Colin[1]; G Maza-Juarez[1]; H Galvan-Oseguera[1]; LE Santos-Martinez[1]; MA Alcocer-Gamba[2]
[1]*cardiology hospital. National Medical Centre "Siglo XXI", IMSS, Division of Heart Failure and Cardiac Transplantation, mexico city, Mexico;* [2]*Instituto del Corazon de Queretaro, Queretaro, Mexico*

On behalf of: OPTIMIZE HEART FAILURE CARE PROGRAM

Introduction . Acute Heart Failure (AHF) is a frequent clinical condition that is related to adverse outcomes. The OPTIMIZE Heart Failure Care program focuses on the early optimization of the integral treatment of heart failure after hospitalization for AHF and during the vulnerable phase. It consider three steps: 1. Start and/or optimization of treatment before discharge, 2. Use of a check-list in the pre-discharge period as a safety barrier and 3. Patient education and follow-up.

Methods: We implement the OPTIMIZE HF program in a prospective cohort of hospitalized AHF patients without inotropic requirements. Optimized treatment was defined as the proper use of drugs recommended by current clinical practice guidelines (ACEIs/BRAs, Beta blockers, Aldosterone antagonists, Ivabradine and diuretics), use of CRT and/or ICDs in selected patients and HF education for patients, relatives and caregivers. The primary outcomes were the frequency of HF re-admissions at 30, 90 and 180 days. The results were compared with a historical cohort of 167 patients with the same characteristics.
Results: 165 patients with AHF were studied prospectively. The average age was 58+/-4 years in the prospective group and 60+/-3 years in the comparative group (p = NS), the leading HF etiology in both groups was ischemic heart disease, the mean LVEF was 29+/-5% in the prospective group and 31+/-6 % in the historical cohort (p=NS). The proportion of patients with optimized treatment was 91% in the prospective group and 63% in the comparator (p <0.05). The impact of the early optimization protocol showed a significant reduction in the readmission rate 12% vs 29 % at 30 days, 8% vs. 20% at 90 days and 4% vs. 15% at 6 months (p<0.05 in all comparisons) (Table I).
Conclusions: In this population, the OPTIMIZE HF program was effective in reducing re-admissions in the short and mid-term after an episode of AHF. It can be considered as a true window of opportunity for a group of patients during the vulnerable phase.

Characteristics and primary outcomes

BACKGROUND: Once a disease that had a 5-year survival rate of only 25%, mortality in heart failure (HF) has reduced markedly. In the past two decades, several large clinical trials have shown an additional mortality benefit (up to 30-40%) with cardiac resynchronisation and/or defibrillator therapy (CRT-P or -D/ICDs) compared to medical therapy alone, in patients with severe left ventricular systolic dysfunction (LVSD). Current international clinical practice guidelines strongly recommend device therapy in the management of HF.
PURPOSE: Although patients may fulfil the guideline-based criteria to warrant a device, in clinical practice, patient selection for device implantation is not straightforward. A systematic approach to identify these challenges has not been previously described. Therefore, we adopted a dedicated multidisciplinary team (MDT) strategy to address these issues.
METHODS: The MDT consisted of 2 HF specialist nurses, 3 cardiology specialist consultants (devices/intervention, electrophysiology/devices and heart failure/imaging). Meetings were held each month to discuss all HF patients who were referred for a cardiac device from both outpatient and inpatient services at our district general hospital. The clinical history of each patient was discussed before device implantation or upgrade, and their imaging (e.g. cardiac MRI, echocardiograms) were also reviewed. Data were collected for 1-year (Sept 2017 – Aug 2018) and then a mixed-method (quantitative and qualitative) analysis was carried out.
RESULTS: Of the 69 patients presented in the MDT, 77% were male and their average age was 71.3±11.3 years. 30% had atrial fibrillation (AF). 71% of patients were NYHA class II or III, with 93% having at least moderate LVSD with an ejection fraction of ≤45%. 70% had either LBBB or a QRS duration of ≥150ms. 33% had pacemakers (PMs) for a bradycardia indication and 94% of these patients had at least moderate LVSD.Qualitative analysis of the MDT outcomes revealed multiple barriers for device implantation or upgrade: 1. not being on optimal disease-modifying pharmacological therapy (11 patients) 2. discrepancies in the

estimation of LV function after imaging review (9 patients) 3. recovery of LV function with medical therapy or no longer symptomatic (6 patients) 4. multiple medical comorbidities and frailty (5 patients) 5. patient choice (4 patients) 6. concomitant AV node ablation due to AF (1 patient). Only 32% of all patients referred were clinically appropriate for a new device or an upgrade from PM to CRT-P/D.
CONCLUSIONS: Our findings show that patients who are considered for cardiac device therapy should be assessed carefully. Inappropriate patient selection could potentially affect mortality, have an adverse psychosocial impact, and increase healthcare cost. We propose that a specialist device MDT, which reviews clinical cases prior to device implantation, will help to overcome these challenges.

P2044

Clinical outcomes after renal replacement therapy in heart failure patients with cardiorenal syndrome and refractory congestion: a comparison between peritoneal dialysis and hemodialysis

FH Flavio Henrique Valicelli[1]; SC Hermann[1]; MFLM Castro[1]; F Marques[1]; LBB Silva[1]; GP Mizziara[1]; JAC Costa[1]; A Schmidt[1]; MV Simoes[1]
[1]*Medical School of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil*

Introduction: Patients with advanced heart failure (HF) frequently present worsening renal function known as cardiorenal syndrome that may participate in causing refractory congestion and repeated hospitalisations. Even though the use of renal replacement therapy (RRT) has already been described in this clinical scenario, there is no previous comparison of the outcomes between different ambulatory methods of dialysis in those patients.
Purpose: Compare the main outcomes between 2 dialysis methods, namely peritoneal dialysis (PD) and hemodialysis (HD), in patients with advanced heart failure with reduced ejection fraction (HFrEF) associated with cardiorenal syndrome and refractory congestion.
Methods: This is a retrospective study, based on the review of medical records of 22 consecutive patients with advanced HFrEF (persistent functional class IV, under optimized medical therapy) with refractory congestion and repeated hospitalisation within 6-months or single hospitalisation with refractory congestive status, associated with cardiorenal syndrome, in which RRT was indicated (PD or HD), aiming at clinical compensation and decrease in subsequent hospitalisation rate. Patients with prior chronic renal disease progressing to heart failure or systemic diseases leading to both cardiac and renal failure (type 5 cardio-renal syndrome) were excluded.
Results: Despite all patients were initially considered for PD, only 11 patients were effectively submitted to PD at long term (n=11; 65±9-year-old, 54% male, left ventricular ejection fraction=27±14%) and 11 patients eventually underwent HD (67±10-year-old, 73% male, left ventricular ejection fraction=25±6%). The reasons leading to indication of HD were: urgent clinical situation (n=4), lack of social conditions for installation of PD (n=1), contraindication of PD by nephrologist (n=1), patient refusal of PD (n=2), patient non-adaptation to the PD method (n=1), ineffective PD (n=1) and repeated peritonitis episodes (n=1). We observed a significant reduction in the number of heart failure hospitalisations between the 12-months previous to the RRT (total number=32; mean hospitalisations per patient=1.38 [range = 6.0 - 0.0]) and the 12-months follow-up after the start of RRT (total number=5; mean hospitalisations per patient=0.09 [range = 1.0 - 0.0]), p = 0.0024. At 12-months after start of the RRT a higher proportion of patients were alive in the PD group (n=9; 82%) as compared to the HD group (n=3; 27%), p = 0.03. There were only 4 hospitalisations for peritonitis in the peritoneal dialysis group within 12-months of RTT.
Conclusions: The use of RRT in patients with HFrEF and refractory congestion due to cardiorenal syndrome is associated to reduction of HF hospitalisations. PD seems to be the preferential dialysis method, as it presents a higher survival rate as compared to HD. Larger studies are needed to confirm the results of this small retrospective study.

P2045

Establishing the first pharmacist-led heart failure medication optimization clinic in the middle east gulf region

B Bassam Atallah[1]; ZG Sadik[1]; I Hamour[2]; H Ghalib[2]; S Al Fardan[3]; A Cherfan[1]; F Bader[2]
[1]*Cleveland Clinic Abu Dhabi, Pharmacy Services, Abnu Dhabi, United Arab Emirates*; [2]*Cleveland Clinic Abu Dhabi, Cardiovascular Medicine, Abu Dhabi, United Arab Emirates*; [3]*Royal College of Surgeons in Ireland, Dublin, Ireland*

Introduction: Heart failure (HF) 30-day readmission rate exceeds 21% and is the highest among any chronic disease state. Medication errors and indiscretions have been found to be prevalent post discharge. It has also been reported that only 1% of eligible HF patients are on target doses of all evidence based medications. Innovative strategies to reduce HF readmissions and improve utilization of guideline-directed medical therapies (GDMT) are needed. We seek to describe a per protocol weekly HF Pharmacotherapy optimization clinic established at our institution in February 2017 as part of a collaborative practice agreement and its impact on HF patients. Methods: Selected HF patients could be referred from the inpatient or outpatient setting by the HF physician. A clinic visit consists of a nursing encounter for volume status assessment followed by a cardiology pharmacotherapy specialist to assess self-care and adherence and to perform medication titration or adjustment. Patients could be scheduled for further pharmacotherapy clinics or referred back to the HF physician at the discretion of the pharmacotherapy specialist. Follow-up period was defined as the time between the first visit and up to 30 days after last pharmacotherapy visit. All assessments, education and interventions were documented using a standard HF pharmacotherapy optimization clinic template. Results: A total of 63 patients and 133 visits were completed between February 2017 and June 2018 for a mean follow-up period of 55.9 ± 42.7 days with about half of them (52.4%) seen for only one visit. Most patients were referred from the outpatient setting (65.1%), had HF reduced ejection fraction (HFrEF) (84.1%) with New York heart association (NYHA) class II symptoms (72.6%), and were admitted with heart failure within the last 3 months (55.6%). The most common reason for referral was medication titration (57.1%) followed by transition of care and medication titration (35%). At the first visit, many patients had inadequate weight monitoring (63.3%) and most (75.4%) had at least one deficiency in either self-care or adherence to salt, fluid, weight, symptom recognition or medications. A total of 219 interventions were documented for an average of 3.5 interventions per patient and the vast majority (96.8%) had at least one intervention. The most common intervention was teaching and correction of an inadequacy (46 patients) followed by renin angiotensin aldosterone system (RAAS) medication titration (48 titrations). More patients were at target doses of GDMT at the last visit (figure 1). A total of 6 patients (9.5%) had a HF related admission during follow-up period, 5 patients (7.9%) within 30 days of first visit, and 12 patients (19%) within 6 months of first visit. Conclusion: Pharmacist-led heart failure clinic establishment corrects noncompliance and optimizes medication therapy. More data regarding cost is necessary to quantify the value and impact of these clinics.

Introduction of a multidisciplinary specialist heart failure team prevented 2 in 3 heart failure readmissions

S Savvas Hadjiphilippou[1]; G Cole[1]; C Plymen[1]
[1]*Imperial College Healthcare NHS Trust, London, United Kingdom of Great Britain & Northern Ireland*

Funding Acknowledgements: No funding received.

Background and objectives:Over half a million people are living in the UK with heart failure (HF), costing 2% of the National Health Service budget, of which 60-70% is incurred from hospitalisation. Management of patients within a dedicated HF unit improves mortality and reduces readmission rates. Our objective was to assess HF length of stay and readmission rates for patients admitted to a dedicated HF unit when compared to standard medical care within a tertiary centre.
Methods: Patients admitted with HF over a single year (2015-16) at a multicentre tertiary NHS Trust were included in this retrospective cohort study. Heart failure length of stay and readmission rates (within 30 days) for patients admitted under the direct care of an inpatient specialist heart failure service were compared to HF admissions under a general medical team.
Results: A total of 479 patients were admitted with HF over 12 months. Of these, 32% were to a dedicated HF unit. Mean age of those admitted to the unit was 69.4yrs compared to 77yrs when admitted under the general medical team (p<0.05).

There was no significant difference in initial length of stay between those admitted under the specialist HF team and those under the general medical team during the initial admission. However, incidence of readmission was significantly less when the index admission was under the specialist HF team (6.5% vs 17.5%, p<0.05). Patients readmitted under the care of a specialist HF team had a numerically shorter length of stay than those admitted under the general medical team (6.3 Vs 9 days respectively).
Conclusion: Direct admission under a HF specialist team prevented 2 in 3 readmissions at 30 days and reduced by 1/3 the length of stay during readmissions. Reasons postulated are earlier pharmacological intervention, faster medication up-titration, discharge on optimal doses, more intensive diuresis during admission and access to advice and guidance to avoid admission. Using an average HF admission cost of £3796, expansion of our service would be expected to save ≃£136656 over one year because of ≃36 fewer readmissions. In addition to the improvement in morbidity and mortality in patients with HF, our results suggest significant financial gains could be made from ensuring patients are admitted under a HF specialist team.

P2047
Current status of palliative care for heart failure; from the clinical experience of a general hospital in Japan

Y Yosuke Nishihata[1]; N Komiyama[1]
[1]*St. Luke's International Hospital, Tokyo, Japan*

Background: Palliative care (PC) for advanced heart failure (HF) was added as medical treatment fee from April 2018 in Japan, but there are some gap in clinical needs and the criteria to taking cost of PC-addition of medical insurance in Japan. We assessed current status of PC for HF and contrasted with the criteria for PC-addition of medical insurance in Japan.
Methods: Between April 2015 and March 2018, there were 894 patients consulted to PC team for any disease in our hospital and 499 patients who admitted to our hospital for HF. We extracted 21 patients with advanced HF who was consulted to PC team, and we examined patients characteristics to contrast with the criteria for PC-addition of medical insurance in Japan; 1) optimal medical therapy, 2) NYHA 4, 3) more than two times of hospitalization for HF within 1 year, 4) left ventricular ejection fraction (LVEF) ≤ 20%, 5) end-stage.
Results: Their mean age was 78.4-years-old and 13 patients (61.9%) were male. All of them were optimally treated but remained NYHA 4, and 16 patients (76.2%) were first-time hospitalization for HF within 1 year. Their median LVEF was 50.7% and only 3 patients (14.3%) were below LVEF 20%. 16 patients (76.2%) were considered as end-stage but the other 5 were not. As a result of those, only 4 patients (19%) were met to the criteria for PC-addition and the other 17 were not met. As a content of PC, 19 patients (90%) underwent symptomatic relief by opioids, and 8 of them withdrew from opioids.
Conclusions: Our data demonstrates that there is obvious gap between clinical needs of PC for HF and the criteria for PC-addition of medical insurance in Japan. We should take appropriate care of patients without being bound by the criteria for PC-addition of medical insurance in Japan.

P2048
An evaluation of heart failure register reviews and virtual clinics 2016-2018

C L Thomson[1]; G L Campbell[1]
[1]*Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom of Great Britain & Northern Ireland*

Background The Integrated Heart Failure Service provides specialist advice and support to local general practices to improve the management of heart failure in primary care.
One way this is delivered is through an annual review of all patients on the general practice heart failure register and a subsequent discussion of the patients as part of a multi-disciplinary team. Virtual clinics are a forum to allow discussion of known heart failure patients, but also those that may be un-diagnosed and need treatment optimisation.
Objectives To review the virtual clinics undertaken in the last two years, to:
· Ensure all patients on the general practice heart failure register have a confirmed diagnosis of heart failure and are coded correctly as having heart failure with a reduced ejection fraction (HFrEF) or heart failure with preserved ejection fraction (HFpEF)
· Ensure all patients on the heart failure register with HFrEF are treated with the maximum tolerated dose or target dose of an ACE inhibitor (or licensed Angiotensin-II receptor blocker) and a beta-blocker, unless contraindicated.
Method Retrospective review of all heart failure virtual clinics and register reviews conducted between April 2016 and March 2018. All data were collected and analysed using Excel.
Results In 2016-17 there were 7 register reviews and 35 virtual clinics, attended by pharmacists, nurses and consultants, and 605 patients were discussed. In 2017-18 this increased to 815 and there were 22 virtual clinics. All 22 practices had completed a register review prior to the virtual clinic.
Results are shown in Table 1 - Outcomes
Conclusions There is a clear need for continued support in primary care as a large number of patients are not coded correctly, nor are on optimal therapy for HFrEF. The increase in interventions in 2017-18 shows that completion of a register review ahead of the virtual clinic allows a greater number of patients to be discussed. This in turn leads to more coding amendments, which helps ensure patients are treated correctly, but also has a financial implication for the general practice.
Further work needs to be completed looking at the long-term outcomes of patients following virtual clinic discussion.

Outcomes from virtual clinics 2106-18		
	Year2016-17	Year2017-18
Total number of patients intervened on	409	609
Number of patients with HFrEF	440	401
Number with HFrEF on optimal treatment prior to review	85	156
Number of patients requiring a coding change	218	519
Number of patients with unclear diagnosis requiring confirmation	45	284

Non-invasive Venous Waveform Analysis (NIVA) estimates static volume

M Monica Polcz[1]; P Liesy[1]; J Lindenfeld[1]; K Hocking[1]; C Brophy[1]; B Alvis[1]
[1]*Vanderbilt University, Nashville, United States of America*

Funding Acknowledgements: NIH Phase I SBIR 1R44HL140669-01A1

Background/Introduction: Volume overload in patients with congestive heart failure (CHF) leads to symptomatic edema and pulmonary congestion, resulting in decreased quality of life and frequent hospital admissions. Clinical signs of volume overload including weight gain, edema grade, and shortness of breath occur late and are not reliable indicators of volume overload. Medical devices for outpatient volume assessment to prevent readmission includes impedance devices such as ZOE (NonInvasive Medical Technologies) but have failed to gain widespread use. Non-Invasive Venous waveform Analysis (NIVA) is a novel technology that captures the peripheral venous waveform with a wristband containing a piezoelectric sensor, allowing analysis of waveform changes that occur at different volume states.
Purpose: This is a proof-of-concept study demonstrating the use of NIVA for estimation of static volume status by correlation with an existing approved non-invasive device, the ZOE impedance monitor and with pulmonary capillary wedge pressure (PCWP), the current gold standard.
Methods: The NIVA device was attached to the volar aspect of the wrist overlying the venous plexus and signals obtained for at least three minutes. The power magnitude of the fundamental pulse frequency (f0) and weighted magnitudes of harmonics of the pulse frequency (f1-7) were used to generate a preliminary proprietary algorithm to derive a NIVA Value. The ZOE device was applied as per manufacturer's instructions and the average of three consecutive measurements used for analysis. PCWP was performed at end expiration by an experienced interventional cardiologist. All measurements were obtained within one hour of right heart catheterization.
Results: With increased fluid, thoracic impedance decreases hence ZOE measurements correlate inversely with volume. NIVA Values correlated inversely with ZOE measurements (r= -0.80, n=29, p < 0.05). PCWP ranged from 4 to 27 mmHg, with a mean of 14.4 mmHg. NIVA correlated significantly with PCWP (r=0.75, n=73, p<0.05).
Conclusions: NIVA correlates with existing thoracic impedance technology (ZOE) and with the gold standard PCWP. NIVA represents a new technology that utilizes a novel physiologic signal, the peripheral venous waveform, to provide an estimation of static volume status for guidance of outpatient treatment in patients with CHF.

P2050
Vaccination uptake in HF patients; identifying a critical gap of care

F Faizan Rathore[1]; RB Pharithi[1]; K Mcdonald[1]
[1]*St Vincent's University Hospital, Department of Cardiology, Dublin, Ireland*

Background Influenza vaccine (IV) & Pneumococcal vaccine(PV) are recommended by multiple heart failure (HF) guidelines. However, despite its importance, poor uptake among HF population has been reported.

In a recent study of precipitants of HF hospitalisation, Lower Respiratory tract infection (LRTI)was identified as a single most common cause of admission in 35 % (n= 47) cases, hence, we sought to investigate the uptake of influenza and pneumococcal vaccines and assess the relationship between the adherence to vaccine and subsequent LRTI-precipitated hospital admission.
Methods Vaccination history was obtained at time of hospitalization.
IV uptake was defined as having the vaccine administered in the previous year,
PV uptake was defined as having the vaccine administered at all in the past
The relationship between Vaccination uptake & HF phenotype (using LVEF 50% as a cutoff) was assessed, along with the relationship between vaccination uptake, LRTI & de novo diagnosis v/s known HF presentation.
Chi-square & Fisher exact test were carried out , with p value<0.05 considered significant
Results Of the total number of patients analysed (n=127 for IV & n=122 for PV), 67% (n=85 (Denovo HF =41, Known HF=44)) were up to date with IV, and 29% (n=35(Denovo HF =17, Known HF=18)) were up to date with PV.
Statistical Analysis revealed patients HFpEF phenotype were more likely to be up to date with IV (p=0.009) & PV (p=0.033)
A statistically significant relationship was observed between Known HF patients who had received the IV & LRTI as a precipitant (p=0.038)
No statistically significant relationship was observed between PV & any of the variables of interest
Conclusion Our findings represent a poor uptake, especially of pneumococcal vaccines in Irish HF population, which is a comparable finding to the reported literature, representing a critical gap of care in HF patients that should be addressed on an urgent basis.
HFpEF phenotype was observed more likely to be up to date with vaccinations which could be reflective of advanced age & higher comorbidity burden of HFpEF population
We observed that LRTI was less likely to precipitate hospitalization in known HF patients, who were up to date with IV compared to patients who were up to date with IV and present as a de novo diagnosis of HF

P2051

Impact of Quality Improvement Strategies on the performance of Specialised Heart Failure Nurses regarding patient managment

S Sonia Moteea[1]; C Coyle[1]; S Grimsdale[1]; V Brady[1]; K Ress[1]; S Bulugahapitiya[1]
[1]Bradford Teaching Hospitals NHS Trust, Cardiology, Bradford, United Kingdom of Great Britain & Northern Ireland

Background: It is important that patients are provided with adequate information about their condition, investigations and treatments. Polypharmacy is inherent in the medical management of heart failure patients. Good communication therefore essential towards patient satisfaction and enhancing patient understanding leading to a better compliance with treatment.
Purpose: Evaluate the use of a pre discharge questionnaire and checklist in enhancing patient understanding of their condition.
Method: The study was conducted using a questionnaire and checklist in association with Specialised heart failure nurses in patient diagnosed with heart failure, to assess their understanding of their diagnosis, investigations and medications including changes made and side effects and OP Follow up plans in the community.
Questionnaire was repeated in the community within 1-3weeks to establish wether the patients readily accepts and understands their condition and assess their compliance to the medications and facility offered to them in community.
(See Fig1&2 - Questionnaire and checklist used)
Results: The study included 50 patients, 37 new LVSD mean age of 60yrs and 13 were known to HF team, with LVSD mean age fo 60yrs post discharge from cardiology ward.
(See TABLE1 for results)
All these patients were on 5 or more medications at the point of discharge (polypharmacy)
Conclusion: 1. Heart Failure patients are at risk of being discharged with insufficient understanding of their in patient stay, medication changes and followup plans.
2. The utilisation of a simple checklist is highly effective in enhancing patient awareness of their management, medication changes and followup plans.

P2052

Impact of a clinical pharmacy service on heart failure guideline-led prescribing at discharge in an Egyptian critical care unit

S El Hadidi[1]; N Bazan[2]; E Darwesh[3]; S Byrne[1]; M Bermingham[1]
[1]University College Cork, School of Pharmacy, Cork, Ireland; *[2]Cairo University, Clinical Pharmacy Department, Critical Care Medicine Department, Cairo, Egypt*; *[3]Future University in Egypt , Faculty of Pharmaceutical Sciences and Pharmaceutical Industries, Cairo, Egypt*

Funding Acknowledgements: the research was funded through a collaboration between University College Cork and Future University in Egypt

Introduction: Guideline-led prescribing improves outcomes in heart failure (HF) patients, however, discharge prescriptions may not adhere to the recommendations of the HF guidelines. The clinical pharmacist is uniquely positioned to address guideline-led prescribing in order to optimise HF care and improve patient outcomes.
Purpose: To assess the impact of the introduction of a clinical pharmacy service on guideline-led prescribing to HF patients at discharge from a Critical Care Unit (CCU) in Egypt.
Methods: This was a retrospective observational study of HF patients discharged from CCU from 1st January 2013 to 31st December 2017. The European Society of Cardiology Guidelines for the Diagnosis and Treatment of Acute and Chronic Heart Failure 2012 were the reference guidelines. Prescribing was assessed using Guideline Adherence Index (GAI-3), that considers prescribing of renin-angiotensin system inhibitors (RASI); beta-blockers (BB) and mineralocorticoid receptor antagonists (MRA). The adjusted GAI-3 considered patient contraindications to these medicines. The GAI-3 target dose considered the prescription of 50% or more of the recommended target dose of each medicine. High-GAI based management was defined as prescription of ≥2 disease-modifying therapies. A clinical pharmacy service was introduced to the CCU in January 2016. Multivariable logistic regression analysis was performed to identify associates of High-GAI prescribing.
Results: The study identified 284 HF patients, mean age 66.7±11.5 years and 53.2% male, who were discharged from CCU during the study period. Loop diuretic was the most frequently prescribed HF medication (85.2%). Prescription rates for GAI-3 agents were RASI 51.4%; BB 29.9%; and MRA 54.9%. Population GAI-3 was 45.5%, however, when adjusted to patients' contraindications, this increased to 51.0%. GAI-3 target dose was 24.3%. High GAI-3 was prescribed to 136 patients (47.9%). Compared to those with Low GAI-3, these patients were younger (62.6 vs. 70.5 years); less affected by kidney disease (22.1% vs. 33.8%); and had fewer comorbidities (4.9 vs. 5.6), (all p<0.05). Post-introduction of the clinical pharmacy service, BB prescription increased from 24.1% to 38.6% (p<0.001) while digoxin prescription decreased (34.7% vs. 23.7%, p=0.049). Associates of High-GAI were age (Odds Ratio, OR=0.96, 95% Confidence Interval, CI 0.92-0.98), serum creatinine >2.5 mg/dl (OR=0.31, 95% CI 0.09-0.98) and reduced ejection fraction (OR=5.50, 95% CI 2.66-11.55).
Conclusion: This study is the first to consider HF guideline-led prescribing and the role of clinical pharmacy in an Egyptian setting. It highlights inconsistencies between guideline recommendations and current practice. Clinical pharmacy services in Egypt are in their infancy and their impact may increase with time.

P2053

Multidisciplinary care for end-stage HF. How to improve care?

P Fluvia[1]; S Mirabet Perez[2]; A Pascual Lopez[2]; MJ Pirla[2]; N Mesado Batalla[2]; I Lumillo Gutierrez[2]; E Roig Minguell[2]
[1]University Hospital de Girona Dr. Josep Trueta, Cardiology, Girona, Spain; *[2]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Palliative care in advanced heart failure (HF) patients is not standardized. Several trials have demonstrated the usefulness of starting palliative care along with cardiac treatment in the final stages of the disease
Purpose: Assess the feasibility of a multidisciplinary team in patients with advanced HF.
Material and methods: Observational, prospective, single-center study performed in outpatients with advanced HF excluded for heart transplantation or LVAD. The multidisciplinary team includes a cardiologist and nurse specialized in advanced HF, a palliative care physician, case manager nurses and primary care physicians.
Patients were identified as palliative according to the clinical clues reported in 2013 ACC/AHA guidelines. All patients and their relatives accepted to be included in the program.We evaluated the level of knowledge of the end-stage phase of the disease, the main non-cardiovascular symptoms and treatments, number of hospital admissions, time to death and place of death.Results: From October 2016 to March 2018, 23 patients were included. Age 77 ± 5 years, 92% men. Most of them had high comorbidity (Barthel 78.6 ± 15) and some degree of dependency (Charlson 6 ± 1.1). Ten patients had HFpEF.
All patients knew the severity of their illness and 65% considered the possibility of dying soon.More than 70% of the patients had non cardiovascular symptoms. The main symptoms and palliative treatments are shown in Figure 1 and 2.During a mean follow-up of 4±2 months, 7 patients (30%) were admitted (4 patients for cardiovascular (CV) problems and 3 for non-cardiovascular) and 16 patients died (14 CV deaths and 2 non-CV). Of those, twelve patients (75%) died at home or in long-stay centers.Conclusion: In our experience the multidisciplinary care for end-stage HF was feasible and well accepted for the patients and their relatives. Most of them knew the severity of the disease and the poor prognosis.The majority of patients received treatments for non-cardiovascular symptoms, being the multidisciplinary palliative care useful for the management of these patients.A

high percentage of patients died outside the hospital. The high short-term mortality probably suggests that palliative care should be considered earlier in end-stage HF.

Chronic Heart Failure - Clinical

P2054

Chronic heart failure in patients with systemic amyloidosis

E Elena Reznik[1]; TL Nguyen[1]; EA Stepanova[2]; AV Salikov[2]; IG Nikitin[1]
[1]Pirogov's Russian National Research Medical University, Moscow, Russian Federation; *[2]12 Moscow's Clinical Hospital, Moscow, Russian Federation*

Funding Acknowledgements: Govermental grant

Introduction . Amyloidosis is a group of diseases with amyloid deposition in various organs, including the heart. The aim of our work was to analysis features of chronic heart failure (CHF) in pts with amyloidosis. Material and methods. We performed a retrospective analysis of the medical records of 36 pts (38.9% men, 61.1% women) with systemic amyloidosis, confirmed by a morphological study, including Congo red color and polarized light (in 63.9% – posthumously, in 36.1% – intravital). The median (interquartile range) of age was 72.5(65.5–80.5)years. Secondary amyloidosis occurred in 8.3% due to rheumatoid arthritis, ankylosing spondylitis, multiple malignant metachronous neoplasms. Results. CHF was in 72.2% of pts: II NYHA class - in 19.2%, III - in 65.4%, IV - in 15.4%. 52.8% of pts had coronary artery disease in diagnosis, 80.6% - arterial hypertension, 33.3% - myocardial infarction in anamnesis. CHF symptoms were dyspnea in 65.4%, weakness - in 65.4%, edema - in 65.4%, palpitations - in 3.8%. ECHO was performed in 44.4% of pts. The left ventricular ejection fraction (LVEF, Simpson) was 55(48-56)%. LVEF<40% was detected in 12.5%, 40-49% - in 12.5%, >=50% - in 75% of pts. Left ventricular hypertrophy (LVH) was present in 93.8% of pts, 80% of them had an interventricular septum/posterior LV wall thickness >=14 mm. 81.3% of pts had mitral, 37.5% – aortic, 12.5% – pulmonary, 75% – tricuspid regurgitation. 25% of pts showed signs of "granular sparkling" myocardium appearance, 13.8% – low ECG voltage, 12.5% – regional LV wall motion abnormalities, 68.8% - pulmonary hypertension, 31.2% – LV diastolic dysfunction (60% – abnormal relaxation pattern, 20% – pseudonormalization, 20% – restriction), 18.8% – normal diastolic function (DF); in 50% LVDF was not assessed. Atrial fibrillation (AF) was detected in 36.1% of pts: in 16.7% – permanent, in 2.7% – persistent, in 16.7% – paroxysmal form. Conduction disorders were presented in 25% of pts: atrioventricular (AV) block – in 11.1%, right bundle branch block – in 16.7%, left bundle branch block – in 16.7%. A pacemaker was implanted in 13.9%. Chronic kidney disease (CKD) was presented in 88.9% of pts: stage 2 – in 14.3%, 3a – in 7.1%, 3b – in 10.7%, 4 – in 32.1%, 5 – in 32.1%. The glomerular filtration rate (GFR, CKD-EPI) was 24.75 (13.4-45.8) ml/min/1.73 m2. Proteinuria was detected in 84.6% of pts, its level was 1.1 (0.5-3.0) g/l, >3g/l - in 30.7%. Leukocyturia was in 59.1% of pts. According to the kidney ultrasound 15.4% of pts had a decreased kidneys size, 7.7% – an increased kidneys size. Conclusions. CHF was presented in 72.2% of patients with systemic amyloidosis, with preserved LVEF in 75%, NYHA class III - in 65.4%, with LVH – in 93.8%, with AF – in 36%, with conduction disorders - in 25%. Patients with CHF of unclear etiology, especially in the presence of preserved LVEF, LVH, CKD 4-5 stages and nephrotic range albuminuria, should be screened for amyloidosis.

P2055

Benefit of buspirone on chemoreflex and central apneas in heart failure

A Alberto Giannoni[1]; C Borrelli[1]; G Mirizzi[1]; GB Richerson[2]; M Emdin[1]; C Passino[1]
[1]G. Monasterio Foundation, Pisa, Italy; *[2]University of Iowa, Iowa City, United States of America*

Background. Increased chemosensitivity to carbon dioxide (CO2) is an important trigger of central apneas in heart failure (HF), with negative impact on outcome. We hypothesized that buspirone, a 5HT1A receptor agonist that inhibits serotonergic chemoreceptor neuron firing in animals, can decrease CO2 chemosensitivity, thus preventing CA in patients with HF.

Methods. Sixteen patients with systolic HF (age 71.3±5.8 years, left ventricular ejection fraction 29.8±7.8%) and moderate-severe central apneas (nighttime apnea/hypopnea index AHI≥15 events/hour) underwent a double-blind, placebo-controlled, cross-over, randomized study of oral buspirone administration (45 mg/day for 1 week).

Results. Buspirone reduced CO2 chemosensitivity compared to placebo (1.2 IR [1.1-1.5] vs. 2.0 [1.6-2.2] L/min/mmHg, p=0.008). Furthermore, buspirone improved the AHI at nighttime (16.5 [8.5-24.7] vs. 27.5 [23.0-37.3] events/hour, p=0.002), and daytime (8.0 [2.3-11.5] vs. 12.5 [6.3-18.8] events/hour, p=0.006), the central apnea index at nighttime (4.0 [1.0-19.0] vs. 12.5 [8.3-27.3] events/hour, p=0.01) and daytime (1.0 [0.0-3.0] vs. 4.0 [1.3-6.0] events/hour, p=0.009) and the oxygen desaturation index at nighttime (4.7 [1.0-11.0] vs. 20.0 [8.7-26.5] events/hour, p=0.004) and daytime (0.2 [0.1-0.7] vs. 1.2 [0.3-4.8] events/hour, p=0.005), showing at the same time a good safety profile.

Conclusions. Buspirone reduces CO2 chemosensitivity and improves central apneas both during the day and the night in patients with systolic HF.

P2056

Efficacy and safety of carvedilol and losartan with various combinations of bronchodilators in patients with chronic heart failure due to coronary artery disease combined with COPD

V Evdokimov[1]; A Evdokimova[1]; E Kovalenko[1]; E Yushchuk[1]
[1]State University of Medicine & Dentistry, Moscow, Russian Federation

Purpose: to compare clinical efficacy and safety of carvedilol and losartan with various combinations of bronchodilators in complex therapy in patient with CHF due to CAD combined with COPD.

Methods: after enrollment in this trial 98 patients (70 men and 28 women), aged 64.1 ± 4.8 years, with CHF classes II to III (New York Heart Association) combined with moderate to severe COPD (GOLD-2015) with initial ejection fraction of the left ventricle (LVEF) less than 45%, were randomized into three groups – tiotropium (18 μg daily, n=36), indacaterol (150 μg daily, n=32) and tiotropium/indacaterol group (18/150 μg daily, n=30). Patients of all groups received the complex CHF treatment comprising carvedilol, losartan, diuretics, nitrates, cardiac glycosides (if necessary) and basic COPD therapy (inhalation corticosteroids). Echocardiography, exercise tolerance, 24-hour electrocardiography, respiratory function test were assessed at baseline and after 6 months of treatment. The quality of life was evaluated by MYHFQ, SGRQ and mMRC.

Results: after 6 months of therapy the improvement of clinical condition and quality of life were marked in all groups. In 1st, 2nd and 3rd group LVEF was increased by 20.9%, 18.3% and 22.5%, pulmonary hypertension decreased by 21.2%, 22.8% and 26.7%, episodes of silent myocardial ischemia decreased by 52.3%, 47.6% and 52.4%, respectively. Towards the end of the observation period, in all groups there was a confident and authentic increase of FEV1 witch made 10.4%, 7.8%, and 11.9% accordingly. Patients showed statistically significant and clinically meaningful reduction of SGRQ, MYHFQ scores and MMRC dyspnea grade (see table 1). All treatment regimens were well tolerated.

Conclusions: the carvedilol and losartan with tiotropium and/or indacaterol administration in patients with CHF combined with COPD raises efficiency of treatment, improves quality of life, basic parameters of central hemodinamics and pulmonary function. Efficacy of long-acting inhaled anticholinergic agent (tiotropium) and long-acting β-agonist (indacaterol) in patient with CHF due to CAD combined with COPD are similar. Combination of these drugs significantly enhances the positive effects of the therapy.

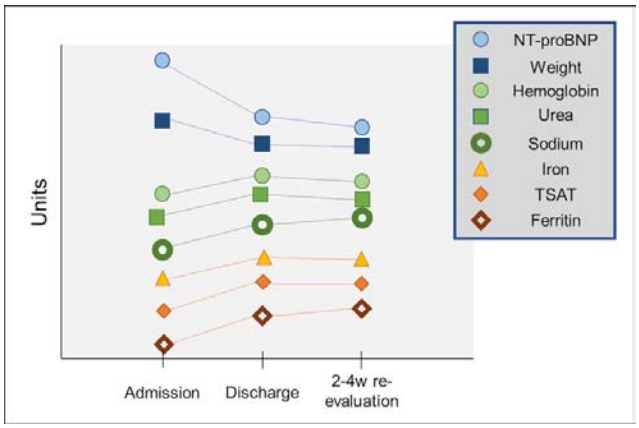
Defining iron deficiency in acute heart failure: preliminary results

G Cunha[1]; B Rocha[1]; R Ventura Gomes[2]; J Duarte[3]; L Campos[4]; L Menezes Falcao[5]; I Araujo[6]; C Fonseca[6]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; *[2]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal*; *[3]Hospital Prof Fernando da Fonseca EPE, Medicine, Amadora, Portugal*; *[4]Hospital de Sao Francisco Xavier, Medicine, Lisbon, Portugal*; *[5]Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte, Medicine, Lisbon, Portugal*; *[6]Hospital São Francisco Xavier, CHLO, Clínica de Insuficiência Cardíaca, Lisbon, Portugal*

Background: Iron Deficiency (ID) is defined in chronic Heart Failure (HF) as absolute (ferritin <100μg/L) or functional [ferritin 100-300μg/L and transferrin saturation

(TSAT) <20%]. In symptomatic chronic HF patients with ID and reduced left ventricular ejection fraction (LVEF), intravenous (IV) iron improves symptoms and quality of life and may reduce hospitalizations. However, these results may not be extrapolated to acute decompensated HF, as the definition is based on markers strongly influenced by inflammation and potentially by plasma volume status.
Purpose: The main goals of this study are to assess the variation of iron status between chronic HF and acute decompensated HF and determine whether current ID definition is adequate to identify patients for correction at discharge.
Methods: Prospective multicenter study of patients aged ≥18 years with "wet and warm" decompensated HF, as per European Society of Cardiology guidelines. The main exclusion criteria were recent iron or erythropoietin intake, increased inflammation (i.e., C-reactive protein >5mg/dL or infection) and significant hemorrhage. Iron status and clinical signs of congestion were assessed at enrollment, discharge (euvolemia) and 2-4 weeks after discharge (reevaluation). 3-month preliminary results are here reported.
Results: A total of 32 patients were included. Mean age was 73.3 ± 13.3 years, most were male (53.1%) with ischemic (34.4%) or hypertensive (37.5%) HF. Mean LVEF was 43.3 ± 16.5%. ID significantly decreased from enrollment to discharge (68.8% vs 34.4%, p=0.039) but not from discharge to reevaluation (34.4% vs 28.1%, p=1.000). Ferritin, TSAT and serum iron levels had a significant incrementfrom enrollment to discharge (p=0.011; p=0.005; p=0.002, respectively), as did sodium, urea and hemoglobin (p=0.013, p=0.05, p=0.02),stabilizing2-4 weeks later (all p≥0.05) (Figure 1). Additionally, weight and NT-proBNP had a significant decreasefrom enrollment to discharge (p=0.001 and p<0.0001, respectively), while remainingstable from discharge to reevaluation (all p≥0.05) (Figure 1).
Conclusions: Iron status in HF patients is strongly influenced by congestion. ID prevalence has a tendency to be overestimated in acute decompensated HF. Current definition appears to be appropriate with euvolemia, thus implying that ID identification and ensuing correction could be adequate at discharge. These preliminary results may be further strengthened with increasing enrollment.



Iron and congestion status evolution

Iron status and skeletal muscle fatigability in men with heart failure with reduced ejection fraction

M Tkaczyszyn[1]; M Drozd[1]; K Wegrzynowska-Teodorczyk[2]; J Tobiszewski[1]; J Bojarczuk[3]; W Banasiak[3]; P Ponikowski[4]; EA Jankowska[1]
[1]Wroclaw Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wroclaw, Poland; *[2]University School of Physical Education of Wroclaw, Department of Physiotherapy, Wroclaw, Poland*; *[3]Military Hospital, Cardiology Department, Centre for Heart Diseases, Wroclaw, Poland*; *[4]Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland*

Funding Acknowledgements: Project was funded by the National Science Centre (Poland) grant allocated on the basis of the decision number DEC-2013/09/N/NZ5/00811

INTRODUCTION: Skeletal and respiratory myopathy constitutes an important pathophysiological feature of heart failure. The aetiology of skeletal muscle dysfunction in these patients is complex and multifactorial, with several contributing and overlapping pathomechanisms.
PURPOSE: We investigated the hypothesis of whether iron deficiency is associated with decreased skeletal muscle performance in men with heart failure with reduced ejection fraction (HFrEF).
METHODS: We comprehensively examined 31 men with stable HFrEF (age: 59±12 years; left ventricular ejection fraction [LVEF]: 28±7%; NYHA class I/II/III: 23/45/32%; ischaemic aetiology: 42%). We analyzed clinical characteristics, iron status, body composition, and skeletal muscle performance regarding forearm flexors compartment. We developed handgrip exercise protocol with simultaneous non-invasive surface electromyography (sEMG) in 3 muscle regions within the forearm: flexor carpi radialis (RAD) and ulnaris (ULN), and brachioradialis muscle (BRA). In brief, patients were asked to rhythmically handgrip the electronic dynamometer for 300 seconds at 50% of predetermined maximal voluntary contraction (MVC) (150 squeezes). Before and after exercise we compared muscle performance index (MPI), i.e. MVC strength (N) divided by processed sEMG signal amplitude (higher MPI = better muscle function). Additionally, during 10-second isometric contraction at 50% of MVC we measured a decrease in sEMG signal frequency (FREQ) and increase in amplitude (AMPL) (both reflecting muscle fatigability) between the first and the last second. Iron deficiency was defined as ferritin <100 ng/mL or ferritin 100-299 ng/mL with transferrin saturation (TSAT) <20%.
RESULTS: In examined men with HFrEF mean serum ferritin was 190±150 ng/mL, TSAT 30±2%, and haemoglobin concentration (Hb) 15.0±1.3 g/dL. Patients with (42%) and without ID had similar decrease in MPI RAD, MPI ULN, and MPI BRA during exercise (all p>0.05). Increase in AMPL RAD correlated with LVEF (r=-0.39, p=0.03), Hb (r=-0.50, p=0.004), red blood cells (r=-0.39, p=0.03), haematocrit (r=-0.51, p=0.003), and TSAT (r=-0.39, p=0.03). Decrease in FREQ RAD correlated with serum ferritin (r=-0.36, p=0.049), and there was a trend towards greater decrease in patients with higher percentage of body fat (r=0.31, p=0.09) and ischaemic vs. non-ischaemic HFrEF (r=0.32, p=0.08). Decrease in FREQ ULN was related to ischaemic aetiology (r=0.43, p=0.02), and there was a trend towards greater decrease in FREQ ULN in patients with higher percentage of body fat (r=0.33, p=0.07) and with lower serum ferritin (r=-0.31, p=0.09). Importantly, in men with HFrEF the fatigability of RAD region during isometric exercise (FREQ RAD) was related to inspiratory muscle strength (maximal inspiratory pressure at mouth) (r=-0.40, p=0.04).
CONCLUSION: These preliminary results suggest that iron deficiency can contribute to increased fatigability of skeletal muscles in men with HFrEF.

P2059

Empagliflozin:effects on the heart and vessels

B Moura[1]; E Moreira[2]; L Coelho[1]; P Dias[1]
[1]Military Hospital, Porto, Portugal; *[2]Faculty of Medicine University of Porto, Porto, Portugal*

Background: In the EMPA-REG Outcome trial, empagliflozin (EMPA) reduced the 3P-MACE (CV death, non-fatal MI or non-fatal stroke) and hospitalizations for heart failure. Cardiac evaluation was not performed, so the underlying mechanisms for these positive results are not known.
Aim: To analyze the impact of EMPA on cardiac and vascular function in patients with Type 2 diabetes mellitus (T2DM).
Methods: We prospectively included patients with T2DM before starting medication with EMPA between June 2017 and May 2018. Other Inclusion criteria were stable anti-diabetic and cardiovascular therapy in the last 3 months, eGRF≥60 ml/min/m2; exclusion criteria were acute coronary syndrome, diagnosis of heart failure or sepsis in the last 6 months. Patients had a visit before and 6 months after starting EMPA, and anthropometric measures, blood analysis, Echocardiogram, and measure of Pulse Wave Velocity (PWV) were performed. Baseline and follow-up data were compared using paired sample t-test.
Results: 38 patients were evaluated, only 23 completed follow-up. Mean follow-up length was 7 months. Mean age 65±7 (47-80) years, 70% males. At baseline, BMI was 31.4±±4.3 Kg/m2, hemoglobin was 14.0±1.2 gr/dL, and 59% of patients had hgbA1c= 7%. Only 8% were treated for cardiac disease.
At baseline, 52% pts had left atrium (LA) area > 20 cm2 (-21.6 ± 3.8 cm2), 57% had left atrium volume index (LAVI) >34 ml/m2 (35.0 ± 9.7 mL/m2), E/e´ was >8 in 71%. Left ventricular mass index (LVMI) was 108.2 gr/m2 in men and 111.6 gr/m2 in women. GLS was <-20 in 85% of patients (mean value -17.3 ± 3.4). No other echocardiographic abnormalities were found.
At the end of follow-up, BMI decreased (31.4 vs 30.4 Kg/m2; p=0.04) and hemoglobin values increased (14.0 vs 14.8 gr/dL, p<0.001).
There was a significant reduction in LA area (21.6 to 20.3 cm2, p=0.036), LAVI (35.0 to 31.7mL/m2 p=0.044) and also in right atrial volume index (21.0 to 18.6 mL/m2, p=0.048). E/e´ decreased (12.1 vs 11.0; p=0.029), but only in those with E/e´ = 8 at baseline.
Additionally PWV showed a significantly reduction – from 9.5 to 8.0 m/s (p=0.006).
Conclusion: In most of our DM patients, Echocardiographic evaluation showed diastolic dysfunction, and abnormal left ventricular Global Longitudinal Strain value. Treatment with EMPA decreased atrial volume, suggesting ventricular unloading. PWV, an important metric of vascular health, was also significantly improved.

P2060

Evaluation of kidney function impairment in patients with chronic heart failure and preserved ejection fraction depending on cardiac rhythm

N Natalia Koziolova[1]; S Mironova[1]; E Polyanskaya[1]
[1]*Perm Medical University, Perm, Russian Federation*

Aim: to evaluate kidney functional status in patients with chronic heart failure (CHF) and preserved ejection fraction of left ventricle (LV EF) depending on cardiac rhythm.
Methods and materials: 60 patients with CHF and preserved LV EF were included. Average age was 67.2±10.9 years. Diagnosis of CHF was confirmed by presence of clinical symptoms and signs and increased level of N-terminal natriuretic peptide NT-proBNP≥125 pg/mL. LV EF was considered as preserved when ≥50%. Additionally, soluble stimulating growth factor expressed by gene 2 (sST2) had been used to confirm CHF and to evaluate its severity. Serum levels of creatinine and cystatin C were measured, as well as glomerular filtration rate (eGFR) using CKD-EPI based on both creatinine and cystatin C were made to evaluate renal filtration function. Neutrophil gelatinase-associated lipocalin (NGAL) was used to detect early tubular kidney damage. Depending on the heart rhythm, the patients were divided into 2 groups. The first group included 30 patients with persistent atrial fibrillation (AF), the rest 30 patients with sinus rhythm.
Results: the groups were matched by sex, age, comorbidity, therapy (except for anticoagulants and antiarrhythmic agents). The parameters of the main criteria for the CHF diagnosis did not differ between groups.Thus, LV FV in the 1st group was 60.4 [CI 58.0-62.8]%, in the 2nd group - 61.1 [CI 59.0-63.2]% (p = 0.624). NT-proBNP level in group 1 is 219.0 [167.4; 548.5] pg / ml, in the 2nd — 258.8 [216.0; 586.1] pg / ml (p = 0.430). No differences between groups among the indicators of renal function - creatinine and creatinine-based eGFR (p = 0.145 and p = 0.695, respectively) were found. A higher level of NGAL in the 1st group - 1.05 [0.63; 2.10] ng / ml, than in the 2nd - 0.75 [0.60; 1.10] ng / ml (p = 0.033) was detected. The sST2 in the 1st group was 46.0 [41.0; 69.0] ng / ml, and in the 2nd 50 [36.0; 109.0] ng / ml (p = 0.773). Also, there were no differences in the level of cystatin C: 2.2 [1.7; 2.7] and 2.0 [1.4; 3.1] ng / ml (p = 0.589). Conclusion: persistent AF in CHF patients with preserved LV EF is associated with impaired tubular kidney function in comparison with patients who have sinus rhythm.

P2061

Endothelial dysfunction in chronic obstructive pulmonary disease patients according to exposure by tobacco or biomass

R Davila- Ramos[1]; DG Gonzalez- Islas[1]; A Orea- Tejeda[1]; Y Pilotzi- Montiel[1]; F Salgado- Fernandez[1]; A Jimenez- Valentin[1]; A Flores- Vargas[1]; R Hernandez-Zenteno[1]; R Sanchez- Santillana[1]; R Martinez- Memije[1]; O Infante- Vazquez[1]; D Alonso- Martinez[1]; N Garcia- Galvez[1]; V Fernandez-Badillo[1]
[1]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico*

Bachground: The endothelium is one of the most important tissues in pulmonary diseases, plays an important role in the regulation of vascular tone, controls blood flow and inflammatory responses. Endothelial dysfunction (ED) is implicated in the pathogenesis of cardiovascular diseases, the important cause in the morbidity and mortality of patients with chronic obstructive pulmonary disease (COPD). However, it is unknown the severity of DE according to COPD type (biomass and smoking)
Objective: To evaluated ED in COPD patients according to exposure by tobacco or biomass.
Material and methods: A cross-sectional study, 260 patients older than 40 years with a confirmed diagnosis of COPD were included; subjects with a diagnosis of asthma were excluded. The population was divided according to to exposure in: Biomass and tabaquism. The ED was evaluated by photoplethysmograph, DE was determinated if quotient between maximum amplitude time / total time of the pulse wave (MAT / TT) greater than 0.30
Results: Mean age was 71 ± 9.6 years. Significant differences were observed between biomass group (n = 100) and smoking group (n = 160). Biomass group had a higher prevalence of women (88% vs 29.3%, p<0.001), heart failure (68.09% vs 50.00%, p = 0.051), and ED (0.36 ± 0.068 vs 0.34 ± 0.064, p = 0.0124) than the smoking group .
Conclusion: Patients with COPD by biomass have greater ED than tobacco smoking subjects. This could induce greater cardiovascular risk.

P2062

Opioid administration for patients with end stage heart failure in Japanese real world

Y Yasuyo Taniguchi[1]; S Oishi[1]; T Onishi[1]; T Takaya[1]; T Miyata[1]; K Yokoi[1]; M Ito[1]; Y Tsukishiro[1]; T Inoue[1]; Y Sawada[1]; A Shimane[1]; K Imamura[1]; Y Yasaka[1]; H Kawai[1]
[1]*Himeji Cardiovascular Center, Himeji, Japan*

Background Safely provide opioids for cancer pain and symptom relief is readily and continually available. However, there are some barriers to palliative care of patients with chronic heart failure their use of opioids. The aim of our study was to ascertain the usage of opioids in the real word of the clinical setting.
Methods: Sixty-seven patients (mean age; 80±12 y.o., male;55.2%) in end-stage heart failure and suffering from moderate to severe dyspnea were included in this retrospective study. All of them were obtained written informed consent and administered opioid intravenously or subcutaneously. Their vital signs, urine volume, VAS face scale, and dietary quantity (feeding volume/number of times) were collected and baseline recording data was compared with 48hours after administration.
Results: Ischemic heart disease was 66.6% and comorbidity was 96.5%. A frequent flyer patient was 85.5%. After administration, rapid heart rate and respiration decreased without significant hypotension (table). Although 3 patients died within 24 hours due to pneumonia and septic shock and 1 patient was discontinued due to excessive sedation, 14 patients could discontinue opioid and 8 patients (57.1%) were able to discharge to home. The administered opioid dose was 6.25 mg (median, 235-20) and duration was 7 days (median, 1-47). Among 67% of the patients with oliguria, volume was improved in 35.5%. Diet intake improved 28.9%. Improvement of dietary intake after 48 hours is only predicted factor for withdrawing opioid(p<0.001, risk ratio 2.73).
Conclusion: In palliative care for end-stage heart failure, opioids have the possibility of allowing symptom control and discharge to the home which contributes to patients' QOL.

Relation between cognitive impairment and blood pressure before psychological stress in right heart failure patients

L Lilian Victoria Pachicano-Romero[1]; V Pelaez-Hernandez[1]; A Orea-Tejeda[1]; GL Luna-Rodriguez[1]; C Pineda-Sanchez[1]; LA Martinez-Bautista[1]; KL Rosales-Castillo[1]; CR Zepeda-Dominguez[1]; L Garcia-Flores[1]; AA Ibarra-Fernandez[1]; A Flores-Vargas[1]; L Hernandez-Urquieta[1]; A Jimenez-Valentin[1]; R Davila-Ramos[1]; MF Salgado-Fernandez[1]
[1]*National Institute of Respiratory Disease, Department of Cardiology, Mexico City, Mexico*

Introduction . Right heart failure (RHF) patients can have dysfunction in several areas, highlighting autonomic and cognitive alterations, due to damage that affects cerebral perfusion and the central nervous system. This syndrome, frequently in comorbidity with COPD, is one of the main type of chronic noncommunicable diseases. However, the characteristics of RHF patients are rarely studied.
Purpose: To describe the relationship between the psychophysiological response of systolic blood pressure (SBP) and diastolic blood pressure (DBP) before psychological stress and cognitive impairment (CI) patients with RHF secondary to COPD.
Methods: Comparative cross-sectional study included 35 patients with RHF participated. They were classified by level of CI with the Montreal Cognitive Assessment (MOCA): Without CI (G1,> 26 points, n=5, 63.57±15.95 years old, 60% men), mild CI (G2, 20-25 points, n=14, 66.16±14.77 years old, 57% women) and moderate CI (G3, <19 points n=16, 66±15.12 years old, 75% women). They were evaluated with a psychophysiological stress profile of three phases of five minutes each with an eight-channel biological feedback system Procomp Infiniti, brand Thought Technology and with Omron baumanometer, model HEM-7320: baseline (BL), arithmetic stressor (AE) and recovery (R), registering SBP and DBP. ANOVA analysis and Pearson test correlation were performed in the SSPS v25 software.
Results: Significant differences were found (p <0.05) between the groups (G1 / G2 / G3) in the SBP during the three phases: BL: 118.77 ± 32.65 / 112.07 ± 12.52 / 139.58 ± 31.31, AE: 122.36 ± 32.78 / 115.20 ± 9.94 /138.91±28.98, R: 115.88 ± 34.08 / 108.47 ± 12.86 / 136.22 ± 28.02. Not so (p < 0.05) in the DBP values: BL: 70.27 ± 12.67 / 71.57 ± 10.09 / 77.79 ± 19.84, AE: 70.26 ± 13.12 / 73.66 ± 13.39 / 80.85 ± 19.33, R: 66.85 ± 14.41 / 67.88 ± 11.71 /75.85±19.75. There was a negative correlation between SBP and MOCA: BL: rP = -.44, p <0.05, AE: rP = -.40, p <0.05, R: rP = -.44, p <0.05. The correlation between DBP and MOCA was not significant (p <0.05).

Conclusions: The higher the SBP the lower the score in the MOCA, indicating higher CI. Patients with higher CI had a psychophysiological pattern less adaptive to psychological stress, with little or no reactivity to the stimulus.

P2064

Impact of obesity on volume status in chronic heart failure

WL Miller[1]; B Barry Borlaug[1]
[1]*Mayo Clinic, Department of Cardiovascular Medicine, Rochester, United States of America*

Background: Volume overload is common in both heart failure (HF) and obesity, but the quantitative relationship between the extent of volume expansion and BMI in obese and non-obese patients with chronic HF has not been defined.
Methods: Total blood volume (TBV) was measured using a standardized nuclear medicine radiolabeled albumin-dilution technique in predominately Class III outpatients referred for clinical assessment. A second sensitivity cohort consisted of patients admitted to hospital for volume overload-related symptoms with acute on chronic HF. Obesity was defined by BMI ≥30kg/m2.
Results: TBV was correlated with body weight and excess body weight (both p<0.01). Severe intravascular volume expansion (defined as >25% expansion above normal expected volume) was highly prevalent and more common in the obese ambulatory cohort (53%) as compared to non-obese HF patients (28%, p=0.04) (Fig 1). In contrast, while severe volume expansion was also highly prevalent in the decompensated HF cohort, there was an equal distribution in obese (50%) and non-obese (52%) patients. RBC polycythemia was a significant contributor to volume overload in ambulatory obese and non-obese HF patients (Fig 1) but was more prevalent in the cohort of decompensated obese and non-obese HF patients (55% and 52%, respectively).
Conclusions: Severe intravascular volume expansion is highly prevalent in ambulatory HF, but is significantly more common in HF patients with obesity supporting the concept of a distinct phenotype of obesity-related HF. However, in the volume overload state of decompensated HF, obesity as defined by BMI no longer serves to stratify volume status. Further study is needed to better understand the mechanisms controlling volume regulation in the setting of obesity and HF.

The new clinical tool of severity assessment in elderly patients with heart failure

VN Larina[1]; MI Zacharova[1]; VI Lunev[1]; MP Mikhailusova[1]
[1]*Pirogov Russian National Research Medical University , Oupatient Medicine, Moscow, Russian Federation*

The symptom of chronic heart failure (CHF), experienced while bending forward for the first 30 seconds, called bendopnea, was suggested in 2014. This symptom is associated with an increase in ventricular filling pressure during a tilt, especially in patients with a low cardiac index. Aims: Evaluation of clinical and hemodynamic parameters of elderly patients with CHF and bendopnea. Methods: The open, comparative single-stage study included 58 outpatients (26M, 32F) with II-IV FC NYHA aged ≥60 years with a BMI <30.0 kg/m2. Depending on the presence or absence of bendopnea, the patients were divided into 2 groups: those with and without bendopnea. All patients were underwent general clinical and laboratory examination, ECG, echocardiography. The program used is IBM SPSS Statistics version 22. Results: coronary heart disease (CHD) was the primary cause of CHF in 46 (79%), arterial hypertension - in 11 (19%) patients. NYHA class II was present in 30 (52%), III - in 27 (47%), IV - in 1 (1.7%) patients. Bendopnea symptom was detected in 25 (43%) patients aged 75 (67-79) years. The age of patients without bendopnea was 75 (67-79) years (p=0.239). Patients of the 2 groups were comparable in BMI (p=0.861), concomitant hypertension (p=0.200), anemia (p=0.673), atrial fibrillation (p=0.204), diabetes mellitus (p=0.932), chronic kidney disease (p=0.375). In patients with bendopnea, the left ventricular ejection fraction (LVEF) was 43 (35-51)%, without bendopnea - 60 (56-62)%, p<0.001. There was the correlation between the bendopnea and the indexed LVESV (p=0.001, r=0.46) and LVEDV (p=0.001, r=0.53), LV aneurysm (p<0.001, r=0.45, LVEF (p <0.001, r=-0.66), left atrium (p=0.039, r=0.29), PASP (p=0.004, r=0.41), EDD (p<0.001, r=0,50), ESD (p<0.001, r=0.50), NYHA FC (p<0.001, r=0.92), NT-proBNP (p=0.26, r=0.44). Conclusion: Twenty-five (43%) patients with CHF and BMI<30.0 had bendopnea. A close association bendopnea with an adverse hemodynamic profile, high NYHA FC and the level of NT-proBNP allows to consider this symptom as a tool clinical state severity of CHF elderly outpatients.

P2066

One stop heart failure clinic- a real world experience

C Mccune[1]; H Hiles[1]; A Santos[1]; L Dixon[1]
[1]*Royal Victoria Hospital, Cardiology, Belfast, United Kingdom of Great Britain & Northern Ireland*

Introduction: UK NICE guidance states that patients with suspected heart failure should be triaged according to risk. Patients with a history of MI (myocardial infarction) should have a specialist assessment and echocardiography within 2 weeks (urgent referral). Patients with no MI history should have a NTproBNP measured. Patients with high levels (>2000pg/ml) should be seen within 2 weeks (urgent referral), patients with raised levels (400-2000pg/ml) should have a review within 6 weeks (routine referral). We developed a One Stop Heart Failure Clinic to allow timely diagnosis and management plan implementation. The clinic provides investigations including bloods, ECG and echocardiogram, access to a cardiologist specialising in heart failure and a heart failure specialist nurse.Purpose: To determine the suitability of referral and referral prioritisation to our One Stop Heart Failure Clinic in comparison to NICE guidance.
Methods: Data from our local One Stop Heart Failure Clinic was collected retrospectively from January 2017 to October 2018. 74 patients (46 male, 28 females) mean age 67 years (range 17-97) were referred. Patients were identified as routine or urgent on the referral form. We reviewed patient's medical history including documented symptoms, history of MI and NTproBNP level and categorised them according to NICE guidance. Diagnosis and outcomes were documented in clinic letters.
Results: 16/74 patients had a previous MI. The mean time to review was 27 days (range 13-57). 5 were appropriately referred as urgent with an average time to review 25 days (13-36). The remainder of MIs were inappropriately referred as "routine" with an average time to review 29 days (13-50). 58/74 had no previous MI. Contrary to guidance 35 patients had no documented NTproBNP with an average time to review 31 days. 15 patients had a NTproBNP >2000pg/ml, 10 were correctly referred as urgent with mean review time of 24 days (median 22, range 12-46). 5 were inappropriately marked as routine and were seen with an average review time of 21 days (median 21, range 4-41). 6 patients had a NTproBNP of 400-2000pg/ml. 3 were incorrectly classed as urgent on the referral (mean review 13 days), 3 were marked as routine (mean review 38 days). Only 2 patients were inappropriately referred with normal NTproBNP and clinic discharge.
Conclusion: The majority of referrals to the One Stop Heart Failure Clinic were appropriate. Referral information was often incomplete and incorrectly prioritised. 21/39 (54%) patients who had a prior MI or documented NTproBNP were inappropriately classed leading to inappropriate triage and subsequent misassignment of clinic appointment. Notably there is poor awareness of prior MI as determinant of an "urgent" classification, and a lack of NTproBNP testing. Time targets are not currently being met, demonstrating the need to expand the clinic. We propose implementing a formal referral proforma to improve concordance with NICE guidance.

P2067

Association between obesity parameters and the risk of left ventricular dysfunction in type 2 diabetic patients

SM Slavica Mitrovska[1]; SJ Jovanova[2]; MS Suslevska[3]
[1]*Polyclinic ProMedika Medical Center, Skopje, North Macedonia*; [2]*University Clinic of Cardiology, Skopje, North Macedonia*; [3]*PHO Atikkor, Skopje, North Macedonia*

Background: Bidirectional link between obesity and diabetes is well established, but the direct connection between obesity and diabetic heart failure, independent of hypertension and coronary artery disease, is not well defined.
Purpose: We aim to estimate the association of obesity with left ventricular dysfunction in asymptomatic type 2 diabetic patients.

Methods: We analyzed 72 asymptomatic normotensive patients with diabetes mellitus type 2, without coronary artery and valve disease. All patients underwent anthropometric measurements– body weight (BW), body mass index (BMI) and waist-to-hip ratio (WHR), and echocardiographic analysis of the left ventricular function, using 2D echocardiography with PW Doppler analysis, Tissue Doppler Imaging-TDI and Speckle-Tracking echocardiography-STE). We assessed the association of echocardiographic parameters of LV dysfunction with obesity parameters using Pearson Product Moment of Correlation.
Results: From the investigated cohort group, 34 (47%) patients have diastolic dysfunction. Twenty one (62%) of them have BMI>25 kg/m2, 22 (65%) have higher WHR. Mann Whitney U Test showed a statistically significant association between BW, BMI, WHR and left ventricular dysfunction (U = 1.9, p = 0.04; U = 2.1, p = 0.03, U = 3.5, p = 0.004).
Pearson Product Moment of Correlation shows strong negative correlation between BMI and E/A ratio (r= - 0.4) and a strong positive correlation with E/E' ratio (r= 0.4). In the analysis of the deformation, the curve has downward trend, i.e. individuals with higher BMI have lower global longitudinal strein- GLS (r= - 0.6), that is indicative of systolic dysfunction.
Conclusion: Strong correlations of obesity parameters with LV dysfunction suggest their role as
predictors of increased risk of heart failure in patients with asymptomatic type 2 diabetes mellitus.

Clinical and echocardiographic features in diabetic and non-diabetic patients with chronic heart failure

V Berisha-Muharremi[1]; E Haliti[1]; S Elezi[1]; I Bytyci[1]; A Poniku[1]; A Ahmeti[1]; A Batalli[1]; P Ibrahimi[1]; R Tafarshiku[1]; Z Rexhaj[1]; G Gani Bajraktari[1]
[1]*University Clinical Centre of Kosova (UCC), Service of Cardiology, Pristina, Kosovo Republic of*

Background and Aim: Heart failure is a common cardiovascular complication of diabetes mellitus (DM) and these two diseases often co-exist. The aim of this study was to investigate the clinical characteristics and echocardiographic indices in diabetic and non-diabetic patients with chronic HF.
Methods: In 344 included chronic HF patients (mean age 61 ± 10 years, 54% female), clinical, biochemical and antropometric data were registered. In all study patients an echo-Doppler study and a six-minute walk test (6-MWT) were performed in the same day.
Results: Among 344 HF patients 111 (32%) had DM. Diabetic patients were older (p=0.026), had greater waist-hip ratio (p=0.041), had more compromised renal function (increased levels of urea and creatinine [p=0.003 and p=0.008, respectively]) and lower hemoglobin level (p=0.02), compared with non-diabetic patients with HF. All echo-Doppler indices, including tissue Doppler measurements, did not differ between diabetics and non-diabetics. On the other hand, diabetic patients with HF had higher New York Hear Association functional class (p=0.008) and shorter walking distance at 6-MWT (p<0.001), compared to non-diabetic patients with HF.
Conclusion: The prevalence of DM in HF patients is high. Diabetes mellitus has deleterious on renal function and anemia in HF patients. Diabetic patients with HF are also more symptomatic and have more compromised exercise capacity, irrespective of structural and functional heart changes, compared to non-diabetic patients with HF. These findings highlight the need for better optimization of medical therapy and regular exercise in diabetic patients with chronic HF.

P2069
Risk factors of heart failure among patients with hypertension

AS Ayodipupo Sikiru Oguntade[1]; IO Ajayi[1]
[1]*University of Ibadan, Epidemiology and Medical Statistics, Ibadan, Nigeria*

Background: Hypertension is the leading cause of heart failure globally. Preventive public health approach to reducing the scourge of heart failure in patients with hypertension must seek to understand the risk factors and determinants of heart failure in at risk populations. This will improve cardiovascular preventive care and aid the prognostic stratification of patients with systemic hypertension.
Purpose: The aim of this study was to determine the risk factors of heart failure (HF) among patients with hypertension attending a tertiary hospital.
Methods: The study was a case control study. The cases were patients with HF secondary to hypertension while the controls were age and sex-matched patients with hypertension without HF.
The patients were interviewed following which they were examined and evaluated clinically for cardiometabolic and lifestyle risk factors. Medication adherence was assessed using the Medication Adherence Questionnaire (MAQ). Subjects underweight cardio-metabolic risk profiling. Conditional logistic regression remodeling was used to determine the risk factors of heart failure in the study population. A two-sided p-value of <0.05 was considered statistically significant in all analyses.
Results: One hundred and one (101) case-control matched pairs were recruited. The mean age of the cases is 62.5±14.3 years while that of the controls is 60.1±13.0 years. There are 50 males (49.5%) and 51 females (50.5%) in each group. Traditional cardiovascular risk factors are prevalent in both groups but they cluster more among the heart failure group. Medication adherence was significantly lower among subjects who developed HF compared to the controls (Low/moderate adherence 80.2% in HF group vs 39.6% in hypertension without HF group; high adherence 19.8% in HF group vs 60.4% in hypertension without HF, p <0.001).
The independent risk factors of heart failure in this study are alcohol consumption (OR: 3.34; 95% CI:1.15-9.74; p=0.025) poor drug adherence (OR: 6.21; 95% CI: 2.30-16.75, p=<0.001), electrocardiographic LVH (OR: 3.10; 95% CI: 1.19-8.05, p=0.020), PVCs (OR:8.37; 95% CI: 1.30-53.90, p=0.025and conduction abnormalities (OR: 6.77; 95% CI: 1.85-24.80; p=0.004).
Conclusion: Alcohol consumption, poor drug adherence and abnormal electrocardiographic markers are strong risk factors that independently tilt patients to heart failure. This is important for public health interventions and preventive cardiovascular care.

P2070
Pulmonary hypertension and left atrial enlargement are associated with blunting of reduction in hospital resource utilization in patients enrolled in specialty heart failure clinic

X Cai[1]; S Jia[2]; SJ Smith[1]; S De[1]; R Mckelvie[1]; RA Davey[1]
[1]*London Health Sciences Centre, Cardiology, London, Canada*; [2]*University of Western Ontario, Schulich School of Medicine and Dentistry, London, Canada*

BACKGROUND: The prevalence of heart failure (HF) has increased demands on the healthcare system and it is a leading cause of hospitalization in the elderly. HF specialty clinics have made a positive impact in decreasing hospital resource utilization (HRU). The presence of left atrial enlargement (LAE), being a surrogate for possible diastolic dysfunction, and pulmonary hypertension (PH) are prognostic indicators in the HF patient population. We sought to determine if HF clinic enrollment would reduce HRU, particularly in those patients with PH or LAE.
METHODS: We conducted a retrospective chart review on patients seen at a high-acuity tertiary care HF clinic. A total of 278 patient charts were reviewed for their clinical characteristics and initial baseline echocardiogram data. Using the first clinic visit day as a reference date, we collected data regarding HRU for each patient. These includes the number of total and HF related hospital admissions, length of stays (LOS), and emergency room visits over the span of one year before and after the reference date. Patients were grouped based on their echocardiogram parameters including baseline ejection fraction (EF), left atrial volume index (LAVI), and tricuspid regurgitation peak gradient (TRPG). Each group was analyzed separately and divided into subgroups based on specific clinical guideline cutoff ranges. Patients were divided by EF into HFpEF (EF>50%) and HFrEF (EF<40%). Presence of PH was defined as TRPG>31.6 mmHg. Possible LAE was defined by LAVI>34 mL/m2. For each group, we compared their respective HRU one year prior and after the reference date.
RESULTS: In all patient groups, enrollment into HF clinic led to significant reduction in all aspect of analyzed HRU including number of total and HF related hospital admissions, LOS, and emergency room visits compared to before enrollment (P=0.000). There was no significant difference between HFpEF and HFrEF groups in terms of HRU reduction after enrollment. Patients with LAE had higher rate of HRU compared to patients without LAE in HF related admission (0.53 vs 0.09, p=0.012) and LOS (3.32 vs 0.25, p=0.016) after enrollment into HF clinic. Patients with PH had higher rate of HRU compared to patients without PH in all admission (0.93 vs 0.38, p=0.015) and HF related admissions (0.48 vs 0.11, p=0.032) after enrollment into HF clinic.
CONCLUSION: There were significant relative reduction in every aspect of the analyzed HRU after a patient has been enrolled in HF clinic. The benefit is best seen in patients without PH or LAE particularly in reducing HF related admission and LOS. These benefits were still present but blunted in patients with PH or LAE. Age may be a confounder as presence of PH or LAE is positively correlated. These findings confirm the benefit of a single-center advanced HF clinic in reducing HRU but also suggest more attention needs to be given to patients with advanced HF complicated with PH or LAE.

P2071
Longitudinal changes in serum creatinine in patients with heart failure receiving oral anticoagulation for atrial fibrillation

S Giovinazzo[1]; M Toma[1]; G Ghigliotti[1]; F Chiarella[2]; C Brunelli[1]; I Porto[1]; M Canepa[1]; P Pietro Ameri[1]
[1]*University of Genova & IRCCS Policlinic Hospital San Martino, Genova, Italy*; [2]*IRCCS Policlinic Hospital San Martino, Genova, Italy*

Background: Recent studies found that an increase in serum creatinine (sCr) over time is less common and milder in subjects with atrial fibrillation (AF) receiving

non-vitamin K antagonist oral anticoagulants (NOAC) than vitamin K antagonists (VKA). This effect may be particularly relevant in patients with heart failure (HF), which is associated with substantial rates of worsening renal function (WRF).

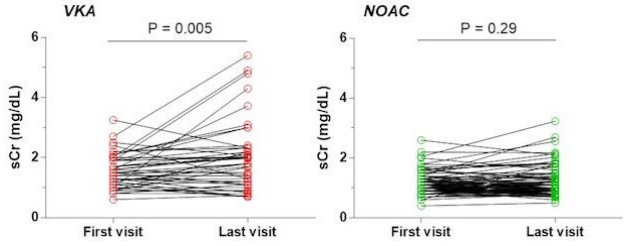
Methods: By reviewing the records of 440 consecutive HF patients referred to a tertiary outpatient clinic between Oct. 2014 and Jan. 2019, we selected those meeting the following criteria: ≥2 visits over the study period; persistent oral anticoagulation for AF; sCr available at both the basal and last evaluation. The characteristics between VKA and NOAC users and the changes in sCr were compared by chi-square or t-test, as appropriate. WRF was defined as an increase in sCr ≥0.3 mg/dL from the baseline value. The association of NOAC treatment with this outcome as well as with sCr doubling was assessed by logistic regression.

Results: After excluding the subjects who received VKA for a mechanical valve or left ventricular (LV) thrombus (n. 26), switched from VKA to NOAC (n. 14) or vice versa (n. 1), interrupted anticoagulation (n. 1), and faced a rise in sCr to >2 SD (n. 1), 46 patients on VKA and 84 on NOAC were included in the analysis.

NOAC users were younger, although not a significant extent (72.7±12.7 vs. 76.4±8.4 years, P=0.07), and had diabetes (22.6% vs. 41.3%, P=0.02) and chronic kidney disease (15.5% vs. 63%, P<0.0001) less frequently than VKA users. They also tended to have less often anaemia (10.7% vs. 23.9%, P=0.08) and a LV ejection fraction ≥40% (39.3% vs. 56.5%, P=0.06). Less subjects on NOAC than on VKA were hospitalised at least once during follow-up (21.4% vs. 39.1%, P=0.03).

At the first visit, mean sCr was 1.6±0.6 mg/dL and 1.15±0.4 in VKA and NOAC users, respectively (P <0.0001). At the last evaluation, it was significantly increased by 0.4±1 mg/dL in the former patients, while a non-significant change of 0.04±0.4 mg/dL was observed in the latter ones (Figure). Consequently, sCr was also significantly higher in VKA than NOAC recipients at the last visit (2±1.1 mg/dL vs. 1.2±0.5 mg/dL, P <0.0001). WRF occurred in 20 (43.5%) cases in the VKA group and in 13 (15.5%) in the NOAC one (P =0.001), while sCr doubled in 6 (13.0%) vs. 1 (1.2%) patients taking VKA or NOAC, respectively (P =0.004). There was a negative association of NOAC therapy with both WRF (OR 0.24, 95%CI 0.1-0.55, P=0.001) and sCr doubling (OR 0.08, 95%CI 0.01-0.69, P=0.02), which persisted after adjusting for age, baseline sCr, diabetes and time between the first and last visit (WRF: OR 0.29, 95%CI 0.12-0.75, P=0.01; sCr doubling: OR 0.08, 95%CI 0.01-0.86, P=0.04).

Conclusions: These data suggest that NOAC are nephroprotective in HF with AF as compared with VKA. Bigger and multicentre studies are warranted to verify this hypothesis.



P2072

Differences between physical and psychological stress in right heart failure patients

L Lilian Victoria Pachicano-Romero[1]; V Pelaez-Hernandez[1]; A Orea-Tejeda[1]; C Pineda-Sanchez[1]; GL Luna-Rodriguez[1]; A Martinez-Bautista[1]; CR Zepeda-Dominguez[1]; L Garcia-Flores[1]; R Davila-Ramos[1]; AA Ibarra-Fernandez[1]; RN Sanchez -Santillan[1]; K Balderas-Munoz[1]; MF Salgado-Fernandez[1]; YA Pilotzi-Montiel[1]; A Flores-Vargas[1]

[1]National Institute of Respiratory Disease, Department of Cardiology, Mexico City, Mexico

Introduction: Frequently, right heart failure (RHF) coexist with COPD. Patients with both diseases have constant psychological stress due to their health condition, even at physical rest. Physical stress and psychological stress have an impact on the health of these patients; altering, among others, the autonomic activity, which makes necessary to know if there are differences between the physiological response to both types of stress in this population.

Purpose: To describe the differences between the physiological responses to physical stress, evaluated in the six-minute walk test (6MWT), and psychological stress, measured during a psychophysiological stress profile in patients with RHF related to COPD.

Methods: Comparative cross-sectional study was conducted. This included 35 patients with RHF, (66.25 ± 14.97 years, 62.85% women). 6MWT and a PSP were performed to evaluate physical stress and psychological stress, respectively. Both test consisted of three phases: baseline, stimulus (reactivity) and recovery.

An Eight-channel biological feedback system Procomp Infiniti, brand Thought Technology; and an Omron baumanometer, model HEM-7320 was used during psychophysiological stress profile. Additionally, a pulse oximeter, model MD300 was used during 6MWT. Heart rate (HR), respiratory frequency (RF), systolic blood pressure (SBP) and diastolic blood pressure (DBP) were recorded. Reactivity and recovery were calculated taking the baseline as reference. Student's t-test was used in SPSS v25.

Results: Statistically significant differences were found between the stimuli (psychological stress / physical stress) in: reactivity HR [t (42.90) = -3.601, p = 0.001]: 1.36 ± 4.98 / 9.58 ± 12.40, recovery HR [t (40.32) = -2.135, p = 0.039]: -0.01 ± 2.65 / 2.97 ± 7.71, reactivity RF [t (69) = 3.015, p = 0.004]: 8.41 ± 5.96 / 4.14 ± 5.96. No significant differences were found between the responses of reactivity and recovery of SBP and DBP to both stimuli.

Conclusions: The reactivity and the recovery of the HR were greater in terms of physical stress, possibly due to the higher metabolic requirement for physical activity. The reactivity of the RF was greater in psychological stress, hypothetically because of the oxygen demand in cognitive tasks. The SBP and DBP in the two types of stress reflect that patients even at rest, maintain high levels of pressure due to psychological stress.

P2073

Sarcopenia and cardiac dysfunction in community-living older adults

E Fung[1]; X Yang[1]; Q Li[1]; K F Cheng[1]; S Liu[1]; F Yau[1]; D Sahota[2]; Y Fan[1]; A P W Lee[1]; L T Lui[1]; J Woo[1]

[1]The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, Hong Kong; [2]The Chinese University of Hong Kong, Obstetrics & Gynaecology, Hong Kong, Hong Kong

Funding Acknowledgements: CUHK Direct Grant 2016/2017

Background/Introduction: Sarcopenia is a generalised skeletal muscle disorder that primarily affects older adults and is common in chronic heart failure (HF). Its association with cardiac dysfunction in community-living older adults remains unclear. As previous studies have found moderate diastolic dysfunction to be predictive of incident HF and reduced survival, we reason that sarcopenia is a component of the preclinical HF syndrome in the elderly.

Purpose: To delineate the prevalence, characteristics and association of sarcopenia and cardiac dysfunction in community-living ambulatory older adults without known HF.

Methods: We recruited 306 community-living individuals aged ≥60 years into the UFO study. A previously validated 5-item questionnaire, SARC-F, was administered at recruitment. A score of ≥4 indicated the presence of sarcopenia, whereas <4 denoted non-sarcopenia. Echocardiography and N-terminal prohormone of B-type natriuretic peptide (NT-proBNP) were used to assess for cardiac dysfunction.

Results: A total of 102 (33.3%) individuals were sarcopenic. Compared with non-sarcopenic individuals, sarcopenic counterparts were older (79.69±7.56 vs 72.25±6.59, P<0.01) and more likely to be female (85.3% vs 60.8%, P<0.01). Hypertension (76.5% vs 60.3%, P<0.01), diabetes mellitus (DM) (35.3% vs 24.5%, P<0.05) and ischaemic heart disease (IHD) (10.8% vs 4.4%, P<0.05) were more prevalent in the sarcopenia group.

Overall, the prevalence rates of diastolic and systolic dysfunction (left ventricular ejection fraction (LVEF) ≤50% by Simpson's method) were 67% and 4.2%, respectively. Diastolic dysfunction was more common in sarcopenic than non-sarcopenic individuals (82.4% vs 59.3%, P<0.01). The prevalence of diastolic dysfunction progressively rose from 49.4% to 100% with increasing SARC-F scores. LVEF did not significantly differ between sarcopenic and non-sarcopenic individuals.

Amongst echocardiographic parameters of diastolic function, the ratio of peak mitral inflow velocity-to-early diastolic mitral annular velocity (E:E') and left atrial volume index (LAVI) were greater in the sarcopenia than non-sarcopenia group (septal E:E', 17.27±5.9 vs 13.24±4.66, P<0.01; lateral E:E', 13.61±5.52 vs 10.36±4.0, P<0.01; LAVI, 31.4±10.08 vs 25.92±10.65 ml/m2, P<0.05), whereas E' was lower in the sarcopenia group (septal E', 4.79±1.44 vs 5.51±1.45 cm/s, P<0.01; lateral E', 6.25±2.05 vs 7.14±2.09 cm/s, P<0.01).

Serum NT-proBNP levels (median, IQR) were significantly higher in the sarcopenia than non-sarcopenia group (177.13 (101.34–399.42) vs 81.95 (43.30–166.62) pg/ml, P<0.01). By regression analysis, NT-proBNP >300 pg/ml was associated with an increased risk for sarcopenia (OR 2.40, 95% CI 1.05–4.19, P<0.01) after adjusting for hypertension, DM and IHD.

Conclusion(s): Diastolic dysfunction was highly prevalent in community-living older adults. Preclinical cardiac dysfunction was associated with an increased risk for sarcopenia.

P2074

Sarcopenia and reduced physical fitness are associated with cardiac dysfunction in community-living older adults

X Yang[1]; L T Lui[1]; Q Li[1]; K F Cheng[1]; S Liu[1]; F Yau[1]; Y Fan[1]; A P W Lee[1]; J Woo[1]; E Fung[1]
[1]*The Chinese University of Hong Kong, Medicine & Therapeutics, Hong Kong, Hong Kong*

Funding Acknowledgements: CUHK Direct Grant; Lui Che Woo Institute of Innovative Medicine, CUHK; Food and Health Bureau of Hong Kong SAR; Research Grants Council, Hong Kong

Background/Introduction: Sarcopenia is an ageing-related disorder characterised by impaired muscle strength, reduced gait speed (GS), and is associated with increased mortality, hospitalisation, and adverse outcomes. It has rarely been investigated in association with cardiac dysfunction in community-living older adults.
Purpose: To evaluate the effects of sarcopenia on cardiac dysfunction and physical performance in community-living older adults.
Methods: Individuals aged ≥60 y and without a history of heart failure were recruited from community and a Geriatric Day Hospital during 2017-18. A SARC-F score (range, 0-10 points) of ≥4 indicated the presence of sarcopenia. Handgrip strength per body mass index (HGS), GS, and 6-min walk distance (6MWD) were assessed. Echo was analysed according to standard international guidelines.
Results: 306 older adults were recruited. The prevalence of guideline-defined diastolic (DD) and systolic dysfunction was 67% and 4.3%, respectively. Among those recruited, 102 (33%) were sarcopenic and had reduced HGS, GS and 6MWD. The prevalence of DD was higher in the sarcopenia than non-sarcopenia group (82% vs. 59%, P<0.01). Sarcopenia was associated with DD after adjusting for co-morbidities (Table 1). Successive increase in SARC-F score from 0 to 1-2, 3-4, 5-6 and 7-10 was associated with increasing risks for DD by 1.8-fold (95% CI 1.0–3.3, P<0.05), 2.8-fold (1.4–5.6, P<0.01), 5.6-fold (2.1–14.8, P<0.01) and 12.8-fold (2.9–57.5, P<0.01), respectively.
Among individual SARC-F components, 'carrying 10 pounds', 'walking across the room', 'climbing 10 stairs', and 'rising from bed or chair' were associated with 2.27- to 8.86-fold increase in the risks for DD, while 'fall(s) within 1 year' was not associated. Decreasing physical fitness was associated with increasing risks for DD by 1.87-fold (95% CI 1.41–2.48, P<0.01) per 0.3 decrement in HGS, 1.83-fold (1.41–2.39, P<0.01) per 0.2-m/s decrement in GS, and 2.09-fold (1.55–2.82, P<0.01) per 100-m decrement in 6MWD.
Conclusion(s):
The prevalence of sarcopenia and DD was high in community-living older adults. Sarcopenia was associated with increased risk for DD and corresponding decline in physical fitness.

Table 1. Logistic regression analysis.

The association of reduced cardiac systolic function with morphological vascular abnormality rather than functional vascular abnormality in coronary artery disease

HT Tomiyama[1]; TC Chikamori[1]; AY Yamashina[1]
[1]*Tokyo Medical University, Tokyo, Japan*

On behalf of: FMDJ study
Funding Acknowledgements: The present study was supported by the Japanese Atherosclerosis Prevention Research Fund (A study of Multi-center Assessment on the Clinical Usefulnes

Aims: FMD-J study is a multicenter prospective observational study to examine the usefulness of vascular function (endothelial function and arterial stiffness) in clinical management in patients with coronary artery disease (CAD). The present cross-sectional study, as a sub-analysis of FMD-J study, was conducted to examine whether reduced cardiac systolic function is differently associated with the vascular functional or morphological abnormalities in patients with CAD.
Methods: Brachial-ankle pulse wave velocity (baPWV), a marker of arterial stiffness, and flow-mediated vasodilatation in brachial artery (FMD), a marker of endothelial function, were obtained in 674 patients with CAD at the baseline of FMD-J study.
Results: Among these patients, left ventricular ejection fraction (LVEF) <50% was observed in 83 patients. While FMD (4.3±2.6 % vs. 4.7±2..8 %, p=0.19) was similar, baPWV (15.5±2.4 m/s vs. 16.4±2.9 m/s, p<0.05) was lower, and diameter of brachial artery was larger (4.5±0.7 mm vs. 4.3±0.6 mm, p<0.05) in patients with LVEF <50% (n=83) than in those with LVEF >50% (n=591). Multivariate analysis, adjusted with age, smoking status, blood pressure, and medication for hypertension, demonstrated that LVEF was a significant determinant for brachial-arterial diameter but not baPWV.
Conclusion: In patients with CAD, reduced cardiac systolic function may be associated with vascular morphological abnormality rather than functional abnormalities.

P2076

Clinical determinants of Doppler derived intrarenal hemodynamics in patients with HFpEF

I Irina Cabac-Pogorevici[1]; V Revenco[1]
[1]*State University of Medicine and Pharmacy, Cardiology, Chisinau, Moldova (Republic of)*

Purpose: The interaction between the systemic and intrarenal hemodynamics (IRH) in hypertensive patients is a complex physiological phenomenon which has been largely discussed and widely analysed, meanwhile there is a lack of consistent data about the clinical determinants of the IRH in patients with heart failure (HF). Thus, the aim of our study is to appraise the clinical and hemodynamic determinants of the IRH in a group of patients with HFpEF.
Methods: The population of our study were 62 patients (34 females and 28 males, mean age 50,15 ± 14,50 years) with HFpEF. All subjects underwent careful clinical history and physical examination. A complete echocardiographic study, ambulatory blood pressure monitoring and color Doppler ultrasound of renal and intrarenal arteries were performed to all the subjects. Intrarenal Doppler measurements were repeated in three parts of both kidneys (superior, median, and lower) untill three reproducible waveforms were obtained. The following IRH parameters were obtained: renal resistive index (RRI), renal pulsatile index (RPI), acceleration time (AT).
Results: The mean RRI was 0,6672 ± 0,0452, mean RPI 1,2533 ± 0,178, mean AT 66,68 ± 2,324 ms, mean daytime ambulatory systolic blood pressure (SBP) was 153,73 ± 12,82 mmHg, mean nighttime SBP was 138,32 ± 16,35 mmHg, mean 24 hours SBP was 146,12 ± 13,96 mmHg, mean daytime ambulatory diastolic blood pressure (DBP) was 92,07 ± 18,93 mmHg, mean nighttime DBP 81,79 ± 8,34 mmHg mean 24 hours DBP 86,59 ± 6,78 mmHg. The mean pulse pressure (PP) was 59,10 ± 22,90 mmHg. The mean 24 hours heart rate (HR) was 75,14 ± 26,86 beats/minute. RRI as well as the RPI were negatively related to ambulatory 24 hours DBP (r = -0,239, p < 0,01), (r = -0,139, p < 0,01), mean nighttime DBP (r = -0,299, p<0,01), (r = -0,129, p<0,01), HR (r = -0,326, p<0,01), (-0,123, P<0,01). There was a positive association of only IRR with ambulatory 24 hours SBP (r = 0,359, p < 0,01), mean daytime SBP (r = 0,260, p<0,05) ambulatory PP (r = 0,266, p < 0,01), age (r = 0,253, p < 0,01), left ventricular mass (LVM) (r = 0,459, p < 0,001) and relative wall thickness (RWT) (r = 0,293 p<0,01), statistically significant even after adjustment for various confounding factors. In multiple regression analysis, mean 24 hours SBP, daytime SBP, PP (p < 0,01) and LVM (p <0,05) were revealed as main determinants of RRI and IPR in patients with HFpEF, meanwhile we didn't find an important correlation of AT and any clinical or hemodynamic parameter in this particular group of patients.
Conclusions: In addition to local renal vascular properties, the central hemodynamic factors significantly influence the intrarenal arterial patterns in patients with HFpEF. Though IRH was initially considered as a reflection of the intrarenal vascular changes, it is actually the result of a complex interaction between renal and systemic vascular factors useful in assessment of a large spectrum of cardiovascular conditions.

P2077

Cerebral blood flow is lower in heart failure patients with reduced ejection fraction who have atrial fibrillation

E Babayigit[1]; Y Yuksel Cavusoglu[1]; M Dural[1]; KU Mert[1]; T Ulus[1]; B Gorenek[1]
[1]*Eskisehir Osmangazi University, Eskisehir, Turkey*

Purpose: There is an adverse interaction between heart and brain in heart failure (HF). The presence of atrial fibrillation (AF) in HF poses an increased risk for stroke and cognitive impairment. Transcranial Doppler (TCD) provides information on the velocity of cerebral blood flow and detects microembolic signals that can be used to determine the risk of cerebrovascular events. In this study, we evaluated the effect of

AF on the blood flow velocities of cerebral arteries in patients with HF and reduced ejection fraction.
Methods: This study included 46 HF patients with an ejection fraction less than 35% who underwent to TCD examination. In addition, 26 healthy individuals with sinus rhythm were included in the study as a control group. We compared the both right middle cerebral arterie's (RMCA) and left middle cerebral arterie's (LMCA) minimum, maximum and mean flow velocities between HF patients with AF and those with sinus rythm or normal healthy individuals.
Results: The average maximum and mean flow velocities of RMCA were 65.87cm/s and 38.55cm/s in HF with AF group and 87.84cm/s and 56.41cm/s in control group, respectively (p=0.002 and p<0.001, respectively). The average maximum and mean flow velocities of LMCA were 62.95cm/s and 37.8cm/s in HF with AF group and 88.73cm/s and 57.15cm/s in control group (p<0.001 and p<0.001). The average minimum flow velocities of RMCA and LMCA were 34.66cm/s and 32.0cm/s in HF patients with AF and 36.53cm/s and 36.34cm/s in control group, respectively (p=0.592 and p=0.286, respectively). The average mean flow velocity of RMCA was 38.55 cm/s in HF with AF group and 50.91cm/s in HF with sinus rhythm (p=0.042). The average mean flow velocity of LMCA was 37.8 cm/s in HF with AF group and 49.95cm/s in HF with sinus rhythm (p=0.026).
Conclusion: The results of this study suggested that cerebral blood flow rates were lower in HF patients with AF as compared to HF patients with sinus rhythm or control healthy subjects, which may partly explain heart and brain adverse interaction in HF patients with AF.

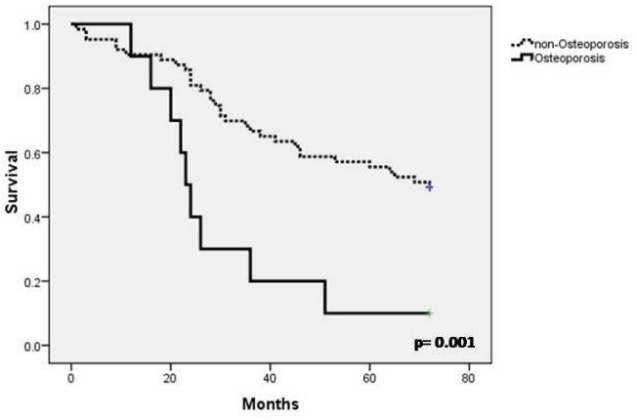
Funding Acknowledgements: Grant of the Ministry of Science of Republic of Serbia 175033

Background: Heart failure (HF) and osteoporosis are highly prevalent aging-related syndromes that exact an enormous impact on society.
Purpose: To evaluate the rate of osteoporosis, its determinants and impact on survival in elderly males with HF.
Methods: A total of 73 no-diabetic, no-cachectic, male patients with HF and reduced left ventricular ejection fraction ≤40% (age: 68±7 years, left ventricular ejection fraction 29±8%) were enrolled. Bone mineral density (BMD) at the level of the hip and body composition were measured by dual energy X-ray absorptiometry, while muscle performance was assessed by hand grip strength. N-terminal pro B-type natriuretic peptide (NT-proBNP), markers of bone turnover (osteocalcin, β -CrossLaps), receptor activator of nuclear factor-kappaB ligand (RANKL) were assessed. Patients were divided into 2 groups according to the diagnosis of the osteoporosis defined as T score of hip total ≤ -2.5 and were compared in respect to survival at 6-years of follow-up.
Results: 10 (14%) patients were diagnosed with osteoporosis. They were similar in age compared to no-osteoporosis patients (69 ± 9 vs. 67 ± 7, p= 0.621). Patients with osteoporosis presented with lower body mass index (24 ± 2 vs. 28 ± 2 kg/m2, p= 0.010) along with more prominent wasting of other body compartments (15 ± 5 vs. 23 ± 11 kg, p= 0.019 for total fat mass; 47 ± 5 vs. 55 ± 9 kg, p= 0.006 for total lean mass). Increased bone turnover was noted in patients with osteoporosis compared to patients without osteoporosis (59 ± 30 vs. 35 ±15 ng/ml, p< 0.0001 for osteocalcin and 830 ± 386 vs. 465 ± 238 pg/ml, p< 0.0001 for β -CrossLaps), while serum RANKL was not significantly increased in osteoporotic patients (p= 0.092). Patients with osteoporosis presented with decreased grip strength (83 ± 14 vs. 97 ± 20 kg, p= 0.019) and renal dysfunction (44 ± 12 vs. 67 ± 22 ml/min, p= 0.002) compared to the patients without osteoporosis. NT-proBNP was increased in osteoporotic patients (4117(5512) vs. 1761 (2259), p= 0.027). A total of 41 (56%) patients died within 6 years of follow-up. Kaplan-Meier survival analysis showed impaired survival in patients with osteoporosis (p= 0.001, Figure 1). In multivariate logistic regression analysis, only creatinine clearance was independently related with osteoporosis [OR 0.92 (95% CI 0.87-0.98), p=0.007]. In multivariate Cox regression analysis, NT-proBNP [HR 3.70 (95% CI 1.93-7.09), p< 0.0001], and presence of osteoporosis [HR 2.76 (95% CI 1.26-6.02), p= 0.011] were independent determinants of all-cause mortality after 6 years of follow-up.



Survival analysis

Conclusions: Although the rate of osteoporosis is modest in no-cachectic, elderly men with HF, these patients have impaired survival compared to the patients without ostoporosis. Osteoporosis was independent predictor of all-cause mortality. Whether specific treatment of osteoporosis in HF patients may improve its survival has not been studied so far.

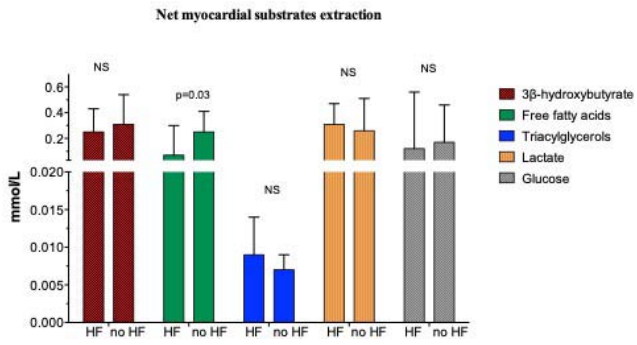
Metabolism evaluation and ketones utilization in the failing human heart

L Luca Monzo[1]; K Sedlacek[2]; P Stavek[3]; F Barilla[1]; L Kryze[2]; C Gaudio[1]; J Kautzner[2]; V Melenovsky[2]
[1]Sapienza University of Rome, Department of Cardiovascular, Respiratory, Nephrological, Anesthesiological, and Geriatric Sciences, Rome, Italy; *[2]Institute for Clinical and Experimental Medicine (IKEM), Cardiology, Prague, Czechia*; *[3]Institute for Clinical and Experimental Medicine (IKEM), Laboratory for Atherosclerosis Research, Prague, Czechia*

Background: Under normal circumstances, free fatty acids (FFAs) are the predominant energetic substrate of the heart. The aim of this study was to identify and quantify the heart substrates utilization in mild to moderate human HF.Methods: β-hydroxybutyrate, lactate, triacyclglycerols, glucose and FFAs concentrations in arterial, coronary sinus (CS), and central venous beds were measured after an overnight fast to derive myocardial substrates utilization in HF patients and controls scheduled for cardiac device implanting procedures.
Results: A total of 15 HF patients and 11 controls were enrolled. Arterial and CS metabolites concentration were similar between the groups. A significant reduction in the myocardial FFAs extraction was showed in HF patients compared to controls (HF 0.07 ± 0.23 mmol/Lvs non-HF 0.25 ± 0.16 mmol/L, p=0.03), together with an inverse association between FFAs and neurohormonal and echocardiographic HF hallmarks. In particular we showed a strong and inverse correlation between left ventricular end-diastolic diameter and FFAs myocardial extraction (p<0.001). Opposite, β-hydroxybutyrate, lactate, triacyclglycerols and glucose extractions were relatively unchanged between groups (Figure). The net cardiac extraction of β-hydroxybutyrate was directly associated to HF duration. When diabetic and non-diabetic patients were compared among HF population, the results were substantially similar, with a slight trend in reduction of FFAs net extraction (HF 0.03 ± 0.30 mmol/L vs non-HF 0.26 ± 0.12 mmol/L, p=0.09).



Conclusions: In our study ketone bodies utilization was unchanged between mild to moderate HF patients and controls. We showed a reduced myocardial FFAs extraction consistent with a downregulation of beta-oxidation in the failing heart in HF population. Future studies are needed to clarify mechanisms that regulate the changes in myocardial substrates utilization and its timing.

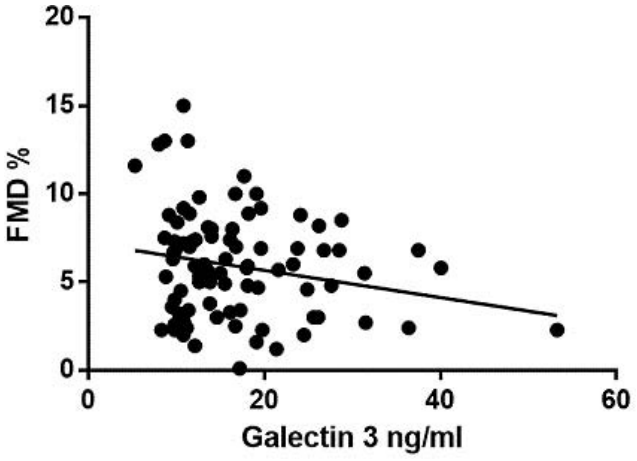
Cross talk between endothelial dysfunction and myocardial fibrosis in patients with heart failure: the role of galectin-3.

E Evagelos Oikonomou[1]; D Karlis[1]; S Tsalamandris[1]; G Siasos[1]; C Chrysohoou[1]; G Vogiatzi[1]; VC Mystakidi[1]; G Marinos[1]; D Tousoulis[1]
[1]*Hippokration Hospital, University of Athens, 1st Department of Cardiology, Athens, Greece*

Background: Endothelial function is impaired in patients with heart failure (HF) and may contribute to clinical status of HF patients. Galectin-3 is a mediator of myocardial fibrosis and remodeling, and is related to prognosis patients.
Purpose: To examine the association of endothelial dysfunction with galectin-3 levels in patients with HF of ischemic etiology.
Methods: We consecutive enrolled 82 subjects with stable ischemic HF and reduced ejection fraction. Ultrasonographic recordings of the brachial artery were used to assed non-invasively endothelial function by means of flow mediated dilation (FMD). Among other factors serum levels of galectin-3 and b-type natriuretic peptide (BNP) were measured in blood samples.
Results: The median values of galectin-3 in our study population was 14. (11.2-19.9) ng/ml and the mean value of FMD in our study population was 5.90±2.99%. There was significant association of Galectin-3 levels with age (r=0.35, p<0.001) with creatine clearance (r=-0.50, p<0.001) and with BNP levels (r=0.29, p=0.003). Importantly there was a significant inverse association of Galectin-3 levels with FMD (r=-0.21, p=0.04) (Figure).
Conclusions: In the present study we found that there is association of endothelial dysfunction with galectin-3 levels in patients with chronic HF of ischemic etiology implying the central role of endothelial ysfunction in the development and progression of ischemic heart failure.



Acute Heart Failure

P2081

Associations of serum extracellular matrix markers with liver stiffness and congestion in patients with decompensated heart failure

M Bayarsaikhan[1]; A Soloveva[1]; O Arisheva[1]; I Garmash[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Department of Internal Medicine with the subspecialty of cardiology and functional diagnostics, Moscow, Russian Federation*

Objective: In patients with heart failure (HF) liver stiffness (LS) assessed by transient elastography (TE) relies heavily on tissue congestion apart of intrinsic fibrosis. In clinical setting it remains unclear how to accurately discern the two processes. The aim of the study was to assess relationship of serum extracellular matrix (ECM) markers levels with LS and congestion in patients with decompensated HF (DHF).
Methods: LS by TE, congestion status by bioimpedance vector analysis (BIVA) and serum ECM markers (collagen type IV, hyaluronic acid, glycoprotein YKL-40 and matrix metalloproteinase–2 (MMP-2)) were assessed in 36 patients with DHF on admission (67% male, 66±12 years [M±SD], arterial hypertension 89%, myocardial infarction 50%, atrial fibrillation 53%, diabetes mellitus 33%, chronic kidney disease 28%, chronic anemia 17%, left ventricular ejection fraction [EF] 37±14%, EF<40% 58%, NT-proBNP 4568 [2187;7014] pg/ml). Mann-Whitney, Spearman correlation tests were performed. P<0.05 was considered significant.
Results: Median value of LS was 11 (7.8;17.9) kPa. Mild, moderate and severe congestion by BIVA was revealed in 11, 25 and 44.4% of patients. Following median values, prevalence of elevation of ECM markers were revealed: collagen type IV 195.3 (163.2;249.8) μg/l, 97.2%; hyaluronic acid 85.3 (36.9;264.8) ng/ml, 77.8%; YKL-40 168.2 (88.4;228.7) ng/ml, 94.4% and MMP-2 215 (167.5;242.5) ng/ml, 36.1%.
LS significantly correlated with parameters BIVA - R/h (r=-0.578) and Xc/h (r=-0.581). Patients with vs without LS>11 kPa had higher levels of collagen type IV (238.4 (193.9;257.1) vs 163.2 (124.2;196.6) μg/l, p=0.002) and MMP-2 (240.5 (200;292) vs 179.5 (134;222) ng/ml, p=0.006). The similar associations were revealed for group with vs without severe congestion by BIVA: collagen type IV (237 (187.9;286.9) vs 176.5 (124.2;252.5) μg/l, p=0.034) and MMP-2 (241 (212;279) vs 184 (145;225) ng/ml, p=0.026).
Collagen type IV and MMP-2 significantly (p<0.05) correlated with LS (r=0.635 and 0.523) and BIVA parameters: R/h (r=-0.388 and -0.540), Xc/h (r=-0.486 and -0.700). YKL-40 and hyaluronic acid were not associated with LS and BIVA parameters.
There was a trend towards to increase of hyaluronic acid in groups with vs without IVC dilation (94.9 (52.1;404.3) vs 42.1 (19.8;141.2) ng/ml, p=0.059), RV dilation (173.9 (41.3;288.2) vs 56.8 (25.6;92.8) ng/ml, p=0.086) and HF history > 2 years (108.7 (43.4;509.8) vs 64.4 (23.4;92.3) ng/ml, p=0.060). Importantly, hyaluronic acid significantly correlated with LS (r=0.519) in 20 subjects from control group without HF and acute conditions.
Conclusions: Collagen type IV and MMP-2 correlated with LS and BIVA parameters in patients with DHF. Absence of correlations of hyaluronic acid with congestion and tendency towards to higher levels with RV dysfunction and longer history of HF may be indicative for intrinsic liver fibrosis.

P2082

Impact worsening renal function on acute decompensated heart failure, depending on ngal changes

I Gorda[1]; A Bezrodniy[1]
[1]*O. O. Bogomolets National Medical University, Kiev, Ukraine*

Background. Our purpose was to determine the value of worsening renal function (WRF) depending on the NGAL and in so-called "wet and warm" patients with acute decompensated heart failure (ADHF).
Methods. In 141 patients with ADHF at the age of 38 to 85 years old (mean age 66,4 ± 2,2) were involved in the prospective study. Worsening renal function (WRF) for creatinine occurred in 38 (27%) patients (WRF+), including 23 pts with increasing NGAL on D3 more than 15% relative to D1 (WRF+NGAL+) and 15 pts without (WRF+NGAL-)
Endpoints were CVP at days 4-6 (D 4-6), dyspnoe by Borg scale, E/E' at discharge (Dsc)
Results. The WRF group with elevated NGAL differed from patients with WRF without elevated NGAL in dyspnoe, E/E' and CVP. In the same time the WRF group without elevated NGAL was comparable with no WRF group (see in table).
Conclusion: In the so-called "wet and warm" patients with ADHF WRF associated with an increase in signs of congestion only in patients with an increase in NGAL after 48 hours.

	No WRF	WRF+ NGAL -	WRF+ NGAL+	P1-2	P1-3	P2-3

P2083

Natriuretic peptides in prognosticating mortality in acutely ill patients: bad news peptide. Investigation beyond heart failure in a single centre tertiary referral centre.

RM Durand[1]; NP Connolly[1]; S Harrington[1]; J Kevans[1]; C O'sullivan[1]; B Mcadam[1]
[1]*Beaumont Hospital, Department of Cardiology, Dublin, Ireland*

Background Natriuretic peptides are commonly used to assist in the diagnosis of heart failure and often used as a biomarker for follow up. We assessed at all NTpBNP results >35000pg/ml performed at our institution, a tertiary cardiology referral centre and dialysis and transplant centre, over a 12 month period.
Methods We assess all eligible patients by accessing the laboratory records of those who had NTpBNP>35000 in 2018, as well as corresponding contemporaneous creatinine, CRP, troponin and clinical data was derived from patient electronic hospital records. Data collected included presence of end stage renal failure (ESRD), history of congestive cardiac failure (CCF), survival status at point of follow up and left ventricular ejection fraction (LVEF) as HFpEF(>45%), HFmEF(45-35%), HFrEF(<35%)as per ESC guidelines.
Results: In our cohort, 71 patients had NTpBNP>35000. The average age was 76(SD +/-13.3), 65% male. Overall 28 had CKD or ESRD, 50% were deceased at follow up and 82% had a history of CCF. 16 patients had recorded troponin-T, 81% with significantly elevated levels (>0.04ng/ml). Of 69 patients with recorded CRP, 62% were >100 with clinical evidence of sepsis.
Overall 30% of patients had both raised CRP and troponin-I with mortality of 57%. Of those without ESRD, average creatinine level was 193(SD +/-84.2). Mortality rates according to LVEF for HFPEF, HFmEF, HfrEF were 67%, 65%, and 48% respectively, and 78% in patients without a echocardiogram.
We divided the data to investigate those with a minimum 6 month follow up; 27 patients, overall mortality 67%. 81% of patients in this category had no ESRD, overall mortality rate 73%.
Of those 15 patients with normal LV function, 4 had features of right ventricular failure and 3 had a diagnosis of a respiratory condition with pulmonary fibrosis, respiratory tract infection, and lung cancer. In addition one patient had systemic sclerosis with RVfailure.
Conclusion: This single centre study demonstrates that a markedly elevated NTpBNP>35000 confers a significant mortality risk of 67% when followed for 6-12 months. Although our numbers are limited, these data raise interesting questions about the prognostic value of NTpBNP measurements irrespective of HF aetiology; sepsis, ACS and AKI may lead to marked elevation in NTpBNP. Interestingly there was no correlation between LVEF, combined raised troponin and sepsis or diagnosis of CKD and mortality. A small subset of patients with normal EF had severely elevated NTpBNP as a consequence of right ventricular failure related to lung pathology.
NTpBNP could potentially be a useful prognostic indicator of mortality on a broad spectrum of acutely ill patients. We plan to follow a larger cohort of patients over an extended period and assess outcomes as a function of treatment for heart failure and other interventions and assess if changes in NTpBNP reflect response to treatment with associated reduction in mortality.

P2084

NT-proBNP as a prognostic marker development of acute kidney injury in patients with acute decompensated heart failure

MV Menzorov[1]; EV Efremova[1]; AM Shutov[1]; VV Kasalinskaya[1]
[1]*Ulyanovsk State University, Ulyanovsk, Russian Federation*

Acute kidney injury (AKI) is often observed in patients with acute decompensated heart failure (ADHF), but it is difficult to predict the development of AKI on the severity of heart failure. At the same time N-terminal pro-B type natriuretic peptide (NT-proBNP) is a marker of cardiac stress and reflects the severity of hemodynamic disorders in patients with ADHF. The aim of this study was to investigate possibilities of NT-proBNP in predicting AKI in patients with ADHF.
Methods. 83 patients (55 males, 28 females, mean age was 65±11years) admitted to hospital with ADHF were studied. The main cause of heart failure was a combination of coronary artery disease and arterial hypertension in 70 (84.4%) patients . ADHF was diagnosed and evaluated according to ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure, 2016. AKI was diagnosed according to the KDIGO Guidelines, 2012. NT-proBNP was evaluated with enzyme immunoassay. We did not include patients who were given X-ray contrast agents during hospitalization or 7 days before it for excluding the development of contrast-induced AKI.
Results. The serum level of NT-proBNP in patients with ADHF was 981.0 (95% CI 546.3-1556.1) pg/ml. AKI was diagnosed in 27 (33%) patients. 16 (59%) patients had hospital AKI, 11 (41%) - pre-hospital AKI. The first stage of AKI was in 19 (70%) patients, the second stage – in 5 (19%) and the third stage – in 3 (11%) patients with ADHF. The level of NT-proBNP was significantly higher in patients with AKI compared with patients without AKI: 1.498.6 (95% CI 938.7-2246.2) and 848.7 (95% CI 510.8-1249.9) pg /ml respectively, p=0.003. NT-proBNP showed good diagnostic capabilities in AKI predicting (Cut Point: NT-proBNP> 1304 pg/ml, sensitivity - 63%, specificity - 79%, AUC = 0.70, p=0.001). Logistic regression analysis showed that NT-proBNP more than 1304 pg/ml was associated with a significant increase of AKI risk developing (RR 5.62; 95% CI 2.04–15.48; p <0.001).
Conclusion. The serum level of NT-proBNP more than 1304 pg/ml is associated with a high risk of AKI in patients with acute decompensated heart failure.

P2085

Usefulness of in-hospital loop diuretic amount and diuretic response measurements in patients with acute decompensated heart failure

G Ruocco[1]; I Evangelista[1]; R Nuti[1]; A Palazzuoli[1]
[1]*University of Siena, Siena, Italy*

Background Intravenous loop diuretic is a landmark treatment in Acute Heart failure (AHF). Despite its wide use, few randomized controlled Trials exist evaluating whether their temporal administration and amount improves or worsens patients outcome.
Purpose: In this study we sought to evaluate:1-different loop diuretic administration in relation to outcome;2-the significance of temporal Diuretic Response (DR) measured over the whole intravenous timing administration.
Methods: AHF patients were screened in relation to loop diuretic dose comparing Low (LD) vs High (HD) dose of drug infusion during hospitalization and oral amount before discharge. DR formula was defined as weight loss/40 mg daily of furosemide and it was examined at day 1, day 3 and during the whole infusion period.
Results 121 AHF patients were consecutively evaluated. ROC curve analysis showed that both infusional treatment and oral diuretic amount at discharge are able to predict poor prognosis (IV dose AUC 0.84; p<0.001; Oral AUC 0.82; p<0.001). DR measured at day 1 (HR 1.69 [1.03-2.80];p=0.04), at day 3 (HR 2.35 [1.41-3.91];p=0.01) and during entire infusion timing period (HR 3.25 [1.92-5.50];p<0.001) were all related to poor outcome. At Multivariable analysis DR measured during the whole infusion (HR 2.45 [1.07-5.66];p=0.03) and oral HD furosemide at discharge (HR 3.36 [1.43-7.88];p=0.005) remained both associated with increased adverse events risk.
Conclusions Both High oral diuretic amount at discharge and low DR during hospitalization are related with adverse outcome. Current analysis could be of potential interest for diuretic dose optimization and strategy after hospitalization.

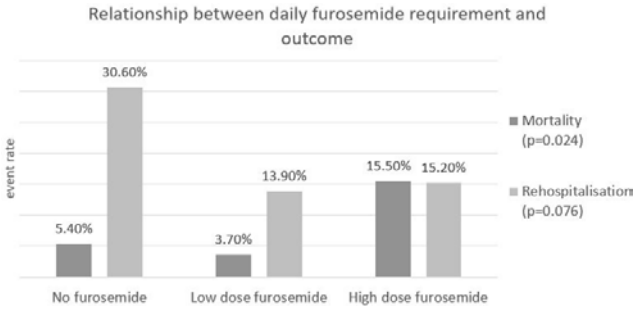
P2086

Higher daily oral furosemide requirement is a predictor for short term mortality in heart failure patients

C Chanattha Thimphitthaya[1]; P Sriparn[1]; M Anuntasainont[1]; P Lalithnithi[1]; S Kittiprachakul[1]; A Trongtorsak[1]; A Ariyachaipanich[1]
[1]*Chulalongkorn University, Bangkok, Thailand*

Background: Loop diuretics are widely used to improve symptoms and exercise capacity in both acute and chronic heart failure patients. Although multiple patient physiologies and disease aspects including its severity determine the dosage required to achieve clinical decongestion, little is known about the prognostic implication of daily diuretic dosage.
Purpose: The purpose of this study is to assess whether higher dose of furosemide is a prognostic factor for worse outcome in patients after discharged from hospitalisation with acute heart failure.
Methods: We conducted a prospective study of 191 consecutive patients admitted due to acute heart failure. Patients fulfilled Framingham criteria for the diagnosis. Doses of oral furosemide at the time of discharge were reviewed whether patients were prescribed with high dose furosemide (≥80 mg/day), low dose furosemide (<80 mg/day) or were loop diuretics free. Outcomes gathered were 30-day all-cause mortality and 30-day rehospitalisation. Chi-square and ANOVA were used for analysis.
Results: Of 191 patients enrolled (mean age 68.41, 53.4% male, mean ejection fraction 36.7%), majority required high dose furosemide (82 patients, 42.93%) compared to those prescribed low dose and no furosemide (64 patients, 33.51% and 45 patients, 23.56% respectively). Age, comorbidity and concurrent treatment with oral disease-modifying heart failure therapy were not different among groups. Patients receiving high dose furosemide had higher NYHA classification (p=0.03). High dose furosemide group showed higher rate of 30-day mortality than low dose group and furosemide free group (15.5% vs 3.7% vs 5.4%, p=0.024). Although 30-day rehospitalisation rate was high in patients not receiving furosemide, no significant difference was found between groups (p=0.076).
Conclusion: Patients requiring higher dose furosemide show to be at increased risks for short term mortality. When prescribing heart failure patients with high dose

diuretics, physician may arrange for closer follow-ups and additional management strategy should be in place in order to prevent adverse disease outcome.



P2087

Interest of Ivabradine in patients with cardiac failure treated with Dobutamine

K Kaoutare Chbini[1]; A Amil[1]; D Benzeroual[1]
[1]*Marrakech University Hospital, cardiology, Marrakech, Morocco*

Background Ivabradine is a selective and specific inhibitor of the pacemaker If current that acts at the sinus node without interfering with cardiac flow and contractility parameters.
Purpose The purpose of the study was to evaluate the changes induced by the slowing of the pacemaker. heart rate by Ivabradine on cardiac output myocardial function in chronic heart failure patients treated with dobutamine.
Methods The study included 20 subjects admitted for acute heart failure, of which 11 received in addition to ivabradine dobutamine. All subjects received ultrasound before and after treatment with ivabradine (3 hours after oral administration of ivabradine 5 mg) .
Results Interestingly, the increase in Dobutamine cardiac output was significantly greater after treatment with Ivabradine (37 ± 9% vs. 27 ± 10%, r <0.001), and was correlated with the reduction in heart rate and the improvement of left ventricular filling.
Conclusion In subjects with heart failure, the reduction in heart rate achieved with ivabradine appears to improve myocardial contractility and cardiac output for a similar dose of dobutamine. This effect is beneficial in the management of patients with acute heart failure who have catecholamine-induced tachycardia.

P2088

The change in noninvasively measured left ventricular end diastolic pressure during outpatient intravenous diuresis is related to ejection fraction and initial filling pressure

Z Zain Gowani[1]; P Patel[1]; M Yu[1]; T Simmons[1]; P Galiatsatos[1]; N Gilotra[1]; R Rouf[1]; H Silber[1]
[1]*Johns Hopkins University of Baltimore, Medicine, Baltimore, United States of America*

Background: The ability to measure left ventricular (LV) filling pressure has shown improvement in heart failure (HF) outpatient outcomes. We have developed a non-invasive device that determines LV end diastolic pressure (LVEDP) based on pulse amplitude changes of a finger photoplethysmography signal in response to a standardized Valsalva maneuver (VM).
Purpose: To evaluate how outpatient LVEDP and hemodynamic response to one session of IV diuresis compares in HF patients with preserved and non-preserved ejection fractions.
Methods: HF outpatients (n=50) undergoing 76 sessions of diuresis with IV furosemide ± metolazone were enrolled. Each participant performed a VM effort of 20 mmHg for 10 seconds into a pressure transducer pre-, and post- (120 minutes after), diuretic administration. LVEDP was calculated in real-time using a previously developed equation. Participants were grouped as having either preserved ejection fraction (HFpEF, EF >50%), moderate ejection fraction (HFmEF, EF 40-49%), or reduced ejection fraction (HFrEF, EF 1-39%). Elevated LVEDP was defined as > 16mmHg.
Results: Mean age 65 +-13 years (46% female; 56% Caucasian); mean LV ejection fraction (EF) was 47±17%. 28 patients had preserved ejection fraction (57%) and 21 (43%) patients did not (13 HFrEF, 8 HFmEF). Mean initial LVEDP was 19.0 +- 4.6 mmHg; mean change in LVEDP was 0.5 +-3.3mmHg; mean urine output (UOP) was 1052 +- 538cc; mean change in weight was 1.0 +- 0.5kg. One participant did not complete testing.
Mean initial LVEDP was 18.6 mmHg in patients with HFpEF and 20.8 mmHg in participants with HFrEF or HFmEF (p = 0.043). There was no detectable difference in LVEDP from pre- to post-diuresis in a single session (20.8 ± 5.6 mmHg versus 20.7 ± 6.0 mmHg, p=0.47) in participants with HFrEF or HFmEF. There was a significant difference in LVEDP (18.6 ± 3.6 mmHg versus 17.8±5.6 mmHg, p=0.047) in HFpEF patients.
Amongst the three groups, there was no significant difference detected in initial LVEDP (p = 0.13) or change in LVEDP (p = 0.62). Regardless of EF, a significant change in LVEDP with a single session of diuresis occurred in participants that had elevated initial LVEDP (p = 0.005) but not in those with non-elevated initial LVEDP (p = 0.12).
Conclusion: Noninvasively measured LVEDP decreased with a single session of outpatient diuresis in HF patients with preserved ejection fractions but not those with non-preserved ejection fractions. This is likely explained by the steeper pressure-volume relation in patients with preserved ejection fractions as compared to those with non-preserved ejection fractions. Participants with non-preserved ejection fractions presented with a higher LVEDP than those with preserved ejection fractions. This may represent clinical tolerance of higher LVEDPs of patients with non-preserved ejection fractions due to the shallowness of their pressure-volume relation curve.

P2089

Patterns of access to medical care in acute myocardial infarction

PM Paulo Maia Araujo[1]; A Nunes[1]; S Torres[1]; P Diogo[1]; C Resende[1]; M Campelo[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Cardiology, Porto, Portugal*

Introduction: Despite the recommendations, a significant proportion of patients [pts] with acute myocardial infarction [AMI] do not activate the Emergency Medical Systems [EMS], thus placing themselves in situations of greater and unnecessary risk.
Purpose: To determine the type of access to medical care in AMI and to evaluate why some pts do not use the EMS.
Methods: It was conducted a prospective survey study of pts with AMI, admitted between June and December of 2018, which included a questionnaire (performed in the first 24h of admission) and consultation of the clinical records.
Results: 95 pts, of whom 73% were male, with a mean age of 63.8 years (95% CI: 61.2 - 66.5) were initially evaluated. 94.4% of the pts considered that in the presence of symptoms suggestive of AMI, EMS should be activated. However, 47.4% (n=45) did not call the EMS and constituted this study population. The time from the symptoms onset to FMC was longer than 24h in 22.2% and in those who took < 24 hours, the mean delay was 153 minutes (95% CI: 113-192). The FMC was: emergency department of public (51.2%) and private (25.6%) hospitals, family doctor (16.3%) and private physician (7%). These pts sought the FMC alone in 20.9% and accompanied in 79.1% and the transport used was: personal car in 81.4% (driving in 28.6%; conducted by third person in 71.4%), public transport in 11.6%, taxi in 4.7% and walking in 2.3%. Although the majority of these pts (82.2%) had typical chest pain, the main reason for not calling the EMS was thinking the condition wasn't serious enough (65.9%). Other reasons were: EMS would take longer - 17.1%; symptoms would pass - 9.8%; other - 7.3%.
Conclusions: Unfortunately, there is a significant proportion of pts with AMI that do not use the EMS and directly seek medical care and this was principally due to an underestimation of the severity of the disease. Implementation of educational programs is imperative, to ensure more appropriate use of the EMS.

P2090

Acute heart failure has many faces- clinical characteristics, response to the treatment and long-term outcome in patients with different physical presentations of cardiac decompensation.

JM Sokolska[1]; M Sokolski[1]; R Zymlinski[1]; J Biegus[1]; K Swoboda[2]; P Siwolowski[2]; S Nawrocka-Millward[2]; P Gajewski[1]; W Banasiak[2]; P Ponikowski[1]
[1]*Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland*; [2]*4th Military Hospital, Cardiology Department, Centre for Heart Diseases, Wroclaw, Poland*

Funding Acknowledgements: The research was financially supported from the statutory grant for Department of Heart Diseases, Wroclaw Medical University, Poland (ST-905)

Background. The severity and onerousness of cardiac decompensation signs and symptoms force patients with acute heart failure (HF) to seek urgent medical help. Acute HF may manifest as a peripheral, central, both types of congestion or none of them. The prevalence of cardiac decompensation signs, its association with patients' clinical characteristics and long-term outcome have not been well established.

Purpose. The aim of this study was to characterize patients with acute HF and assess their long-term outcome according to the signs of congestion presented during hospital admission.
Methods. We investigated 360 patients (mean age: 68±13 years, 77 % men) hospitalized due to acute HF, who were divided according to the type of physical signs of cardiovascular decompensation on admission to the hospital into four groups: A- patients with no physical signs on admission (n=8, 2 %), B- those with isolated pulmonary congestion (n=52, 14 %), C- patients with isolated peripheral signs (peripheral oedema, ascites, hepatomegaly, elevated jugular venous pressure; n=31, 9 %), D- those with mixed signs of acute HF (pulmonary and peripheral congestion; n=269, 75%). Concomitant acute coronary syndrome was a criteria for exclusion from the study.
Results. There was a difference in the baseline level of NT-proBNP between studied groups, with the highest level in patients with lung and peripheral congestion (A vs. B. vs. C vs. D: 4905 [2102-9579] vs. 4113 [2495-7980] vs. 3634 [2772-6372] vs. 6093 [3646-11958] pg/mL, P=0.007). In group D there was also a highest percentage of patients with HF de novo (A vs. B. vs. C vs. D: 25 vs. 54 vs. 57 vs. 74%, P=0.0006). Patients with isolated signs of lung congestion had the highest systolic blood pressure (SBP) on admission (A vs. B. vs. C vs. D: 139±39 vs. 141±36 vs. 120±20 vs. 127±29 mmHg, P=0.007) and the biggest change in SBP after 24 and 48 hours (P<0.01 in both comparisons). There were also differences in urea, bilirubin, white and red blood cells, C-reactive protein, GGTP, albumin level, weight and heart rate change after 24 and 48 hours between studied groups (P<0.05 for all comparisons). After one year of follow up there was a difference in all-cause mortality (A vs. B. vs. C vs. D: 0 vs. 12 vs. 28 vs. 29%, P=0.02).
There were no other differences in baseline clinical characteristics and laboratory indices.
Conclusions. Patterns of physical signs of acute HF are associated with baseline differences in clinical characteristics, treatment response and the long-term outcome. Therefore, better understanding of the pathophysiology underlying the acute HF signs, especially a fluid overload caused either by fluid redistribution or by fluid accumulation is needed to correctly determine goals of the therapy.

P2091

Recognition of risk factors and symptoms of acute myocardial infarction

PM Paulo Maia Araujo[1]; A Nunes[1]; S Torres[1]; C Resende[1]; P Diogo[1]; M Campelo[1]; MJ Maciel[1]
[1]*Sao Joao Hospital, Cardiology, Porto, Portugal*

Introduction: Health education for the general public is essential to ensure better medical care. Specifically in Acute Myocardial Infarction (AMI), symptom recognition is critical to ensure proper and prompt activation of the necessary medical care for the best treatment of this disease.
Purpose: To assess the knowledge of patients (pts) admitted with AMI about cardiovascular risk factors (CVRF) and symptoms of this disease, as well as their ability to recognize these symptoms during the acute event.
Methods: Prospective evaluation of pts admitted with AMI between June and December of 2018. The survey included a questionnaire (performed in the first 24h of admission) and consultation of the clinical records.
Results: The study population consisted of 95 pts, of whom 73% were male, with a mean age of 63.8 years (95% CI: 61.2 - 66.5). Almost all pts (96.8%) had at least one CVRF, but only 35.8% considered to have any of. When asked, the majority of pts correctly considered the following conditions as CVRF: smoking – 96.6%, hypertension –95.5%, obesity – 94.4%, dyslipidemia - 92.1%, sedentary lifestyle – 86.5%, diabetes – 84.3%, family history of coronary heart disease – 84.3%. Recognition of AMI symptoms was assessed by asking the pts from a list of typical symptoms and others not related to AMI. 19.6% declare that did not know the symptoms of AMI. Among pts who reported to know these symptoms, the most frequently identified were central chest pain (100%), dyspnea (79.7%) and diaphoresis (72.6%), while pain in other classic locations -epigastrium/left arm/neck (67.1%) and nausea/vomiting (54.8%) were sub-identified. Furthermore, 65.3% mistakenly attributed non-cardiac symptoms to AMI, especially symptoms of stroke, such as hemiparesis (67.1%), paresthesia (61.6%) and dysarthria (49.3%). At the acute phase of the event, less than half of the pts (45.2%) thought that they were having an AMI. The remaining attributed their symptoms to: indigestion - 37.8%, anxiety – 13.3%, respiratory causes – 11.1%, muscular causes – 8.9% and others – 17.8%, while 11.1% did not consider their symptoms to be serious. From the total population, 28.4% had previous history of ACS/stable coronary heart disease (PHD) and these pts were more capable to attribute their symptoms during the event to an AMI(70.4% vs 34.8%; p=0.002).
Conclusions: Although most pts were able to theoretically identify the main symptoms and CVRF for AMI, in practice this did not translate into a correct identification of the acute event in more than half of them. Pts with PHD were more effective in assigning their symptoms to an AMI, even though there was still a significant proportion of these that were not capable to do that. These findings may have important and adverse implications on the clinical outcomes.

P2092

When is heart failure not heart failure?

G Lee[1]; A Ali Kirresh[1]; R Baruah[1]
[1]*Chelsea and Westminster Hospital NHS Trust, London, United Kingdom of Great Britain & Northern Ireland*

Background/ introduction: The diagnosis of heart failure is based on the history, clinical findings and specialist investigations. A single measurement of B-type natriuretic peptide (BNP) over 100ng/l or a N-terminal pro-B-type natriuretic peptide (NT-proBNP) over 300ng/l is suggestive of heart failure and should prompt a transthoracic echocardiogram within 48 hours to help guide early specialist management. If the serum peptides and transthoracic echocardiogram are normal, despite clinical overload, an alternative diagnosis should be sought after such as liver disease or nephrotic syndrome.
Purpose Identifying patients with heart failure is critical in ensuring that their care processes are streamlined and life prolonging medications are commenced and up titrated to the maximal tolerated doses. Evidence has shown that patients on optimal therapy in conditions such as left ventricular systolic dysfunction have a significantly better prognosis than those without treatment. We aimed to identify the number of patients incorrectly coded as having heart failure despite having a normal serum BNP and echocardiogram.
Methods A retrospective data search was performed on all patients that were discharged from our centre in a 6 month period with the coding of any of the following; 'Heart failure, unspecified', 'Congestive Cardiac failure' or 'Left Ventricular Failure'. Echocardiogram reports for these patients were then assessed for features of heart failure and ejection fractions were recorded. Those with no evidence of heart failure on echocardiography were also assessed using their medical notes and BNP to correlate the echocardiogram findings with an alternate diagnosis.
Results 107 patients were discharged from our centre with the coding of either CCF, LVF or heart failure. Of these 95 had an echocardiogram performed before discharge of which 44 patients had evidence of LVSD and 27 had evidence of heart failure with preserved ejection fraction. The remaining 24 patients did not have any evidence of heart failure on their echocardiogram (6 of these had a small rise in their BNP which could be explained by other causes).
Conclusion Around a quarter of the admissions which were coded as CCF during this 6 month period had normal BNP's and normal transthoracic echocardiograms. Despite this they were discharged with the diagnosis of heart failure and therefore the alternative causes of fluid overloaded were not sufficiently investigated. We suggest that all patients with a normal BNP and echocardiogram have a protein: creatinine ratio and an albumin level to look for alternative causes of the fluid overload. Ensuring that heart failure registers only contain patients with heart failure will help cardiologists and HF nurse specialists focus their efforts on the most at risk patients.

P2093

Frequency and severity of geriatric syndromes in elderly patients with acute coronary syndrome in relation to left ventricular ejection fraction

N Nino Soseliya[1]; O Lukina[1]; A Metelkin[1]; A Soloveva[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation*

Background. Frailty reflects the complex functional disorders and is associated with negative outcomes both in patients with acute coronary syndrome (ACS) and in heart failure (HF) patients. The aim of the study was to characterized geriatric syndromes and risk scales in ACS elderly patients depending on left ventricular ejection fraction (EF).
Methods. 6-month prospective study included 130 patients ≥75 years (83±5 years, arterial hypertension 92%, previous myocardial infarction 32%, atrial fibrillation 32%, diabetes 27%, chronic HF 77%, acute HF (Killip I - 60%, II- 29.2%, III - 10%, IV- 0.8%) admitted with MI (75%) or unstable angina (25%). Frailty by national validated questionnaire, physical disability (Barthel index), functional mobility, nutritional status (Mini Nutrition Assessment), cognitive function (Mini Mental State Examination), morale scale, Charlson Comorbidity Index (CCI), mortality (GRACE) and hemorrhagic risks (CRUSADE scale) were compared by groups depending on EF. Outcomes data were available for 118 patients.
Results. Patients with vs without frailty had similar EF and incidence of reduced EF. Patients with vs without EF <40% were characterized by similar incidence (77,1 vs 62,1 %, p=0,11) and severity of frailty (3 (3;4) vs 3 (2;4), p=0,28) and cognitive function (27 (24;31) vs 29 (24;31), p=0.43), functional mobility (35 (29.5;38) vs 36 (30;38), p=0.29), nutritional status (23.5(22;25) vs 22.5 (21;24), p=0.07), morale scale (35 (18;48) vs 46 (21;50), p=0.13), and other, except higher incidence of malnutrition (5.7 vs 0%, p=0.019).
8.6 % of the participants with EF <40% were non-frail, 14.3 % pre-frail and 77.1 % frail.
Overall, disorders of functional mobility were revealed in 100% of patients with EF <40% (mild and moderate in 57.1 and 42.9%); 25.7 and 42.8% of patients had mild

and moderate physical disability of daily living. The risk of malnutrition was revealed in 51,4% of patients, two (5,7%) patients were malnourished. 40% of patients had cognitive dysfunction (mild 25.7%, moderate 14,3%), 8,5% of patients had mild violations in morale scale.
EF<40% was associated with higher CCI (7.4±1.8 vs 6.5±1.5 points, p<0.05), hemorrhagic risk (50.8±10.9 vs 45.9±9.2 points, p<0.05) and risk of mortality (181.1±40.7 vs 153.3±29.8 points, p<0.01).
There were no differences in length of hospital stay, in-hospital mortality, 6-month mortality between EF groups.
Conclusion. Among elderly ACS patients incidence and severity of frailty was not associated with EF. Elderly patients with reduced EF were characterized only by higher incidence of malnutrition and higher risk of ischemic and hemorrhagic complications.

P2094
Is dyspnoea a different sign in men and women with ACS?

M Maria Plaza Martin[1]; S Del Prado Diaz[1]; M Sanmartin Fernandez[1]; GL Alonso Salinas[1]; S Hernandez Jimenez[1]; J Ramos Jimenez[1]; H Manjon Rubio[1]; A Pardo Sanz[1]; A Marco Del Castillo[1]; JM Monteagudo Ruiz[1]; M Pascual Izco[1]; M Abellas Sequeiros[1]; JD Sanchez Vega[1]; JL Zamorano Gomez[1]
[1]University Hospital Ramon y Cajal de Madrid, Madrid, Spain

Introduction: Atypical symptoms are more frequently described by women with ACS. This differences in clinical presentation has traditionally been identified as one of the reasons of delayed diagnosis and poorer outcomes in women with ACS.
Methods: An observational study was designed in order to evaluate if dyspnoea at admission was related to acute heart failure while hospitalisation due to an ACS. A comparison analysis between gender was accomplished.
Results: A total of 243 patients (from a database of 1042 patients admitted due to ACS in ten tertiary-care Spanish hospitals) referred dyspnoea at admission. Meanwhile, 142 (58%) of them referred dyspnoea but did not show pulmonary congestion or heart failure signs.
Women represented 41% (100) of the sample. Baseline characteristics between men and women included are reflected in table 1. In the group of men with dyspnoea at admission, 68 (47,6%) were on Killip-Kimball class > I, whereas only 33 (33,0%) patients of the female group (p 0,024). As a result, regarding women admitted with ACS diagnose, two out of three of them are in Killip-Kimball class I in spite of feeling breathlessness (with or without chest discomfort associated).
Conclusions: Presence of dyspnoea at admission due to ACS was less frequently related to an acute heart failure state between women. This symptom might reflect more an atypical angina pattern than a congestive state.

Acute decompensated heart failure therapy enriched with angiotensin-neprilysin inhibitor, a single-center real life experience.

V Viktorija Grebneva[1]; I Kurcalte[2]; Y Safro[1]; A Kalnins[1]; A Lejnieks[2]; O Kalejs[2]
[1]Eastern Clinical University Hospital, Riga, Latvia; [2]Riga Stradins University, Department of Internal Diseases, Riga, Latvia

Background: Sacubitril/valsartan therapy initiation has been intensively studied among patients with acute decompensated heart failure(HF) in the last years.
Methods: We enrolled in observational cohort study 18 patients(age 55(35-70) years,14 males)who were hospitalized due to acutely decompensated congestive HF from June to September, year 2018. HF was caused by CHD(5 patients), a hypertensive heart disease(8 patients), a dilated cardiomyopathy(5 patients). All these patients had a significantly increased NT-proBNP level(5000pg/ml on average); no hypotensive patients were enrolled. At the admission all patients received therapy with beta-blocker,ACEI, mineralocorticoid antagonist and intravenous(i/v) diuretics. After detection of LV EF <35% and i/v diuretics change to perioral, ACEI was switched to angiotensin-neprilysin inhibitor. Doses of sacubitril/valsartan were optimized to individual tolerance. Distance of six minute walk test(6MWT), ECHO parameters and laboratory analyses results received before patient's discharge from the hospital were compared to ones obtained after 3 months.
Results: Statistically significant increase of 6MWT distance, ECHO signs of reverse heart remodelling and renal function improvement were found(see table). None of studied patients died, experienced hypotension, was rehospitalized or cancelled sacubitril/valsartan therapy due to adverse effects during the 3 month long follow-up period.

GFR(ml/min)(mean(SD))	57(25)	62(14)	.000
6MWT(m)(mean(SD))	303(49)	371(74)	.000

EF- Left ventricular (LV) ejection fraction; EDD- end-diastolic LV diameter; EDS- end-systolic LV diameter; LAVI- left atrial volume index; RVD- right ventricle diameter; TAPSE- tricuspid annular plane systolic excursion; GFR- glomerular filtration rate; 6MWT - six minute walk test distance.

Conclusions: An advanced medication therapy of decompensated HFrEF including sacubitril/valsartan improved study patients functional status, ECHO parameters and renal function. Early inclusion of sacubitril/valsartan in decompensated HFrEF therapy scheme was safe in the study population.

P2096

Evolution of level of evidence c recommendations in European Society of Cardiology clinical practice guidelines on heart failure

D Candeias Faria[1]; M Trindade[2]; M Santos[1]; J Serodio[2]; M Beringuilho[1]; F Batista[1]; J Augusto[3]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiologia, Amadora, Portugal*;
[2]*Hospital Prof Fernando da Fonseca EPE, Medicina IV, Amadora, Portugal*;
[3]*University College London, London, United Kingdom of Great Britain & Northern Ireland*

Background: Over the past two decades, the European Society of Cardiology (ESC) Clinical Practice Guidelines (CPG) on Heart Failure have increasingly become a familiar part of Cardiology practice and are used worldwide. Level of Evidence C recommendations are based on expert consensus and/or small retrospective studies and registries with limited and non-representative populations evaluated. Furthermore, Task Force members for a given subject are often unbalanced on specialty.
Purpose: The purpose of our study was to describe and evaluate the evolution of Level of Evidence C recommendations of ESC CPG on Heart Failure and to provide a quality assessment of its benefits in the following years.
Methods: In this retrospective observational Case-Control study, we identified and collected all Level of Evidence C recommendations in five consecutive published documents of ESC CPG in the years 2001, 2005, 2008, 2012 and 2016. Each identified recommendation was classified between two major groups: Diagnostic and Complementary Exams (group 1) and Therapeutics and Interventions (group 2) and were followed up in the following documents. Primary outcomes were classified as: (1) Upgrade to Level of Evidence A or B [Upgrade], (2) Elimination or disproven benefit/harm [Downgrade] and (3) Maintenance or minor reformulation with unchanged benefit/harm [Maintenance]. We applied Kaplan-Meyer survival analysis to estimate the probability of Upgrade or Downgrade in each group.
Results: A total of 239 different Level of Evidence C recommendations were submitted to final analysis, 22.6% (n=54) in group 1 and 77.4% (n=185) in group 2. On follow-up, 35.2% (n=76) of recommendations were upgraded, 29.6% (n=64) were downgraded and 35.2% (n=76) were maintained. Regarding outcomes, downgrade of recommendations occurred predominantly in the Therapeutic and Interventions group (94.4%). Considering all the eliminated recommendations, 60.9% took place on the next following published ESC CPG document. Likewise, 60.5% of upgraded recommendations also occurred on the next following published ESC CPG document. The probability of upgrade or downgrade in the next following document was 52.8%, predominantly in the Therapeutics and Interventions group (37.5% vs 57.9%, p=0.012).
Conclusions: Level of Evidence C recommendations constitute an important asset of ESC CPG on Heart Failure as they are usually updated on new treatment options and are developed by experts in the specific topic. However, the probability of elimination due to disproven benefit or potential harm was high (29.6%), particularly regarding therapeutics and interventions (94%). Since a significant fraction of Level of Evidence C recommendations remain unchanged on the following document (35%), the need for high quality data derived from randomized trials or meta-analyses for prompt revalidation, specifically regarding therapeutic interventions, is warranted.

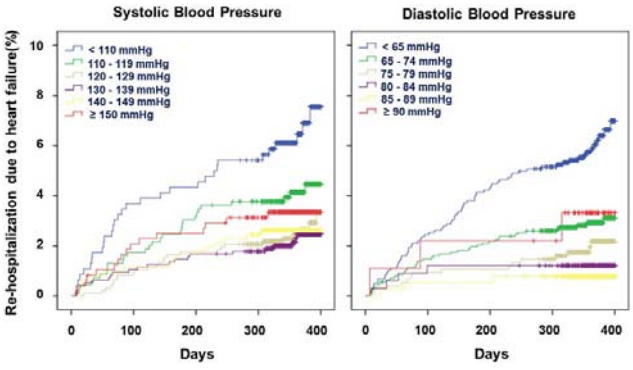
Background;Hypertension is the most prevalent modifiable risk factor for the development of heart failure (HF). Elevated blood pressure (BP) increases the pressure load on the left ventricle, causing systolic and diastolic dysfunction of the left ventricle and promoting left ventricular remodeling.In recent study, systolic BP and diastolic BP lower or higher than optimal level increased clinical events in hypertensive patients with stable coronary artery disease. This study aimed to investigate the association between 1-year BP level and 1-year HF events in hypertensive patients with acute myocardial infarction (AMI).
Methods: Among 13,104 patients who enrolled in nationwide AMI database of South Korea, the KAMIR-NIH Registry, 4,166 hypertensive patients, who had 1-year BP data, were selected in this study. They were divided into six systolic or diastolic BP groups according to BP levels.
Results;Lowest 1-year systolic BP group of <110 mmHg had the highest 1-year readmission due to heart failure (7.6± 1.4%). Lowest 1-year diastolic BP group of <65 mmHg also showed the highest 1-year re-hospitalization due to heart failure (7.0 ± 0.9%). On univariate and multivariate Cox-proportional hazard analysis with 1-year systolic BP 130-139 mmHg or diastolic BP 90-99 mmHg as a reference respectively, lower systolic BP (<110 and 110~119 mmHg) or diastolic BP (<70 and 70~79 mmHg) than reference group increased 1-year re-hospitalization due to heart failure. However, on multivariate analysis including age, gender, Killip class, renal function, and left ventricular systolic function, lowest systolic BP and lowest diastolic BP was a significant risk factor for 1-year re-hospitalization due to heart failure.
Conclusion;Systolic and diastolic BP lower than optimal level at 1-year increased 1-year re-hospitalization due to heart failure in hypertensive patients with AMI.



Re-hospitalization due to heart failure

Background Renal function change is common during decongestion of patients with acute decompensated heart failure. Worsening renal function (WRF) during decongestion has been considered as a predictor for poor prognosis. In post-hoc analysis of DOSE trial, improvement of renal function (IRF) during decongestion was also strongly associated with poor outcomes. This study was aimed to analysis 1) the characteristics and prognosis of the patients with WRF and IRF and 2) association between renal function changes and other confounders to evaluate the causal relation of renal function changes to prognosis of patients with acute heart failure.
Methods From Korean acute heart failure registry, 4,364 in-hospital survivors were included. WRF and IRF was defined as more than 0.3mg/dL decrease and increase of serum creatinine at discharge compared to that at admission. Patients underwent renal replacement therapy during index admission were excluded. Composite event of all-cause mortality and hospitalization for hear failure was evaluated as prognosis.
Results During 1-year follow-up, composite event was observed in 32.7% of patients. Patients classified as WRF and IRF was 359 (8.2%) and 806 (18.5%) patients, respectively. In patients with WRF and IRF, 1-year event was observed in 40.1% and 39.7%, which was significantly higher event rate compared to 30.2% of patients with stationary renal function (SRF) (WRF vs. SRF; p<0.001, IRF vs. SRF p<0.001). However, change in renal function more than 0.3mg/dL, whether increase or decrease, was highly dependent upon natriuretic peptide level and baseline serum creatinine level. Renal function change occurs in 8.0%, 12.6%, 36.2%, 65.9%, and 88.1% in patients with initial estimated glomerular filtration rate (eGFR) >90, 60-89, 30-59, 15-30, and < 15 mg/mmol, respectively (p<0.001). Renal function change also occurs more frequently depending on the increase of natriuretic peptide levels. (18.2%, 23.15, and 38.7%, p<0.001). Impact of renal function change on prognosis was completely neutralized after adjusting the baseline eGFR and natriuretic peptide levels, and baseline renal function and natriuretic peptide levels remained independent predictor for prognosis. Those findings are implying that changes in renal function, whether increase or decrease, can be a clinical confounder and may not have a causal relationship with prognosis.
Conclusions WRF and IRF was associated with poor prognosis. However renal function changes largely depend upon baseline renal function and natriuretic peptide level, which are proven prognostic indicators for patient with heart failure. Changes in renal function during decongestion can be a clinical confounder rather than independent prognostic indicator.

P2100
Low T3, it is not the same. Part II.

S Silvana Mettini[1]; L Secco[1]; DA Fernandez[1]; MG Masuelli[1]; M Taboada[1]; C Cejas[1]; C Biglia[1]; SM Pereiro Gonzalez[1]
[1]*Hospital Center Churruca-Visca, Buenos Aires, Argentina*

Intro: Two years ago, we analyzed that our patients (p) with low T3 had a worse prognosis than the normal one, regardless the rest of the thyroid profile. We add p to our statistics, so we want to figure if this difference remains significantly.Objective: To establish the difference between p hospitalized with decompensating heart failure (DHF) according to T3 values (normal or diminished).
Method: A retrospective analysis of 578 patients (p) admitted for DHF, consecutively, in our Cardiology Department, from June 2012 to December 2018. Median follows up: 44 months (27 – 64). We divided 2 groups according to admission T3 values (normal T3 60-220 ng/dl): NT3: normal T3 (274 p) and LT3: low T3 (201 p). Quantitative variables were expressed with median (m) and quartiles (analyzed by Mann Whitney's Test). Dichotomous variables were analyzed by Chi^2.
Results: Median age was 69 years old in NT3 and 78 years old in LT3, with statistically significant difference (SSD); there was a higher prevalence of males in NT3. Those p in LT3 required more days at hospital (p=0.01), had more valvular etiology (p=0.006), smaller ventricular diameters (LVED p=0.0017 and LVES p=0.0008) and more p with preserved ejection fraction. On LT3, labs values were worst: BNP at admission (A) and at discharge (D) and renal function (RF) (urea and creatinine, A and D) were higher, with also, worst 24 hours glomerular filtration rate (all of them with SSD). We observed, otherwise, that on NT3 there was higher worsening RF during hospitalization. NT3 had more sinus rhythm (p=0.003).
There was more in-hospital mortality on LT3 (p=0.0135), without any difference on mortality or rehospitalization on the follow-up.
Conclusions: Patients with low T3 were associated with worst hospital outcome, also showed a subgroup with more serious heart failure. We believe it is very important to detect this sort of patients in admission to be aware of and to adjust treatment. Hormonal replace treatment is still controversial.

P2101
Determinants and consequences of new acute kidney injury in acutely decompensated heart failure: a retrospective analysis at a tertiary australian centre

R Rahil Moriswala[1]; C Neil[2]; C Nelson[2]; C Zammit[1]; E Scholes[1]; H Altamimi[1]; R Falls[1]
[1]*Western Hospital, Department of Cardiology, Melbourne, Australia*; [2]*University of Melbourne, Department of Medicine, Melbourne, Australia*

Background: Acute Kidney Injury (AKI) is common in patients with acutely decompensated heart failure (ADHF), but few studies have reported routinely assessed renal function early post-discharge. We sought to determine the determinants of serum creatinine (SCr) and incidence of new AKI within 2 weeks of discharge from index admission.
Method: Patients with ADHF admitted to a single tertiary centre (July 2015 – July 2017, adjudicated by Boston criteria), excluding those with ongoing dialysis, were included. AKI was defined by the KDIGO criteria, (a raise in creatinine levels >30mg/L or an increase of 50% from baseline levels); incident post-discharge AKI [AKI(post)] was defined as AKI occurring within 30 days of discharge, in those without AKI during index admission. Determinants of follow-up SCr [SCr(post)] and incident AKI(post) were evaluated were evaluated using multivariate models.
Results: 375 patients (median age 82 years, 54% male, 51% HFpEF) had SCr(post) determined at a median of 8 days post discharge. Incident AKI(post) occurred in 39 (11%), was mainly mild and was associated with higher mean creatinine at both baseline (mean 118 vs 93umol/L, p <0.001) and admission (129 and 98umol/L, p<0.001). Median length of index hospital admission was significantly longer in the AKI(post) group (6 vs 4 days; p<0.02) and the mean number of days to readmission 33 versus 65 in the remainder (p <0.001). Determinants of SCr(post) included discharge SCr (p<0.0001), admission SCr (p<0.001) and baseline SCr (p<0.04), as well as ischaemic aetiology of heart failure (p<0.05). Determinants of AKI(post) included, both baseline and discharge serum creatinine (p<0.0001), MAP at presentation (p<0.03) and ischaemic aetiology (p<0.02). Pharmacotherapies including diuretics were not associated with excess AKI(post).
Conclusion: Routine post-discharge screening of SCr reveals a significant post-discharge incidence of AKI in those not manifesting AKI. This may represent another facet of the complex pathophysiology of renal injury in ADHF, for which predictive models need to be refined. Although an excess of rehospitalisation is not surprising in this group, preventative strategies may specifically offset this risk.

P2102

Clinical characteristics of patients with acute heart failure with adverse reactions to anticoagulation. Clinical impact of time in therapeutic range with acenocoumarol

R Martin-Sanchez[1]; C Chocron Benbunan[1]; A Calvo Elias[1]; E Dubon Peralta[1]; L Lopez Garcia[1]; M Rivas-Molinero[1]; X Rivas Regaira[1]; R Iguaran[1]; E Calvo Manuel[1]; A Nieto Sanchez[1]; T Lopez Caballero[1]; R Herranz Hernandez[1]; C Cano De Luque[1]; I Gonzalez Carrasco[1]; M Mendez-Bailon[1]

[1]*Hospital Clinic San Carlos, Madrid, Spain*

Introduction: Generally, patients with acute heart failure (HF) require oral anticoagulation for the treatment of other comorbidities such as atrial fibrillation.

Goals: To assess the impact of INR lability, defined as therapeutic time in the range of less than 60% in the last 6 months (TTR <60%), in patients diagnosed with HF who have presented an adverse effect related to oral anticoagulation.

Methods: Retrospective and cross-sectional study of 180 patients hospitalized in the San Carlos Clinical Complex, during the period from January 2016 to July 2018. All presented as diagnoses HF and adverse reaction to oral anticoagulation with acenocoumarol (overdosage, underdosage, hemorrhage or thrombosis), and were divided into two groups according to whether they presented TTR <60% or not.

Clinical characteristics (CHADSVASC, HASBLED), analytical (INR, hemoglobin, glomerular filtration according to the CKD-EPI formula), therapeutic and prognostic characteristics (readmission at 30 days, mortality) were collected and compared between the two groups described. A bivariate analysis was performed with Student's T and Chi-square, using SPSS v23 (statistical significance of $p < 0.05$).

Results: Of the 180 patients, the mean of age was 82 years, 56% were women of whom 52.8% had TTR <60%. Patients with TTR <60% had a higher score of CHADSVASC (4.8 vs 4.4, p = 0.09) and HASBLED (4.1 vs 2.7, p <0.05), higher INR value at the time of the event (5.8 vs 4.7, p <0.05), lower hemoglobin (11.6 vs 12.8, p = 0.09) and glomerular filtration (48.7 vs 51, p = 0.501). They also had a higher re-entry rate at 30 days (24.2% vs 14.1%, p = 0.06) .Treatment with Acenocoumarol was maintained at discharge in 52.6% of patients with TTR <60%.

Conclusions: In this sample of patients diagnosed with acute HF and adverse reaction to Acenocoumarol, the TTR <60% was associated with an increased risk of bleeding, INR at the time of the event and an early admission rate. In addition, in more than half of the patients with TTR <60%, treatment with Acenocoumarol was maintained on discharge. A change of oral anticoagulation towards direct oral anticoagulation should be assesed in this patients.

P2103

The old and new echocardiographic predictors of acute heart failure in STEMI patients

G Krljanac[1]; D Trifunovic[1]; M Asanin[1]; L Savic[1]; G Stankovic[1]; J Dudic[2]; M Polovina[1]; V Sulovic[2]; L Cucic[2]; I Mrdovic[1]

[1]*Clinical Centre of Serbia, Cardiology Clinic, Medical Faculty, Belgrade, Serbia*; [2]*Clinical center of Serbia, Cardiology Clinic, Belgrade, Serbia*

Parameters of echocardiographic myocardial mechanic could be good substrate of prediction acute heart failure (AHF) in myocardial infarction with ST elevation (STEMI). Aim: To determine the best parameters of myocardial mechanic as predictors of AHF. Method: 260 consecutive STEMI patients with PPCI were prospectively included. Echo examination performed on day 4±2 (VIVID 9GE, Echo PAC Ver 202). We analysed conventional echo parameters and parameters of left ventricle myocardial mechanics of systolic and diastolic function, as well as left atrial function. Results: 37/260 (14.1%) patients had AHF. Global longitudinal strain (GLS) of all three layers, global circumferential strain (GCS) of all three layers (epi, mid, endo) were impaired in patients with AHF (p<0.001). Parameters which obtain diastolic dysfunction: E/E´, E/SrE, LA reservoir, LA conduit were significantly different in patients with AHF (table 1). The largest area under the ROC found for GLS (epi 0.866, mid 0.865, endo 0.862) and GCS (endo 0.804, mid 0.786, epi 0.750), p<0.000, with high sensitivity and specificity. The EF was also significant predictor of AHF and area under the ROC was lower for EF (0.848), p<0.000. Conclusion: In STEMI patients parameters of left ventricle and left atrial myocardial mechanic could be important predictors of AHF. Still, larger studies are needed to define the best of these.

	Patients with AHF (n=37)	Patients withouth AHF (n=223)	p
LVEF (%)	37.1±8.9	48.7±9.1	<0.001

Acute cardiac failure and fatal arrythmia in severe respiratory infections

J Julia Pervoushina[1]; S Lukyanov[1]; VV Gorbunov[1]; T Aksenova[1]; A Burlakova[1]; A Utuzhnikov[1]

[1]*Chita State Medical Academy, Chita, Russian Federation*

Funding Acknowledgements: No any financial supports and conflicts of interest presented

Introduction . Cardiac complications such as acute cardiac failure (ACF) and fatal arrythmia (FA) in severe respiratory infection (SRI) remains an important problem. In recent studies cardiac complications expose as the main cause of death in those patients. However, a real prevalence of the ACF and FA in severe respiratory infections is still unclear, alike the influence of this complications to the prognosis of the individual patient.

Aims and objectives. The main purpose of the given study was the analysis of ACF and FA frequency in SRI and their influence on the patient's prognosis.

Methods. 99 patients with SRI in the respiratory intensive care department were examined. SRI diagnoses (including severe pneumonias and severe COPD exacerbations) were set in accordance of ERS/ECCMID joint-guidelines, 2011. The verification of the diagnoses was based on the clinical symptoms and / or the existence of lung consolidation on a chest X-ray or CT-scans. All the patients recieved antibiotics, additional oxygen or respiratory support and fluid resuscitation. Multifactorial regression analysis and the relative risk indicator were calculated.

Results. On the whole investigated group 24 patients (24,24%) died. The fatal arrythmia (mostly respresented as ventricular tachicardia/ ventricular fibrillation) occurred in 8 patients (8,0%) and resulted in their death. All of patients at the time of FA were in full consciousness, and had no signs of multiorgan dysfunction and/ or septic shock. The third tone, as a simple marker of ACF was observed in 31 patients (31,1%). Among patients whose third tone was detected, 16 died (51,6%), 15 patients survived. The multiple regression analysis showed the main predictors of FA were the extended QTcF interval (>500 msec): RR=2,56 [1,27; 5,15] and the low level of SpO2 during oxygen therapy/ respiratory support (<90%): RR=3,55 [1,79; 7,03]. Also the revealing of the third tone was linked to higher mortality: RR=4,38 [2,1; 9,1].

Conclusion. The one third of patients died of severe respiratory infection had the fatal arrythmia as the main cause of death. The appearance of the third tone was a strong predictor of mortality, compared in importance with other cardiac complications markers. This problem demands further studying.

Acute Heart Failure - Epidemiology, Prognosis, Outcome

Characteristics and management of post-acute coronary syndrome acute heart failure patients in indonesia

AF Sunjaya[1]; AP Sunjaya[1]; A Priyana[2]

[1]*Tarumanagara University, Faculty of Medicine, Jakarta, Indonesia*; [2]*Tarumanagara University-Cengkareng General Hospital, Department of Cardiology, Jakarta, Indonesia*

Funding Acknowledgements: This study was funded by the Directorate of Research, Tarumanagara University

Background Acute Coronary Syndrome (ACS) is the leading cause of heart failure (HF) in the world today, including Indonesia. Acute HF post-ACS have been linked with adverse outcomes and increased mortality rates in previous studies. Even so, while acute HF post-ACS have been described in several large scale epidemiological studies in the West, few studies in Indonesia have described this important complication of ACS.
Purpose This study aims to compare the characteristics and management of post-ACS patients with and without acute heart failure in Indonesia.
Methods A retrospective non-randomized cohort study was conducted involving ACS patients at Cengkareng General Hospital admitted from 1 January – 31 December 2016.
Results A total of 145 ACS patients (mean age 56±9 years) were admitted, most of them male (81.4%), overweight and obese (59.4%), and suffer from STEMI (71%). Thirteen patients (8.9%) had HF prior to ACS and were excluded from analysis. Fifty-seven patients (43.2%) suffer from acute HF post-ACS, most of which were male (78.9%), hypertensive (61.4%) and with STEMI (73.7%). Only 6 patients (10.5%) had a known history of dyslipidemia and had a history of statin prescription. Diabetes was found in 33.3% of patients. When compared with non-acute HF post-ACS patients, acute HF post-ACS patients did not show significant differences in the prevalence of diabetes, hypertension, dyslipidemia and history of statin use. Even so, significantly higher prevalence of overweight and obesity (70.2% vs 51%, p-value <0.05) were found in the acute HF group. Surprisingly, significantly lower LDL levels were found in the acute HF group (mean LDL 108±33 mg/dL vs 125±40 mg/dL, p-value 0.048). No significant differences in anti-hypertensive, β-blocker, antiplatelet/anti-coagulant and statin prescription was found between both groups. Rates of fibrinolytic use and percutaneous coronary intervention also did not significantly differ between both groups. However, those with acute HF were at significantly higher risk of recurrent myocardial infarction (Relative Risk 2.016, 95% Confidence Interval 1.414-2.874, p-value 0.005). They also have a higher risk of cardiogenic shock, acute lung edema and mortality although these were non-significant. Significantly higher GRACE risk score results (p-value 0.005), higher percentage with high risk score (50.9% vs 26.7%, p-value<0.05) were found in the acute HF group as well as risk of in-hospital (p-value 0.008), 6 months (p-value 0.007), 1 year (p-value 0.004) and 3 year (p-value 0.017) mortality rates.
Conclusion ACS patients with acute HF have a significantly higher risk of recurrent myocardial infarction, worse GRACE risk score, GRACE risk category and a higher risk of future mortality compared with those without acute HF.

P2107

Acute kidney injury in patients with acute decompensation of chronic heart failure

E Mezhonov[1]; Y Vyalkina[2]; S Shalaev[2]
[1]Tyumen Regional Hospital, Tyumen, Russian Federation; *[2]Tyumen State Medical University, Tyumen, Russian Federation*

Background. Acute kidney injury (AKI) as a manifestation of acute cardiorenal syndrome is a pathological condition with a poor prognosis in patients with acute decompensation of chronic heart failure (ADCHF). Purpose. To assess the prevalence and prognostic value of AKI in patients with ADCHF depending of ejection fraction of left ventricular, to identify predictors of AKI. Materials and methods. In a prospective study included 141 patients with ADCHF. AKI was diagnosed according to KDIGO recommendations. The end point was defined as death from cardiovascular causes. Outcomes were assessed at 3, 6, and 12 months after discharge of the patient from the hospital during a telephone survey. Result. During the follow-up from 1 to 37 months (median follow-up was 18 months) in 24.8% an endpoint was reported. AKI developed in 13.5% of patients. When patients were divided into groups with heart failure with a reduced ejection fraction (HFrEF) (69.5% of patients) and heart failure with preserved ejection fraction (HFpEF) (19.1% of patients), there were no differences in comorbidities depending on the presence of or lack of AKI, as well as the frequency of administration of various groups of drugs, including intravenous diuretics (p=0.561 and p=1.0, respectively), vasodilators (p=0.545 and p=1.0, respectively) and the need for inotropic support (p=1.0 and p=0.155 respectively). The development of AKI has been associated with an increase in cardiovascular deaths in patients with HFrEF compared with patients without AKI (90.9% and 9.2%, p<0.001), but did not increase the incidence of death from cardiovascular causes in patients with HFpEF (50.0% and 34.8%, p=0.613). An analysis of the OR for onset of death from cardiovascular causes during the observation period, depending on the presence or absence of AKI and the separation of patients on HFrEF and HFpEF, showed that AKI increases the risk of this endpoint among patients with HFrEF many times (OR 95% 98.750 (11.158-873.976), p<0.001), but does not increase the OR among patients with HFpEF (OR 95% 1.875 (0.221-15.930), p=0.565). In multivariate analysis in patients with HFrEF, the following risk factors for the development of AKI were identified: high albuminuria (AU) from 30 mg/l (OR 95% 5.763 (1.338-24.819), p=0.019), GFR<45 ml/min initially at admission to hospital (OR 95% 6.593 (1.193-36.446), p=0.031) and age>75 years (OR 95% 15.933 (1.020-248.856), p=0.048). It was not possible to identify any risk factors for the development of AKI in patients with HFpEF. Conclusion. In patients with ADCHF HFrEF development AKI is associated with a poor prognosis, but does not affect the prognosis of patients with HFpEF. AKI in patients with ADCHF HFrEF can be predicted using predictors: GFR<45 ml/min, AU more than 30 mg/l.

Funding Acknowledgements: BAYER AG, Berlin, Germany was the funder of this study

BACKGROUND: In France the prevalence of HF has been estimated at 2.3% in the adult population and is expected to increase further. Contemporary data on patient characteristics, treatment and outcomes is needed. This real-world data study aimed to describe patient characteristics, outcomes and treatment patterns for adult HF patients in a French setting. METHODS: A descriptive retrospective cohort design was applied using a French health insurance claims database (Echantillon Généraliste de Bénéficiaires, EGB); an anonymous, representative national sample listing outpatient and inpatient healthcare consumption of the population covered by the general insurance scheme, which covers most of French citizens. EGB data was available from 1st July 2008 to 31st December 2016. Adult HF patients were included in the study from 1st January 2010 to 31st December 2016 to allow a minimum 18 months baseline period for patients. Patients were described at baseline and followed over time from their index HF diagnosis to describe outcomes and exposure to treatment. RESULTS: A total of 10813 HF patients were identified in the EGB. Among these, 5563 patients had no recorded HF at least 18 months prior to their index HF diagnosis and constituted the analysis cohort for this study. Majority of patients were female (54%), elderly (mean age 78 years (standard deviation 12.8)), and highly comorbid; hypertension (87%), diabetes (27%), atrial fibrillation (18%), malignant cancer (16%) and myocardial infarction (12%). During follow-up patients had a very high rate of all-cause hospitalization (Incidence rate (IR) 10938/10000 person-years (PYs); 95% confidence interval (CI) [10609 - 11274]), HF-related hospitalizations (IR 1702/10000 PYs; 95% CI [1620 - 1788]), and all-cause death (IR 1882/10000 PYs; 95% CI [1805 - 1961]). At 1 year after their index diagnosis date patients had a 70% risk of all-cause hospitalization and 24% risk of all-cause death (see Kaplan Meier curves in Figure 1). HF guideline recommended drugs were prescribed as follows during follow-up: Beta-blockers (BBs): 61%; Renin-angiotensin system inhibitors (RASi) 63%; diuretics: 77% and 10% of patients were exposed to the recommended combination of BBs+RASis+diuretics. Polypharmacy was common and discontinuation of individual HF drugs occurred for more than 50% of patients for each studied drug class.
CONCLUSIONS: The study showed the high burden of hospitalizations and mortality of HF patients in France, among the highest in Europe, and highlights the current shortcomings in addressing the HF epidemic in France.

Background: Data on the the prognostic value of potassium level (K) in heart failure (HF) are conflicting. No studies were conducted in the Middle East where patients' characteristics might be different from Western countries.

Purpose: We sought to determine the prognostic value of K at admission and discharge regarding all-cause mortality in a multi-center Egyptian cohort with acute HF.

Methods: We investigated a subgroup of the European Society of Cardiology-Heart Failure (ESC-HF) registry. A total of 1475 patients with acute HF were recruited from 20 Egyptian centers between 2011-2014. Data on K at admission and discharge and 12-month mortality were available for 1085 patients who constituted our final analysis cohort. Patients were divided into three groups according to K: hypokalemia, normal, and hyperkalemia (K <3.5, 3.5-5.0, and >5.0 mEq/l, respectively).

Results: In all, 71 patients died in-hospital and additional 256 died during 12-month follow-up. Restricted cubic spline analysis showed a U-shaped relationship between admission K and 1-year mortality (Figure 1 A). Admission and discharge hyperkalemia were significant univariable predictors of 1-year mortality (p-value <0.001 and 0.004, respectively; Kaplan-Meier curves shown in Figures 1 B and C). On multivariable Cox-regression analysis, hyperkalemia was only a border-line significant predictor of mortality (p-value = 0.094), with significant/border-line predictors shown in Table.

Conclusion: In this large multi-center study of Egyptian patients with acute HF, hyperkalemia at admission and discharge were significant univariable predictors of 12-month all-cause mortality. However, serum potassium was marginally significant on multi-variable analysis, with age, ejection fraction, and inhibitors of renin/angiotensin system upon discharge being the most powerful predictors of mortality.

Table

Variable	Coefficient	Hazard ratio (95% confidence interval)	p-value
Age	0.038	1.039 (1.027-1.051)	<0.001
COPD	0.294	1.342 (0.987-1.825)	0.06
Coronary artery disease	0.397	0.673 (0.513-0.881)	0.004
Diastolic blood pressure	0.01	0.990 (0.982-0.998)	0.015
Ejection fraction	0.046	0.955 (0.943-0.966)	<0.001
Haemoglobin	0.078	0.925 (0.871-0.981)	0.009
Hyperkalemia at admission	0.288	1.333 (0.952-1.866)	0.094
Discharge ACE-I/ARB	0.860	0.423 (0.311-0.576)	<0.001

Introduction: In the settings of acute dyspnea a significant overlap of congestion and pulmonary diseases may take place. The relevant risk stratification according to the primary diagnosis and co-morbidities is important.Purpose: We aimed to compare the clinical profile and outcomes of patients with acute dyspnea due to worsening heart failure, exacerbated pulmonary diseases, and their combination.

Methods: Prospective two-centre observational cohort study enrolled consecutive patients admitted to the emergency department with acute dyspnea. All patients were categorised into three groups according to their adjudicated diagnosis: I - acute heart failure (AHF) patients with no pulmonary comorbidities, II - pulmonary diseases (chronic obstructive pulmonary disease/ bronchial asthma, pneumonia and pulmonary embolism) and III -AHF with pulmonary comorbidities. Quantitative variables and categorical variables were compared among those groups using chi-square test.

Results: A total of 979 patients were included in the study. Clinical profiles and outcomes of three groups are summarized in the Table.

Conclusions: Combination of AHF with pulmonary comorbidities was consistent with the most severe congestion and kidney disease as well as with the highest short-term mortality compared to either heart failure or pulmonary disease alone. Patients presenting with acute dyspnea due to pulmonary diseases died after 1 and 3 months more frequently than acute heart failure patients.

Background The association between diabetes mellitus (DM) and heart failure (HF) is well-established and studies have shown that their co-existence contributed to poorer patients' outcome. The adverse interaction between these two disease entities are complex and not well understood and results from existing studies are often conflicting, suggesting the need for further studies.
Purpose: The aim of this study was to describe the baseline characteristics and outcomes differences among patients with acute HF with and without DM. In addition, we investigated parameters which were related to mortality in patients hospitalized for acute HF.
Methods We studied 2,785 hospitalized patients with acute HF from 1 January 2009 to 31 December 2015 in a single cardiac centre in Malaysia. Data analysis were carried out to evaluate differences in clinical characteristics and outcomes in acute HF patients with DM and non-diabetics. Multivariable analysis was performed using logistic regression forward stepwise method.
Results: Among 2,785 patients admitted with acute HF, 64% (n= 1771) had DM. Patients with diabetes were more likely to be male, older, with ischaemic etiology of HF, and had multiple co- morbidities such as renal insufficiency, hypertension, dyslipidaemia and stroke. The median left ventricular systolic function for diabetic cohort was 30% (IQR 40.0-24.0) and majority of the patients had HFrEF (72%). There was no difference in the prescription of ACE inhibitors/ Angiotensin Receptor Blockers and beta blockers between the groups. However, patients with diabetes were morely likely to be treated with antiplatelet and lipid lowering agents compared to non-diabetics. Diabetic patients had significantly lower in-hospital mortality (3.8% vs 5.5%, p=0.03) but no differences in 30-day (1.7% vs 2.7% in non-diabetic, p= 0.14) and 1-year mortality (8.9% vs 9.6% in non- diabetic, p=0.68). In contrast, diabetic patients had non- statistically significant increase in 30-day readmission (8.5% vs 7.2%, p=0.25) and significant 1-year readmission (24.9% vs 19.6%, p=0.002). Multivariate analysis revealed that presence of atrial fibrillation (OR 2.87; 95% CI 1.19-6.94, p=0.02), systolic BP (>140mmHg) (OR 0.27, 95% CI 0.09-0.78, p= 0.02), higher NT proBNP (> 4800 pg/ml) (OR 4.87; 95% CI 1.71-13.85, p=0.003), low sodium (<120mmol/L) (OR 23.51; 95% CI 2.71-203.61, p=0.004) and positive troponin T level (≥ 0.014ug/L) on admission (OR 7.16; 95% CI 3.09-16.59, p<0.001) were independent predictors of in-patient mortality.
Conclusion: Diabetes mellitus contributed to significant proportion of patients admitted with acute heart failure with the presence of multiple co-morbidities. There were discordant in mortality and morbidity outcomes in which diabetics with AHF had lower in-hospital mortality but with higher readmission rates.

On behalf of: Korea Acute Myocardial Infarction Registry-National Institutes of Health
Funding Acknowledgements: Fund by Research of Korea Centres for Disease Control and Prevention

BACKGROUND: Patients who survive an index acute myocardial infarction (AMI) are at an increased risk for future cardiovascular events. However, there have been few studies about heart failure (HF) readmission after AMI in an unselected group of patients.
PURPOSE: We, therefore, sought to explore the incidence, predictors, and subsequent clinical outcomes of post-AMI HF readmission from nationwide AMI registry.
METHODS: The study population consisted of 13,104 patients admitted for an index AMI between Nov 2011 and Dec 2015. The index in-hospital mortality rate was 3.85%, and these patients were excluded from the subsequent analysis, leaving 12,600 patients in the study cohort.
RESULTS: A total of 510 HF readmission (4.0%) had occurred in 444 patients during median 732 (696–760) days follow-up; 382 (86.0%) were readmitted once and 62 (14.0%) were readmitted ≥2 times. The median time to first HF readmission was 123 (42–335) days. A HF readmission occurred in in 270 patients (60.8%) within 6 months; the incidence of HF readmission steadily increased thereafter, with 174 more patients (39.2%) having a HF readmission between 6 months and 2 years. Among 444 patients with HF readmission, 42 (9.5%) patients were adjudicated as directly related to the myocardial re-infarction, occurring before 6 months, and between 6 months and 2 years in 22, and 20 patients, respectively. By multivariable analysis, the independent predictors of HF readmission at 2-year follow-up were age (older); gender (female); previous heart failure; acute HF (Killip classification ≥2); lower baseline estimated creatinine clearance and left ventricular ejection fraction; anterior AMI as culprit location; multivessel coronary disease; and major bleeding and acute kidney injury during index hospitalisation. Percutaneous coronary intervention as principal management strategy and discharge use of renin angiotensin aldosterone system blocker were predictors of less HF readmission. However, β-blockers was not associated with HF readmission at 2-year follow-up. In a time-adjusted multivariable analysis, HF readmission was a significant independent predictor of myocardial re-infarction (adjusted hazard ratio [HR] 3.008 [2.099-4.310]), any repeat revascularisation (adjusted HR 2.484 [1.187-5.200]), and stent thrombosis (adjusted HR 3.352 [1.623-6.925]); and a borderline predictor of cardiac death but did not reach statistical significance (adjusted HR 1.390 [0.964-2.004], p=0.078).
CONCLUSIONS: In the nationwide AMI registry, HF readmission within 2 years after AMI occurred in 4.0% of patients, with 60.8% within 6 months. Several baseline and procedural factors were identified as independent predictors of HF readmission.

A HF readmission was strongly associated with subsequent adverse clinical outcomes, and therefore, strategies to identify and treat the risk factors for post-AMI HF readmission should be implemented to prevent this devastating complication.

Funding Acknowledgements: Medical Faculty of Lund University, Skane University Hospital, the Crafoord foundation, Swedish Heart and Lung foundation, Wallenberg Center of Mollec

Introduction: Although endemic selenium deficiency has been proposed to be pathogenic in Keshan cardiomyopathy, the involvement of selenium in acute heart failure (AHF) prognosis remains uninvestigated. Selenium mediates its antioxidant effects through incorporation with the 25 selenoproteins currently known, of which Selelonprotein P (SePP) has been associated with cardiovascular disease and septic shock.
Purpose: We examined the value of SePP in predicting 30-days hospitalisation and 1-year mortality in a Swedish acute heart failure (AHF) cohort.
Methods: Plasma SePP was measured in subjects with AHF from the Swedish Heart and Brain Failure Investigation study (HARVEST-Malmö) (n=295, 30.7% females; mean age 74.4 ± 11.5 years).
Results: After adjusting for traditional risk factors, each 1 SD increment in SePP levels was inversely associated with risk of 30-days hospitalisation (n=61) (Hazard ratio, HR (95% confidence interval (CI)): 0.67 (0.51-0.89), p=0.005), as well as one-year mortality (n=54); HR 0.65 (0.48-0.88), p=0.005. Subjects with the lowest SePP levels were at greater risk of 30-day re-hospitalisation (HR 4.29 (1.59-11.6)) and one-year mortality (HR 4.13 (1.64-10.4)), as compared to subjects in the remaining quartiles (p for trend 0.004 and 0.001, respectively).

Sepp and outcomes

	One-year mortality(n=54)		30-day re-hospitalisation (n=61)		Composite endpoint (n=98)	
	HR (95%CI)	p	HR (95%CI)	p	HR (95%CI)	p

Sex	0.41 (0.21-0.82)	0.012	1.14 (0.65-1.99)	0.644	1.21 (0.72-2.05)	0.471
BMI	0.99 (0.93-1.06)	0.881	0.99 (0.94-1.05)	0.779	1.01 (0.96-1.05)	0.803
SBP	0.98 (0.97-0.99)	0.001	1.00 (0.99-1.01)	0.462	0.99 (0.98-1.00)	0.217
Smoking	1.33 (0.51-3.50)	0.562	1.03 (0.47-2.25)	0.943	1.09 (0.52-2.23)	0.820
Prevalent AF	0.59 (0.33-1.03)	0.063	1.05 (0.63-1.76)	0.852	0.99 (0.61-1.63)	0.985
Prevalent diabetes	1.76 (0.96-3.23)	0.068	0.97 (0.54-1.74)	0.925	0.99 (0.57-1.72)	0.204
Prior CHF	1.02 (0.51-2.06)	0.948	1.25 (0.69-2.25)	0.462	1.21 (0.69-2.11)	0.697
NT-proBNP	1.46 (1.07-1.98)	0.017	0.92 (0.70-1.19)	0.516	0.96 (0.75-1.23)	0.743
SePP	0.65 (0.48-0.88)	0.005	0.67 (0.51-0.89)	0.005	0.66 (0.51-0.86)	0.002

Values are hazard ratios (HR) and 95% confidence intervals. BMI=body mass index; SBP=systolic blood pressure; AF=atrial fibrillation; CHF=congestive heart failure, SePP=Selenoprotein P.

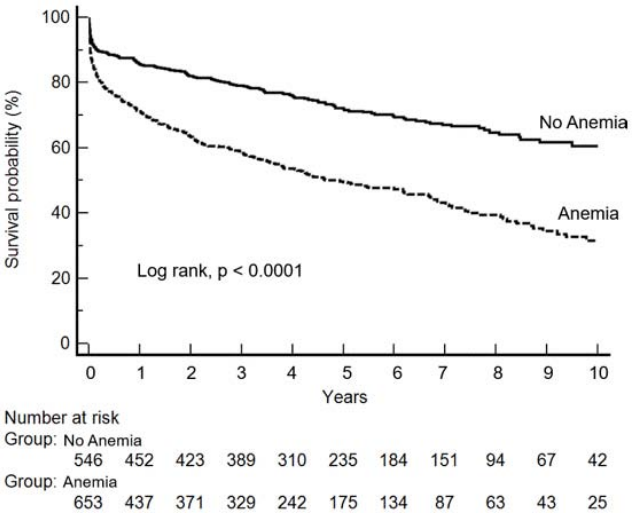
Conclusion: This observational study identifies SePP as a novel marker of poor outcome in AHF and encourages future studies examining if supplementation of selenium might improve prognosis in AHF-patients.

P2114

Impact of anemia on long-term clinical outcome in patients with left ventricular systolic dysfunction after acute myocardial infarction

EE Kim[1]; BH Hwang[1]; K Chang[1]; Y Ahn[2]; JJ Kim[1]
[1]*Catholic University Hospital, Seoul, Korea (Republic of)*; [2]*Chonnam National University Hospital, Gwangju, Korea (Republic of)*

Background: Anemia may confer a poor prognosis among patients with acute coronary syndrome. However, contemporary data are lacking on the prognostic importance of anemia in patients with left ventricular (LV) systolic dysfunction after acute myocardial infarction (AMI).
Methods: AMI patients receiving percutaneous coronary intervention were consecutively enrolled from January 2004 to August 2014. A total of 1,246 patients with LV systolic dysfunction: LV ejection fraction <40% as measured by echocardiography, were divided according to the presence of anemia. Anemia was defined as a hemoglobin level <14 g/dL in men and <12 g/dL in women. All-cause mortality within a follow-up period was compared in groups of patients with and without anemia.
Results: Median follow-up duration was 44 months (interquartile range 10 to 75 months). Patients with anemia were older, more likely to have hypertension and diabetes, but the two groups did not differ in sex, presence of dyslipidemia, and status of smoking. Patients with anemia had greater all-cause mortality (30.4% vs. 52.6%). Anemia was an independent predictor of all-cause mortality after adjusting confounding risk factors (hazard ratio: 1.705, confidence interval: 1.404-2.069, p < 0.001).Conclusion: In patients with LV systolic dysfunction after AMI, anemia is associated with increased risk of poor outcome independently of coexisting risk factors.



P2115

The relationship between hemoconcentration during hospitalization and outcomes in patients hospitalized for acute heart failure

S Sirinda Kittiprachakul[1]; M Anuntasainont[1]; C Thimphitthaya[1]; P Sriparn[1]; P Lalitnithi[1]; A Trongtorsak[1]; A Ariyachaipanish[1]
[1]*King Chulalongkorn Memorial Hospital, Bangkok, Thailand*

Background: In acute heart failure (AHF) treatment, hemoconcentration during hospitalization represents the effectiveness of decongestion. However, the association between changes in hematocrit (Hct) and outcomes is still controversial.
Purpose: We aim to investigate the association between hemoconcentration within the first 7 days of hospitalization and 30 and 180-day all-cause mortality or rehospitalization in AHF patients.
Methods: This was a retrospective study of consecutive patients hospitalized for AHF at a tertiary care hospital from July 2017 to April 2018. Changes in Hct within the first 7 days of hospitalization were used to identify hemoconcentration. The patients who received blood transfusion and/or erythropoietin were excluded. The primary outcomes were 30 and 180-day all-cause mortality or rehospitalization. The analysis tool was one-way ANOVA.

Results: From total of 191 patients admitted for AHF, 114 patients with available Hct data were included (mean age of 68.5±13.2, 52.9% male). Mean Hct change was 2.06±3.604 percent-point. When classifying patient based on changing in Hct level into 3 tertiles, there were no statistically significant differences in baseline characteristics or body weight changes. The second tertile had significantly lower rates of primary outcomes both at 30 and 180 days ($p < 0.05$) (Table).

Conclusion: Most patients with AHF had increased Hct level during hospitalization as a part of a decongestive therapy. The optimal hemoconcentration during first 7 days of hospitalization, not too low or too high, was predictive of favorable 30-day and 180-day clinical outcomes.

Neutrophil-lymphocyte ratio predicts in-hospital and post-discharge 3-year mortality in acute heart failure patients

JH Jun Hwan Cho[1]; HJ Cho[1]; HY Lee[1]; BH Oh[1]
[1]*Seoul National University Hospital, Department of Internal medicine, Seoul, Korea (Republic of)*

Funding Acknowledgements: This work was supported by grants from Research of Korea Centers for Disease Control and Prevention

Aims: Neutrophil-lymphocyte ratio (NLR) is reported as independent predictor for all-cause mortality or cardiovascular events in patients with acute coronary syndromes. However, the prognostic implications of NLR on short and long-term mortality have not been fully elucidated in patients with acute heart failure (AHF).

Methods: Of the 5,625 patients enrolled in the Korea Acute Heart Failure (KorAHF) registry, 5,580 patients were evaluated. Patients were stratified into quartiles by their NLR level and their in-hospital mortality and post discharge 3-year mortality were analyzed.

Results: Among 5,580 patients, patients in the highest NLR had the highest in-hospital mortality (adjusted-odds ratio (OR) 2.21, 95% Confidence Interval [CI] 1.43–3.42) and post-discharge 3-year mortality. (adjusted OR 1.50, 95% CI 1.30–1.74) (Table 1.) In addition, a positive trend between post discharge 3-year mortality and NLR was observed. (Figure 1-A.) The same trends were observed by dividing the aggravating factor into the infection or ischemia group and the non-infection or ischemia group. (Figure 1-B and C)

Among the patients whose aggravating factor were infection or ischemia (n = 3,127), NLR ≥ 7.0 was associated with increased risks of in-hospital mortality (adjusted OR 1.90, 95% CI 1.30-2.78) and post-discharge 3-year mortality (adjusted OR 1.20, 95% CI 1.02-1.40). Among the patients whose aggravating factor were not infection or ischemia (n = 2,453), NLR ≥ 5.0 was associated with increased risks of in-hospital mortality (adjusted OR 2.12, 95% CI 1.33-3.37) and post-discharge 3-year mortality (adjusted OR 1.43, 95% CI 1.24-1.65).

Conclusions: Elevated NLR on admission is an independent predictor for in-hospital and post-discharge 3-year mortality even if adjust well-known predictors and interactions. Increased NLR may reflect increased sympathetic tone at admission. NLR is an inexpensive, easy to obtain marker to aid in the risk stratification of patients with AHF.

Short-term outcome of hypokalemia in patients hospitalized for acute heart failure in a heart failure unit.

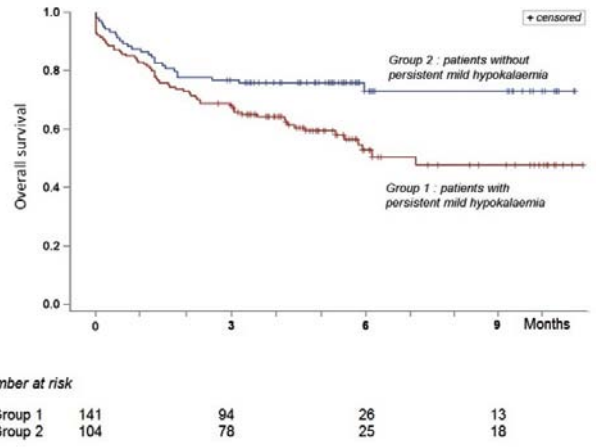
S Atesler[1]; C Goetz[1]; M Benichou[1]; K Khalife[1]; N Noura Zannad[1]
[1]*Regional hospital Center of Metz-Thionville, Cardiology, Metz, France*

INTRODUCTION: Acute heart failure (AHF) is frequent with heavy morbidity and mortality. Hypokalemia as a prognostic factor has been previously studied with heterogeneous findings.

PURPOSE: We aimed to determine the association of hypokalemia during stay with the short-term outcome after discharge in patients hospitalized for AHF in a Heart Failure Unit.

METHODS: We prospectively included all consecutive patients admitted for AHF in our center Heart Failure Unit, between February and December 2017. We defined several hypokalemia models: punctual severe hypokalemia (any serum potassium level < 3.5mmol/L occurrence during stay), punctual mild hypokalemia (any serum potassium level < 4 mmol/L occurrence during stay), persistent severe hypokalemia (serum potassium level < 3.5mmol/L lasting at least 3 days during stay), persistent mild hypokalemia (serum potassium level < 4 mmol/L lasting at least 3 days during stay). The primary composite endpoint was all-cause death and rehospitalizations for heart failure 3 months after discharge.

RESULTS: Two hundred and forty-five (245) patients were studied with 59% male patients and a mean age of 77.7±10.2 years. 41.6 % of the patients had a reduced ejection fraction, 43.3 % had a preserved ejection fraction, and 15.1% a moderately reduced ejection fraction. During the hospitalization, 86.9% received an intravenous loop diuretic depletion with a mean dosage of furosemide of 280±287 mg. The mean serum potassium level at admission was 4.13±0.57 mmol/L and it increased by 0.5±1.5% at discharge. Though 83.3% of the patients received potassium supplementation, severe persistent hypokalemia and mild persistent hypokalemia were found in 13.9% and 57.6% of the cases, respectively. Overall, the primary composite outcome occured for 87 patients (35.5%). This rate was significantly higher for patients with persistent mild hypokalemia compared to patient without (43.3% versus 25.0% respectively, OR=2.3[1.3-4.0], p=0.004). This result remained significant in multivariate survival analysis (p log rank=0.005).



CONCLUSION: Hypokalemia remains frequent despite current strategies in hospitalized patients for AHF and it is associated with poor prognosis. It could be a surrogate marker of an uncontrolled neurohormonal activation and the severity of the disease.

P2118

Heart failure detection in an urban population

A Ali Kirresh[1]; A Mathew[1]; A Kaba[1]; S Hashmy[1]; R Grant[1]; S Khan[1]; B Unger-Graeber[2]
[1]*Chelsea and Westminster Hospital NHS Trust, London, United Kingdom of Great Britain & Northern Ireland*; [2]*Hounslow CCG and Chiswick Health Practice, London, United Kingdom of Great Britain & Northern Ireland*

Background: Heart failure (HF) is a chronic and progressive condition characterised by recurrent exacerbations and frequent hospital admissions. Epidemiological studies suggest that the incidence of HF is around 1-2%. Our study was conducted in an area responsible for the health care of 308,000 people. The observed prevalence of HF within this population is 0.7% meaning that there are a significant number of HF patients in the community who have apparently not yet been identified.
Purpose: Early diagnosis, prompt treatment and effective community follow up reduces hospital admissions and improves outcomes in patients with left ventricular systolic dysfunction (LVSD). We aimed to identify whether patients with LVSD were being accurately recorded within this area.
Methods: There were 1663 patients with a diagnosis of heart failure cared for by 48 primary care practices. A virtual (desktop) clinical review was undertaken at all of these practices by searching existing heart failure registers. The clinical records were reviewed to confirm the diagnosis of HF, to assess the aetiology of HF and in particular to identify whether LVSD was present.
Results: At the start of the virtual clinics there were 451 individuals with a diagnosis of LVSD. Following the virtual clinics this number had increased to 849, of whom 146 were confirmed by reviewing echocardiogram results from secondary care. The original cohort of 451 also included 50 patients in whom the diagnosis of LVSD could not be confirmed.
Conclusions: The data demonstrates a near doubling of LVSD recording in primary care. This has significant implications for the optimisation of therapy and care processes for the individuals where the primary care record is inaccurate as not all of these patients are under active secondary care surveillance. Poor communication between service providers across primary, secondary and community settings is commonly to blame and one of the fundamental issues is the various IT systems which do not automatically transfer information between the different healthcare sectors. We suggest that commissioners should work with IT providers to ensure that the sharing of patient information is streamlined. Improving this will ensure more patients receive prompt management and has the potential to reduce the number of HF hospital admissions and improve patient outcomes. With e-noting becoming increasingly prevalent in secondary care, this will facilitate accurate recording of information for heart failure and other conditions. Furthermore, SNOMED CT is a simple clinical vocabulary that can be used within electronic health records to simplify the transfer of information between the different healthcare sectors.

Short and mid-term prognosis of acutely decompensated heart failure by clinical scenarios on admission

K Ishizu[1]; A Isotani[1]; N Fukunaga[1]; T Morinaga[1]; M Yano[1]; S Ito[1]; S Mori[1]; K Hirose[1]; S Fujioka[1]; M Nakamura[1]; K Ando[1]
[1]*Kokura Memorial Hospital , Cardiovascular medicine, Kitakyushu, Japan*

Background: Patients presenting with acutely decompensated heart failure (ADHF) are a complex and heterogeneous population. Five clinical scenarios (CS1 systolic blood pressure >140 mmHg; CS2 100-140 mmHg; CS3 <100 mmHg; CS4 with acute coronary syndrome; and CS5 isolated right ventricular failure) were proposed to identify an initial therapeutic approach and are commonly used by physicians. However, the difference of time course by CS has not been clarified.
Purpose: To recognize the difference of prognosis in ADHF according to the type of CS.
Methods: We retrospectively analyzed consecutive 641 ADHF patients admitted to our institution. Initial treatments were determined according to CS on admission and subsequent guideline-directed medical therapies were performed.
Results: Of 641 patients, 194 (31.6%) were classified as CS1, 349 (56.8%) as CS2, 45 (7.3%) as CS3, 46 (7.5%) as CS4 and 7 (1.1%) as CS5. Baseline characteristics and exam data are shown in Table. In-hospital cardiac mortality, occurred in a total of 24 (3.7%) patients, was significantly higher in CS4 patients than CS1 or CS2 patients (p=0.01 or 0.02, respectively). Of 593 patients discharged, 226 patients were rehospitalized for ADHF. CS5 patients had significantly lower survival rates free from rehospitalization for ADHF than CS1 patients (p=0.02), while CS4 patients had significantly higher survival rates than CS1 patients (p=0.05). (Figure)
Conclusion: CS4 patients had high in-hospital cardiac mortality despite first hospitalization for HF. Although CS5 patients were not majority, rates of rehospitalization for ADHF were highest among all the CSs.

The prognostic impact of hepatic injury in acute heart failure

LM Lisa Maria Ferraz[1]; JL Martins[1]; P Carvalho[1]; AC Faustino[1]; JA Santos[1]
[1]*Centro Hospitalar do Baixo Vouga, Cardiology, Aveiro, Portugal*

Introduction: Hepatic injury has been reported in patients with acute heart failure (AHF).
Purpose: This study aims to assess the prognostic value of elevated transaminases (TM) and alkaline phosphatase (AP) in patients (P) admitted for AHF.
Methods: Retrospective study of 618 consecutive P admitted in our Hospital for AHF: 57% women, 79±11 years, 61% hypertensive, 23% with chronic kidney disease, 16% with coronary artery disease. A comparative analysis was performed according to the elevation above 2x the upper normal limit of aspartate or alanine TM (TM+: with vs TM0: without) and of AP (AP+: with vs AP0: without), regarding demographic, clinical and analytical parameters, and medication during hospitalization, to evaluate potencial predictors. Prognosis (mortality) was assessed by Cox Regression during a 6 month follow-up.

Results: AP elevation occurred in 14.8% P. By univariate analysis, the group AP+ had higher basal values of urea (63.6 vs 54.9mg/dL, p=0.02) and creatinine (1.24 vs 1.08mg/dL, p=0.02), and required higher doses of furosemide during hospitalization (387 vs 316.2mg, p=0.04). By multivariable regression, only basal creatinine was independent predictor of AP+ (OR 0.137, 95%CI 0.001–0.253, p=0.048). TM elevation occurred in 22.5% P. By univariate analysis, P with TM+ were younger (78±11 vs 80±10 years, p=0.02), showed higher values of AP (157.2 vs 128U/L, p=0.001) and hemoglobin (12.7 vs 12.2g/dL, p=0.02), with no difference in furosemide dose (p=ns). By multivariable regression, AP was an independent predictor of TM+ (OR 0.173, 95%CI 0.000–0.002, p=0.01). No differences were found regarding blood pressure, ejection fraction, NT-proBNP value or lenght of stay for both AP+ and TM+ groups. Mortality was 21% at 30 days and 38% at 6M. Survival was worse at 30 days for AP+, after adjustment for demographics and comorbidities (HR 0.4, 95CI%: 0.25–0.74, p=0.002). Regarding TM elevation, no survival difference was found; however, in TM+ group, hemoconcentration occurred in 41.2% of P and was associated with increased survival at 6M (HR 49.8; 95%CI 2.44–1016.72; p=0.011), as well as the use of higher doses of furosemide (HR 1.0; 95%CI 1.001–1.005; p=0.012).
Conclusion: Elevation of AP was associated with higher mortality in P admitted for AHF. TM elevation alone didn´t show prognostic impact; nevertheless, its association with hemoconcentration and higher furosemide doses seems to improve survival.

P2121
Incidence and prognostic value of acute kidney injury in patients with acute decompensated heart failure

S Avdoshina[1]; M Efremovtseva[1]; Z Kobalava[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Introduction: Acute kidney injury (AKI) is a commonly encountered syndrome associated with worse prognosis in patients with cardiac diseases.
Purpose: to evaluate the incidence and prognostic value of AKI in patients with acute decompensated heart failure (ADHF).
Methods: 278 patients with ADHF were examined: mean age 69.7±10.2 tears (M±SD), 55% were male, 47.8% current smokers, 30.6% alcohol abusers. Comorbidities: arterial hypertension 90.3%, 70% had anamnesis of symptomatic heart failure with frequent hospitalizations, obesity 55.8%, (mean BMI 30.1±6.4 kg/m2), previous myocardial infarction (MI) 47.1%, atrial fibrillation 46%, chronic kidney disease (CKD) 45%, stable angina 43.5%, anemia 40.6%, chronic obstructive pulmonary disease 34.9%, diabetes mellitus (DM) 33.1%. CKD and AKI were diagnosed according to KDIGO 2012 Guidelines. AKI phenotypes depending on time of development (community-acquired or in-hospital), persistence (transient or persistent), history of CKD (AKI de novo or AKI on CKD) were identified.
Results: Incidence of AKI in ADHF was 43.5%. AKI stage 1 was prevalent (54.5%). Patients with ADHF with vs without AKI had higher rate of previous MI (70.3 vs 29.3%, p<0.001), stable angina (59.5 vs 31.2%, p<0.01). outpatient therapy rarely included beta-blockers (p<0.05) and loop diuretics (p<0.01), at the time of admission those with AKI more frequently had systolic blood pressure (SBP) <110 mmHg (15.7 vs 4.5%, p<0.01) and serum creatinine (SCr) above the median level (98 μmol/l) (60.3 vs 41.2%, p<0.05).
Community-acquired AKI, AKI on CKD, AKI de novo and persistent AKI were found in 20.5, 20.8, 23% and 20% of patients respectively. Changes of SCr during hospitalization in the range 10-50%, which did not meet AKI criteria, were designated as subclinical AKI and occurred in 19.4% of patients.
In-hospital mortality was higher in patients with vs without AKI (12.4 vs 5%, p<0.01) and was the highest in patients with in-hospital persistent AKI de novo and community-acquired persistent AKI on CKD (41 and 29%, p<0.01). In the group of subclinical AKI mortality was comparable with the patients with AKI (11.8%).
Independent predictors of AKI were: GFR <30 ml/min/1.73 m2 (odds ratio (OR) 6.5, 95% confidential interval (CI) 3.4-12.6, p<0.001), SCr >118μmol?l (OR 5.5, 95% CI 3.6-8.5,p<0.001), SBP <90mmHg (OR 4.6, 95% CI 1.2-17.1) (all parameters at admission).
Conclusions: The incidence of AKI in ADHF was 43.5% and was associated with higher in-hospital mortality. Patients with baseline tendency to hypotension and severely impaired kidney function are at high risk of developing AKI.

P2122
Long-term outcomes of patients discharged from acute heart failure hospitalisation and differences between patients with preserved and reduced left ventricular ejection fraction - AHEAD registry

M Miklikova[1]; R Miklik[1]; R Spacek[2]; J Spinar[3]; K Zeman[2]; K Benesova[4]; M Felsoci[1]; L Pohludkova[2]; L Dusek[4]; J Jarkovsky[4]; P Lokaj[1]; J Parenica[1]

Funding Acknowledgements: This work was supported by the Ministry of Health of the Czech Republic–conceptual development of research organisation (FNBr, 65269705)

Background The latest European heart failure guidelines define patients as those with reduced (HFrEF), mid-range, and preserved (HFpEF) left ventricular ejection fraction (LVEF; <40%, 40%-49%, and 50%, respectively). We investigated the causes of rehospitalisations/deaths in our institution's heart failure patients and focused on differences in the clinical presentation, risk profile, and long-term outcomes between the HFrEF and HFpEF groups in a real-life scenario.
Methods and Results
We followed 1274 patients discharged from heart failure hospitalisation in 2 centres. The mean patient age was 75.9 years, and men and women were represented equally. During the minimal follow-up of 2 years, 57% of patients were hospitalised for any cause, 24.9% for decompensated heart failure, and 43.3% for any cardiovascular cause. A total of 36.1% of patients died, either with prior (11.8%) or without prior (24.3%) heart failure rehospitalisation. Heart failure was also the most frequent cause of cardiovascular hospitalisation, followed by gastrointestinal problems, infections, and tumours for noncardiovascular hospitalisations. Patients with HFrEF had different baseline characteristics and risk profiles, experienced more hospitalisations for acute heart failure (28.6% vs 20.2%, p = 0.012), and had higher cardiovascular mortality (82.4% vs 63.5%, p < 0.001) when compared with HFpEF patients. Overall mortality and rehospitalisation rates were similar.
Conclusion: Within 2 years, half of the patients died and/or were hospitalised for acute decompensation of heart failure, and only one-third of the patients survived without any hospitalisation. HFrEF and HFpEF patients were confirmed to be different entities with diverse characteristics, risk profiles, and cardiovascular event rates.

P2123
Incidence and impact of renal dysfunction in patients with acute heart failure

C Lesgidis[1]; C Christos Mantis[1]; K Kintis[1]; A Anadiotis[1]; S Patsilinakos[1]
[1]*Konstantopoulio General Hospital, Cardiology, Athens, Greece*

Introduction: During treatment of acute heart failure (HF), renal function is often worsened, leading to a complex clinical course. In addition, renal impairment is a strong predictor of long-term adverse outcomes in patients with acute HF.
Purpose: To investigate the incidence of renal dysfunction in acute HF, the risk factors that are related to its appearance, and how it is affecting the patients' outcome.
Methods: We studied consecutive patients who were admitted to the hospital with acute HF during one year. Renal function was compared on the day of admission and the day of discharge from the hospital, and correlated with the various characteristics and risk factors.
Results: The sample consists of 259 patients, mean age of 77 ± 12 years, 61% men with mean duration of hospitalization 6 ± 4 days. A total of 16 deaths (6%) were observed. The etiology of HF was ischemic in half of patients, valvular in 21%, dilated in 9% and other or mixed etiology in 20%. The mean creatinine clearance (GFR) on admission was 54 ± 28 ml / min and on discharge 49 ± 28 ml / min (9% decrease, p <0.01). 49 patients (19%) had a GFR drop ≥ 20%. Patients with GFR drop during hospitalization were associated with the incidence of death (r = -0.16, p = 0.04) and anemia (r = 0.27, p = 0.04). Independent prognostic factors for renal dysfunction during hospitalization were ischemic cardiomyopathy, age, prolonged hospitalization, use of aldosterone antagonists, low T3, low T4 and high C-reactive protein on admission.
Conclusion: Deterioration of renal function in acute HF is not a rare phenomenon and is associated with anemia and death. Factors such as ischemic cardiomyopathy, age, duration of hospitalization seem to play a role, and caution is needed in these patients to prevent its occurring.

Coronary Artery Disease

P2124
Comparison of outcomes of patients with ST-elevation myocardial infarction with vs without hypothyroidism

H Hassaan Arshad[1]
[1]*New Jersey Medical School, Internal Medicine, Newark, United States of America*

Introduction: Close link between thyroid hormonal status and cardiovascular disease is apparent by the significant effects of hypothyroidism, both subclinical and overt, on the cardiovascular system. The aim of this research is to draw comparison analysis of rates of revascularization, Length of stay, in-hospital mortality and

incidence of cardiogenic shock in patients with ST-Elevation Myocardial Infarction (STEMI) with and without hypothyroidism.
Methods: The study examined National Inpatient Sample (NIS) database ,which is the largest database for hospital admissions in United states, from years 2007-14 for all hospital admissions with acute STEMI using ICD9 codes. We compared baseline characteristics of the two groups using parametric and non-parametric tests for continuous variables and Chi-Squares test for dichotomous variables. Multivariate logistic regression was used to analyze the odds of revascularization (Percutaneous Coronary Intervention (PCI) and Coronary Artery Bypass Graft (CABG)), cardiogenic shock and in-hospital mortality. We adjusted for age, sex, race, payer, income quartiles, hospital location, region, size and teaching status. In addition, our study also accounted for multiple comorbidities during our analysis.
Results: Hypothyroidism was present in 170,918 of 1,887,055 (9.06%) patients in the STEMI population. Patients with hypothyroidism were more elderly (mean 73.67 vs 65.00 p<0.001) and were more likely to be women (65.54% vs 34.11%, p<0.01). They were also more likely to have multiple comorbidities e.g. Anemia, Arthritis, Depression, Congestive Heart Failure, Diabetes Mellitus and related complications, Hepatitis C, Coagulopathy, Hypertension, Lymphoma, Chronic Kidney Disease, Valvular disease, Peripheral Vascular Disease and Neurological Disease (p<0.001 for all). In addition, they were also more likely to have a history of CABG procedure (6.01% vs 4.35% p<0.001) but were less likely to have alcohol use disorder and weight loss (p<0.001 for both). They were also less likely to be diagnosed at teaching hospital (44.40% vs 48.38%, p<0.01) and had lower income quartiles. Median length of stay was longer (LOS) for patients with Hypothyroidism (median 4.00 vs 3.00 p<0.001). After adjustment, STEMI patients with hypothyroidism had greater in-hospital mortality (odds ratio 1.24, CI 1.19-1.27 p<0.001). They were also less likely to undergo revascularization (odds ratio 0.60, CI 0.58 to 0.61 p<0.001). Both PCI and CABG procedures had lower occurrences in hypothyroid group (PCI-odds ratio 0.63, CI 0.62 to 0.65 p<0.001, CABG-odds ratio 0.78 CI 0.74 to 0.82 p<0.001). However, hypothyroid group was less likely to develop cardiogenic shock (odds ratio 0.91, CI 0.88 to 0.95, p<0.001).
Conclusions: Hypothyroidism confers greater odds for in-hospital mortality and is associated with lower likeliness to receive revascularization in the setting of a STEMI

P2125

Effect of cardiac rehabilitation on the cardiac structure and function in patients with acute myocardial infarction

IW Seong[1]; JH Jae-Hyeong Park[1]; BS Seo[1]; JA Kim[1]; JH Lee[2]
[1]Chungnam National University Hospital, Daejeon, Korea (Republic of); [2]Chungbuk National University Hospital, Cardiology, Cheongju, Korea (Republic of)

Backgrounds: Cardiac rehabilitation (CR) is one of option to improve symptoms and survivals in patients with acute myocardial infarction (AMI). However, there are little information about the structural change of the heart according to the CR. Thus, we studied the cardiac structural and functional change after CR.
Materials and methods: We retrospectively reviewed all consecutive AMI patients from January 2012 to October 2015. Baseline clinical data were obtained from their medical records and echocardiographic data were acquired from their stored images.
Results: Of total 944 patients (mean age 63.7±12.4 years old, 709 males) including 531 patients with ST-segment elevation MI, we analyzed 410 patients (mean age 63.7±11.7 years old, 302 males) with follow-up echocardiographic examinations during the mean duration of 19.6±16.3 months. We divided our study group into 2 groups according to the presence of CR (group 1 with CR, n=333, group 2 without CR, n=77). At baseline, there was no significant difference of echocardiographic parameters between 2 groups. At follow-up echocardiographic examination, group 1 showed significantly lower left atrial volume index (31.4±38.8ml/m2, P=0.005), lower E/E' ratio (11.3±6.5 vs 13.2±6.9, P=0.043) and lower TR Vmax (2.6±0.5 vs. 2.8±0.5m/sec, P=0.014). However, there were no statistical significance in the systolic echocardiographic parameters.
The presence of CR is a significant prognostic marker in the prediction of all cause mortality in the univariate analysis (HR=0.258, 95% CI=0.123-0.542. P<0.001) and in the multivariate analysis after adjustment of age, gender, Killip class and LV ejection fraction (hr=0.376, 95% CI=0.173-0.817, P=0.013)
Conclusion: In this study, CR was associated with the improvement of diastolic function and better survival in patients with AMI.

P2126

Long-term prognostic impact of post-discharge heart failure after ST-segment elevation myocardial infarction

L Savic[1]; I Mrdovic[1]; M Asanin[1]; G Krljanac[1]; R Lasica[1]; B Kastel[1]; D Rajic[1]
[1]Clinical Center of Serbia, Institute for Cardiovascular Disease, Emergency Hospital, Belgrade, Serbia

Background/aim: Heart failure (HF) is relatively common complication of ST-elevation myocardial infarction (STEMI) and can be transient (typically resolved by hospital discharge) or persistent (post-discharge). It was shown that early post-discharge HF is a strong independent predictor for 1-year mortality. The aim of this study is to analyze the prognostic impact post-discharge HF after STEMI on long-term mortality.
Method: we analyzed patients included in our Clinical Center STEMI Register hospitalized between 2006 and 2011 year. All patients were treated with primary PCI. Patients presenting with cardiogenic shock were excluded. Echocardiographic examination was performed before discharge and left ventricular ejection fraction (EF) was assesed using bi-plane method. Patients were divided in two groups accocrding to the presence of HF symptoms at 30-day visit (New York Heart Association- NYHA class): without HF (NYHA class 1) and with post-dscharge HF (NYHA class ≥2). The follow-up period was 6 years. A landmark analysis beyond 30-days was performed to analyse the prognostic impact of post-discharge HF on 6-year mortality.
Results: Of 3033 patients included in the Register, 2895 (95.4%) were alive at 30 days, among whom 232 (8.1%) had HF; 200 patients with HF (86.2%) were in NYHA class 2 and 32 patients with HF (13.8%) were in NYHA class 3. As compared with patients without HF, those with post-discharge HF were older, more commonly women and presented more often with Killip class II and III; thay had more frequent previous myocardial infarction, diabetes, reduced baseline kidney function, longer pain duration, multivessel coronary disease on initial angiogram and post-procedural flow TIMI<3. Pre-discharge EF was lower in patients with HF as compared with patients without HF (36.44%, IQR 28.30%-45.12% vs 49.62%, IQR 42.20%-57.40%, p<0.001). In multivariable logistic regression analysis independent predictors for post-discharge HF were lower EF HR 1.04 (95%CI 1.02-1.08), p<0.00, Killip class II and III at presentation HR 2.54 (95%CI 1.84-3.92), p=0.003, post-procedural TIMI<3 HR 2.07 (95%CI 1.12-3.89), p=0.023 and older age (years) HR 1.02 (95%CI 1.01-1.04), p=0.001. Mortality between 30 days and 6-year was significantly higher in patients with post-discharge HF as compared with patients without HF (11.9% vs 3.55%, p=<0.001). In Multivariable Cox regression analysis post-discharge HF was an independent predictor for 6-year mortality - HR 2.21 (95%CI 1.82-3.17), p=0.004. Other independent predictors were lower EF (HR 1.02, 95%CI 1.01-1.06, p<0.001) and older age (HR 1.05, 95%C 1.03-1.07, p<0.001).
Conclusion: The presence of early post-discharge HF after STEMI is independently associated with more than 2-times increase in long-term mortality. This finding is consistent with previous findings and underscores the importance of introducing treatments that improve clinical outcome in patients with HF as soon as possible.

P2127

Comparison of eplerenone and spyronolacton effects in prevention of left ventricular remodeling and development of heart failure in patients after STEMI

I Iulia Rodionova[1]; YV Hilova[1]; MP Kopytsya[1]; I N Kutya[1]; OV Petyunina[1]
[1]L.T.Malaya Institute of Therapy, Kharkiv, Ukraine

Background: The development of post-infarction remodelling of the left ventricle in patients with ST segment elevation myocardial infarction (STEMI) is an urgent problem of cardiology, as its development worsens the prognosis. Soluble ST2 (sST2) is a marker of fibrosis, which plays a significant role in the development of myocardial remodelling. Antagonists of mineralocorticoid receptors affect the development of myocardial fibrosis and improve the left ventricle remodelling (LV).
Purpose: Compare eplerenone and spironolactone efficacy in preventing LV remodelling and development of heart failure in patients after STEMI with elevated sST2
Methods: 103 STEMI patients were screened (72.8% male and 27.2% female), mean age was 61.85±12.23 years. The levels of sST2 were determined during the first day of hospitalization. A group of 56 patients with sST2 ≥35 ng / ml and stored LV. The examined patients were divided into two groups: the first received eplerenon, and the second one - spironolactone
Results: After 6 months of observation, the groups with remodeling of LV and without it were compared. The blood serum sST2 in the remodeling group was 50.35 [27.17-103.20] ng / ml and 28.02 [21.75-34.70] ng / ml in the group without LV remodelling (p <0.015) Multivariate logistic analysis revealed a significant effect of sST2 on the development of LV remodelling after 6 months of observation (β = -0.079; OR: 0.924; 95% CI 0.8624 - 0.9902; p = 0.025). To study the significance of sST2 in predicting the onset of LV remodelling, ROC analysis was performed. The level of more than 44.5 ng / ml allows to predict the development of LV remodelling, AUC = 0.707, (95% CI 0.533-0.882; P = 0.0198), with a sensitivity of 85.7% and a specificity of 57.1%.
Eplerenon significantly lowered sST2: from 116.00 [36.91-193.41] to 44.24 [29.52-83.96] (p = 0.039), in the spironolactone group, no significant changes in sST2 occurred. In the group of patients receiving spironolactone there was an increase of end-diastolic volume (EDV) from 117,00 ± 27,64 ml to 143,06 ± 47,12 ml (p = 0,014), but eplerenone prevented EDV LV incresaing. The studied drugs did not effect on ejection fraction (EF) LV. In addition, in the eplerenone group, the distance of the 6-minute walk test (6MWT) augmented from 411.3m to 524.4m (p = 0.048), there were no 6MWT changes in the spironolactone group.

Conclusions: The increased sST2 serum level is a prediction of LV remodelling. The use of eplerenone in patients after STEMI with an elevated sST2 level has the advantage of spironolactone using. Eplerenone significantly decrease sST2 level, prevents the development of abnormal left ventricular remodelling and increases the tolerance to physical activity after 6 months of observation.

P2128

Long-term results of coronary artery bypass surgery in patients with Q-myocardial infarction and postinfarction angina

A Alena Medvedeva[1]; L Gelis[1]; I Lazareva[1]; N Rineiska[1]; V Shumovets[1]; D Kovalenko[1]; S Pashkevitch[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Cardiology, Minsk, Belarus*

Purpose: To study the long-term results of coronary artery bypass surgery (CABG) in pts with Q - myocardial infarction (Q-MI) complicated by early postinfarction angina.
Methods: The study involved 104 patients with Q-MI complicated by postinfarction angina underwent CABG on pump. The mean age was 57.4±6.4 years, arterial hypertension was detected in 76 patients (73%), type 2 diabetes was detected in 34 patients (32.7%). The baseline of EF LV was 44.5±6.6%. Class of heart failure (NYHA) amounted 2.75±0.12. All pts were performed general blood analysis, determination the levels of troponin I, BNP, C-reactive protein, myeloperoxidase, von Willebrand factor, fibrinogen, antithrombin III; 6-minute walk test, ECG, Echocardiography. The average number of affected arteries was 3.2±1.4. All pts underwent CABG on pump. CABG with reconstructive operations were performed in 23 (21.7%) pts. The average number of anastomoses were 2,9±1,4.
Results: in the early postoperative period, acute heart failure developed in 26 (25%) pts, perioperative myocardial infarction developed in 5 (4.8%) patients. 6 patients died (5.8%). The NYHA class of heart failure significantly decreased at discharge to 1.7±0.04, and after 12 months it was 1.8±0.01.
Preoperative adaptive remodeling of the myocardium of the left ventricle was 50 (48%) pts, non-adaptive type in 54 (52%) pts. After 1 year of follow-up showed an increase in the number of patients with type adaptive remodeling of the myocardium to 72 (of 73.5%) pts, non-adaptive type was preserved in 26 (26.5%) pts.
Repeated cardiovascular events developed in 42 pts (42.8%) during the 10-year follow-up period: recurrent angina in 26 (26.5%) pts, repeated myocardial infarction in 8 (8.2%) pts, and progression of HF in 26 pts (26.5%). Died 7 (7.1%) pts with baseline EFLV ≤ 35%. The HF class (NYHA) was 2.1±0.01 from 10 years of observation. The main independent predictors of cardiovascular risk for the 10 year follow-up period were baseline EF LV ≤ 35%, wall motion index>2 points, BNP>1500 pg/ml.
Conclusions: Cardiovascular events were recorded in 42.8% pts with Q – MI and postinfarction angina who underwent CABG on pump during a 10-year follow-up period, mainly in pts with initial non adaptive type of LV myocardial remodeling, progression of heart failure and baseline EF LV ≤ 35%, wall motion index>2 points, BNP>1500 pg/ml.

P2129

Mid-term follow-up after Coronary Bypass Surgery in low ejection fraction patients including preoperatively treated with levosimendan

E Elina Vlasova[1]; V Gazizova[1]; E Dzybinskaya[1]; V Gramovich[1]; V Vasilyev[1]; A Shiryaev[1]; R Akchurin[1]
[1]*Cardiology Research and Production Center, Cardiac surgery, Moscow, Russian Federation*

Background: Pharmacological preparation for coronary bypass surgery in patients (pts) with low left ventricle ejection fraction (LVEF), especially including levosimendan (L), aimed at compensating chronic heart failure (CHF), is known to improve early operative results. There is a need for more data regarding mid-and long-term results.
Purpose: to evaluate 6-months follow-up data after revascularization in pts with low LVEF who were prepared to surgery by base therapy + L and in pts who received only base therapy since it was enough to compensate for CHF.
Methods: Non-randomized prospective study. 42 pts (90% - mal; mean age 61±7years) with multivessel coronary disease, postinfarction zone, LVEF≤35%, proven viable myocardium were operated in 2016-17. All were treated with loop diuretic, MRA, ACEI/ARB and beta-bloker for several weeks preoperatively. Those who steel had at least one of four signs: orthopnea, pulmonary congestion by -ray, 6min-walk-distance < 300m, or BNP ≥ 400pg/ml, - received levosimendan infusion (12.5mg for 24 h,no bolus), 2 days before surgery (group L, n=22). The rest were in the comparison group (group C, n=20).
Results: are presented in the table "6 months after surgery".
The overwhelming majority in both groups showed a significant clinical improvement: an increase in 6 min-distance, reduced need for diuretic, BNP decrease were recorded; almost no hospitalizations, no mortality was registered. However, the dynamics of LVEF and EDD turned out to be hardly noticeable: LVEF increased by 4,5% and 5,7%, EDD decreased by 1,5% and 0% in groups L and C respectively.
Conclusion: We regard this data as a revascularization effect, which was successful, including due to accurate medical preparation with L. At this time interval, a significant increase in LVEF was not observed.

Dynamics of functional condition in patients with NSTEMI depending from hospital treatment strategy.

IA Mezhiievska[1]; VI Maslovskyi[1]; YV Maslovskyi[1]
[1]*National Pirogov Memorial Medical University, Internal medicine #3, Vinnitsa, Ukraine*

Purpose. The aim of the present work is the evaluation of the functional status of patients with NSTEMI with the test of 6-minute walking depending on the treatment strategy in acute period within 6 months of observation
Methods. Were examined 77 patients (63.6% women) with NSTEMI aged 50 to 79 (average 64,1 ± 1,0) years. The level of troponin I (Tp I), which was determined not earlier than 3 hours after the onset or exacerbation of pain in all patients was higher reference upper limit of normal (> 2.0 ng / mL). The median of Tp I in the group was 7.1 ng / ml, interquartile magnitude - 5.4 and 22.9 ng / ml.
Stratification of patients according to a GRACE ACS Risk Assesment in 48.1% were defined as high risk (>3% and> 140 points on the scale) and 33.8% - as moderate risk of fatal consequences in the near future (1-3% 140-109 points a scale). Low risk (<1% <109 points on the scale) registered by us only in 18.2% of patients.
All of research corresponding to the principles of the Declaration of Helsinki of the World Medical Association.
Results. The analysis of dynamics of functional status of patients with NSTEMI after the test of 6-minutewalking depending on the treatment strategy in acute within 6 months of observation. Were proved that percutaneous angioplasty in patients with NSTEMI in the acute period accompanied with a significant increase functional status of patients within 3 and 6 months, characterized by a significant increase in the value of the distance traveled by 10.6% and 23.9% respectively (p <0 , 0001) and a decrease in the average functional class (FC) of heart failure (HF) of 16.2% and 27.9% respectively (p<0.002). In patients with NSTEMI, which in the acute period did not receive invasive treatment, the positive dynamics of the functional status of patients had not received, were recorded only a tendency to increase the value of the distance traveled by 1.2% (p = 0.13) on the 3rd and tendency to reduce the rate to 0.5% (p = 0.51) in the 6th month. A significant decrease in the average FC HF in these patients is determined only for 3 months by 7.9% (p= 0.04), while the 6th month registered only a tendency to decrease in 1.7% (p = 0.78) compared with the original value.
Conclusion. It is proved that percutaneous angioplasty in patients with NSTEMI in the acute period accompanied
by a significant increase functional status of patients within 3 and 6 months, characterized by a significant increase in the value of the distance from 364 to 402 m (+ 10.6%, p<0.0001) at 3rd and from 364 to 450 m (+23.9%, p <0.0001) at 6 months according to test 6-minute walk and a decrease in the average FC from 1.97 to 1.65 (- 16.2%, p = 0.001) on the 3rd and from 1.97 to 1.42 (-27.9%, p <0.0001) at the 6th month follow-up.

P2131

Use of aspirin as primary prevention prior to an acute coronary syndrome

F M Fonseca Goncalves[1]; JP Guimaraes[1]; SC Borges[1]; JJ Monteiro[1]; PS Mateus[1]; JI Moreira[1]

[1]*Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal*

Introduction: The use of aspirin as primary prevention of cardiovascular events in certain subgroups of patients is currently controversial. This study aimed to evaluate the prognostic impact of prior use of AAS as primary prevention in patients with an acute coronary syndrome (ACS).

Methods: This was a retrospective study of patients with non-fatal ACS between October 2010 and November 2017. We excluded patients with prior history of myocardial infarction (MI), percutaneous or surgical coronary revascularization, stroke and peripheral arterial disease. The endpoints evaluated were MI, stroke, decompensation of heart failure (DHF), major bleeding and all-cause mortality, at a median follow-up of 42 months (IQR 24-59).

Results: A total of 444 patients were selected, 72.5% were male, with a mean age of 65.0±13.5 years old, and 11.7% was previously medicated with aspirin. This group had more patients with history of arterial hypertension (86.5% vs 54.1%, p<0.001) and diabetes (40.4% vs 24.2%, p<0.05), less smokers (7.7% vs 24.7%, p<0.05), without significant differences in dyslipidemia (61.5% versus 47.4%, p=0.133). Compared to patients who were not treated with aspirin, during hospitalization, a higher incidence of new-onset atrial fibrillation occurred (15.4% vs. 4.6%, p<0.05). There were no differences in the overall treatment prescribed at discharge between the two groups.

In a multivariate analysis, we haven't found any statistically significant differences for any of the proposed endpoints, namely MI (HR 1.1, 95% CI 0.4-3.6), stroke (HR 1.0, 95% CI 0.2-5.1) and DHF (HR 1.0, 95% CI 0.5-2.4). There was even a tendency for greater overall mortality (HR 1.7, 95% CI 0.9 -3.4) as well as for major bleeding (HR 1.8, 95% CI 0.8 -4.0).

Conclusion: In this study the use of aspirin as primary prevention prior to an ACS did not hold any long-term beneficial effect, as it couldn't reduce, in an independent and significant manner, the incidence of ischemic or hemorrhagic events.

P2132

Coronary revascularization does not improve echocardiographic ejection fraction or serum NT-proBNP levels but may improve left ventricular diastolic function in patients with developed heart failure.

M Popovska-Petrova[1]; P Petrov[1]; M Grigorov[1]; P Gatzov[1]; H Kamah[1]; N Ivanov[1]; S Dimitrov[1]

[1]*Second MHAT, Cardiology, Sofia, Bulgaria*

Introduction: Chronic heart failure is a major problem in cardiology because of its high mortality, increasing number of hospitalizations and enormous expenses for its treatment. Survival rate is worse than that of breast cancer in women and prostatic cancer in men. The most common reason for chronic heart failure is ischemic heart disease. Percutaneous coronary intervention (PCI) and coronary artery bypass grafting (CABG) are two of the therapeutic options when coronary artery disease is present.

Purpose: The aim of this study was to assess the impact of coronary revascularization (PCI and CABG) on ejection fraction, serum NT-proBNP levels ant left ventrical diastolic function in patients with chronic heart failure and stable coronary artery disease.

Methods: Twenty-three female and male patients (mean age 62 ±12 years) with chronic heart failure NYHA class II-IV and stable angina pectoris CCS class III were included in this study. Coronary arteriography was performed and coronary artery disease was established in all of them. Nineteen patients (82.6%) were revascularized by PCI and 4 patients (17.4%) were referred to a cardiothoracic surgery for CABG. Prior to revascularization measurements of echocardiographic ejection fraction and diastolic function, serum NT-proBNP levels, and evaluation of NYHA class were performed. On six-month follow-up visit the same parameters were reassessed. Student's t-test for dependent samples was used for the statistical analysis of the results.

Results: There was a significant reduction in ejection fraction (53.4±7.3% vs. 49.8±6.6%, P<0.001) six months after revascularization and significant reduction in E/e' (11.85 vs. 9.59, p<0.05). Serum NT-proBNP levels (1748±2673 pg/ml vs. 1522±1285 pg/ml, p=0.69) and NYHA class failed to show any statistically significant difference.

Conclusions: Our study provides evidence that coronary revascularization does not have positive impact on ejection fraction, serum NT-pro-BNP levels and NYHA class but may improve left ventricular diastolic function evaluated by E/e' on six-month follow-up.

P2133

Impact of the baseline systolic dysfunction on the long-term outcomes of elective percutaneous coronary interventions

E Elena Vershinina[1]; AN Repin[1]

[1]*Cardiology Research Institute, Tomsk National Research Medical Center the Russian Academy of Science, Tomsk, Russian Federation*

Purpose To investigate the effect of baseline systolic dysfunction on long-term outcomes of coronary artery disease in patients after elective percutaneous coronary interventions (PCI).

Methods An retrospective observational study included 162 patients referred for elective percutaneous coronary intervention (PCI). The first group included 141 patients with left ventricular ejection fraction (LV EF) ≥50% according to ultrasound of the heart before PCI. The second group included 21 patients with baseline LV EF less than 50%. Outcomes of interventions were assessed 6 years after the index PCI, by analyzing medical records and telephone interviews. The primary endpoint of the study was the frequency of death from cardiovascular causes. The secondary endpoints were total mortality, the incidence of major adverse cardiovascular and cerebral events (MACCE), incidence of nonfatal acute myocardial infarction (AMI).

Results

6 years after index PCI, death from cardiovascular events was recorded in 10.9% of patients in the observed cohort (7% in the first group and 38.9% in the second, p = 0.0002). Total mortality during this period was 14.4% (10.9% in the first group and 41.2% in the second, p = 0.003). MACCE were registered in 39.9% of patients (36.2% in the first group and 66.7% in the second, p = 0.026). AMI developed in 10.1% of patients (7.3% in the first group and 31.3% in the second, p = 0.01). It was shown that the baseline decrease in LV EF 50% is associated with an unfavorable course of the disease in the long-term period (6 years) after planned PCI, and is a predictor of the development of the fatal cardiovascular events (OR = 8.41; 95% CI [2.63– 26.97]; p = 0.000), total mortality (OR = 6.19; 95% CI [2.01–19.04]; p = 0.000), MACCE (OR = 3.61; 95% CI [1 , 27–10.25], p = 0.012); AMI (OR = 5.62; 95% CI [1.44–21.99]; p = 0.006).

Conclusion Baseline systolic dysfunction is a predictor of general and cardiovascular mortality, as well as major adverse cardiovascular events in the long-term period after elective PCI.

P2134

In-hospital results of Coronary Artery Bypass Grafting in patients with low left ventricular ejection fraction: focus on preoperative medical prepare, experience in the use of levosimendan

V Gazizova[1]; E Vlasova[1]; E Dzybinskaya[1]; D Galyautdinov[1]; A Shiryaev[1]; R Akchurin[1]

[1]*Cardiology Research and Production Center, Cardiac surgery, Moscow, Russian Federation*

BACKGROUND: Low cardiac output syndrome (LCOS) – the main complication of coronary artery bypass grafting (CABG) in patients with low left ventricular ejection fraction (LVEF). Preoperative levosimendan, added to standard therapy for chronic heart failure (HF), promotes compensation, thus it's expected to reduce LCOS risk and to accelerate recovery.

PURPOSE: to evaluate CABG outcomes and postoperative parameters of patients (pts) with LVEF≤35% who was treated only standard therapy for CHF and who additionally received levosimendan.

METHODS: Non-randomized prospective study. 42 pts with multivessel coronary disease, extensive postinfarction zone and proven viable myocardium included; 90% - mal, mean age = 61±7 years. All pts received medication for CHF - loop diuretic, MRA, ACEI/ARB, beta-bloker - for at least 1 month preoperatively. Those who had at least one of the four criteria: 6min-walk-distance < 300m, orthopnea, pulmonary congestion by radiography or BNP ≥ 400pg/ml, - received levosimendan as infusion of 12.5mg for 24 h (no bolus), 2 days before surgery (group 1, n=22). The others made up the comparison group (group 2, n=20). Median (IQR) BNP (pg/ml) was 282 (153;618) and 164 (112; 383), median (IQR) LVEF was 33,5% (30;35) and 35,0% (32;35), median (IQR) LV end-diastolic dimension (mm) was 66 (65;71) and 65 (61;69) in groups 1 and 2 respectively.

RESULTS: problems during pre-perfusion period occurred less frequently in group 1 (p>0,05); the other parameters were comparable. The results are presented in the table.

CONCLUSION: It is reasonable to support the preoperative therapy with levosimendan in patients with low LVEF scheduled for CABG in cases if signs of CHF persist despite standart medication; at this rate the results of the surgery and the in-hospital period parameters are expected to be the same as in patients with clinically compensated CHF.

Platelet aggregation test with adenosine diphosphate in prevention of early coronary stent thrombosis

E Ekaterina Gitelzon[1]; A Faybushevich[1]; D Gitelson[1]; V Baranovich[1]; G Veretnik[1]; D Maximkin[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Funding Acknowledgements: The publication has been prepared with the support of the 'RUDN University Program 5-100'

The coronary artery stenting is a common and effective endovascular treatment for various forms of coronary artery disease. In most cases prescribed dual antiplatelet therapy helps prevent stent thrombosis. However, the effectiveness of dual antiplatelet therapy is rarely monitored. Despite there are 0.6-2% chances in the first year of having stent thrombosis with high mortality rate after coronary artery stenting. Aim: to study the effectiveness of platelet aggregation management in early coronary stent thrombosis prevention in patients with unstable angina.Materials and methods. The study included 215 patients with unstable angina. All patients were randomized in II groups. There were 112 patients in group I and 103 patients - in group II. Group I had the platelet aggregation managment based on platelet aggregation test with adenosine diphosphate and group II had not. Percutaneous coronary intervention with stenting perfomed in both groups.
The odds ratio for the development of early coronary stent thrombosis in patients with unstable angina with platelet aggregation management compared with the patients without platelet aggregation management is 3.36 ($p < 0.05$).Conclusion. The study shows the importance of platelet aggregation management in the prevention of early coronary stent thrombosis in patients with unstable angina

P2136

Heart failure control in patient with coronary artery disease

SL Svetlana Liliana Mosteoru[1]; R Pleava[1]; C Totorean[1]; A Dumitrescu[1]; L Gaita[2]; D Gaita[1]
[1]*University of Medicine Victor Babes, Cardiology, Timisoara, Romania*; [2]*University of Medicine Victor Babes, Diabetes, Nutrition and Metabolic disorders Department, Timisoara, Romania*

Introduction: Coronary artery disease (CAD) has been steadily raising in the past few years and enhanced survival fueled by better medication and revascularization techniques has placed it as one of the primary risk factors for developing heart failure (HF). Therefore, it is essential for patients suffering from HF to have a good adherence to their treatment.
Purpose: The aim of our study was to investigate the prevalence of HF in the CAD population as well as evaluate the compliance of patients towards guideline recommendations.
Methods: We have enrolled 194 consecutive patients who have undergone PCI or CABG for acute myocardial infarction or unstable angina or stable angina between October 2016 and June 2017. Out of this lot we have selected 160 patients who developed heart failure. We have interviewed these patients regarding their medication and lifestyle and have determined their ejection fraction (EF).
Results: Out of the population with heart failure, 76.8% had a preserved EF, while 15.6% had an intermediate EF and 7.5% a reduced EF. However just over half of the patients with intermediate EF (64%) were taking an angiotensin converting enzyme (ACE) inhibitor or an angiotensin receptor blocker (ARB). The most used medication was Ramipril (43.7%), followed by Zofenopril (31.2%), Valsartan (6.2%) and Olmesartan (6.2%). In the group with reduced EF 50% of these patients were on ACE inhibitor or ARB treatment, which included Zofenopril in 66.6% of the cases, Ramipril in 33.3% of the cases and Valsartan in 33.3% of the cases. Moreover, 59% of the entire population with heart failure were not currently taking Spironolactone.
Conclusions: We have noticed that patients at very high cardiovascular risk are poorly controlled regarding their heart failure medication which might be explained by non-adherence to treatment. Awareness should be raised among patients to ensure better compliance regarding medication adherence.

Valvular Heart Disease

Usefulness of balloom aortic valvuloplasty in the management of patients with aortic stenosis

E Munoz-Garcia[1]; M Munoz-Garcia[1]; A J Antonio Jesus Munoz Garcia[1]; JH Alonso-Briales[1]; C Alonso-Laza[1]; AJ Dominguez-Franco[1]; JM Garcia-Pinilla[1]; JJ Gomez-Doblas[1]; JM Hernandez-Garcia[1]; MF Jimenez-Navarro[1]
[1]*University Hospital Virgen de la Victoria, Department of Cardiology, Malaga, Spain*

The introduction of Transcatheter Aortic Valve Implantation (TAVI) has generated a renewed interest in the treatment of patients with severe aortic stenosis. The aim of our study was to analyze the indications and survival of patients with severe aortic stenosis treated with balloon aortic valvuloplasty (BAV).
Methods: Between 2005 and 2017, 159 consecutive patients with severe aortic stenosis were treated with BAV at our center. Three cohorts of patients were identified according to the definitive treatment performed: A) bridge to TAVI n = 67 B) bridge to surgical aortic valve replacement (AVR) n = 70 and C) medical-palliative treatment n = 22.
Results: The mean age of patients was 76.8±8 years, and had a high surgical risk, (mean logistic EuroSCORE 24.17±14%, and EuroSCORE II 9.01±6. There were differences in the gender, according to definitive planned therapy, being the most prevalent female sex for TAVI compared with AVR and palliative therapy (53.9% vs. 31.3% vs. 40%, $p = 0.012$). Highlight that 33 patients (20.8%) were in cardiogenic shock. The success of the procedure was 96.9%. Two patients died during the procedure. In-hospital mortality was 17.6% and occurred mainly in patients with cardiogenic shock [OR = 9.84 (95% CI 3.91-24.7) $p < 0.001$]. The rate of major events was 14.6%. The mean survival in patients to bridge TAVI was 51 months (95% CI 42-60.2), to AVR was 83 months (95% CI 58.9-107.6) and medical-palliative treatment was 6.2 months (95% CI 3.208- 9.26), log Rank 102, $p < 0.001$. Frailty was an independent predictor of late mortality [HR=4.310 (95% CI 1.98-9.38), $p < 0.001$).
Conclusion: In our series, the number of BAV has increased due to the introduction TAVI. The procedure is safe and the mean survival was acceptable for the population of patients receiving subsequent definitive treatment. Cardiogenic shock conditions in-hospital mortality, and the frailty of patients (based on the Fried scale) is a predictor of late mortality that should be considered in the clinical evaluation

P2138

Predictors of heart failure after aortic valve replacement in 2,500 patients

WP Mistiaen[1]; I Deblier[2]; KME Dossche[2]; A Vanermen[2]
[1]*University of Antwerp, Faculty of Medicine & Health Sciences, MOVANT - division of physiotherapy, Antwerp, Belgium*; [2]*ZNA Middelheim Hospital , Cardiovascular surgery , Antwerp, Belgium*

Introduction: Heart failure after aortic valve replacement (AVR) is a highly lethal complication, which might be prevented by avoiding the development of its modifiable predictors.
Methods: A retrospective analysis was performed of 2,500 consecutive patients, who underwent AVR from 1987 to 2017. Patients with a mitral valve or mechanical valve in any position were excluded. Concomitant procedures such as CABG, mitral and tricuspid valve repair were included. Preoperative parameters under investigation are listed in the results section. Statistical analysis included an univariate chi-square analysis (first step). To identify independent predictors, significant univariate categorical variables were entered in a multivariate logistic regression analysis (second step).
Results: Postoperative heart failure has a hospital mortality of 58.5% (mortality of all patients: 4.6%). Predictors of postoperative heart failure are age > 80, chronic pulmonary and renal disease, high NYHA class, preoperative heart failure, permanent pacemaker, need for non-elective surgery, additional cardiac procedures, atrial fibrillation ($p<0.001$ in all cases), diabetes ($p=0.002$) and coronary artery disease ($p=0.015$). Seven predictors could be identified (table)

Heart failure is also associated with other postoperative events, including infective endocarditis bleeding, arrhythmias, atrial fibrillation, conduction defects, myocardial infarction, delirium, renal and pulmonary complications, increased need for blood products, prolonged mechanical ventilation and length of stay in the intensive care unit (p<0.001 in all cases).
Conclusions: Most predictors are not modifiable except for the development of preoperative heart failure and need for non-elective surgery. Once aortic valve disease has become symptomatic, early referral could prevent these developments and improve postoperative results.

predictors for postoperative CHF

Preop predictor	Odds ratio	95% confidence interval	p-value
Age > 80y	1.92	1.26 - 2.92	0.002
FEV1<70%	2.03	1.36 - 3.28	0.004
CKD	2.08	1.35 - 3.20	0.001
NNES	2.12	1.10 - 4.09	0.026
CHF	1.55	0.98 - 2.43	0.059
PCI	1.81	1.08 - 3.02	0.024
AF	1.70	1.10 - 2.63	0.017

AF: atrial fibrillation; CHF: congestive heart failure CKD: chronic kidney disease; FEV1: forced expiratory value - 1 second; NNES: need for non-elective surgery; PCI: percutaneous coronary intervention

P2139
Hemostatic system changes in infective endocarditis patients before and after surgical heart valves operation

O Olesya Shatova[1]; N Feaktsistava[1]; N Kazaeva[1]; S Sudjaeva[1]; O Sudjaeva[1]
[1]Republican Scientific and Practical Centre of Cardiology, heart failure, Minsk, Belarus

The particular interests are the features of hemostasis in patients with infective endocarditis (IE) in the early postoperative period after heart valvular correction. There isn't frequency established the development of disseminated intravascular coagulation syndrome (DIC syndrome) in the postoperative period and its involution after surgical treatment and which y hemostasis changes are generally happen.
Materials and methods: we included 65 patients with IE: 52 men and 13 women. Control group (CG n = 35), whose anti-inflammatory and anticoagulant therapy was traditionally performed; the main group (MG n = 30), in whom anti-inflammatory and anticoagulant therapy was prescribed taking into account the complications of the early postoperative period.
Results: we was found that in the preoperative period there was a DIC syndrome: MG in 33% cases and 34% in the CG. 1st and 2nd stages of DIG were noted in an equal 50% of cases among MG patients. Among the CG patients, the 1st stage of DIC was noted in 58% of cases, the 2nd stage in 42%. In the preoperative period patients of both groups had moderately disturbances in the 2nd and 3rd phases of the coagulation cascade (thrombin formation and fibrinogenesis), platelet link along with moderate activation of spontaneous fibrinolysis. For patients with IE characterized by an increase in the blood markers of thrombinemia D-dimer (MG - 874±1141 ng/ml and CG - 1096±1704 ng/ml, p = 0.56) and fibrinogen (MG - 4.4±1,5 g/l and CG - 4.1±1.4 g/L, p=0.45) and one of the markers of plasminemia (D-dimer or plasminogen). Thus, for the detection of hypercoagulability in the preoperative period in patients with IE it is determine in complex fibrinogen, D-dimer and plasminogen. decrease in blood plasma levels of natural anticoagulants (PC and PS) was registered predominantly in patients with chronic hepatitis B or C. In general, the PC in groups was 98 ± 22% in the MG, and 118 ± 32% in the CG, p = 0.012, and PS was 107 ± 26% in MG and 114 ± 40% in CG, p = 0,45
Conclusion On the 1st day after the operation, the DIC-syndrome begins to progress in patients with IE. Significant disturbances are revealed in the system of natural anticoagulants, platelet link, as well as thrombinemia and plasminemia markers.

P2140
A systematic review on the LAmbre atrial appendage closure device

M Noutsias[1]; M Ali[1]; M Mammadov[1]; AR Torky[1]; M Matiakis[1]; E Abate[1]; B Bigalke[2]; AR Rigopoulos[1]
[1]University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany; *[2]Charite - Campus Benjamin Franklin, Berlin, Germany*

Background: Percutaneous closure (LAAC) of the left atrial appendage (LAA) has emerged as an efficacious preventive procedure for patients with non-valvular atrial fibrillation (NVAF) and considerable bleeding risk. The LAmbreTM LAA-occluder is a novel device characterized by full retrievability, repositionability during the implantation process, and the characteristic umbrella with hooks directed towards the LAA, which act synergistically to prevent from LAA perforation. In this systematic review, we summarized the safety and therapeutic success of LAAC using the LAmbreTM occluder evaluating the published data.
Methods & Results: A systematic search of the literature retrieved n=10 publications, encompassing n=403 NVAF patients treated with a LAmbreTM LAAC, with relevant data regarding safety and therapeutic success of the procedure. The majority of the publications were prospective monocenter observational registries, while 4/10 publications were multicenter registry publications. The mean age was 73.6 + 4.0 years, 58% of the treated patients were male, and their mean LVEF was 56.9 ± 5.3%. The mean CHA2DS2-VASc Score was 4.0 + 0.9, and the HAS-BLED score was 3.4 + 0.5. The reported implant success was 99.7%, with a mean procedure time of 45.4 ± 18.7 min, and a mean fluoroscopy time of 9.6 ± 5.9 minutes, with mean contrast agent volume of 96.7 ± 0.7 ml per LAAC procedure. The anticoagulation regime was switched to DAPT post procedure in the majority of the patients (96.8%). Partial recapture was reported in 45.5%, full recapture was done in 25.6%, and resizing of the device was undertaken in 3.6% of the patients, respectively. Major complications were reported in 2.9%, with 0.3% mortality, 1.7% pericardial tamponade, 0.3% stroke, and 0.6% major bleeding complications. During follow up at 6 or 12 months, major adverse cardiovascular events were reported in 3.3%: Stroke or TIA in 1.7%, thrombus formation on the device in 0.7%, and residual flow >5 mm in 1.0 %. No major bleeding or device embolization events were reported. In some publications, the favorable implant properties of the LAmbreTM for difficult anatomies such as shallow or multilobular LAA anatomies were described.
Conclusions: This systematic review on the LAmbreTM LAA-occluder n=403 NVAF patients from various centers and countries summarizes an excellent implant success rate, low periprocedural complications, favorable implant properties for difficult LAA anatomies, and promising follow up clinical outcome. Further larger prospective multicenter registries and randomized trials are warranted to scrutinize the value of LAmbreTM LAA-occluder, comparing its feasibility, safety and efficacy with other LAAC devices.

P2141
Increase of MitraClip and further structural heart disease procedures at a tertiary center by enhanced awareness, standardized screening and interdisciplinary networks

M Noutsias[1]; M Ali[1]; M Matiakis[1]; E Abate[1]; M Mammadov[1]; AG Rigopoulos[1]
[1]University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany

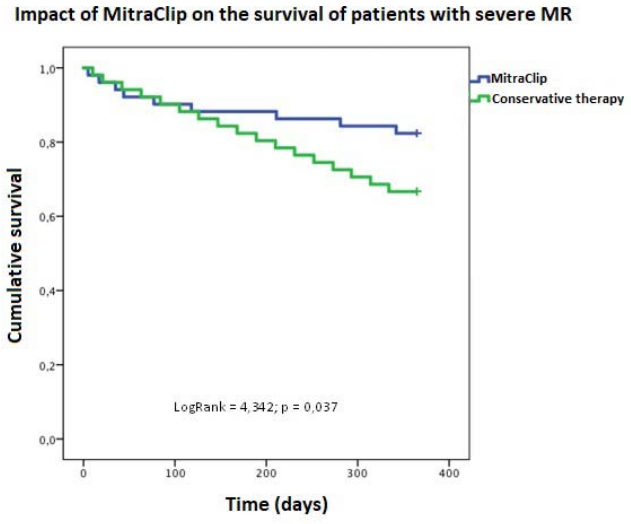
Background: Heart failure patients are often eligible for interventional procedures for structural heart diseases (SHD). Transcatheter mitral valve repair by MitraClip (TMVr-MC) and left atrial appendage closure (LAAC) are important procedures within structural heart disease (SHD) programs. The identification of eligible patients may depend among others on the awareness for these SHD procedures, standardized screening, as well as on interdisciplinary networks for the identification of eligible patients.
Methods & Results: We retrospectively analyzed the number of procedures carried out at a tertiary cardiology center before and after (since 2018) the implementation of a program enhancing awareness for these rather infrequent SHD indications, standardized screening in the echocardiography department and on the wards, as well as the setup of interdisciplinary networks for the improved identification of eligible patients. The set up of this enhanced focus on SHD was directed by the new temporary chief of the department of the tertiary center. The new focus was enhanced by the introduction of related regular continuous education courses for the doctors both at the department of cardiology and in further in-house departments (e.g. internal medicine, emergency department, cardiac surgery; external courses for allocating centers), and the foundation of interdisciplinary networks especially for LAAC indications (with departments of neurology, gastroenterology and nephrology). The numbers of TMVr-MC and LAAC procedures were varying in the years before 2018, and low. After the implementation of the above mentioned program for identifying eligible patients, the numbers increased substantially in this ward for both TMVr-MC (p=0.0058) and LAAC (p=0.0021). Compared with the procedures of 2017, in 2018 we increased the volume of TMVr-MC by 522%, and of LAAC by 1,950 %.
Conclusions: Our data confirm the impressive effects of the implementation of enhanced awareness for the SHD procedures among others by continuous education, standardized screening in the echocardiography department, as well as by introducing interdisciplinary networks for the identification of eligible patients for these rather infrequent SHD indications. These data support also for heart failure patients the importance of enhanced screening and education strategies for SHD indications, also comprising interdisciplinary networks.

P2142

Impact of percutaneous mitral repair with MitraClip on the natural history of severe mitral regurgitation

I Aguiar Ricardo[1]; E Oliveira[1]; AR Francisco[1]; PC Ferreira[1]; J Agostinho[1]; J Rigueira[1]; R Santos[1]; A Nunes-Ferreira[1]; T Rodrigues[1]; N Cunha[1]; P Morais[1]; M Nobre-Menezes[1]; FJ Pinto[1]; P Canas Da Silva[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology, Lisbon, Portugal

Background: severe mitral regurgitation (MR) under conservative management is associated with high morbidity and mortality. Percutaneous mitral valve repair, with MitraClip System is a complement to medical therapy in patients with surgical contraindication. Recent studies question the impact of this system on mortality.
Purpose: to evaluate the prognostic impact of mitral valve repair with MitraClip in the natural history of severe MR.
Methods: prospective, single-center registry of consecutive patients (pts) undergoing percutaneous MR repair with MitraClip system from 2013 to 2018. Demographic, clinical and echocardiographic data were analyzed. Anticipated 1-year mortality was estimated based on the Seattle Heart Failure Model score (Seattle HF score). Kaplan-Meier curves were analyzed for comparison of predicted mortality (by Seattle HF score) and our sample mortality.
Results: 51 procedures (mean age 71.8 ± 13.5 years, 30 males) were performed in pts with symptomatic MR, grade III or IV. 14 pts (27.5%) had primary MR and 37 (72.5%) had secondary MR.
The mean left ventricular ejection fraction was 39.0 ± 14.1%. The success rate per patient was 92.0% and the complication rate was 7.7% (n=4; 2 procedure failures, 1 pericardial effusion and 1 vascular complication).
During a mean follow-up of 615 ± 613 days, there were 14 hospitalizations due to cardiac cause (27.5%) and 17 deaths (33.3%), 9 of which occurred in the first year(17.6%).
According to the Seattle HF score the predicted mean mortality at the end of one year for the sample studied under conservative therapy was 33.1% ± 16.7%, corresponding to 17 deaths. Based on predicted mortality, there was a statistically significant reduction of 8 deaths (LogRank = 4.342, p = 0.037, relative risk reduction of 44.0%).
Conclusion: the percutaneous MR treatment was a safe and effective procedure, with an additional impact on the vital prognosis of pts with severe MR, presenting a relative reduction of mortality risk of more than 40% at 1 year. This reduced real-world experience, with a majority of patients with functional MR, suggests a reduction in mortality that will be in line with the COAPT Trial results.



Graphic 1

P2143

one year mortality outcomes in patients with aortic stenosis and reduced left ventricular ejection fraction undergoing tavr procedure

BARIS Kilicaslan[1]; ERDEM Ozel[1]; BARIS Unal[1]; BAYRAM Arslan[2]; CENK Ekmekci[1]; ONER Ozdogan[1]; FARUK Ertas[2]; CENK Sari[1]
[1]Tepecik Training and Research Hospital, Izmir, Turkey; [2]Dicle University, Diyarbakir, Turkey

Intraduction: In this study we aimed to investigate the association between baseline LVEF and one year mortality of patients after TAVR and also describe the most appropriate patients for TAVR procedure in reduced LVEF with AS.
Method: Records of 133 patients who underwent TAVR in two heart centers were evaluated into two groups (Group 1 (LVEF >40%)(n=82), Group 2 (LVEF < 40)) (n=51). We examined rates of 1-year mortality and clinical parameters.
Results: Baseline characteristics of patients were paired. Over the first year of follow-up after TAVR, patients with LV dysfunction had similar rates of death with patients who had preserved LVEF. Procedural success, complication rates and in-hospital mortality rates were similar in both groups. (table 1) Aortic peak and mean gradients were correlated with 1- year mortality (r=0.180, p=0.038;) (r=0.178, p= 0.04). LVEF was significantly increased after TAVR procedure in group 2 patients (p<0.01). Logistic regression analyses showed that 1-year mortality was related to patient's age (t=-2,31, p=0.02), creatinine levels (t=-3,34, p<0.01) and pulmonary artery systolic pressure (SPAP) (t=-2,61, p=0.01).
Conclusion — In our study LVEF was increased in HF patients after TAVR. This might be reflect myocardial reserve and it is important for post procedural period and could be protected earlier stages of HF patients with AS. By the time myocardial necrosis and irreversible myocardial damage will be seen therefore mortality rates are increased. Early periods of AS in HF would be most effective time for TAVR. As a conclusion some parameters like patients' age, creatinine levels, and SPAP are important as LVEF in patients with AS undergoing TAVR.

Comparison results of two groups.

	Group 1 (LVEF≥40%)	GROUP 2 (LVEF<40%)	T-Test (p)
1 year mortality (n)	17/82	9/51	0.564
Age (year)	77.6±6.2	75.3±8	0.105
LVDD1 (mm)	48.2±5.2	55.2±6.3	<0.01

P2144

Patients with prosthetic valve endocarditis admitted in non-reference centers may substantially benefit from infectious diseases specialist wisdom in antibiotic regimen selection

MM Monica Mariana Baluta[1]; E Panaitescu[2]
[1]Carol Davila University of Medicine-St Pantelimon Clinical Emergency Hospital-Cardiology Department, bucharest, Romania; [2]University of Medicine and Pharmacy Carol Davila, Complementary sciences Dpt., Medical Informatics and Biostatistics, Bucharest, Romania

Background. The fatal outcome of prosthetic valve endocarditis (PVE) was improved over time due to changes in management strategies. The optimal treatment approach involves now multiple hospital specialists but in the early 21st century, infectious disease (ID) physicians were the ones who effectively combined bactericidal antibiotic to determine antimicrobial clearance and adequately cure the infection.
Purpose. To identify whether PVE patients admitted in non-reference centers may benefit from an initial medical strategy established by an infectious disease physician with antibiotic regimens that not fulfill cardiologist guidelines necessarily.
Method. Retrospective study which included 56 with early and late PVE patients admitted in two non-reference centers over 5 years period contemporary with The International Collaboration on Endocarditis-Prospective Cohort Study. Heart failure symptoms were present in 69% of early PVE and 41 % in late PVE. Demographic,

clinical, laboratory and echocardiographic findings were analyzed at baseline and after exclusion of patients lost to follow up.
Results. 36 men and 20 women included in this study had 54.64±11.34 years (28–74y) at baseline. They had either early PVE (n=29) or late PVE (n=27). Antibiotic therapy (AT) established by ID specialist generated the cure of the disease in71% cases with an in-hospital death rate of 2% and a rate of referral to early surgery of 21,4%. Full antibiotics course duration was 33.55 ± 12.8 days. Combined therapy (medical and surgical) determined an excellent outcome in 90.4% patients at the end of full antibiotic cure. The positive outcome does not depend on the type of antibiotic selection (multivariate analysis) even if they are not per cardiologists guidelines. Moreover the ID physician changed frequently antibiotic type due to intolerance of some AT (Oxacilline, p=0.035; Vancomycin, p=0.005). Imipenem+Amikacin when combined, they determine less adverse effects, a shorter time to fever disappearance (p=0.004). There was no relationship between heart failure presence or aggravation and the type of antibiotic regimen. Conclusion. Irrespective of PVE type or etiology, decision making process for antibiotic treatment conducted by infectious disease specialist determine a high rate of PVE cure and reduce mortality directly attributable to infection.

P2145
Current characteristics of infective endocarditis in a developing country: a prospective cohort study

S Shumaila Furnaz[1]; NQ Qamar[1]; TS Saghir[1]
[1]National Institute of Cardiovascular Diseases (NICVD), Cardiology, Karachi, Pakistan

Objective: The epidemiology and the clinical features of infective endocarditis(IE) has changed substantially over past few years in the developing countries. We aimed to explore the current trends and outcomes of IE in a tertiary care hospital in Karachi, Pakistan.
Methods: Prospectively collected data was analyzed from the National Institute of Cardiovascular Diseases (NICVD) registry from June 2017 to April 2018.The primary outcome was length of hospital stay, and in-hospital mortality was the secondary outcome. Fisher's exact test was used to compare categorical variables, while Mann Whitney or Kruskal Wallis tests were used to compare continuous variables. Univariate and multivariate logistic regression was conducted to identify predictors of in-hospital mortality.
Results: A total of 49 patients were included, of which 33 were males (67.3%). The mean age of the participants was 28.1 years. Length of stay ranged from 1 to 92 days. Upon univariate analysis, male sex was found to be associated with longer length of stay (median 24.0 days) than female sex (median 11.0 days) (p=0.008). Of the 33 (67.3%) patients with positive blood cultures, streptococcus viridans (24.2%) was found to be the most common individual pathogen. Only cerebral complications (p<0.001), indication of surgery/procedure (p<0.017), and positive valve or lead culture (p<0.002) were identified as independent predictors of length of stay. Eight patients died during hospital stay, leading to an in-hospital mortality rate of 16.3. Conclusion: Independent predictors for length of hospital stay in patients with IE in our study were cerebral complications, indication of surgery/procedure, and positive valve or lead culture. A relatively high mortality rate of 16.3% was detected

Myocardial Disease

P2146
Myocardial fibrosis and long-term outcome after septal myectomy in hypertrophic cardiomyopathy

V Vadim Zaitsev[1]; K Badaev[2]; A Gurshchenkov[1]; A Ryzhkov[1]; L Mitrofanova[1]; E Kazakova[1]; O Moiseeva[1]
[1]Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation; *[2]Saint-Petersburg State Medical University named I.P.Pavlov, Saint-Petersburg, Russian Federation*

Background: Diastolic dysfunction, life-threatening rhythm disturbances and sudden cardiac death are associated with myocardial fibrosis in patients (pts) with hypertrophic cardiomyopathy (HCM). We assumed that the long-term outcome after septal myectomy depends on myocardial fibrosis severity.
Materials and methods: 47 pts (m:f 18:29) undergoing septal myectomy for HCM and 30 healthy pts as control group were included. ECHO, contrast enhancement cardiac MRI, histology specimens (obtained at septal myectomy) analysis, circulating fibrosis biomarkers (TGFß1, MMP-2,9, TIMP-1, galectin-3, sST2, CITP, PICP, PIIINP, NT-proBNP) were performed. Pts with HCM were examined before surgery, as well as 7 days, 6 and 12 months after surgery.
Results: The mean value of maximum LVOT gradient was 88 (55; 192) mm Hg, maximum wall thickness - 22±3 mm in pts with HCM. The extent of late gadolinium interventricular septum enhancement ranged from 32 to 53%. Square of myocardial fibrosis by histological data was 13.9±6.9%. Increased serum PICP, PIIINP, galectin-3, sST2, TGFß1 levels were revealed in pts with HCM in comparison with the controls. Increased CITP level was associated with myocardial fibrosis by histological assay (r=0.356; p=0.028) and TIMP-1 level was related with wall thickness (r=0.502; p<0.001). Nevertheless, level MMP-9 was increased. Male pts had a higher level of TIMP-1 (p = 0.004), level of sST2 (p = 0.0008) and risk of SCD (=0.028) in compare with female pts. Pts with severe myocardial fibrosis had a negative prognosis of left atrium size reduction.
Conclusion: Circulating fibrosis markers can be used for risk stratification in pts with HCM. Myocardial fibrosis is mainly determined factor in the long-term outcome in pts with HCM after septal myectomy.

Clinical characteristics of patients

	Patients with HCMM±n=47	The control groupM±n=30

P2147
Etiological structure of phenocopies of hypertrophic cardiomyopathy in different age groups

AA Poliakova[1]; EN Semernin[1]; AN Krutikov[1]; AA Kostareva[1]; AYA Gudkova[2]
[1]Almazov Federal Medical Research Centre, Saint-Petersburg, Russian Federation; *[2]Pavlov First Saint Petersburg State Medical University, Saint-Petersburg, Russian Federation*

Introduction . Etiology of hypertrophic cardiomyopathy (HCM) can be heterogeneous, with sarcomeric gene disease as the leading cause in up to 60% of the patients, and with a number of phenocopies in about 5%–10% of the patients. However, publications reflecting the etiological structure of phenocopies of HCM in different age groups are not enough.
Purpose. To study the etiological structure of phenocopies of HCM in different age groups of patients of the North - West region of Russia.
Methods. The study included 321 patients with HCM. The standard clinical-laboratory and instrumental methods of diagnosis idiopathic HCM and phenocopies of HCM were applied.
Results. Of the 153 studied elderly patients with HCM: idiopathic HCM was diagnosed in 85% of the cases (n = 131), phenocopies of HCM were found in 15% of the patients (n = 22). In the etiological structure of phenocopies of HCM in the elderly patients, transthyretin amyloidosis was observed in 10% of the cases: 6% (n = 9) of the patients were affected by wild-type of transthyretin amyloidosis, 4% (n = 6) — hereditary transthyretin amyloidosis (Val30Met-amyloidosis (n=2) and not Val30Met-amyloidosis (n=4)). The second most common phenocopy of HCM is AL-amyloidosis (4%, n=6). Acromegalic cardiomyopathy was verified in 1 patient (1%).
In the middle age group idiopathic HCM was diagnosed in 85% of the cases (n = 86), phenocopies of HCM were found in 15% oh the patients: isolated cardiac sarcoidosis - in 3% (n = 3), AL-amyloidosis - in 11% (n=11) and hereditary transthyretin amyloidosis - in 1% (n=1) of the cases.
At the young age group of the patients, idiopathic HCM was observed in 92% of the cases (n=62), phenocopies of HCM were diagnosed in 8% of the patients: Danone disease — in 2% (n = 1), isolated cardiac sarcoidosis — in 2% (n = 1) and AL-amyloidosis — in 4% (n = 3) of the cases.
Conclusions. Idiopathic HCM prevails in all age groups. Etiological structure of phenocopies of HCM in the elderly patients is represented mainly hereditary and wild-type of transthyretin amyloidosis. At the young age group are more common glycogen storage diseases. AL-amyloidosis is found in all age groups of patients.

Analysis of ICD therapies in patients with hypertrophic cardiomyopathy

L L Lisa Lauren Buttigieg[1]; M Zammit Burg[1]; T Felice[1]
[1]*MaterDei Hospital, MaterDei Hospital, Malta, Malta*

Background: Patients suffering from Hypertrophic cardiomyopathy (HCM) are at an increased risk of sudden cardiac death (SCD). In Malta, there are approximately 150 patients with HCM being followed-up at the Inherited Cardiomyopathy Clinic of which 19 have had an Implantable Cardioverter Defibrillator (ICD) implanted.
Purpose: To retrospectively analyse the risk of SCD and ICD therapies delivered in patients with HCM at our Hospital, Malta.
Method: Data Collection was done using IT systems used in the Department of Cardiology (CVIS). The HCM Risk-SCD calculator was used appropriately to calculate risk of SCD at 5 years.
Results: Locally, 19 patients with HCM have had an ICD inserted. 69% were males and 31% were females. The mean age at device implantation was 50 years. ICDs were inserted in 2 patients <16years of age, in 1 patient with Fabry's disease and in 3 patients for secondary prevention. For the other 13 patients, the HCM Risk SCD calculator was used to calculate risk of SCD at 5 years. 5 patients had >6% risk of SCD at 5 years meaning that ICD insertion should be considered whereas 8 patients had 4-6% risk of SCD at 5 years meaning that ICD insertion may be considered. Cardiac MRI was used in most borderline cases to decide regarding ICD insertion. 15.7% (n=3) had appropriate therapies for VT; n=2 had SCD risk>6% and n=1 had SCD risk 4-6% (SCD risk 5.92%) at 5 years. One patient received anti-tachypacing (ATP) and shock therapies whereas the other two patients received only ATPs. 15.7% (n=3) had inappropriate therapies for AF. 15.7% (n=3) had complications related to device insertion including upper limb thrombosis, upper limb swelling and lead dislodgement.
Conclusion: ICD therapies are effective in terminating ventricular arrhythmias leading to SCD in patients with HCM. Identifying patients at risk of SCD is still an ongoing challenge. 15.7% have received appropriate therapies for VT.

P2149

Is 24-hour Holter ECG monitoring a useful baseline assessment for the detection of arrhythmias in patients with peripartum cardiomyopathy?

C A Charle Andre Viljoen[1]; J Hoevelmann[2]; F Azibani[2]; O Briton[2]; A Chin[1]; K Sliwa[2]
[1]*University of Cape Town, Division of Cardiology, Cape Town, South Africa*;
[2]*University of Cape Town, Hatter Institute for Cardiovascular Research in Africa, Cape Town, South Africa*

Background: Peripartum cardiomyopathy (PPCM) is an important cause of pregnancy-associated heart failure, which occurs in previously healthy women towards the end of pregnancy or within the first five months post-partum. The 12-lead ECG is frequently abnormal in patients with PPCM. These abnormal ECG features predominantly include waveform abnormalities such as T wave inversion and a prolonged QT interval. However, data on arrhythmias remain sparse in this population. We aimed to evaluate whether 24-hour Holter ECG monitoring in addition to a routine 12-lead ECG recording is useful to detect arrhythmias in PPCM.
Methods and Results: Eleven consecutive, consenting patients with PPCM were prospectively enrolled, of which two women presented during pregnancy. In addition to clinical, echocardiographic and electrocardiographic data, a 24-hour Holter ECG was performed for all patients. This cohort had a median age of 32.25 years (IQR 26.35-35.65) and BMI of 27.77 kg/m2(IQR 24.04-37.18). Baseline clinical assessment recorded a median systolic blood pressure of 114mmHg (IQR 103-104) and diastolic blood pressure of 72mmHg (IQR 69-87). Overall, the left ventricle was dilated (LVEDD 63mm) with severely reduced left ventricular ejection fraction (median LVEF 31%, IQR 25-35). The 12-lead ECG recorded sinus tachycardia in more than half the cohort (median QRS rate of 88). With a median QTc interval of 451ms (IQR 411-470), a third of this cohort presented with a prolonged QTc interval. The average heart rate on Holter monitoring ranged between 73 and 119. Whereas none of the patients had any episodes of bradycardia, the average time in tachycardia on Holter monitoring was 30% (IQR 13-39). None of the 12-lead ECGs or Holter recordings found evidence of atrial fibrillation, supraventricular tachycardia or atrioventricular blocks. The Holter ECG recorded non-sustained ventricular tachycardia (VT) in two patients, both of which had a prolonged QTc interval on their baseline ECG and an LVEF of <35%. Subsequent management included an implantable cardioverter-defibrillator in the one patient and cardiac transplantation in the other. The three patients that were readmitted for heart failure during the study period had a significantly higher average time in tachycardia on Holter (44.33% ±26.41 versus 25.63% ±19.06). There was a poor correlation between the QRS rate on the 12-lead ECG and the average heart rate on Holter recordings (Spearman's rho 0.267, P=0.430).
Conclusion: Holter monitoring may be more accurate than the 12-lead ECG in defining the extent of sinus tachycardia. This is important as sinus tachycardia has been shown to be associated with poor outcome in PPCM. Moreover, the Holter ECG was able to detect non-sustained VT in two patients, which influenced clinical decision making. Our findings highlight the importance of a larger study to evaluate the vulnerability of this population to the development of arrhythmias and its impact on long-term outcome.

P2150

Cardiomyopathies due to primary myodystrophies in the russian cohort of patients: clinical, morphological, genetic diagnostics and outcomes

O V Olga Blagova[1]; AV Nedostup[1]; VP Sedov[1]; EA Kogan[1]; AG Shestak[2]; ME Polyak[2]; EV Zaklyazminskaya[2]
[1]*I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation*;
[2]*Russian Research Center of Surgery, Moscow, Russian Federation*

Purpose: to analyze the clinical signs, follow-up and outcomes of cardiomyopathies in different genetically verified and unspecified primary myopathies in the Russian cohort of patients.
Methods: the study included 9 patients, five male and four female, with cardiac involvement (predominantly by the phenotype of dilated cardiomyopathy, DCM) in the primary myodystrophies, mean age 31.4 ± 13.8 years (16 to 63), which was 4% in total cohort of 220 patients with DCM. The examination included the investigation of the anti-heart antibodies, the genome of viruses, creatine phosphokinase, EchoCG, Holter monitoring, cardiac MSCT (n=7), MRI (n=3), electroneuromyography (n=5), neurologic study (n=7), endomiocardial biopsy (n=1), explanted heart examination (n=3), skeletal muscle biopsy (n=1), autopsy (n=1), direct Senger's sequencing of the genes LMNA, DES, EMD, MYBPC3, TAZ, TPM1, LDB3, MYL2, ACTC1, MYL3, MYH7, TNNI3, TNNT2.
Results. Pathogenic mutations were detected in 7 patients: in 3 patients from unrelated families in the DES gene, in 2 in the LMNA gene and in 2 members of the same family in the EMD gene. De novo mutation was diagnosed in 2 out of 7 patients. In 1/3 patients (2 with mutations in the DES gene and 1 with the unknown genetic nature of the disease), a noncompact myocardium was detected. The mean age of cardiomyopathy debut was 28 [18; 30] years. Chronic heart failure 3-4 NYHA class was diagnosed in 88.9%. The average LV EDD was 6.0 [5.3; 6.5] cm, EF 30% [19; 41.5]. Desminopathy was characterized by a pronounced body mass deficit, a decrease in the voltage of the QRS complexes and left bundle branch block. Lamino- / emerinopathies were characterized by a progressive AV block and sick sinus syndrome. In all forms there is a high frequency of unstable (77.7%) and stable ventricular tachycardia / ventricular fibrillation (44.4%). Associated myocarditis caused decompensation in half of the patients (EF 22.0 ± 7.9% v 44.5 ± 16.3% in patients without myocarditis, p <0.05). ICD / CRTD are implanted in 2 / 3 patient, a dual chamber pacemaker - in one patient. The rate of appropriate shocks was 60.0%. In one case, the ICD was replaced by CRTD due to the increase in heart failure. At the time of follow-up 29 [6; 45] months three patients died due to heart failure and three patients underwent successful heart transplantation (66.7% in total). Three women with mutations in DES, LMNA and EMD genes are alive and free from transplantation (all three successfully survived pregnancy). Conclusions. Target DNA-diagnostics is highly informative in this category of patients (77.8% efficiency). DCM in verified myopathies should be considered as an indication for the implantation of cardioverter-defibrillators or CRTD (if there are the indications for continuous stimulation), preferably before pacemakers. The prognosis of cardiomyopathy in primary myodystrophies is unfavorable, especially in men and in the patients with the unknown genetic nature of the disease.

Familial acute myocarditis or inherited dilated cardiomyopathy antigen-triggered debut? The role of genetics in understanding disease.

P Jorda[1]; M Farrero[1]; E Sandoval[2]; MA Castel[1]; D Pereda[2]; E Quintana[2]; E Arbelo[1]; A Sanchez[3]; O Campuzano[4]; J Casal[1]; R Brugada[5]; L Mont[1]; M Castella[2]; F Perez-Villa[1]; A Garcia-Alvarez[1]
[1]*Hospital Clinic de Barcelona, Cardiology Department, Institut Clínic Cardiovascular, Universitat de Barcelona, Barcelona, Spain*; [2]*Hospital Clinic de Barcelona, Cardiovascular Surgery Department, Insitut Clinic Cardiovascular, Barcelona, Spain*; [3]*Hospital Clinic de Barcelona, Department of Genetics, Insititut Bioquímica i Genètica Molecular, Barcelona, Spain*; [4]*University of Girona, Medical Science Department, Cardiovascular Genetics Center, IDIBGI, Girona, Spain*; [5]*University Hospital de Girona Dr. Josep Trueta, Cardiology Department, Cardiovascular Genetics Center, IDIBGI, Universitat de Girona, Girona, Spain*

A familial dilated cardiomyopathy (DCM) manifested as cardiogenic shock (CS) is presented.The first case occurred in 2004 when the family member IV.6 was admitted for acute heart failure (HF) at the age of 15. Being previously asymptomatic, she presented a 15-day course of abdominal pain, nausea and vomiting followed by progressive shortness of breath. Severe biventricular impairment with dilated left

ventricle (LV) was present at admission. HF rapidly progressed to CS in spite of inotropic and intraaortic balloon pump (IABP) therapy requiring a biventricular assist device (BiVAD). Diagnosis suspicion was fulminant myocarditis as biopsy showed severe myocardial neutrophilic infiltration. She received heart transplantation (HTx) 9 days after BiVAD implant.In 2005, a cousin of her mother (III.1) was admitted at the age of 38 due to a 45-day onset of progressive HF preceded by fever and myalgias. At admission, he was in CS with severe LV impairment and dilatation. He was transplanted 2 days after in INTERMACS 2 situation. No myocarditis signs were observed in the explanted heart.Nine years later, in 2016, the sister of the index case (IV.7) was admitted due to CS at 17 years old. Echocardiography showed severe LV dilatation and dysfunction. Rhinorrhoea and dry coughing had been present 15-days before. An LV assist device was implanted (INTERMACS 2) and she received HTx after 12 days. No signs of myocarditis were observed at pathology. At that time, familial disease suspicion raised and genetic study was performed (see figure). The 4 affected members carried the same variant p.Gln88* in the BAG3 gene, previously reported as pathogenic. The 2 sisters also had a novel variant -p.(Pro52Arg)- in BAG3, classified as probably pathogenic. In addition, two other variants in the TTN (VI.6 and IV.7) and RyR2 (IV.7) genes were identified, and both classified of uncertain significance.Family screening showed that the mother of cases IV.6 and IV.7 (III.6) carried the pathogenic variant BAG3_p.Gln88*, and the variants in TTN and RYR2. The screening at 45 years old demonstrated DCM and HF (NYHA II). The grand-mother of cases IV.6 and IV.7 (II.3), carried BAG3_p.Gln88* and the variant in the TTN gene. Clinically assessment at the age of 67 ruled out DCM.More than 60 genes have been reported as disease-causing in inherited DCM. Pathogenic variants in the BAG3 gene have been associated to an aggressive course of DCM. Interesting features are observed in this family; DCM appeared at very young ages, specifically in 2 individuals (15 and 17 years-old). Early onset and myocarditis-like presentation may be partially explained by compound heterozygous mutations in BAG3 and/or combination with other genes (TTN and/or RyR2). It is of notable interest that all 3 cases that progressed to CS had previous symptoms of viral infection suggesting an infectious antigenic trigger that activates the disease in genetically predisposed patients.

Clinical, echocardiographic and laboratory profile of dilated cardiomyopathy with and without atrial fibrillation.

E M Dziewiecka[1]; A Karabinowska[1]; M Glimak[2]; M Winiarczyk[2]; A Karapetyan[2]; S Wisniowska-Smialek[1]; P Podolec[1]; P Rubis[1]
[1]John Paul II Hospital, Department of Cardiac and Vascular Diseases, Krakow, Poland; *[2]Jagiellonian University Medical College, Students' Scientific Group at the Department of Cardiac and Vascular Disease, Krakow, Poland*

Introduction: Atrial fibrillation (AF) is the most common chronic arrhythmia in heart failure. The epidemiology, pathology and clinical significance of AF in dilated cardiomyopathy (DCM) is poorly defined.
Methods: Between January 2010 and October 2018 we analysed hospital records of 373 DCM patients. Patients were divided according to the presence or absence of AF.
Results: AF was present in 118 patients (31.6%). Patients with AF were older, had larger BMI and worse NYHA class, larger left and right atrial areas (LAA and RAA), pulmonary arterial systolic pressure (PASP) and lower tricuspid annular plane excursion (TAPSE) [Table 1]. However, both groups did not differ in terms of ejection fraction (EF), left ventricle end-diastolic diameter (LVEDd), and NT-proBNP and troponin (hs-TnT) levels. The predictive value of those parameters were assessed in univariate and multivariate logistic regression analyses. Only age and RAA were found to be AF predictors in multivariate analysis. The diagnostic accuracy of the predictive model comprised of those two parameters was 0.774 [95%CI 0.721-0.827; p<0.05].
Conclusions: Almost one-third of unselected DCM patients had AF. Most clinical and echocardiographic parameters differentiate patients with and without AF. However, only age and RA area were found to be independent AF predictors. Interestingly, EF and NT-proBNP were similar in both groups.

Table 1

	Baseline characteristics			Univariate regression	Multivariate regression
	With AF (n=118)	Without AF (n=255)	p-value	p-value	p-value
Age [years]	58.6 ± 12.0	51.7 ± 14.1	<0.001	<0.001	0.04
BMI [kg/m2]	29.0 ± 4.2	26.6 ± 5.8	0.03	0.08	
NYHA	2.7 ± 0.8	2.4 ± 1.2	0.006	0.04	0.58
LVEDd [mm]	66.2 ± 9.9	66.4 ± 10.2	0.81		
PASP [mmHg]	36.0 ± 13.0	31.5 ± 14.2	0.002	0.03	0.38
EF [%]	26.8 ± 9.9	26.4 ± 10.2	0.48		
TAPSE [mm]	16.5 ± 4.7	20.0 ± 10.4	<0.001	<0.001	0.27

P2154

Left ventricular functional reserve is a main determinant of exercise capacity in patients with idiopathic dilated cardiomyopathy

H Hala Badran[1]; N Faheem[1]; M Rabaie[1]; MH Yacoub[2]
[1]Menoufiya University, Shebin, Egypt; *[2]Imperial College London, London, United Kingdom of Great Britain & Northern Ireland*

Objectives:
Myocardial mechanics and ventricular dyssynchrony are frequent findings in idiopathic dilated cardiomyopathy (IDCM). We hypothesized that IDCM patients have differentially abnormal systolic function reserve limiting their exercise capacity and related to cardiac phenotype. We investigated whether exercise capacity is independently related to contractile reserve as measured by 2D strain imaging in (IDCM).
METHODS: 30 IDCM patients(39.1±12 years) and 33 healthy individuals underwent resting and peak exercise echocardiography using 2D-strain imaging. Peak longitudinal strain(sys), strain rate(SRsys,SRe, SRa) were measured in apical views. Circumferential (circ) sys, LV twist were analyzed from short axis views. LV systolic dyssynchrony was measured from regional longitudinal strain curves as SD of TTP (time from beginning of Q wave on ECG to peak sys) between 12 segments. The differences between resting and peak exercise values were analyzed (Δ) and the functional reserve is calculated as Δ /resting value.
RESULTS: The absolute values of longitudinal sys and SRsys were significantly smaller in IDCM patients than control at segmental and global level both at rest and at peak exercise (P < .001). Functional reserve was markedly impaired in IDCM(sys: 7±6% versus 28±5% SRsys: -39±11% versus 40±12%; SRe : -26±10% versus 48±9% SRa -6±14 versus 21±22 %; %Circ strain: 22.4±9.3 versus 33.4±50%) compared to control group (P < .0001). LV mechanical dyssynchrony (TTP-SD) was marked in IDCM at rest and amplified at peak stress (68±35, 104±70 ms) compared to control (28±17, 21±12 ms) P < .000. Exercise capacity in IDCM showed direct correlation to both systolic and diastolic reserve(P < .01).Multivariate regression analysis demonstrated that reserve in early diastole, SRe (β 0.501; P=0.001) and late diastole , SRa (β:0.722; P=0.007) were independent predictor of exercise capacity.
CONCLUSION: IDCM patients have limited systolic and diastolic function reserve and more dynamic dyssynchrony with exercise compared to healthy individual. However functional reserve during diastole remains the principle and independent predictor of exercise capacity in this population.

P2155

New insights into genetic architecture of recent onset dilated cardiomyopathy by whole-exome sequencing

A Chaloupka[1]; L Piherova[2]; I Grochova[1]; J Krejci[1]; J Binova[3]; B Kmoch[2]; L Spinarova[1]; M Kubanek[3]

[1]St. Anne's University Hospital, 1st Department of Internal Medicine, Brno, Czechia; *[2]First Faculty of Medicine and General Teaching Hospital, Department of Paediatrics and Adolescent Medicine, Prague, Czechia*; *[3]Institute for Clinical and Experimental Medicine (IKEM), Prague, Czechia*

Funding Acknowledgements: This study was supported by the re- search grant of the Ministry of Health, Czech Republic: MZ 15-27682A. All rights reserved.

Background: Recent-onset dilated cardiomyopathy (DCM) is a disease of heterogeneous aetiology and clinical outcomes ranging from complete recovery of left ventricular (LV) systolic function to rapid progression to end-stage heart failure or sudden cardiac death. A substantial proportion has genetic determination. Recognition of the genetic component, particularly in patients with recent-onset DCM or their asymptomatic relatives, could improve risk stratification and thus diagnostic and therapeutic management.Purpose:In this pilot study, we are first to assess the genetic architecture of recent-onset dilated cardiomyopathy in the Czech Republic by whole-exome sequencing and correlate genotype with LV reverse remodelling, a marker of favourable prognosis.

Methods:This multi-centre prospective observational study enrolled 83 patients with recent-onset DCM with a history of symptoms less than 6 months for whole-exome sequencing. All patients underwent 12-month clinical and echocardiographic follow-up. LV reverse remodelling was defined as an absolute increase in LV ejection fraction > 10% accompanied by a relative decrease of LV end-diastolic diameter 10% at 12 months.

Results: We identified disease-related variants in 45 patients (54%). Left ventricular reverse remodelling occurred in 28 patients (34%), most often in carriers of isolated titin truncated variants, followed by individuals with a negative result and carriers of other disease-related variants (56% vs. 42% vs. 19%, P 0.041).

Conclusion:A substantial proportion of recent-onset DCM cases has a monogenic or oligo-genic genetic background. Carriers of non-titin disease-related variants are less likely to reach LV reverse remodelling at 12- months, which could be seen as a negative prognostic marker of disease development. Thus, genetic testing could contribute to better prognosis prediction and individualized treatment of patients with recent onset DCM. Further studies are needed to assess the relationship between genotype and hard clinical outcomes.

Genotype and LV reverse remodelling

	Exome negative or non- conclusive(n=38)	Isolated titin truncating mutation(n=9)	Other variant or combination(n=36)	P value
12 months Δ LVEF absolute(%)	16 (6-23)	15 (9-34)	6 (3-15)	0.036*
12 monthsΔ LVEF > 10 points (n= 44; 53%)	24 (63%)	7 (78%)	13 (36%)	0.019*
12 monthsΔ LVEDD < -10%(n= 34; 41%)	18 (47%)	6 (67%)	10 (28%)	0.058
Δ LVEF > 10 points and Δ LVEDD < -10%(n=28;34%)	16 (42%)	5 (56%)	7 (19%)	0.041*

Relationship between results of whole-exome sequencing and LV reverse remodellingn – number, ΔLVEF – change of left ventricular ejection fraction, Δ LVEDD – change of left ventricular end-diastolic diameter

QRS dispersion in dilated cardiomyopathy, clinical and echocardiographic correlations

R Rodica Diaconu[1]; I Donoiu[2]

[1]Emergency County Hospital, Craiova, Romania; *[2]University of Medicine and Pharmacy, Craiova , Department of Cardiology, Craiova, Romania*

Introduction: QRS dispersion is the difference between the maximum and minimum QRS complex duration measured on standard ECG. It has been suggested that an increased QRS dispersion is a marker of inhomogeneous ventricular depolarization and it could be associated with negative prognosis in different clinical settings: ischemic heart disease, heart failure, cardiomyopathies.

Objectives: We analyzed the correlates of QRS dispersion in an unselected group of dilated cardiomyopathy patients.

Methods: We included 90 patients (72 men, 65,7 ± 12 years). We performed standard echocardiography and measured serum creatinine, sodium and potassium. QRS dispersion was measured from standard 12-lead ECGs, using a computerized method.

Results: Mean LVEF was 27,8 ± 9,5%. Mean QRS duration was 115,4 ± 31,6 ms. Maximum QRS duration was 129,6 ± 49,4 ms and minimum QRS duration was 83,4 ± 36,3 ms. Mean QRS dispersion was 46,1 ± 23,8 ms, median – 41,1 ms. Using a cut-off value of 50 ms for QRS dispersion we identified patients with lower LVEF (25,4 ± 10,2% vs. 29,1 ± 9%, p Mann-Whitney = 0,023) and lower potassium (4,4 0,5 mmol/l vs. 4,7 0,8 mmol/l, p Mann-Whitney = 0,034). QRS dispersion correlated strongly with maximum QRS duration (r = 0.717, p < 0.0001, Pearson correlation).

Conclusion: In patients with dilated cardiomyopathy QRS dispersion correlated with LVEF and serum potassium level. Its independent value is questionable due to the strong correlation with QRS maximum duration.

Genetic screening of patients with dilatated cardiomyopathy assessed by next-generation sequencing

J Janos Borbas[1]; A Tringer[1]; V Nagy[1]; B Csanyi[1]; L Hategan[1]; A Borbely[2]; N Nyolczas[3]; R Faludi[4]; Z Hegedus[5]; I Nagy[6]; T Forster[1]; R Sepp[1]

[1]University of Szeged, 2nd Deparment of Internal Medicine Clinic and Cardiological Center, Szeged, Hungary; *[2]University of Debrecen, Institute of Cardiology, Debrecen, Hungary*; *[3]Medical Centre, Hungarian Defence Forces, Medical Centre - Cardiology, Budapest, Hungary*; *[4]University of Pecs, Heart Institute, Pecs, Hungary*;

[5]Biological Research Centre of Szeged, Institute of Biophysics, Szeged, Hungary; [6]Biological Research Centre of Szeged, Institute of Biochemistry, Szeged, Hungary

Background: Dilated cardiomyopathy (DCM) is a myocardial disease characterized by left or both ventricular dilation and reduced systolic function. One quarter of the cases are inherited with autosomal dominant pattern, caused by mutations in the genes encoding for cytoskeletal-, sacomer/Z-band-, nuclear membrane or intercalated disc proteins. Involvement of the titin gene could be the most frequent.
Aim: In our work molecular genetic analysis was carried out in patients with DCM using a new method, called Next-Generation Sequencing.
Patients and methods: Twenty-one patients with dilated cardiomyopathy (11 female, 10 male, avg. age: 43±21 year) were assessed by genetic screening. Genotyping was performed by Next-Generation Sequencing and validated by capillary sequencing. During next-generation sequencing we performed the targeted resequencing of 103, known causative cardiomyopathy genes. Target region covered 500.000 base pairs.
Results: Pathogenic or likely pathogenic genetic variants were identified in 6 patients (6/21, 29%) during our genetic examination. Four of them affected the titin gene (TTN, Ser8519*, Thr18527fs, Val18616fs, Glu13828fs), one affected beta myozin heavy chain gene (MYH7, Arg904Cys), and one affected the desmoplakin gene (DSP, Leu1669fs). All of the TTN variants were novel and were predicted to lead to truncation of the protein (stop codon or frame-shift).
Summary: Our findings show that causative genetic variants could be identified in 30% of Hungarian patients with DCM. Most of them affect the TTN gene.

Sympathetic Renal denervation in patients with refractory arterial hypertension: 2-years follow-up

Z Shugushev[1]; D A Maximkin[1]; A Chepurnoy[1]; O Safonova[1]; A Faibushevich[1]
[1]RUDN University, Moscow, Russian Federation

Funding Acknowledgements: Russian Academic Excellence Project 5-100

Aim: to evaluate the efficacy of the sympathetic renal denervation procedure in patients with refractory arterial hypertension and heart failure.
Methods: the study included 72 patients with refractory arterial hypertension. We used randomization in 2 main groups: the Group I (n=36) included patients, who underwent denervation procedure of the main trunk of the renal artery and the Group 2 (n=36) - included patients who underwent denervation procedure in main trunk and also in second-order renal arteries. Additionally, patients were divided into 2 subgroups: the subgroup A (n=30) included patients, who underwent denervation procedure with a SYMPLICITY catheter, and the subgroup B (n=42) - included patients who underwent denervation procedure with a VESSIX catheter. Also, the renal denervation procedure efficacy, in patients with chronic heart failure (CHF) was analyzed. In all groups, 24-hour blood pressure monitoring, echocardiography and a 6-minute walk test were monitored. Inclusion criteria: refractory hypertension, age of patients 18-85 years, systolic blood pressure (SBP) ≥140/90 mmHg and ≥130/90 mmHg in patients with diabetes mellitus, functioning kidneys, renal arteries ≥40 mm in diameter and the length of the site up to the first bifurcation of at least 20 mm, absence of stenoses in the renal arteries, GFR≥40 ml/min/1.73m^2, suitable anatomy of the renal arteries for endovascular procedure.
Results: 24 months result after the denervation procedure was demonstrated significantly decreased SBP in patients of both groups. In group I, it was, compared with pre-operative data (174.9±1.6 vs. 151.7±2.3 mmHg, respectively; p<0.05), and in group II - 181.9±2.1 vs. 140.4±3.8 mmHg, respectively; p<0.05). However, when comparing SBP values between groups, SBP in group I was significantly higher, than in group II (151.7±2.3 vs. 140.4±3.8 mmHg, respectively; p<0.05). In addition, the average number of drugs in group I was decreased to 2.1±0.8 after 24th month, and in group II - to 1.4±0.6 (p<0.05). When comparing SBP value in subgroup A and subgroup B, the average daily SBP also significantly difference and amounted to 147.8 ± 1.8 vs. 138.4 ± 3.2 mmHg, respectively; p <0.05). Among the all patients included in the study, 38 patients were with CHF. The 6-minute walk test results, compared with pre-operative data, showed a significant improvement and amounted to 321.24 ± 83.22 vs. 212.42 ± 54.72m, respectively; p <0.05.
Conclusions: the sympathetic renal denervation may be regarded as an effective method of treatment of patients with resistant hypertension, as well as patients with concomitant chronic heart failure. Performing denervation in the arteries of the second order, significantly improves the prognosis of patients, and in patients with concomitant heart failure significantly increases the quality of life and exercise tolerance.

P2159
Oxidative stress levels in obese hypertensive patients versus obese normotensive patients

MA Mihnea Alexandru Gaman[1]; ME Epingeac[2]; CC Diaconu[1]; AM Gaman[2]
[1]University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; [2]University of Medicine and Pharmacy of Craiova, Pathophysiology, Craiova, Romania

Background: Since the vascular wall is an important source of reactive oxygen species (ROS), oxidative stress has emerged as a putative pathogenic factor in the development of hypertension. NADPH oxidase, xanthine oxidase and mitochondrial dysfunction are involved in the increased production of superoxide anion. The uncoupled endothelial nitric oxide synthase (eNOS) produces nitric oxide, which combined with superoxide forms peroxynitrite, a molecule that interferes with the actions of eNOS and leads to an even higher generation of superoxide, entertaining a vicious cycle. The adipose tissue, which is generally well represented in hypertensive patients, is another source of ROS, mainly via adipokine production and maintenance of a low-grade chronic inflammatory state. Purpose: Our purpose was to measure OS levels in obese hypertensive subjects and normotensive subjects vs. controls. Methods: Oxidative stress levels were evaluated from a single drop of capillary blood via the FORT (Free Oxygen Radical Testing; normal range: ≤ 2.3 mmol/L H2O2) assay. Antioxidant levels were evaluated via the FORD (Free Oxygen Radical Defense; normal range: 1.07 – 1.53 mmol/L Trolox) assay. Unpaired t-test was employed to assess differences between groups. Results: We enrolled 35 obese hypertensive patients (mean age 64.26 ± 8.29 years), 19 obese normotensive patients (mean age 59.63 ± 8.71 years) and 20 non-obese normotensive controls (mean age 64.10 ± 2.26 years). Hypertensive obese subjects registered higher FORT (3.30 ± 0.41 vs. 2.99 ± 0.29; p=0.0057) and lower FORD (0.62 ± 0.16 vs. 0.73 ± 0.14; p=0.017) values vs. obese normotensive subjects. Hypertensive obese and normotensive obese patients depicted higher FORT and lower FORD values vs. controls (p<0.001) (Table 1). In hypertensive obese patients, FORT values correlated positively with BMI, LDL-cholesterol, total cholesterol, total cholesterol/HDL-cholesterol ratio and uric acid values and negatively with age. FORD values evolved oppositely (Table 2).
Conclusions: Obese hypertensive subjects recorded higher FORT and lower FORD values vs. obese normotensive subjects, implying that hypertension is associated with higher levels of oxidative stress. Oxidative stress levels were increased in both obese hypertensive and obese normotensive patients vs. controls. In obese hypertensive subjects, ROS levels correlated positively with lipid values, BMI, uric acid and negatively with age. Total antioxidant levels evolved oppositely. Although aged subjects have higher ROS values and lower antioxidant levels, the negative correlation between age and ROS levels and the positive correlation between antioxidant levels and age suggest that the relationship between ageing, obesity and hypertension is complex and needs further investigation in larger studies.

The effect of initial pulse pressure on heart failure readmission in hypertensive octogenarian patients presenting acute myocardial infarction treated with percutaneous coronary intervention

JC Jeong Cheon Choe[1]; JH Choi[1]; JY Shin[1]; J Ahn[1]; JS Park[1]; HW Lee[1]; JH Oh[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]; MH Jeong[2]

[1]Pusan National University Hospital, Department of Cardiology, Pusan, Korea (Republic of); [2]Chonnam National University Hospital, Department of Cardiology, Gwangju, Korea (Republic of)

Background: We aimed to evaluate if initial blood pressure (BP) index was predictive for clinical outcomes in hypertensive octogenarian patients treated with percutaneous coronary intervention (PCI) for acute myocardial infarction (AMI).

Methods: Among 13104 AMI patients who underwent PCI in a nationwide registry (November 2011 to December 2015), 901 hypertensive octogenarian (defined as ≥80 years) patients without cardiogenic shock were analyzed. The study endpoints were the composite events (cardiac death, non-fatal MI, any revascularization, stroke, or heart failure re-admission) and their components during follow-up.

Results: Composite events, all-cause death, and cardiac death occurred in 210 (23.3%), 186 (20.6%), and 141 patients (15.6%), respectively, during a median follow-up of 359 days. Cox proportional model showed that high initial pulse pressure (PP) was significantly associated with lower risk of composite events (hazard ratio [HR] 0.987, 95% confidence interval [CI] 0.977-0.998), all-cause death (HR 0.989, 95% CI 0.978-1.000), cardiac death (HR 0.981, 95% CI 0.968-0.994), and heart failure readmission (HR 0.968, 95% CI 0.937-1.000). On receiver operating characteristic curve analysis, the optimal cutoff value of PP for composite events was 42 mmHg (sensitivity 0.42; specificity 0.70; area under the curve 0.568). Compared to the patients with PP <42mmHg, those with PP ≥42mmHg had fewer composite events (29.3% vs. 20.4%, HR 0.662, 95% CI 0.503-0.872). However, systolic BP, diastolic BP, and mean arterial pressure at admission were not associated with any study endpoints.

Table 1. Association of clinical outcome

	Systolic BP	Diastolic BP	Pulse pressure	MAP
All-cause death	0.997 (0.989-1.004)	1.007 (0.994-1.019)	0.989 (0.978-1.000)	1.001 (0.990-1.012)
Cardiac death	0.994 (0.985-1.002)	1.008 (0.994-1.022)	0.981 (0.968-0.994)	0.999 (0.987-1.012)
Non-fatal MI	0.987 (0.968-1.007)	1.004 (0.973-1.035)	1.002 (0.984-1.021)	0.993 (0.966-1.021)
Any revascularization	1.000 (0.986-1.015)	0.999 (0.974-1.025)	1.001 (0.981-1.022)	1.000 (0.978-1.022)
Stroke	1.003 (0.980-1.025)	1.030 (0.993-1.068)	0.983 (0.947-1.019)	1.017 (0.984-1.051)
Heart failure re-admission	1.000 (0.987-1.013)	0.997 (0.974-1.020)	0.968 (0.937-1.000)	0.998 (0.979-1.018)
Composite events	0.996 (0.990-1.003)	1.007 (0.995-1.018)	0.987 (0.977-0.998)	1.001 (0.991-1.011)

Conclusions: In this study, high initial PP was associated with improved clinical outcomes in hypertensive octogenarian patients with AMI undergoing PCI.

Introduction: Advanced glycation end products (AGE) have been implicated in vascular stiffness in diabetes and renal disease, but the associations between chronic AGE accumulation and vascular stiffness in a general population are less extensively explored.

Purpose: We examined the associations of long-lived collagen cross-linked AGE measured by skin autofluorescence (SAF) and arterial stiffness measured as augmentation index (AIx) using Pulse Wave Analysis in a healthy, general population.

Methods: SAF was measured using AGE Reader® in 1005 subjects (mean age 51.6 ± 8.1 years; 53.7 % females, 5.9% subjects with diabetes) in the Malmö Offspring Study. Augmentation index was measured using the novel, validated oscillometric device SphygmoCor XCEL.

Results: After adjusting for age, sex, body mass index, systolic blood pressure, smoking status, renal function, diabetes status andanti-hypertensive treatment, each 1 SD increment in SAF was associated with increased AIx (β 0.77, p=0.009, Table 1). Figure 1 illustrates AIx within quartiles of SAF.

Conclusion: This cross-sectional, observational study identifies associations between elevated AGE-levels measured by skin autofluorescence and arterial stiffness measured by Pulse Wave Analysis in a general population independently of diabetes and renal function. This suggests that SAF could be used as a screening tool for non-diabetic subjects at increased cardiovascular risk.

Associations of Aix and SAF

	β	p
Skin autofluorescence (AU)	0.76	0.010
Age (per one year)	0.54	<0.001
Sex (male)	12.2	<0.001

Chemerin in prognosis of heart failure development in hypertensive patients with obesity and diabetes mellitus

B Borys Shelest[1]; I V Rodionova[2]; YULIIA Kovalova[2]

[1]Kharkiv National Medical University, Kharkiv, Ukraine; [2]L.T.Malaya Institute of Therapy, Prevention and treatment of emergency conditions, Kharkiv, Ukraine

Background: The deterioration of heart function in hypertensive patients with concomitant pathology, particularly with diabetes mellitus type 2 and obesity, is a significant problem of cardiology. Chemerin is a marker associated with inflammation and metabolic syndrome, and possibly can play a significant chain in the development of heart failure signs.

The aim is to find the link between increased chemerin concentration and the deterioration of heart function in obese hypertensive patients with diabetes mellitus type 2 (DM2T).

Methods: 72 hypertensive patients were enrolled (61.8% females and 38.2% female), mean age was 58.73±11.54 years, systolic blood pressure – 156.18 ± 7.7 mmHg, diastolic blood pressure – 92.97 ± 4.51 mmHg, HbAc1 – 7.35 ± 2.41 %, BMI – 32.56 ± 3.11 kg/m2. The serum chemerin level was measured at the beginning and after one-year follow-up period by ELISA.

Results: After 12 months of observation, the groups with decreased 6MWT and without it were compared. The serum chemerin in the heart failure group was 298.75 [212.64 - 393.92] ng/ml and 128.02 [91.82-169.11] ng/ml in the group without heart failure signs (p <0.035) Multivariate logistic analysis revealed a significant effect of chemerin on the development of heart failure after one –year follow-up time (OR: 0.912; 95% CI 0.794 - 0.988; p = 0.039). ROC analysis showed that the level of more than 183.5 ng / ml allows to predict the development of heart failure deterioration, AUC = 0.73, (95% CI 0.53-0.882; P = 0.047), with a sensitivity of 85.7% and a specificity of 63.1%.

Conclusions: The increased chemerin serum level is a predictor of heart failure. The study found the possibility of chemerin usage as additional marker for stratification of the obese hypertensive patients with DM2T.

P2163

The use of natriuretic peptides in predicting renal and cardiovascular outcomes after renal stenting in high-risk renal artery stenosis patients

DO Geavlete[1]; C Beladan[1]; D Deleanu[1]; MR Zaharia[2]; O Tautu[3]; BA Popescu[1]; C Ginghina[1]; O Chioncel[1]

[1]Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Cardiology, Bucharest, Romania; *[2]Emergency Clinical Hospital St John, Internal Medicine, Bucharest, Romania*; *[3]University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*

Introduction: Controversial data were gathered in the literature concerning the use of B-type natriuretic peptide (BNP) in the prediction of renal function preservation and blood pressure (BP) control after renal revascularization. Recently, the marker's predictive value in assessing the morbi-mortality in renal artery stenosis (RAS) patients was suggested.

Purpose: The current analyses aimed to evaluate the role of BNP in the prediction of primary (renal function improvement, BP control) and secondary (severe renal complications and major adverse cardiac events - MACE) clinical outcomes after renal stenting in selected hypertensive patients with significant RAS.

Methods: There were prospectively enrolled 78 hypertensive patients diagnosed with significant uni- and bilateral RAS, subsequently resulting in 3 groups (34-unilateral, 28-bilateral RAS and 16-RAS in solitary kidney). Clinical, biological and echocardiographic parameters were comparatively evaluated between groups at admission and 12 months' after renal stenting. Renal function' and BP evolution after stenting were evaluated at 12 months. Secondary outcomes were assessed after a mean follow-up period of 24.27±12.16 months. Regression logistic analysis - univariate and multivariate (stepwise Likelihood ratio method) was used in order to define the independent predictors for major outcomes.

Results: BNP and lnBNP (logarithmic value of corresponding BNP) did not correlate neither with the evolution of BP nor with renal function improvement after renal revascularization. Multivariate logistic regression analysis confirmed baseline lnBNP as an unique independent predictor for major renal events (area under the receiver-operating characteristics curve was 0.95 (95% CI, 0.83-1.01, p=0.002). The same analysis for MACE prediction confirmed 5 independent predictors assessed 12 month' after stenting: BP non-responder, lnBNP level, left ventricular (LV) dysfunction, antiplatelet therapy and smoking. The accuracy of the model was 86.8%, while lnBNP alone as an unique predictor of MACE, provided 76.3% of the accuracy of the multi-parametric model.

Conclusions: The present findings demonstrated that BNP is not a reliable predictor for renal function improvement and BP control after renal revascularization in patients with significant renal artery stenosis, but could be a valuable biomarker in the assessment of long term (4 years follow-up) major adverse renal events and major adverse cardiac events.

P2164

Adropin as prognostic factor in heart failure development in hypertensive patients

B Borys Shelest[1]; YULIIA Kovaleva[1]; I V Rodionova[2]

[1]Kharkiv National Medical University, Kharkiv, Ukraine; *[2]L.T.Malaya Institute of Therapy, Prevention and treatment of emergency conditions, Kharkiv, Ukraine*

Background: The low levels of adropin is associated with higher cardiovascular events, coronary atherosclerosis, endothelial dysfunction, herewith there is study evidenced that augmented adropin is associated with heart failure severity. The aim of the study was to investigate the predictive role of adropin serum levels in the development of heart failure severity in hypertensive patients.

Methods: 137 patients (males – 65 (47%), age 61.07 ± 12.03) with diagnosed essential hypertension were enrolled into this study. 64 hypertensive patients had concomitant diabetes mellitus type 2. Serum levels of adropin were measured by ELISA. 6-minute walk test (6MWT) was done to assess exercise tolerance. The severity of heart failure was evaluated by functional classes (FC) according to the New-York Heart Association (NYHA) classification.

Results: Serum levels of adropin, were significantly lower in patients with NYHA III functional class than those with FC I heart failure in the group of patients with only hypertension (mean adropin level: 3.11 [1.98-4.11] vs. 4.01 [3.89-5.87] ng/ml, p=0.039). Meanwhile, there were no significant differences in adropin concentrations between heart failure III FC and FC I in patients with hypertension associated with diabetes mellitus type 2 (2.71 [1.53-3.97] vs. 3.09 [2.31-4.15] ng/mL, p=0.069). Logistic regression demonstrated that adropin level was independent predictor for severity of heart failure with cutoff level <3.47 ng/ml specificity – 67% sensitivity – 87% AUC=0.71, p<0.041, CI 95%: 0.41-0.89, p=0.041).

Conclusions: The study confirms that serum adropin can be considered as prognostic factor for heart failure severity in hypertensive patients in one-year period.

Cardiovascular Disease in Special Populations

Clinical features of immune checkpoint inhibitor-related cardiotoxicity

Y Yulia Kirichenko[1]; Y Belenkov[1]; AR Lyon[2]

[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; *[2]Royal Brompton Hospital, London, United Kingdom of Great Britain & Northern Ireland*

Background Immune checkpoint inhibitors (ICI) are increasingly used for a range of various cancers more frequently over the last years. Seven different agents are currently licensed by the FDA and EMEA. There is an emerging problem with cardiotoxicity secondary to ICIs.

Methods: We reviewed 47 patients referred to our Cardio-Oncology service over a 90 months period. The principal reason for referral was suspected ICI-medicated cardiotoxicity. All patients underwent clinical review, measurement of cardiac biomarkers, electrocardiography, echocardiography and cardiac MRI. 11 patients were excluded as six had non-cardiac diagnoses (non-cardiac chest pain, vasovagal syncope), in 3 we found ischaemic heart disease prior to ICI exposure & two referrals were for cardiac metastasis.

Results: Total of 36 patients received either single or dual ICI therapy: Pembrolizumab n=12 (33 %), Pembrolizumab + Nivolumab n=1 (2.7%), Nivolumab n=4 (11%), Atezolizumab n=3 (8.3%), Avelumab n=2 (5.5%), Ipilimumab n=2 (5.5%), Ipilimumab + Nivolumab n=12 (33.5%). The underlying malignancies warranted immunotherapy include: Metastatic melanoma in 15 patients (42%), non-small cell lung cancer in 7 cases (19.4%), 5 had renal cell carcinoma and 3 other urothelial cancers (14% and 8.3%, respectively), stomach cancer, breast, ovarian, mesothelioma in 1 patient each (2.7%) and skin cancer in 2 cases (5.5%).

The median patient age was 62 years (range 29-80). 64% were male and 47% had a prior cardiac illness: hypertension (n=11, 31%), AF (n=6, 16.7%), tricuspid regurgitation (n=1, 2.7%) and mitral regurgitation (n=1, 2.7%). Concentrations of brain natriuretic peptide (BNP) and troponin were increased in 26 (72%) and 4 (11%) of patients, respectively. The most frequent complications were myocarditis in 30.5% of patients (n=11), non-inflammatory left ventricular impairment in 19.4% of patients (n=7) [the median LVEF=46% (range 40-49%)] and palpitations in 14% of cases (n=5), 2 had microvascular ischaemia (5.5%) and 3 had pericarditis (8.3%). Also we identified some different arrhythmias: atrial fibrillation and atrial tachycardia in 1 patient each (2.7%) including those due to ICI-mediated thyroiditis and complete atrioventricular block in 1 case. Concomitant signs of myositis were present in 2.7% of patients.

Conclusion: ICI-mediated cardiotoxicity is a growing problem. With the increasing use of such agents to treat various malignancies, clinicians should be aware of cardiotoxicity in the form of myocarditis, pericarditis, conduction disease as well as non-inflammatory left ventricular impairment and arrhythmia. Measurement of cardiac troponin and BNP might be considered as useful screening biomarkers.

P2166

Does a clinical scientist led cardio-oncology clinic improve surveillance for cardio-toxicity for patients receiving trastuzumab compared to oncology services alone?

J Jane Draper[1]; K Victor[1]; J Smith[1]; J Webb[1]; S Kapetanakis[1]

[1]St Thomas' Hospital, London, United Kingdom of Great Britain & Northern Ireland

Background Cardiac dysfunction as a side effect of Trastuzumab is well documented and reliable surveillance of cardiac function is recommended. Transthoracic Echocardiography (TTE) is a common modalities used for this but coordinating timings for sequential follow up between separate Oncology and Cardiology departments can be challenging.

Purpose To compare the consistency of serial TTE performed for patients reviewed within a clinical scientist led cardio-oncology service and those manged by oncology services alone.

Method Patients identified as receiving Trastuzumab between January 2016 and June 2018 were reviewed. Two groups were identified, those seen in a scientist led cardio-oncology clinic (Group 1) and those seen only in oncology clinics (Group 2). The period between consecutive TTEs was calculated within each group. In line with local and international guidelines serial TTE surveillance within 4 monthly intervals using 3D TTE was considered appropriate follow up. In addition other modalities of evaluating left ventricular ejection fraction (LVEF) were listed.

Results 191 patients were reviewed with 154 in Group 1 (95% Female, Ave age 57yrs), and 37 in Group 2 (73% female Ave age 69yr). 98 % of patients in Group 1 received appropriate follow up compared to 5% in Group 2 (Figure 1). There were variations in modalities used in reporting LVEF within Group 2 across serial studies including a visual assessment with a 5% range, Simpsons Biplane, Teicholz and 3D. In comparison evaluation of LV function in Group 1 used one consistent modality which was 3D TTE.

Conclusion Patients seen in a clinical scientist led cardio-oncology clinic had more consistent surveillance of left ventricular function during treatment with Trastuzumab when compared to those seen by oncology services alone. Furthermore these clinics utilised one consistent modality of reporting LVEF providing greater accuracy and more reliable side by side comparison of studies making the identification of cardio-toxicity easier.

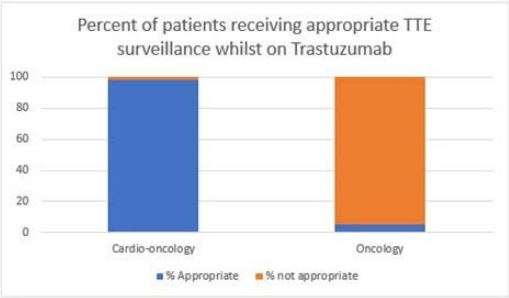

Figure 1. Comparison between the percentage of patients receiving appropriate TTE surveillance in a cardio-oncology clinic and oncology clinic

P2167

The prevalence of elevated heart rate in oncology patients: a risk factor revisited.

H Hussam Aridi[1]; G Iskandarani[1]; J El Cheikh[1]; A Bazarbachi[1]; H Skouri[1]
[1]*American University of Beirut Medical Center, Beirut, Lebanon*

Background: Among patients with established cardiovascular disease, an elevated heart rate is a marker of all-cause mortality. Chemotherapy, radiotherapy, and their subsequent side effects such as nausea, vomiting, intravascular depletion from decreased P.O. intake and fluid loss such as diarrhea, fever, hypoxemia, cardiovascular autonomic dysfunction, pain, in addition to psychosocial stress and anxiety result in a chronic state of increased sympathetic activity and thus elevated heart rate. Recently, a long-term prospective cardiovascular follow-up study showed that in patients with colon, pancreatic and non-small cell lung cancer a heart rate > 75 b.p.m is an independent predictor of mortality. To our knowledge, no study has reported the prevalence of elevated heart rate among the oncology population.
Purpose: To evaluate the prevalence of elevated heart rate in the cancer inpatient population.
Methods: We performed an analysis on the first 200 oncology patients from our retrospective cross-sectional study on "The heart rate prevalence and prognostic significance among oncology patients admitted to the inpatient oncology service" from January 1, 2017 till December 31, 2017. All oncology patients ≥ 18 years old admitted for more than 48 hours at the inpatient oncology service were included. Only patients admitted for fever or febrile neutropenia, sepsis or in septic shock were excluded. Data were collected from the electronic healthcare records after IRB approval. We evaluated patients' heart rate at admission, the first 24 hours and at discharge. For this analysis, an elevated heart rate is defined as a HR >75 b.p.m.
Results: The 200 patients analyzed were 89 (44.5%) females and 111 (55.5%) males with a mean age of 54±16 yrs. 51.5% of the patients were admitted for chemotherapy administration, 23 (11.5%) for chemotherapy adverse events, 34 (17%) for pain and cancer related complications, 13 (6.5%) for infections, and 27 (13.5%) for other reasons. 52 (26%) of patients were receiving at admission a heart rate lowering medication such as beta-blocker, calcium channel blocker and/or Ivabradine. Among patients receiving a heart rate lowering medication, 35 (67.3%) had an elevated heart rate; meanwhile, among patients not receiving a heart rate lowering medication, 119 (80.4%) had an elevated heart rate. The heart rate at discharge did not significantly differ from that on admission with 69% of patients having elevated heart rate on discharge. Conclusion: Among admitted oncology patients, there is a very high prevalence of elevated heart rate even in those on rate lowering medications. This may signify a higher mortality rate among this group of patients. Further research is needed to evaluate the heart rate effect on mortality and cardiovascular complications. This may have future implications on rate lowering interventions among this population.

P2168

Endovascular treatment of ischemic heart disease in patients with blood cancer

E Ekaterina Gitelzon[1]; A Faybushevich[1]; V Baranovich[1]; G Veretnik[1]; D Maximkin[1]; D Gitelson[1]
[1]*Peoples Friendship University of Russia (PFUR), Moscow, Russian Federation*

Funding Acknowledgements: The publication has been prepared with the support of the 'RUDN University Program 5-100'

Improvement of the treatment setting for oncohematological diseases allowed to improve the treatment results, to increase the life expectancy, to change life quality. This is one of the factors explaining the tendency of the increase in the incidence of coronary heart disease with oncological disease combination.
Materials and methods. Our study included two-stage treatment of 54 patients with coronary artery disease and blood cancer. The average age was 64 ± 11.63 years. The 1st stage was performed percutaneous coronary intervention, the 2nd - the treatment of oncopathology (11 patients underwent surgical treatment, 43– chemotherapy/radiation therapy). All patients were prescribed double antiplatelet therapy before revasciarization (acetylsalicylic acid at a dose of 100 mg/day and clopidogrel at a dose of 75 mg /day). Immediately before myocardial revascularization the level of platelet aggregation was assessed by the method of light transmission aggregometry of platelets with adenosine diphosphate (the target level of platelet aggregation before performing percutaneous coronary intervention is less than 45%).We chose the stent type individually based on the duration of the surgical intervention by the reason of cancer, anatomy of the coronary arteries and the nature of coronary arteries atherosclerotic lesions.If surgical intervention was planned for 1 month after percutaneous coronary intervention, then bare-metal stents were preferred. There were no intraoperative and hospital mortality and also no mortality cases due to coronary artery disease during the 1st year after percutaneous coronary intervention.All patients received dual antiplatelet therapy for at least 1 month before performing surgical treatment of oncopathology if bare-metal stents was implanted and 3 months - if drug-eluting stents. Dual antiplatelet therapy was stopped 5–7 days before the surgical treatment replaced by unfractionated heparin to prevent thrombotic and hemorrhagic complications. After the surgery dual antiplatelet therapy was restarted in 6-48 hours. During the 1st year after percutaneous coronary intervention the recurrent angina was observed in 2 patients. Hemodynamically significant 'in-stent' restenoses were identified on the coronary angiography. In 1 patient the recurrent angina occurred 4 months after myocardial revascularization with bare-metal stent implantation. In the 2nd patient the recurrent angina was observed 11 months after previously performed percutaneous coronary intervention with drug-eluting stent.Conclusion. Percutaneous coronary intervention is an effective and safe method of myocardial revascularization in patients with coronary artery disease and oncopathology. The use of endovascular myocardial revascularization in cancer patients reduces the risk of developing cardiovascular complications during the oncological treatment.

Cardio-renal interaction in young patients with Type 1 Diabetes Mellitus

N Safarova[1]; Z Kobalava[2]; Y Mahamat[2]; A Safarova[2]; V Efimova[3]
[1]*M.V. Lomonosov Moscow State University, Moscow, Russian Federation*; [2]*RUDN University, Moscow, Russian Federation*; [3]*City Clinical Hospital No 64, Moscow, Russian Federation*

Objectives: To study relationship between kidney injury and early markers of left ventricular dysfunction in young patients with Type 1 Diabetes Mellitus (DM) without ischemic heart disease (IHD) and arterial hypertension (AH).
Materials and methods: In 90 patients with Type 1 DM without IHD and AH, mean age 29.1 ± 8.2 years, 57% of men, disease duration of 6.7 [2; 11] years, early markers and associated clinical signs of heart injury were studied. All patients were performed treadmill test, as well as NT-proBNP, CKD-EPI, albumin/creatinine tests. Echocardiography included a standard study of EF (Simpson method) and longitudinal systolic function of the left ventricle (GLS) using speckle tracking method.
Results. A total of 58 (64.4%) patients had optimal GFR> 90 ml/min/1.73 m2, 27 (30%) patients had a slight decrease in GFR (from 60 to 89 ml/min /1.73 m2), 3 (3,3%) - moderately reduced GFR (45-49 ml/min/1.73 m2) and 2 (2.2%) - significantly reduced GFR (30-44 ml/min/1.73 m2). Twenty five patients (28.2%) had optimal albuminuria, 54 (60%) - moderately increasde; 9 (10%) - highly and 2 (1.8%) considerably highly increased albuminuria. In 24 (26.6%) patients GFR was over 120 ml/min /1.73 m2. These patients significantly differed in diabetes duration (2.2 years vs 7.2 years, p <0.001) and in HbA1c value (10.9% vs 9.7%), compared to patients with GFR <120ml/min/1,73 m2. Subclinical systolic LV dysfunction, defined as GLS<20%, was observed in 67.7% (61/90), diastolic LV dysfunction - in 10 (16.4%) patients.
Multivariate regression analysis showed that albuminuria is one of independent factors, which determine diastolic dysfunction of LV- E/E '(β = 0.22, p <0.001),

together with age (β = 0.36, p <0.001) and female sex (β = 0.24, p <0.004), and that GFR closely correlates with GLS (r = 0.28, p <0.006).
Conclusions. Close associations between albuminuria and diastolic function and between GFR and longitudinal systolic function of the left ventricle were revealed in young patients with type 1 DM without IHD and AH.

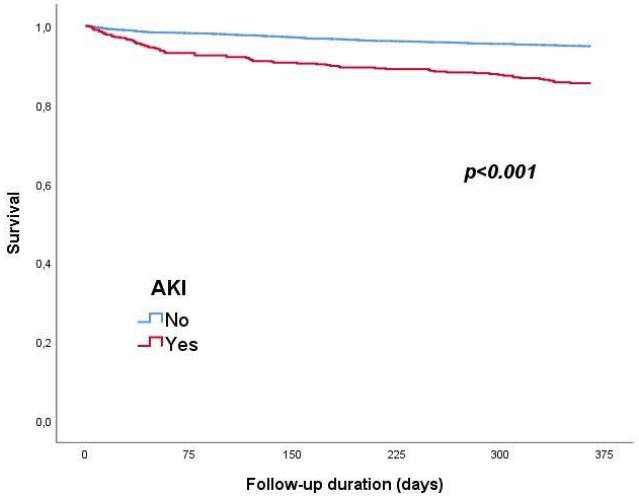
Clinical impact of acute kidney injury in patients with acute coronary syndrome

F M Fernando Manuel Fonseca Goncalves[1]; PS Mateus[1]; JP Guimaraes[1]; JI Moreira[1]
[1]*Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal*

On behalf of: Registo Nacional de Síndromes Coronárias Agudas, Sociedade Portuguesa de Cardiologia

Introduction: Kidney dysfunction is often found in hospitalized patients and is usually associated with a worse prognosis. In an acute coronary syndrome (ACS) it can arise not only due to the disease itself but also due to the associated procedures. This study aimed to evaluate the clinical consequences of acute kidney injury (AKI) in patients hospitalized for ACS.
Methods: Retrospective study of patients with ACS included consecutively in a multicenter national registry between October/2010 and October/2018, whom serum creatinine was evaluated at the admission and whom maximum value was also evaluated during hospitalization. We excluded patients with history of chronic kidney disease, creatinine at admission ≥1.4mg/dL and maximum creatinine reached after the 7th day of hospitalization. KDIGO criteria were used for the definition of AKI. In addition to the in-hospital complications we also evaluated mortality rate and hospital readmission during a one-year follow-up.
Results: A total of 10979 patients were selected, of which 11.3% met criteria for AKI. In this group there were more female patients (35.5% vs 25.5%, p<0.001) and they were older (72±12 vs 64±13 years, p<0.001). Patients with AKI had generally a higher number of comorbidities, including hypertension (76.1% vs 64.6%, p<0.001), diabetes mellitus (34.3% vs 27.4%, p<0.001), stroke (10.3% vs 5.9%, p<0.001), peripheral artery disease (7.0% vs 3.9%, p<0.001) and chronic obstructive pulmonary disease (6.8% vs 4.2%, p<0.001).
Patients with AKI showed up more often in Killip class ≥2 (29.4% vs 8.4%, p<0.001). ST-segment elevation myocardial infarction (STEMI) was more frequent in patients with AKI (45% vs 41.5%, p=0.019).
Patients with AKI had worse left ejection fraction (47±12% vs 53±12%, p<0.001). During coronariography AKI patients used more often the femoral artery access (23.6% vs 18.2%, p<0.001). Multi-vessel disease was more common in this group (59.8% vs 47.5%, p<0.001) but angioplasty was less performed (65.4% vs 69.4%, p=0.004).
An analysis adjusted for potential confounders demonstrated that the rate of in-hospital complications was significantly higher in the group with AKI: re-infarction (OR 1.77, 95% CI 1.09-2.88), stroke (OR 1.89, 95% CI 1.03-3.45), major bleeding (OR 2.93, 95% CI 1.95-4.41) and death (OR 5.18, IC 95% 3.61-7.44). During the one-year follow-up, in a multivariate analysis, there was a higher mortality rate (HR 1.66, 95% CI 1.22-2.24) and hospital readmission (HR 1.35, 95% CI 1.11-1.65) in patients with AKI.
Conclusions: In this study we found that AKI is more common in patients with more comorbidities. AKI was independently and significantly associated with higher in-hospital complications and higher mortality during a one-year follow-up.



AKI Kaplan Meier Curves for Mortality

P2171

Anemia and cardiovascular mortality in dialysis patients.

M Cafka[1]; M Rroji[2]; J Seiti[1]; S Seferi[2]; J Djamandi[3]; E Zace[1]; A Goda[1]
[1]*University Hospital Center Mother Theresa, Department of Cardiology & Cardiac Surgery, Tirana, Albania*; [2]*University Hospital Center Cardiology Department & Nefrology and Dialysis Department, Tirana, Albania*; [3]*Hygeia Hospital, cardiology department, Tirana, Albania*

INTRODUCTION: Anemia is a common complication of uremia, while cardiovascular disease is a major cause of death in dialysis patients, accounting over 40% of the mortality. Association between anemia and mortality risk may be mediated through cardiovascular disease, malnutrition, and inflammation. The aim of this study was to evaluate the presence of anemia and its association with cardiovascular mortality and morbidity in patients with end stage renal disease on peritoneal and hemodialysis treatment.
METHODS: A case control study was conducted in the Dialysis Center enrolling all patients on chronic dialysis (HD and PD) older than 18 years who had more than 3 months in therapy with a follow up 2 years. Two-dimensional echocardiography was performed by a single experienced cardiologist who was blinded to all clinical details of patients. The echocardiography was performed 2-24 h after the dialysis session, and the measurements of diameters and volumes were done according to AEE recommendation
RESULTS: Our dialysis population studied consisted in 122 pts, 78 pts (61%) on hemodialysis, mean age 53.4±14.5 years and mean time on therapy was of 40.4 ± 14.4 months. Left ventricular hypertrophy was present in 86.7% of patients; concentric hypertrophy was found in 64 (49.1%) and eccentric hypertrophy in 48 patients (37.2%). Patients with left ventricular hypertrophy were further divided into tertiles according to their left ventricular mass index where was found significantly increasing severity of anemia, in the third tercile through three groups with increasing LVMi p=0.03. Cardiovascular mortality during follow up was 15.5% (19 events).
Multivariable analysis showed that Hb <11g/dl [OR=.1.26; 95% CI, 1.01 to 1.48, p=0.041
C-reactive protein (OR, 1.06; 95% CI, 1.01 to 1.10; P = .01), pulse pressure (OR, 1.01; 95% CI, 1.0 to 1.26; P = .046), and left ventricular mass index (OR, 1.03; 95% CI, 1.01 to 1.21; P = .03) were independent risk factors for cardiovascular mortality.
CONCLUSION: Anemia is associated with increased left ventricle mass index and Hb < 11g/dl is a risk factor for survival in patients with end stage renal disease on dialysis treatment.

P2172

Echocardiographic predictors of interatrial block in patients with severe chronic kidney disease

M Kalcik[1]; M Yetim[1]; T Dogan[1]; L Bekar[1]; I Dogan[2]; B Eser[2]; O Karaarslan[3]; I Ekinozu[3]; MM Yilmaz[3]; T Gokdeniz[3]; Y Karavelioglu[1]; Z Golbasi[1]
[1]*Hitit University Faculty of Medicine, Department of Cardiology, Corum, Turkey*; [2]*Hitit University Faculty of Medicine, Department of Nephrology, Çorum, Turkey*; [3]*Hitit University Çorum Training and Research Hospital, Department of Cardiology, Çorum, Turkey*

Introduction: Interatrial block (IAB), defined as a conduction delay between the right and left atrium, is manifested on the electrocardiogram as a prolonged P-wave duration. Large number of studies recently have been published regarding the prevalence of IAB and its associations with the risk of atrial fibrillation, ischemic stroke, and left atrial dilatation. Cardiovascular diseases are the leading causes of mortality in chronic kidney disease (CKD). Previously, higher prevalence of IAB was reported in patients with CKD as compared to healthy controls. In this study, we aimed to investigate echocardiographic predictors of IAB in patients with severe CKD.
Methods: This study enrolled a total of 155 patients [male: 95 (61.3%), mean age: 56.3±12.8 years] with severe CKD (glomeruler filtration rate <30mL/min). Patients with atrial fibrillation were excluded. IAB was defined as P wave duration of ≥120 ms with or without presence of notching. All patients were evaluated by transthoracic echocardiography.
Results: Electrocardiography revealed IAB in 54 patients. The baseline demographic characteristics of the patients with and without IAB were similar in both groups. Left atrial diameter (LAD), left ventricular end-systolic and end-diastolic diameters, interventricular septal thickness, posterior wall thickness, left ventricular mass, left ventricular mass index (LVMI), and the prevalence of left ventricular hypertrophy were found to be significantly increased in patients with IAB. Increased LAD (OR=1.119; 95%CI: 1.019-1.228; p=0.019) and LVMI (OR=1.036; 95%CI: 1.003-1.070; p=0.031) were found to be independent predictors of IAB (Figure 1). In the receiver operating characteristic curve analyses, LAD values above 38 mm predicted IAB with a sensitivity of 75%, and a specificity of 65% (AUC= 0.750; 95%CI: 0.669-0.831; p<0.001) and LVMI values above 104.5 g/m2 predicted IAB with a sensitivity of 74%, and a specificity of 72% (AUC= 0.741; 95%CI: 0.662-0.819; p<0.001).

Conclusion: A significant association exists between the presence of IAB and echocardiographic parameters related to left ventricular hypertrophy and left atrial dilatation. The presence of IAB may be used as an electrocardiographic marker of cardiac remodelling in patients with severe CKD.

Electrocardiographic predictors of the future development of atrial fibrillation in patients with end-stage renal disease

H Chung[1]; JML Lee[1]; JSW Woo[1]; JBK Kim[1]; SJK Kim[1]; WK Kim[1]; WSK Kim[1]
[1]Kyunghee University, Cardiology, Seoul, Korea (Republic of)

Background: Atrial fibrillation (AF) is a common cause which leads to adverse cardiovascular outcome. It is unclear what predicts future AF in patients with ESRD.
Purpose: We investigated the electrocardiographic predictors for future development of AF in patients with ESRD who had never documented AF.
Methods: We enrolled 226 patients with ESRD who has performed transthoracic echocardiography. We excluded the 16 patients who had been received a diagnosis of AF, and 210 patients (130 males, mean 62 ±13 years) were analyzed. We reviewed the patients' medical records, and analyzed the echocardiography and electrocardiography. The frontal QRS-T angle was calculated from the 12-lead electrocardiogram, and the patients was divided into tertiles (0-21, 22-56, and 57-180).
Results: During a mean follow-up period of 911±725 days, AF occurred in 24 (11.4%) patients. The patients with AF development was older (68±12 vs. 61±14 years, p=0.038). There were no differences in history of hypertension, diabetes, stroke, coronary artery disease between two groups. On the Kaplan-Meier survival analysis, AF development was tended to be higher in patients with increased QRS-T angle pulmonary HTN (p=0.068 by log-rank test). The 1st tertile group (QRS-T angle>56) was an independent predictor of future AF event in multivariate analysis (hazard ratio, 2.373; 95% confidence interval, 1.023-5.503; p=0.044).
Conclusion: In patients with ESRD, increased QRS-T angle predicts an increased risk of future AF development.

Relationship between echo parameters and reduced LV longitudinal strain in end stage renal disease patients undergoing hemodialysis with preserved LV systolic function

E Tamulenaite[1]; R Zvirblyte[1]; E Ziginskiene[2]; E Ereminiene[1]
[1]Hospital of Lithuanian University of Health Sciences, Department of Cardiology , Kaunas, Lithuania; [2]Hospital of Lithuanian University of Health Sciences, Department of Nephrology , Kaunas, Lithuania

Background. In patients with end-stage renal disease (ESRD), cardiovascular diseases are the most common and life-threatening comorbidities. Purpose. The aim of our study was to evaluate changes of left ventricle (LV) longitudinal strain (LS) and to determine the role of clinical and echocardiographic parameters for the reduced LV LS in patients with ESRD undergoing hemodialysis (HD) and preserved LV systolic function. Methods. The conventional echocardiography was performed to 70 patients with preserved LV EF (>50%) who were divided into two groups: HD group – patients with ESRD undergoing HD (n=38) vs. controls – patients with normal kidney function (GFR>90mL/min/1.73m2) (n=32). LS was analysed using 2D speckle-tracking echocardiography. LV LS >-20% was defined as reduced. Pearson correlation and multivariate regression analyses were performed to evaluate the relationship between clinical and echocardiographic parameters and reduced LV LS. The value of p<0.05 was considered as statistically significant. Results. There were no significant differences of clinical characteristics, comorbidities and LV EF between groups (p>0.05). HD group had significantly lower LV LS than control group (-21.94±3.35 vs -24.04±1.97, p=0.003). Correlation analysis revealed significant moderate relation between LV LS and right ventricle (RV) LS (r=0.6, p<0.001). Multivariate regression analysis showed that LV myocardial mass index was significantly related to LV LS reduction (p=0.025) (Table1). Conclusion. ESRD is associated with reduced LV LS in patients with preserved LV EF. Significant relation was revealed between LV LS and RV LS (p<0.001), as well as, LV myocardial mass index (p=0.025). Conflict of interest. None.

Table1

Univariate analysis	Multivariate analysis

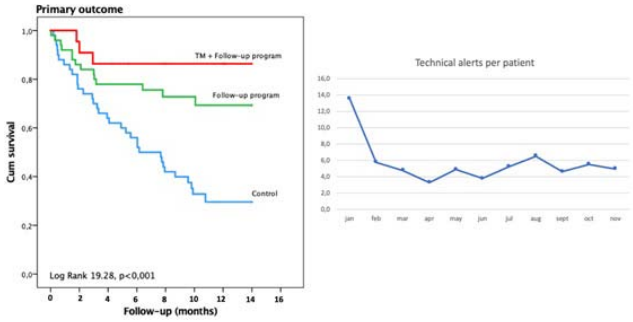
Clinical impact of non-invasive telemonitoring in patients with chronic heart failure

A Nunes Ferreira[1]; JR Agostinho[1]; J Rigueira[1]; I Aguiar-Ricardo[1]; IS Goncalves[1]; R Santos[1]; T Rodrigues[1]; N Cunha[1]; T Guimaraes[1]; M Mendes Pedro[1]; F Veiga[1]; FJ Pinto[1]; D Brito[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal

On behalf of: RICA-HF Team

Introduction: Non-invasive remote monitoring of patients with heart failure (HF) may be useful in the early detection of signs and symptoms of decompensation, allowing therapeutic optimization and avoiding rehospitalization.
Objectives: To assess the efficacy of telemonitoring (TM) integrated in a protocol-based follow-up program (PFP) of patients with HF.

Methods: Prospective and single center study of patients (pts) discharged from hospital after an episode of decompensated HF, with nested-case control design. Three groups of pts were considered: a group of 50 pts integrated in a PFP after hospital discharge, another group of 25 pts who integrated the PFP together with a telemonitoring program (TM), and a control group of 50 pts who were discharged before the PFP had been put into practice.
Pts in the 3 groups were matched according to age, NYHA at discharge and ejection fraction (EF).
The TM group included only patients with HF and reduced EF plus ≥1 HF hospitalization in the last year. In these pts, biodata were evaluated remotely and generated clinical alerts whenever altered in relation to the limits defined for each patient, with evaluation by the clinical team 24/7.
TM success was assessed by primary outcome (death or hospitalization from any cause) at 12 months, using Cox regression and Kaplan-Meier survival analysis.
Results: Patients included concomitantly in PFP and TM were 65.7 ± 9 years-old, 76% were male, median EF 25% (IQR 20-30), median NTproBNP 2707pg/mL (IQR 590-3947), 84% were in NYHA II or III, 52% had dilated cardiomyopathy, and the mean follow-up time was 9.5 ± 4.5 months.
During the TM program, alerts were generated mainly because of changes in heart rate and systolic blood pressure. However, only in 3% were clinical alerts confirmed. During the program there has been a significant reduction in technical alerts per patient, which were due to difficulties in the measurement or in transmission of the biodata, demonstrating a learning process of the patients, and also decreasing the team workload.
At 12-months of follow-up, a higher success rate regarding the primary outcome was observed in the TM group vs. the control group (86% vs. 32%, HR 0.17, 95% CI 0.05-0.56, p= 0.001), with a relative risk reduction (RRR) of 83%. This reduction was superior to that demonstrated with the PFP alone (72% vs. 32%, HR 0.36 95% CI 0.19-0.67, p= 0.001), which presented RRR of 64%. Similar results were found in rehospitalization for HF (Log Rank p=0.016), all-cause rehospitalization (Log Rank 0=0.016) and death (Log Rank p<0.01).
Conclusions: When integrated into a structured clinical follow-up program, TM is associated with a marked reduction in mortality, readmissions for HF, and rehospitalization for any cause, compared to usual follow-up. This study further suggests that the addition of a TM program to a protocol-based follow-up program of pts with HF can improve results already considered optimized.



P2176

Hybrid telerehabilitation in heart failure patients (TELEREH-HF) a randomized, prospective, open-label, parallel group, controlled, multi-center trial -study design and description of the intervention

E Piotrowicz[1]; G Opolski[2]; M Banach[3]; W Zareba[4]; M Pencina[5]; R Piotrowicz[6]
[1]Institute of Cardiology Telecardiology Center, Warsaw, Poland; *[2]Medical University of Warsaw, The 1st Department of Cardiology, Warsaw, Poland*; *[3]Medical University of Lodz, Lodz, Poland*; *[4]University of Rochester, Rochester, United States of America*; *[5]Duke University's School of Medicine, Duke, United States of America*; *[6]Institute of Cardiology, Department od Cardiac Rehabilitation and Noninvasive Electrocardiology, Warsaw, Poland*

Funding Acknowledgements: TELEREH-HF study is supported by the National Centre for Research and Development, Poland grant number STRATEGMED1/233547/13/NCBR/2015

Background Current guidelines strongly recommend exercise training as an important component of heart failure (HF) management. Despite this, there are large regional disparities in access to rehabilitation both in Poland and in Europe. One of the possibilities to solve this problem is to introduce hybrid telerehabilitation (TR) in HF patients (pts). Purpose The primary objective of the TELEREH-HF trial is to determine whether introducing a novel hybrid model of TR in HF will significantly increase days alive and out of hospital when compared with usual care. The secondary objectives are to assess the effects of a hybrid TR compared to usual care on all-cause and cardiovascular mortality and all-cause, cardiovascular and heart failure hospitalization. The tertiary analyses will include: evaluation of the safety, effectiveness, quality of life (QoL), depression, anxiety, pts acceptance of and adherence to a hybrid TR. Methods The TELEREH-HF study is designed as a randomized (1:1), prospective, open-label, parallel group, controlled, multi-center (5 centers) trial among 850 clinically stable HF pts after a hospitalization incident, NYHA I-III, LVEF≤40%. Eligible pts were randomized to either hybrid TR+usual care (telerehabilitation group[TG]) or to usual care only (control group[CG]) and are followed for a maximum of 24 months. The TG pts underwent a 9-week hybrid TR program consisting of an initial stage (1 week) conducted at hospital and a basic stage (8-week) home-based TR five times weekly. The goals of the initial stage are: a baseline clinical examination, education, individual planning of exercise training and performing a few monitored educational training sessions. The TG pts received a device for remote supervision of the exercise training (telemonitoring ECG, blood pressure, weight). The primary study outcome is the number of days alive and out of hospital (DAOH) in the 12 months following the end of the preliminary 9-week training program. Secondary outcomes assessed at 12 months include all-cause and cardiovascular mortality, all-cause, cardiovascular and heart failure hospitalization. Secondary outcomes assessed at 9 weeks include: the effectiveness based on peak oxygen consumption in cardiopulmonary exercise test and the distance in 6-minute walking test; the QoL based on SF-36 Survey; the depression based on Beck inventory; the anxiety based on STAY; the acceptance based on questionnaire and the adherence based on the percentage of pts who carried out the prescribed exercise training.
Results All pts were randomised and completed the intervention (TG) and observation (CG) period. The follow up is now in progress. The results will be available in 2019/2020.
Conclusion The TELEREH-HF trial will provide novel data on the effect of the hybrid TR on days alive and out of hospital, hospitalization and mortality in HF pts and safety, effectiveness, QoL, depression, anxiety and pts acceptance of and adherence to this intervention.

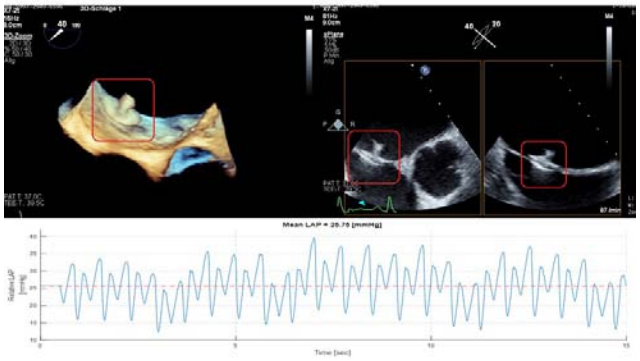
VECTOR-HF: The first human experience with a wireless left atrial pressure monitoring system for patients with heart failure

H Sievert[1]; D Erdheim[2]; K Sievert[1]; P Matic[1]; M Reinartz[1]; B Jovanovic[1]; S Zaker[1]; I Hofmann[1]; L Vaskelyte[1]
[1]CardioVascular Center Frankfurt, Frankfurt am Main, Germany; *[2]Vectorious Medical Technologies, Tel Aviv, Israel*

Funding Acknowledgements: H2020

Background: Invasive pressure-guided therapy has been shown to improve outcomes in patients with heart failure (HF). Thus far, only right-sided pressure sensors have shown clinical efficacy and safety.
Purpose: We hereby describe the first human experience with a novel battery-less and wireless left-sided pressure monitoring system, directly assessing left-atrial pressure (LAP) in an ambulatory setting. In pre-clinical studies, it was shown to enable accurate and safe measurement of LAP.
Methods: The V-LAP left atrial monitoring systEm for patients with Chronic sysTOlic and diastolic congestive heart failuRe first-in-human (VECTOR) study is a prospective, multicenter, single arm, open-label clinical trial to assess the safety, performance and usability of the V-LAP system in patients with heart failure. The V-LAP wireless sensor is implanted using a trans-septal access, under angiographic and echocardiographic guidance. The system includes an external unit, which both powers the implant and collects data via radio frequency communication upon activation, designed to be operated on a daily basis. We hereby describe the first case/s implanted.
Results: At this point in time, there has been one implantation of the V-LAP performed in a 52-year-old male patient who suffered from non-ischemic cardiomyopathy, with symptoms corresponding to NYHA Class III. The patient was admitted repeatedly for exacerbations of HF, and demonstrated elevated NT-ProBNP levels. He was therefore considered a candidate for the monitoring system, to enable optimal medical therapy. The procedure was performed in a trans-femoral, trans-septal fashion, under mild sedation, with a successful implantation of a V-LAP and calibration for pressure measurement. There were no intra-procedural complications, procedure time was less than one hour, deployment time of the device took less than 6 minutes from sheath insertion to implant disengagement (see 3D Echo image below) and that the patient was discharged home early morning the day after the procedure. During discharge the patient performed independently LAP measurements using the external system that were captured in the data display software at the hospital via a cloud-based system (please see below LAP waveforms measured).
Conclusions: In the first-in-human case, the implantation of the novel wireless left atrial pressure sensor V-LAP was feasible, safe, and showed good accuracy and precision. We now await both short and long-term efficacy and safety outcomes of the device in this patient and others, with the hopes of optimizing care for patients with HF.



Patient DE-01-01 Echo and LAP wave forms

Wearable multi-sensor platform with 7 days-ECG

KJG Schmailzl[1]; H Toumi[2]; F Thomas[2]; M Woellenstein[3]
[1]*Carl-Thiem-Klinikum, Strategische Projektentwicklung, Cottbus, Germany*; [2]*Ruppiner Kliniken, Medizinische Klinik A, Neuruppin, Germany*; [3]*AthenaDiax GmbH, Neuruppin, Germany*

Background Today you either get a fitness tracker out of the consumer health products' world easy to apply but with seriously limited informative value, or you go for a medical product like a traditional Holter ECG with proven validity but limited suitability for daily use. There is a need for serious monitoring of vital data beyond pulse rate and counting steps, data which could be integrated in a professional setting.
Approach As a spin-off of the digilog ('Digital and analog companions of an ageing society') project (funded by the Federal State of Brandenburg, Germany), we developed a wearable multi-sensor platform with a 7 days-ECG implemented. The device is glued to the thorax and does not have any cables; you even can have a shower with it. You get a full-disclosure ECG with 3 leads. We tested validity and reliability with 200 patients and compared the results in a subset to a simultaneously applied conventional (24 h) Holter ECG.
Results Drop-out rate (mainly due to operating errors or technical problems) was 3 % (6/200). Acceptance by patients and referring doctors was excellent. Atrial fibrillation was detected in the 7 days-devices more often and more reliable than in the 24 h-Holter ECGs. Detected heart rates, ectopic beats and atrial fibrillation were comparable. The rate of artifacts was significantly lower in the wearable group.
Conclusions A wearable multi-sensor platform with a 7 days-ECG implemented was successfully tested as proof-of-concept and compared to conventional Holter ECG.

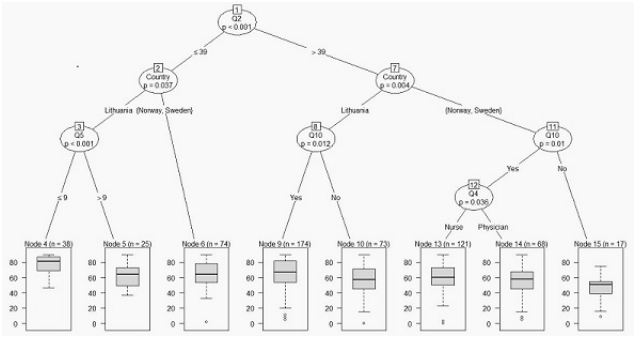
Young computer-literate health care professionals have the greatest expectations for heart failure telemonitoring

E Lycholip[1]; I Thon Aamodt[2]; I Lie[3]; R Helleso[2]; A Stromberg[4]; T Jaarsma[5]; J Celutkiene[1]
[1]*Institute of Clinical Medicine of the Faculty of Medicine of Vilnius University, Clinic of Cardiac and Vascular Diseases, Vilnius, Lithuania*; [2]*University of Oslo, Faculty of Medicine, Institute of Health and Society, Department of Nursing Science, Oslo, Norway*; [3]*Oslo University Hospital, Centre for patient centered heart- and lung research, Department of Cardiothoracic surgery, Oslo, Norway*; [4]*Linkoping University, Department of Medical and Health Sciences, Linkoping, Sweden*; [5]*Linkoping University, Department of Social- and Welfare studies, Norrkoping, Sweden*

On behalf of: NordForsk
Funding Acknowledgements: Nordic Program on Health and Welfare. Pr. No 76015

Background: The attitude and expectations of health care professionals (HCPs) for using remote telemonitoring (TM) in patients with heart failure (HF) may be important for implementation of the remote care into clinical practice.
Objective: To identify the characteristics of HCPs who have high expectations for TM of HF patients.
Design and Methods: Data from a cross-sectional survey examining HCPs' expectations of non-invasive HF telemonitoring was performed nationwide in three Nordic Baltic countries. Participants were cardiologists and nurses working with HF patients in 41 hospitals in Lithuania (n=310), 57 hospitals in Norway (n=226) and 61 hospitals in Sweden (n=120).
The degree of expectations for TM was calculated as the sum of the 10 items (each score from 0–10) listed as reasons for TM such as reducing admissions/readmission, improving patient self-care, reducing the workload on the HF clinics, reducing costs, etc. Thus, the maximal score could be 100, consistent with the highest expectations for TM. A regression tree analysis was performed, with a continuous target variable of expectations for TM and HCPs' characteristics as input variables. Age, sex, country, discipline (nurse or cardiologist), years of post-graduate experience, familiarity with TM and experience with computer programs were all entered as input variables.
Results: The regression tree analysis (Figure 1. Regression tree showing HCPs' characteristics with the highest expectations for telemonitoring of heart failure patients) revealed that HCPs who were younger (under 39 years of age), and among them Lithuanians with a work experience of up to 9 years, had the highest expectations. Meanwhile, among HCPs that were older (above 39 years old) those who had longer experience with software such as Word, PowerPoint and Excel, showed the highest expectation level. In this group, the Norwegian and Swedish nurses had significantly higher expectations than physicians in those two countries.
Conclusion: Age, work experience, computer skills and profession have influence on the level of expectations for heart failure telemonitoring. These findings may be important for future interventions to implement non-invasive telemonitoring.
Legend of Picture: Central lines represents median scores, boxes represent the 25th and 75th percentiles, and whiskers extend to the lowest data point within 1.5 IQR of the lower quartile and the highest data point within 1.5 IQR of the upper quartile. Dots represent extreme values.
Inputs: Country; Q1 (Sex); Q2 (Age); Q4 (What is your current job?); Q5 (How many years of postgraduate experience do you have?); Q10 (Do you have experience with software such as Word, PowerPoint, Excel?); Q15 (Are you familiar with heart failure telemonitoring?).
Output: the sum of all scores chosen in the question about reasons for TM and expressed as median value with IQR.



Regression tree

The place of telemedicine in the management of heart failure in community medicine: general practitioner perceptions of a regional telemedicine platform in Normandy, France

R Sabatier[1]; D Legallois[1]; G Tonani[2]; V Donio[3]; M Dova-Boivin[4]; T Thibault De Chalus[4]; A Belin[1]
[1]*University Hospital of Caen, Cardiology Department, Caen, France*; [2]*URML Normandy, Caen, France*; [3]*CEMKA Eval Medical Center, Bourg La Reine, France*; [4]*Amgen SAS, Boulogne-Billancourt, France*

Funding Acknowledgements: This work was supported by an unrestricted grant from AMGEN SAS

Background: Telemedicine provides a solution to the challenges posed by the ageing population and the low density of medical services in rural areas. Telemedicine is particularly appropriate for following chronic patients with unpredictable course. Telemedicine programmes for monitoring patients with heart failure (HF) have been established in France in recent years, but little is known about how they are used by general practitioners (GP). The Suivi Clinique A Domicile (SCAD) is a regional telemedicine platform in Normandy open to all GPs and community cardiologists to promote monitoring and empowerment of HF patients after hospitalisation. Patients provide data to the system daily and are receiving advices for diet, treatment and physical activity self-management. In addition, an alert is automatically triggered if values depart from the normal range allowing dedicated HF-nurses to intervene. The SCAD platform has been shown to reduce the need for emergency hospitalisation.Purpose: To evaluate perceptions of GPs concerning the utility of the SCAD platform.

Methods: An on-line survey was sent to all GPs in Normandy in May 2018 by the regional GP association (URML). This was a multiple-choice questionnaire asking 10 questions about awareness and perceptions of the SCAD platform. Data were analysed separately for Lower Normandy, where GPs had been able to include patients in SCAD since 2015, and Upper Normandy, where the platform had not yet been opened to GPs.
Results: 137 GPs participated in the survey (69 in Lower Normandy and 68 in Upper Normandy). Most of these (70.1%) had less than five patients with unstable HF in their practice. In Lower Normandy, 52/69 GPs (75.4%) were aware of the SCAD platform, 14.5% used it for their patients, 52.2% considered the platform useful and 76.0% would like to include patients in it. In Upper Normandy, 49/68 (62.1%) were aware of the platform, but 58.8% did not know if it would be useful. However, 66.7% would like to include patients. In both areas, the platform was considered most useful for following key clinical variables of their patients at home (64.0% overall), for teaching patients to self-monitor and detect warning signs (66.0%) and the availability of a nurse for monitoring alerts and contacting the GP (58.0%). Aspects of the platform that could be improved were to be better informed about SCAD (62.0% overall), to have access to the data on their patients held in the platform database (48.0%), and to train the patients better and to develop patient education (40.0%) and to enrol patients independently of the hospital (20.2%).
Conclusion: GPs in Normandy are interested in using telemedicine for managing patients with HF even though only a minority have any practical experience with the available platform. Better information on the SCAD platform could encourage GPs to become actively involved in telemonitoring. The programme could also be adapted to allow GPs to include patients directly.

P2181
Awareness study of patients with arterial hypertension

O Oleksii Demikhov[1]; S Nei[2]; N Demikhova[1]
[1]Sumy State University, Sumy, Ukraine; *[2]Tartu University Hospital, Family Medicine, Tartu, Estonia*

Important aspects of the organization of medical care for patients with arterial hypertension (AH) are the motivation of patients for treatment, their compliance with the recommendations for modification of lifestyle and regimen of medical therapy. In most countries, only 12% of the patients with hypertension are diagnosed, the therapy is prescribed and the target blood pressure is reached.
The question of using the information obtained as a result of monitoring, on the processes of making management decisions in the field of quality management of medical aid remains inadequately studied. To improve the effectiveness of medical care for patients with AH, it is necessary to determine the degree of patient adherence to treatment by monitoring their level of awareness.
Purpose: to analyze the results of medical and social studies of the level of awareness of dispensary patients with AH in Sumy city regarding the course of their disease, implementation of preventive measures, diagnosis, treatment.
Material and methods of research. They conducted questionnaires, measurements of pressure, preventive conversation with patients regarding lifestyle modification and risk factors. 2100 patients were interviewed. Of these, men comprised 29.3%, women 70.7%. By age, the audience was distributed as follows: 18-34 years - 7.3%; 35-59 y. - 29.9%; 60 and over - 62.7%.
Results. Most of the respondents exercise control over arterial pressure. Thus, 63% of patients constantly monitor pressure; 29% periodically measure it; 8% - did not measure during the year at all. The following data testify to the high level of advisory support for patients: the vast majority of respondents - 97% - confirm receipt of detailed information about their illness in the clinic. Drug treatment was prescribed in 93% of patients. However, despite the high level of awareness of the patients, the results of the survey indicated an inadequate level of their responsibility for their own health. Only 48% of respondents regularly take medications, 33% - regularly take medication; 19% - do not accept at all. The main causes of irregular drug intake are the following: 48% - I forget, 27% - high cost of medicines, 14% - I do not want, 11% - does not help. According to the results of the survey, 29% of patients with arterial hypertension had crises in the analyzed period. 12% of the respondents called the district doctor, 5% - ambulance, 11% - were inpatient treatment. During the year, 42% of the respondents dispensary patients visited a district doctor more than two times; 10% - 2 times; 16% - one time; 32% - never asked a doctor.
Conclusions. Patients with AH in Sumy are aware of the course of their illness. The main reason for unsatisfactory performance of the doctor's recommendations is that the patients indicate: 'I forget', 'I have no time', 'I do not want to'. A system of constant reminders for the need for control of pressure, treatment, and a healthy lifestyle is needed.

P2182
Daily monitoring parameters of arterial stiffness and central aortic pressure in patients with ankylosing spondylitis

T Aksenova[1]; N Ivashenko[1]; V Gorbunov[1]; S Tsarenok[1]; P Gromov[1]
[1]Chita State Medical Academy, The hospital within the Russian Railroad Network, Chita, Russian Federation

Background. In recent years the increased arterial stiffness in Ankylosing Spondylitis (AS) was shown. However today this issue has not been adequately studied.
Purpose: To investigate the central aortic pressure and arterial stiffness parameters during daily monitoring in patients with AS.
Methods. 49 patients with AS (mean age 39.6 ± 10.6, 38 men, 11 woman) were examined. AS Disease Activity Score (ASDAS-CRP) was 3.11±0.55. Duration of AS was 5.87 ±4.76 years. X-ray stage sacroiliac joints (according Modified New York Criteria) was 2.59±1.42. The control group included 24 healthy nonsmokers. The groups were similar in age, sex and daily peripheral blood pressure parameters. 10 patients with AS had history of arterial hypertension, however, at the time of inclusion in this study their blood pressure was stabilized. 18 patients with AS had smoking history, the smoking index was 18.05±11.57 pack-years. The ambulatory (daily) monitoring of the peripheral, central aortic pressure and parameters of arterial stiffness were made by device with Vasotens technology. This device uses an oscillometric method of blood pressure measurement with automatic calculation of aortic pressure parameters. For statistical analysis we used Mann-Whitney criteria and Spirmen correlation method. The study was based on GCP principles.
Results. Increased levels of aortic systolic blood pressure (SBP) (114.8±12.4 vs 106.9±6.9, =0.006), aortic diastolic blood pressure (DBP) (78.5±9.3 vs 68.7±11.1, = 0,0001) were determined in patients with AS. Patients with AS demonstrated the increase of minimum, medium and maximum pulse wave velocity (PWV) compared to healthy individuals on 7.44% (p = 0.048), 15.78% (p = 0.0001) and 26.17% (p = 0.0001), respectively. Ambulatory Arterial Stiffness Index (ASI) in patients Ankylosing Spondylitis was higher compared with control group on 59.09% (p=0,002). Subendocardial viability ratio (SERV) medium per day was lower compared with control group on 9.4% (p=0,0001). PWV medium per day was directly correlated with total cholesterol (r= 0,41; p=0,026). SERV maximum per day was negative correlated with X-ray stage of sacroiliitis (r= 0,38; p=0,008). SERV medium per day was negative correlated with C-reactive protein (r= - 0,40; p=0,017), and with ASDAS-CRP (r= - 0,43; p=0,003). Smoking index was directly correlated with aortic SBP minimum per day (r= 0,49; p=0,044), aortic SBP medium per day (r= 0,52; p=0,032), aortic pulse pressure minimum per day (r= 0,55; p=0,021), aortic augmentation pressure (r= 0,62; p=0,017). The aortic blood pressure profiles were non-dipper on 57,15%, dipper on 30,61%, over-dipper and night-piker on 6,12% respectively in patients with AS.
Conclusions: Increasing indicators of arterial stiffness were determined in patients with AS. The relationship between clinical and laboratory data and arterial stiffness parameters was demonstrated. The aortic non-dipper type was dominated in the patients with AS.

P2183
Prothrombotic state as a causative of impaired left ventricular diastolic function in patients with primary antiphospholipid syndrome

A Djokovic[1]; L Stojanovich[1]; N Stanisavljevic[1]; M Zdravkovic[1]; DV Simic[2]
[1]University Hospital Medical Center Bezanijska Kosa, Belgrade, Serbia; *[2]University Clinical Center of Serbia, Clinic of cardiology, Belgrade, Serbia*

BACKGROUND: Cardiovascular manifestations, encountered in antiphospholipid syndrome, may develop as consequence of thrombophilia mediated by antiphospholipid antibodies and accelerated atherosclerosis as well. Our study aims to assess the impairment of left ventricular diastolic performance, as an early evidence of myocardial involvement in primary antiphospholipid syndrome (PAPS).
METHODS: We analyzed 100 APS patients, average age 47.70±13.14. Anticardiolipin antibodies (aCL IgG/IgM), anti-ß2 glycoprotein-I (anti-ß2GPI IgG/IgM) and lupus anticoagulant (LA) were determined. Abnormal cutoff values (more than half) for left ventricular diastolic dysfunction (LVDD) were septal e′ < 7 cm/sec, lateral e′ < 10 cm/sec, average E/e′ ratio > 14, LA volume index > 34 mL/m2 , and peak tricuspid regurgitation velocity > 2.8 m/sec. Results were compared to 45 healthy, age and sexmatched controls.
RESULTS: LVDD was significantly more prevalent in PAPS patients comparing to healthy controls (24.8% vs 2.2%, p=0.001). It was significantly related to age, body mass index, hyperlipidemia, venous thromboses and LA positivity in PAPS patients (p=0.0001, p=0.008, p=0.039, p=0.001, p=0.047 respectively). Patients with PAPS had higher LAVI (29.76±6.40 ml/m2 vs 26.62±7.8 ml/m2, p=0.012). Higher isovolumic relaxation time, lower lateral Ee velocity and lower lateral E/Ee ratio were seen in PAPS compared to controls (p=0.0001, p=0.020, p=0.038, respectively).

CONCLUSION: Echocardiography and LVDD recognition identifies preclinical cardiac involvement in PAPS patients, especially in those with venous thromboses and LA positivity. Given that LVDD is a main determinant of heart failure with preserved ejection fraction, timely recognition of prothrombotic state presence, seems to be mandatory

P2184

Echocardiographic differences between early- and late anthracycline-induced cardiotoxicity reveals a distinct cardiomyopathy phenotype

JAM Kamphuis[1]; MPM Linschoten[1]; A Van Rhenen[2]; RM Bijlsma[3]; MJM Cramer[1]; FW Asselbergs[1]; PAF Doevendans[1]; AJ Arco Teske[1]
[1]University Medical Center Utrecht, Department of Cardiology, Utrecht, Netherlands (The); [2]University Medical Center Utrecht, Hematology, Utrecht, Netherlands (The); [3]University Medical Center Utrecht, Oncology, Utrecht, Netherlands (The)

Background: Anthracycline-induced cardiotoxicity (AIC) can be classified to be an early effect (diagnosed <1 year after treatment; EAIC) or late effect (diagnosed >1 year after treatment; LAIC) of cancer treatment. Previous studies suggest that the success of conventional heart failure treatment in patients with AIC is dependent on the timing of treatment initiation.
Objectives: We hypothesize that echocardiographic parameters of cardiotoxicity, such as left ventricular dysfunction and –dilatation, are more pronounced when there is a delay in AIC diagnosis.
Methods: At our cardio-oncology outpatient clinic, we identified 106 newly diagnosed patients with AIC the last 3 year, of which 59 patients were diagnosed within 1 year after treatment (EAIC) and 47 > 1 year after treatment (LAIC). Left ventricular dimensions (end-diastolic volume (EDV); end-systolic volume (ESV)), 3D left ventricular ejection fraction (LVEF) measurements were performed on the echocardiography on which the diagnosis of AIC was confirmed.
Results: Median time [range] between last administration of anthracyclines and diagnosis of AIC was 4.0 [0.2 – 10.6] months for EAIC and 55.7 [12.7 – 445.2] months for LAIC. Overall, 33/106 (31%) patients showed increased end-diastolic volume, against 82/106 (77%) patients in which end-systolic volume was increased. There were no significant differences in left ventricular volumes between the two groups (EDV: EAIC 63.9 ± 14.5 ml/m2; LAIC 63.6 ± 18.2 ml/m2; p=0.941 || ESV: EAIC 36.1±10.0 ml/m2; LAIC 36.7±13.2ml/m2; p=0.784). Mean LVEF was comparable between groups, with a mean LVEF of 43.7±5.6% for EAIC, and 43.0±6.0% for LAIC (p=0.546). There was no correlation between LVEF and time between treatment and diagnosis of AIC (r=-.187; p=0.055).
Conclusion: In our study we have found that the echocardiographic phenotype of EAIC and LAIC were comparable. In contrast to other causes of dilated cardiomyopathy, prolonged left ventricular dysfunction due to anthracyclines does not seem lead to dilation of the left ventricle.

P2185

Association of expression of steroid receptors with development of chemotherapy induced cardiotoxicity in Patients with breast cancer

MN Mi-Na Kim[1]; SM Park[1]; HD Kim[1]; DH Cho[1]; SP Jung[1]; KH Park[1]; WJ Shim[1]
[1]Korea University Anam Hospital, Seoul, Korea (Republic of)

Background The expression of estrogen receptor (ER) and progesterone receptor (PR) in tumor cell has prognostic value and is crucial to determine treatment strategy in breast cancer. The protective functions of these steroid hormone in cardiovascular disease are mediated via their receptors that exist in heart and vessels. Nevertheless, the relation between steroid receptor profile and development of chemotherapy induced cardiotoxicity (CIC) have not been clearly demonstrated.
Methods.
Forty one consecutive patients (mean age=54.4±8.9 years) with breast cancer who undergone chemotherapy were included. Baseline echocardiography was performed within 1 day before chemotherapy and was followed up 3month after start of chemotherapy. The CIC was defined as a decrease of left ventricular ejection fraction (LVEF) by 5% or more to less than 55% in the presence of symptoms of HF or an asymptomatic decrease in LVEF by 10% or more to less than 55%. ER and PR status were evaluated and their expression was accessed by quantitative percent on an immune-histochemical method.
Results: Seven patients (17% of study population) was developed CIC in 3 month follow up. Not only prevalence of clinical risk factors, including hypertension, diabetes, dyslipidemia and obesity, but also administrated chemo agents were not different between patient with and without CIC. The baseline LVEF and global longitudinal strain (GLS) of LV were not different between patients with and without CIC (LVEF: 60.3+7.3% vs 61.8+5.1%, P=0.497 and GLS: -18.2+3.5% vs -19.7 2.9%, P=0.232).
The prevalence of positive both receptors was higher in patients with CIS, but that were not significant (ER-85.7% vs 64.7% P=0.399 and PR-85.7% and 70.6%, P=0.651, respectively). However, in patients with CIC, the expressions of ER and PR were significantly increased than in patients without CIC (figure 2). In total study population, ΔGLS was related ER expression (r=-0.317, P=0.047) and it had a favorable trend to associate with PR expression (r=0.-276, P=0.081).
Conclusion: From these finding, the association of quantity of expression of steroid receptors with the development of CIC might be supposed. Further study is necessary to elucidate this result in large population with long term follow up.

Figure 1. The comparison of changes of LVEF and GLS between patients with and without CIC

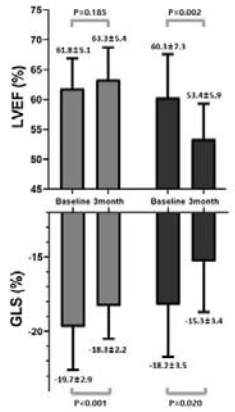

Figure 2. The differences of expression of both steroid receptors between patients with and without CIC

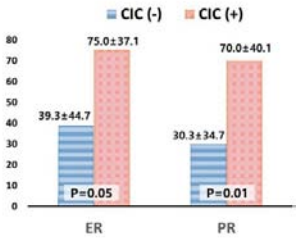


P2186

Hand grip strength testing in cancer patients

P Weinlaender[1]; S Hadzibegovic[1]; A Lena[1]; L-C Lueck[1]; A Letsch[1]; W Doehner[1]; U Landmesser[1]; S Von Haehling[2]; SD Anker[1]; MS Anker[1]
[1]Charite University Hospital, Berlin, Germany; [2]University Medical Center Gottingen (UMG), Gottingen, Germany

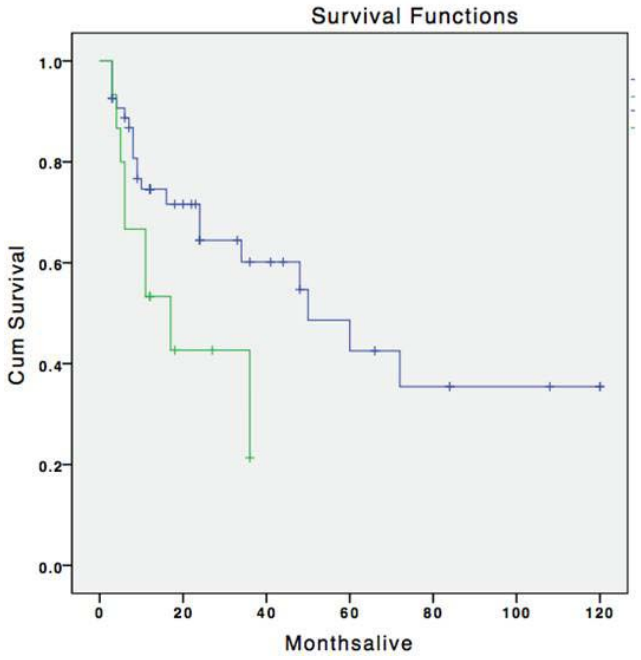
Background: Many cancer patients develop sarcopenia and cardiovascular dysfunction. Maximum Hand grip strength (HGS) is a simple and quick measurement to test for possible cardiovascular dysfunction and sarcopenia – but a consensus on the exact methodology for the assessment of maximum HGS is missing.
Purpose: To prospectively test how many trials are needed to determine maximum HGS and its correlation with body composition parameters, appetite and CV disease status.
Methods: From September 2017 to December 2018, we prospectively enrolled 113 patients with histologically confirmed cancer without significant cardiovascular disease (age 62±14yrs, 46% men, body mass index (BMI) 25.2±5.1kg/m2) and 25 controls (age 57±10yrs, 36% men, BMI 25.1±3.4kg/m2). The cancer group consisted of 6 non-small cell lung cancers (5%), 7 colorectal cancers (6%), 19 breast cancers (17%), 6 other cancers (5%), and 75 lymphoma patients (66%). At baseline, with a digital hand dynamometer, maximum HGS was tested 4x on the preferred arm and 3x on the non-preferred arm and transthoracic echocardiography was performed.
Results: Cancer patients demonstrated lower maximum HGS than controls (30.7±12 vs 38.9±14kg, p=0.0028). Subgroup analysis by sex showed higher maximum HGS in male vs female in cancer patients and controls (39.3±11 vs 23.4±6kg, p<0.0001; 54.1±11 vs 30.4±5kg, p<0.0001). Maximum HGS on the preferred arm was reached during the 1st/2nd/3rd/4th trial in 36/19/17/9% of cases and on the non-preferred arm during 1st/2nd/3rd trial in 12/5/2%. 81% of patients reached their maximum HGS on their preferred arm and 19% on their non-preferred arm. Patients with NYHA grade 3/4 (23% of patients) compared to NYHA grade 1/2 (77%) showed lower maximum HGS (26.6±8.8 vs 32.0±12.5kg, p=0.0436). In regression analysis, cancer patients' maximum HGS correlated with upper arm (r=0.323, p=0.0006), forearm (r=0.348, p=0.0002), thigh (r=0.319, p=0.0007), calf (r=0.203, p=0.0333) circumference, appetite (visual analogue scale from 0-100, r=0.294, p=0.0022), left ventricular internal diameter end diastole (LVIDd, mean: 46±5mm, r=0.341, p=0.0024), and mean E/e' ratio (mean: 9.2±3.5, r=-0.268, p=0.0150). Ejection fraction and E/A ratio did not show significant correlation with maximum HGS.
Conclusion: Maximum HGS should be tested 4x on the preferred arm and 3x on the non-preferred arm. Maximum HGS was reduced in cancer patients and correlated with upper arm, forearm, thigh, calf circumference, appetite, LVIDd and mean E/e' ratio.

P2187

Echocardiographic phenotype and long-term prognosis in patients with light-chain cardiac amyloidosis

A Ntalianis[1]; E Tseliou[1]; E Repasos[1]; E Papadopoulou[1]; M Tselegkidi[1]; N Zografos[1]; D Ziogas[1]; A Koutsoukis[1]; G Maglaras[1]; J Stamoulopoulos[1]; A Koen[1]; I Dialoupi[1]; E Kastritis[1]; MA Dimopoulos[1]; I Paraskevaidis[1]
[1]University of Athens Medical School, Dept of Clinical Therapeutics, Alexandra Hospital, Athens, Greece

Background/Introduction: Light-chain cardiac amyloidosis (CA) associates with a poor prognosis. No data exist about the prognostic impact of the different remodeling patterns observed in heart echo in CA patients.
Purpose: To investigate whether different remodeling phenotypes are related with long-term prognosis in patients with CA.
Methods: Consecutive patients with light-chain CA followed in our cardio-oncology unit were prospectively recruited. Remodeling pattern was characterized at baseline heart echo after calculating relative wall thickness (RWT) and left ventricular mass index (LVMI). An RWT>0.42 and LVMI≤95 for women or ≤115 for men characterized a concentric remodeling pattern (CR), whereas an RWT>0.42 and LVMI>95 for women and >115 for men characterized a concentric hypertrophy pattern (CH). NT-proBNP as well as k and l chains were also assessed. All patients were treated by the oncologists with appropriate chemotherapy regimen.
Results: In total, 73 patients with a mean age of 65±2 years were followed from 6 to 120 months. From those, 57 patients presented with a CR pattern and 16 with a CH pattern. The CH phenotype associated with better survival rates (p=0.04, figure 1). There was no difference in left ventricular ejection fraction, diameters, NT-proBNP and light chain levels between CR and CH groups. Higher E/E' values were found in the CH group (18.9±2 vs 13±0.9, p=0.009).
Conclusions: Concentric hypertrophy associates with a better long-term prognosis in patients with CA.



Remodeling phenotype and survival

P2188

Evidence for a cardiac metabolic switch in patients with Hodgkin's Lymphoma

M B Heckmann[1]; B Totakhel[1]; D Finke[1]; M S Anker[2]; C Mueller-Tidow[3]; U Haberkorn[4]; H A Katus[1]; L H Lehmann[1]
[1]University Hospital of Heidelberg, Cardiology Department, Heidelberg, Germany; [2]Charite - Campus Benjamin Franklin, Department of Cardiology, Berlin, Germany; [3]University Hospital of Heidelberg, Department of Hematology, Oncology and Rheumatology, Heidelberg, Germany; [4]University Hospital of Heidelberg, Department of Radiology, Nuclear Medicine, Heidelberg, Germany

Aims: Our aim was to investigate the glucose uptake in cancer patients suffering from different entities, using 18F-FDG PET-CT scans. Further, to identify potential variables altering cardiac and skeletal muscle glucose metabolism.
Methods and results: We retrospectively analysed cardiac and skeletal muscle 18F-FDG uptake in Onco-PET-CT scans conducted between 2014 and 2018 from 337 consecutive adult patients suffering from Hodgkin's lymphoma, non-Hodgkin's lymphoma, and non-lymphatic cancer (thyroid carcinoma, bronchial carcinoma, and malignant melanoma). Univariate logistic regression models were created for increased cardiac and skeletal muscle 18F-FDG uptake using cancer entity, sex, age, previous radiation, previous chemotherapy, diabetes, obesity, serum glucose levels, renal function, and thyroid function as parameters. High serum glucose levels were accompanied by lower absorption rates in both cardiac and skeletal muscle. Hodgkin's lymphoma was associated with an increase in cardiac uptake. Decreased skeletal muscle 18F-FDG uptake was noted in elderly and obese patients. In multivariate models, Hodgkin's lymphoma patients showed higher 18F-FDG uptake, while non-Hodgkin's lymphoma patients did not differ significantly from non-lymphatic cancer patients. High serum glucose levels and prior chemotherapy were both associated with a significantly decreased cardiac 18F-FDG uptake. Notably, prior chemotherapy did not influence FDG uptake in skeletal muscle to the same extent. Obesity and older age were both significantly associated with decreased gluteal 18F-FDG uptake.
Conclusion: Our data provide first evidence for a metabolic alteration in patients with Hodgkin's lymphoma related to cardiac glucose uptake in humans. This effect seems to be independent from skeletal muscle metabolism.

P2189

Early detection of cardiotoxicity in breast cancer patients: red flags according to a traffic lights - like coding system after long-term experience at a referral centre

M E Tettamanti[1]; I Gimenez[1]; C Chacon[2]; V Costanzo[3]; J Nadal[3]; A Nervo[3]; F Losco[3]; R Chacon[3]; D A Santos[1]
[1]Alexander Fleming Institute, Cardio Oncology, Buenos Aires, Argentina; [2]Alexander Fleming Institute, Radiotherapy, Buenos Aires, Argentina; [3]Alexander Fleming Institute, Oncology, Buenos Aires, Argentina

Background: breast cancer treatment (adriamycin, cyclophosphamide) or its association to trastuzumab for HER 2 positive breast cancer, can produce cardiotoxicity (CTX) and lead to the transient or permanent stop of oncologic treatment. In some cases patients remain with some degree of left ventricular dysfunction (LVD) in the long term.
Purpose: to design a red flags coding system to label the patients according to the magnitude of LVD and to early detect and treat CTX associated to breast cancer treatment.
Methods: we performed an echocardiographic evaluation at baseline and every 3 months during the first year, and then every 4 months along follow up. We assessed left ventricular ejection fraction (LVEF) by Simpson's method, global longitudinal strain rate and tissue Doppler velocity (lateral wall of the left ventricle). We assigned patients to one of three groups of CTX according to a traffic lights- like coding system: red code patients showed a >10 percentage points drop of their LVEF from baseline, an LVEF <55% or had heart failure symptoms; yellow code patients showed an LVEF drop between 5 to 10 percentage points along treatment; green code patients showed a non-significant LVEF drop of <5 percentage points.
Results: between January 2010 to April 2017, we assessed 555 consecutive breast cancer patients (mean follow up period 22 ± 35,2 months). Table shows the three different groups of patients and their echocardiographic results, need to start cardiologic treatment and the impact on their oncologic treatment (the need to transient or permanently stop it).
Conclusions: classification of breast cancer patients according to a traffic lights – like coding system along their oncologic treatment let us identify patients in terms of their LVD behavior. Patients in the red code group showed the highest need of stopping oncologic treatment and of starting neurohormonal antagonists for their LVD. This system allowed us to early detect patients who develop LVD along their oncologic treatment and follow up period and to concisely communicate the CTX associated to breast cancer treatment to the oncologists.

Results

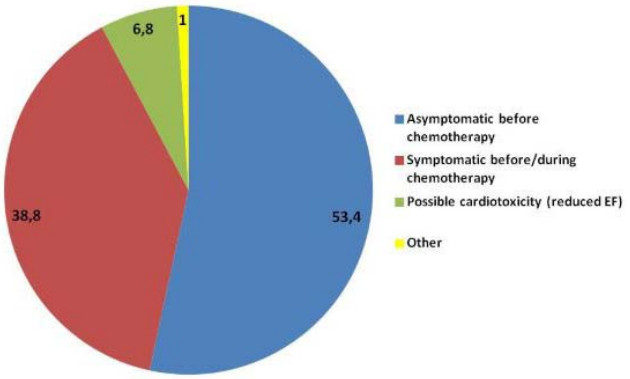
First preliminary demographic data of the referrals from a university hospital Cardio-Oncology outpatient clinic

A Ntalianis[1]; A Misegiannidis[1]; K Tampakis[1]; E Repasos[1]; M Kondylis[1]; I Petropoulos[1]; G Maglaras[1]; E Aninos[1]; A Mareti[1]; E Venieri[1]; N Zografos[1]; F Zagouri[1]; N Pampoukas[1]; MA Dimopoulos[1]; I Paraskevaidis[1]
[1]*University of Athens Medical School, Dept of Clinical Therapeutics, Alexandra Hospital, Athens, Greece*

Background/Introduction: The management of patients with cancer is complex and requires a multidisciplinary team approach involving oncologists, surgeons, radiologists and clinical cardiologists. To meet this need Cardio-Oncology units have been recently developed worldwide.
Purpose To report demographic data from all the referrals to a Cardio-Oncology outpatient clinic of a tertiary university hospital.
Methods From January 2016 to December 2018 all Oncology patients referred to our Cardio-Oncology unit were included. The following clinical and laboratory data were recorded at baseline visit and analyzed: gender, age, predisposing risk factors for cardiotoxicity (PFC), reason for referral (RFR), ejection fraction (EF), end diastolic diameter (EDD), end systolic diameter (ESD), biochemical parameters, oncology history and therapies and cardiological diagnostic and therapeutic plan.
Results A total of 88 patients (mean age of 64.7 years, 52.3% female) were included. The most common RFR was consultation before chemotherapy in high risk asymptomatic patients (53.4%) (figure 1). From the patients' oncology history, the most frequent malignancy was amyloidosis (47.1%) and the second most common breast cancer (14.9%). The most frequent PFC were: hypertension (30.7%), diabetes mellitus (19.3%), hypercholesterolemia (18.2%), smoking (18,2%) and coronary artery disease (13.6%). The mean EF of the study population was 46.9%, the mean EDD 48mm, and the mean ESD 33.3mm. The most common diagnostic tests ordered before chemotherapy included: heart ultrasound with strain (36%), 24-hour Holter monitoring (24%) and myocardial perfusion imaging (24%). Before chemotherapy, beta blockers were prescribed in 28% and diuretics in 32% of patients.



Reason for referral

Conclusions Oncology patients referred for consultation to a tertiary Cardio-Oncology unit present with a constellation of PFC. Further diagnostic work-up and drug adjustment are warranted for at least one third of the patients before chemotherapy.

Cardio-toxicity among sarcoma patients: a cardio-oncology registry

LM Michal Laufer-Perl[1]; Z Rozenbaum[1]; O Merimsky[1]; J Sherez[1]; G Keren[1]; Y Topilsky[1]; Y Arbel[1]; S Shamai[1]
[1]*Tel Aviv Sourasky Medical Center, Cardiology, Tel Aviv, Israel*

Background: Chemotherapy induced cardio-toxicity has been recognized as a serious side effect since the first introduction to anthracycline (ANT). Cardio-toxicity among breast cancer patients is well studied but the impact on sarcoma patients is limited, even though they are exposed to higher ANT doses. The commonly used term for cardio-toxicity is cancer therapeutic related cardiac dysfunction (CTRCD), defined as a left ventricular ejection fraction (EF) reduction of >10%, to a value below 53%.
Objectives: To estimate the prevalence of CTRCD among sarcoma patients, to perform risk stratification for its development and evaluate whether CTRCD is associated with mortality.
Methods: Data were collected as part of the International Cardio-Oncology Registry (ICOR), enrolling all patients who were evaluated in the cardio-oncology clinic at our institution. All sarcoma patients were enrolled and divided into two groups - CTRCD group vs. "EF preserved" group.
Results: Among 43 consecutive patients, 6 (14%) developed CTRCD. Elevated left ventricular end systolic diameter (p=0.007), high levels of Red Blood Cell Distribution Width (p=0.044) and platelets (p=0.023) and a trend of lower Global Longitudinal Strain (p=0.092) were observed among the CTRCD group. During follow-up, 2 (33%) patients died in the CTRCD group vs 3 (8.1%) patients in the "EF preserved" group. In a multivariate analysis, adjusted to age and EF, CTRCD remained a significant predictor for mortality (p=0.039).
Conclusions: CTRCD is an important concern among sarcoma patients, regardless of baseline risk factors, and is associated with mortality. Echocardiography and blood parameters may provide an early diagnosis of cardio-toxicity.

Heart failure with reduced ejection fraction is characterized by systemic NEP downregulation

N Noemi Pavo[1]; J Winkler[1]; D Traxler[1]; D Lukovic[1]; K Zlabinger[1]; A Gugerell[1]; G Goliasch[1]; P Bartko[1]; M Huelsmann[1]; M Gyoengyoesi[1]
[1]*Medical University of Vienna, Vienna, Austria*

Background. Neprilysin (NEP) inhibition is beneficial in heart failure with reduced ejection fraction (HFrEF) however pathophysiologic alterations in HF nor the contribution of different organ systems are not elucidated. The aim of this study was to investigate differential NEP expression (mRNA levels), NEP content (protein concentrations), and enzymatic NEP activity of various tissues in a translational model of chronic heart failure.
Methods. Ten pigs were randomized either to control- or HF-groups at an age of three months (n=5 each). The HF-group underwent reperfused myocardial infarction of 90 minutes via percutaneous balloon occlusion of the mid-LAD. At day three and at six months cMRI was performed. At six months the animals were sacrificed and tissues of the main organs and different cardiac regions were harvested. NEP concentrations and activity were measured from fresh-frozen samples using a specific ELISA (R&D systems,UK) and a fluorimetric peptide-cleavage-assay, NEP expression was determined from RNA-later samples by performing duplex qPCR. NEP concentrations and activities were equally determined in plasma and liquor samples. Relative values for all organs were pooled and compared by a non-parametric test and linear regression models were calculated between NEP expression, concentration and activities.
Results. cMRI confirmed myocardial infarction with a scar area of 21.5%(IQR:20.2-22.4) of the LV at day 3 and a higher end-diastolic volume of 100.8ml(IQR 95.2-110.2) and reduced LV EF of 41.8%(IQR:41.3-44.1) at 6 months of the HF-group compared to 79.0ml(IQR:78.9-82.9) and 53.0%(IQR:51.8-55.0) of controls. NEP expression was downregulated and translated into reduced protein concentrations and activity for the sampled organ systems in HF animals [p=0.003,p=0.005 and p=0.013] (Figure1A). Control and HF hearts showed clearly detectable NEP measures with different patterns for ventricles and atria. NEP concentrations and activity between plasma and liquor samples were comparable. Tissue NEP expression and tissue NEP concentrations showed modest correlation [R2=0.284,p<0.001], tissue NEP concentrations and tissue NEP activity however an excellent correlation [R2=0.727,p<0.001]. Again, plasma NEP concentrations and activity could not be correlated to their tissue equivalents (Figure1B). NEP kidney levels were 20- to 100-fold higher compared to all other organs, as also observed in immunohistochemistry (Figure1C).
Conclusions. The condition of HF is characterized by a systemic downregulation alongside reduced concentrations and activity of NEP in various organs. The success of ARNI in HFrEF might lie in the enhancement of the already initiated pathophysiological counter-regulation of natural NEP action. The regular function of the ubiquitous membrane-bound NEP is located at the tissues, and since plasma NEP concentrations and activities seem not to reflect tissue levels they might not serve well as a biomarker.

Metabolic signature of fibrotic remodeling in heart failure: role of galaninergic system

O Kunduzova[1]; A Timotin[2]; FB Boal[1]; HT Tronchere[1]
[1]*Inserm-UPS U1048, Institute of Cardiovascular and Metabolic Diseases (I2MC), Toulouse, France*; [2]*University Hospital of Toulouse - Rangueil Hospital, Toulouse, France*

BACKGROUND: Myocardial fibrotic remodeling is a prominent feature of advanced heart failure (HF), however, the mechanisms underpinning fibrosis progression and the modern therapeutic options remain elusive.
OBJECTIVES: This study examined the role of galaninergic system in the progression of HF and evaluated whether galanin can reverse pre-established metabolic remodeling of fibrotic hearts in an experimental model of HF.
METHODS: Male C57Bl/6 mice were subjected to pressure overload for 5 weeks to induce HF. One week after surgery, the mice received vehicle or galanin for 4 weeks. Cardiac fibrosis, metabolism and function were analyzed.
RESULTS : In a mouse model of pressure overload-induced HF, chronic galanin treatment counteracted pre-established myocardial fibrotic remodeling, inflammatory responses and promoted a cardioprotective phenotype in mice. Analysis of myocardial energy metabolism demonstrated galanin-mediated reactivation of fetal-like metabolic phenotype associated with reduced mitochondrial fatty acid oxidation and increased glucose oxidation in fibrotic hearts. In vitro, galanin reversed TGFß-promoted cardiac fibroblast pro-fibrotic phenotyoe through FoxO1 pathways. In addition, using in vivo knock out of galanin receptor 2 (GalR2), we demonstrated that GalR2 deficiency promotes pro-fibrotic myocardial remodeling.
CONCLUSION: These findings identify novel mechanistic insights into cardiac fibrotic remodeling and open new perspectivefor the therapy of HF.

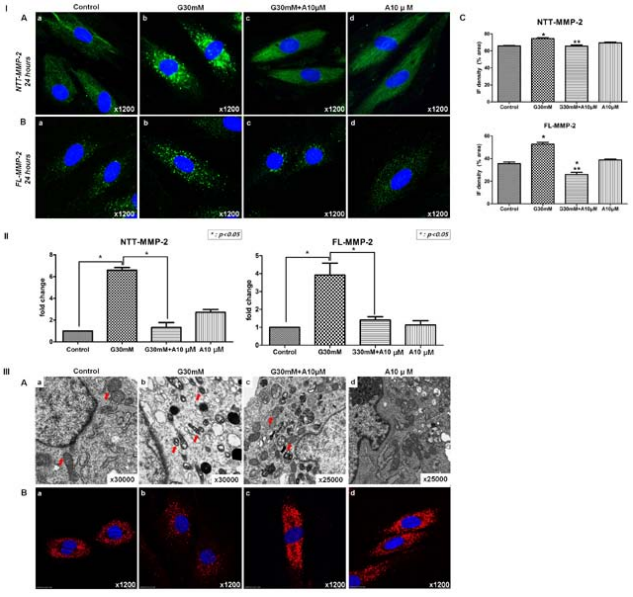
Funding Acknowledgements: This work was supported by a CJ pharmaceutical (2016)

Background: Matrix metalloproteinase -2 (MMP-2) is increased in diabetic cardiomyopathy (DM CMP).We previously reported MMP-2 intracellular isoforms are also elevated in animal model. Some study showed atorvastatin alleviated experimental DM CMP by suppressing apoptosis and oxidative stress beyond lipid-lowering effect. Purpose : We investigated whether atorvastatin can alleviate DM CMP by reducing intracellular MMP-2 isoform expression.
Methods: Rat cardiomyoblasts (H9C2 cells) were tested to determine whether atorvastatin treatment after high glucose could reduce the expression of the two isoforms of MMP-2. For the in vivo study, we used the streptozotocin murine model of Type I DM and age-matched controls. The changes of each MMP-2 isoform in the diabetic mice hearts were determined using quantitative real-time polymerase chain reaction (qRT-PCR). Immunohistochemical stains were conducted to identify MMP-2 isoform expression. Echocardiography was performed to compare and analyze the changes in cardiac function induced by diabetes and atorvastatin.



Expressions of the two MMP2 isoforms i

Results: Quantitative RT-PCR and immunofluorescence staining showed that the two MMP-2 isoforms strongly induced by high glucose stimulation were attenuated

by atorvastatin treatment in H9C2 cells. Although no definite histologic features of diabetic cardiomyopathy were observed in diabetic mice, left ventricular systolic dysfunction observed in diabetic heart was also normalized by atorvastatin treatment by echocardiographic evaluation. These findings accompanied reduced TUNEL staining and mitochondrial morphological change in atorvastatin treated diabetic group. Quantitative RT-PCR and IHC staining showed this abnormal cardiac function was accompanied with the increases in the mRNA levels of the two isoforms of MMP-2 and attenuated with atorvastatin treatment. Conclusion: Atorvastatin attenuated deterioration of cardiac dysfunction induced by diabetic condition by reducing expression of two isoforms of MMP-2 in vitro and in a Type I diabetes heart model. The roles played by these isoforms and atorvastatin treatment in diabetic cardiomyopathy require further study.

MicroRNAs expression profile in advanced heart failure patients: perspectives for risk stratification

A Alessandro Galluzzo[1]; S Gallo[2]; B Pardini[2]; D Celentani[1]; P Boretto[1]; G Birolo[2]; S Gatti[2]; A Volpe[1]; M Spilinga[2]; S Pidello[1]; G Matullo[2]; S Bergerone[1]; T Crepaldi[2]
[1]Hospital Molinette of the University Hospital S. Giovanni Battista/City University Hosp of Health an, Cardiology, Turin, Italy; [2]University of Turin, Turin, Italy

BACKGROUND: Early diagnosis and risk stratification of patients with advanced heart failure (HF) remain a challenge. Circulating microRNAs (miRNAs) have shown promising results as biomarkers for HF, whereas little is known about their role in advanced stages.
PURPOSE: In this study, we assessed if a peculiar miRNA expression pattern identifies stable advanced HF patients compared with healthy subjects and whether it may be related to prognosis.
METHODS: Consecutive patients hospitalized for HF in our intensive care unit were screened. Inclusion criteria were the following: age >18 years old, patients presenting an ischemic or idiopathic cardiomyopathy, and fulfilling the 2007 ESC criteria for advanced HF. Blood samples were collected at ambulatory level in stabilized patients 1 month after hospital discharge. An equal number of healthy volunteers were recruited matched by age and sex. RNA was extracted from plasma and miRNA libraries for next-generation sequencing (NGS) were prepared. miRNAs resulting differentially expressed between the two groups were identified through bioinformatic software (p-value < 0.05) and then correlated with patients' clinical prognostic parameters and outcome.
RESULTS: Between January 2016 and July 2018, 32 patients were enrolled (mean age 60.4 years, 59% ischemic cardiomyopathy, mean EF 24%) and matched with 32 healthy controls. During a mean follow up of 9±5 months, there were 5 (16%) CV death, 6 (19%) heart transplantations and 3 (9%) LVAD implantations. After NGS sequencing we found a different expression profile in 58 miRNAs between patients and controls. Among patients, those with VO2 max < 14 ml/min/kg showed higher levels of miR-22-5p/24-3p/942-5p than those with higher VO2 max values (p 0.003; 0.026; 0.012 respectively), while levels of miR-1271-5p/139-5p/326 were significantly lower in patients with LV end diastolic diameter > 61 mm than in those without LV enlargement (p 0.009; 0.006; 0.017 respectively).No specific miRNA showed a significant correlation with mortality or the composite outcome of CV death, heart transplantation and LVAD implantation.
CONCLUSION: Advanced heart failure patients show a specific miRNAs expression pattern compared to healthy controls. A subgroup of these miRNAs was associated with predictors of worse prognosis such as low VO2 max or dilated LVs, though not with worse outcome. Further research is needed to create a miRNA risk stratification model in this setting.

Efficacy of combination therapy with empagliflozin and baseline drugs in postinfarct heart failure in normoglycemic rats

M Marina Krasnova[1]; AN Kulikov[2]; SV Okovityi[1]; DYU Ivkin[1]; AA Karpov[3]
[1]Saint-Petersburg State Chemical-Pharmaceutical Academy, Saint-Petersburg, Russian Federation; [2]Saint-Petersburg State Medical University named I.P.Pavlov, Saint-Petersburg, Russian Federation; [3]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation

Sodium-glucose co-transporter 2 inhibitor empagliflozin (Empa) reduces death from cardiovascular causes, death from any cause, hospitalisation rate for heart failure in patients with diabetes mellitus type 2. In our previous publications comparative efficacy monotherapy of Empa for chronic heart failure (CHF) relative baseline drugs was shown (second stage).
Purpose. In this study (3 stage) we continued to study the cardial effects of Empa in combinations for treatment normoglycemic rats with experimental CHF.
Methods. CHF in 50 rats was simulated via permanent ligation of the left coronary artery. After second stage (previous experiment) surviving animals in addition received second medicine (angiotensinconverting enzyme inhibitor, ß-blocker and aldosterone antagonist) (tabl.1). After 3 months of the combination therapy, status of cardiovascular system by echoCG was analyzed.
Results. Analyzing the third stage, we will stop on such factors as: survivance, growth rate of left ventricular shortening fraction (FS) and left ventricular ejection fraction (EF) in comparison with the previous stage (fig. 1). At this rate, the maximum survivance (90%) was observed in groups of animals receiving an Empa with accession of a fosinopril and classical therapy of a fosinopril with accession of a bisoprolol, encore while the semi-annual survivance of animals with CHF without treatment was 70% (natural mortality was estimated). In comparison with the second stage, FS animals without treatment decreased by 16.22%. In groups of treatment (with the second on the fifth) FS increased by 2.36%, 0.59%, 4.32%, 4.06% respectively. EF practically grew by 6% at animals without treatment, decreased by 15.32% in the group receiving an bisoprolol and an Empa, and increased by 13.38%, 28.59%, 48.08% at animal groups 2, 3, 5 respectively. In summary, addition of an Empa to means of standard therapy has positive pharmacological effect.

Design of therapy

1ststage	2ndstage	3rdstage
CHFformation- 30 days	Monotherapy- 90 days	Addition second medicine-90 days
Group 1 (CHF)		
Group 2 (CHF + empagliflozin)	+ fosinopril	
Group 3 (CHF + fosinopril)	+ bisoprolol	
Group 4 (CHF + bisoprolol)	+ empagliflozin	
Group 5 (CHF + spironolactone)	+ empagliflozin	

CHF - chronic heart failure

Group /Measurement	Survivance , %	ΔFS, %	ΔEF, %
№ 1	70%	-16,22	+5,98
№ 2	90%	+2,36	+13,38
№ 3	90%	+0,59	+28,59
№ 4	80%	+4,32	-15,32
№ 5	80%	+4,06	+48,08

FS – left ventricular shortening fraction; EF – left ventricular ejection fraction.

Introduction: In a pressure-mediated model of heart failure with reduced ejection fraction (HFrEF) it has been shown that targeting the Liver X Receptor (LXR) in the heart led to a significant reduction of cardiac fibrosis and improvement of cardiac function.
In this study we aim to investigate the pharmacological effect of the novel LXR-agonist AZ876 in an isoproterenol induced HFpEF-like cardiomyopathy model on subendocardial fibrosis and cardiac function using advanced speckle tracking echocardiography.
Methods: Male 129SV mice were fed the LXR-agonist (20 μmol/kg/day) for 11 days. Starting from day 6 mice were injected with the nonselective β-agonist isoproterenol (ISO) for 4 consecutive days to induce diastolic dysfunction with subendocardial fibrosis in the presence of preserved systolic function. One day after the last ISO injection mice were characterized by conventional echocardiography as well as by speckle tracking echocardiography.

Results: ISO treatment led to a marked impairment of global longitudinal strain (GLS) (VEH vs. ISO, -19.07±1.27 vs. -15.43±1.76, **p≤0.01) which was significantly improved by the LXR-agonist (ISO vs. ISO/LXR-agonist., -15.43±1.76 vs. -19.05±3.66, **p≤0.01). Other strain parameters (radial, circumferential) were not regulated. Ejection fraction, a crucial parameter for systolic function, was affected neither by ISO nor by the LXR-agonist. Histological examination also revealed a significant reduction of ISO-induced subendocardial fibrosis in the LXR-agonist treated group.
Conclusion: This study shows that the LXR-agonist AZ876 attenuates subendocardial damage and improves GLS parameters in an HFpEF-like mouse model. Pharmacological LXR activation may provide a promising approach for the prevention and therapy of HFpEF.

Tenascin-C may accelerate left ventricular remodeling and function after myocardial infarction by enhancing hypertrophy

P M Patrick Michael Pilz[1]; I F Goncalves[1]; E Acar[1]; S Costantino[2]; L Szabo[1]; O Hamza[1]; E V Tretter[3]; K U Klein[3]; S Trojanek[4]; D Abraham[4]; F Paneni[2]; S Hallstroem[5]; A Kiss[1]; B K Podesser[1]
[1]Medical University of Vienna, Center for Biomedical Research, Vienna, Austria; *[2]University of Zurich, Center for Molecular Cardiology, Zurich, Switzerland*; *[3]Medical University of Vienna, Department of Anesthesiology Intensive Care and Pain Therapy, Vienna, Austria*; *[4]Medical University of Vienna, Center for Anatomy and Cell Biology, Vienna, Austria*; *[5]Medical University of Graz, Physiological Chemistry, Otto Loewi Research Center, Graz, Austria*

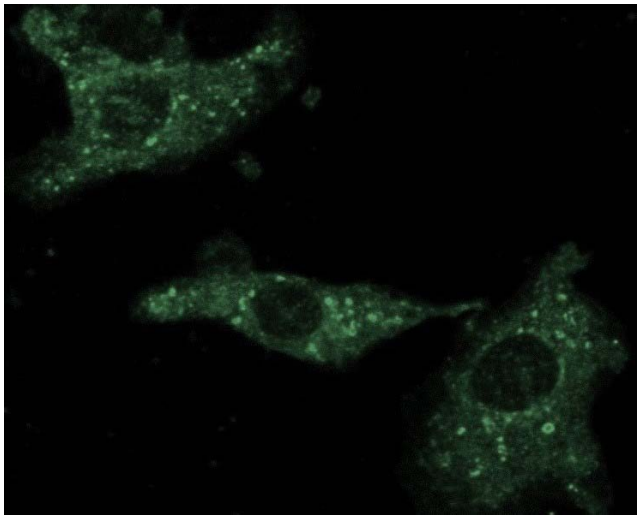
Tenascin C (TN-C) is considered to play a pathophysiological role in maladaptive left ventricular remodeling. Yet, the mechanism underlying TN-C-dependent cardiac dysfunction following myocardial infarction remains elusive. The present study was designed to investigate the effect of hypoxia and hypertrophic stimuli on TN-C expression in H9c2 cells and its putative regulation by epigenetic mechanisms, namely DNA promoter methylation. In addition, rats subjected to myocardial infarction (MI) were investigated. H9c2 cells were subjected to oxygen glucose deprivation (OGD), incubated with Angiotensin II (Ang II) or human TN-C (hTN-C) protein. Hypertrophic and fibrotic markers, TN-C promoter methylation and TN-C protein levels were assessed by ELISA. TN-C mRNA expression was markedly increased by both, OGD and Ang II ($p<0.01$, respectively). In addition, Ang-II-dependent TN-C upregulation was explained by reduced promoter methylation ($p<0.05$). Cells treated with hTN-C displayed upregulation of BNP, Mmp2, β-MHC, integrin $\alpha 6$ and integrin $\beta 1$. In vivo, plasma and myocardial TN-C levels were increased 7 days post myocardial infarction (MI; $p<0.05$, respectively). In conclusion, both, hypoxic and hypertrophic stimuli, lead to epigenetically-driven TN-C upregulation and subsequent impairment in cardiomyoblasts. These findings might enlighten our understanding on maladaptive left ventricular remodeling and direct towards a strong participation of TN-C.

P2200
Excitation-secretion coupling in ventricular cardiomyocytes

K Kun Zhang[1]; P Wakula-Heinzel[1]; B Pieske[1]; F Heinzel[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Department of Cardiology, Berlin, Germany

Funding Acknowledgements: German Cardiac Society, Berlin Health Insitute

Introduction The heart secretes hormones and can be considered as an endocrine organ. However, little is known about the mechanisms of secretion. In neuronal cells, a regulated pathway of exocytosis is well described. Parallels between neurons and cardiomyocytes can be expected since both belong to the group of excitable cells. Thus, it is feasible to believe excitation-secretion-coupling is a mechanism that also exists in cardiomyocytes.
Purpose We hypothesize that a calcium regulated pathway of brain natriuretic peptide (BNP) secretion exists in ventricular cardiomyocytes.
Methods We isolated neonatal rat ventricular myocytes from 2-day-old Wistar rats. Briefly, hearts were removed and ventricles dissected from atrias. Dissociation of ventricular cardiomyocytes was achieved by sequential digestion with trypsin. After pre-plating for 1 hour at 37°C, myocytes were seeded on gelatin coated wells. BNP ELISA (Abnova) was performed with measuring BNP concentrations in collected cell lysates and their corresponding supernatants. Immuno-fluorescence was conducted using following antibodies: synaptobrevin 1:250, goat anti-rabbit Alexa488 1:1000 (Life Technologies). Cells were visualized via confocal microscope (Zeiss).
Results We could show via immunofluorescence that ventricular cardiomyocytes express synaptobrevin (figure), which can be found in neurons and endocrine cells and is a marker protein of secretory vesicles that undergo calcium regulated exocytosis. When stimulating cardiomyocytes with 1 μM angiotensin II (Ang II) for 2h, which has been shown to activate inositol 1,4,5-trisphospate (IP3) and increase calcium release from intracellular stores into cytoplasm, we could see an increase in BNP secretion as described in the literature. Interestingly, the ratio of BNP secretion/production increased under Ang II stimulation (189 ± 54% normalized to vehicle control, p=0.05), indicating that Ang II induced increased exocytosis and thus BNP release. Moreover, ratio of BNP secretion/production returned back to baseline after 4h of Ang II stimulation (113 ± 18% normalized to control, p=0.25).
Conclusion We showed that ventricular cardiomyocytes exhibit a vesicle protein involved in calcium regulated exocytosis. Ang II, which increases intracellular calcium, led to increased BNP secretion in relation to production. Moreover, a time dependency could be observed. Based on these data, we propose that a calcium dependent, regulated way of exocytosis exists in cardiomyocytes. Further studies are ongoing to elucidate this mechanism.



Synaptobrevin staining

Reduced mitochondrial aldehyde dehydrogenase-2 activity and protein levels in left ventricular myocardium of dogs with Heart Failure

HN Hani Sabbah[1]; RC Gupta[1]; V Singh-Gupta[1]
[1]Henry Ford Hospital, Detroit, United States of America

Background: Heart failure (HF) promotes an increase in oxidative stress that leads to a build-up of reactive aldehydes such as 4-hydroxynonenal (4-HNE) that contribute to cardiomyocyte injury and death and to progressive global left ventricular (LV) dysfunction. Aldehyde dehydrogenases (ALDHs) are key enzymes that play a pivotal role in eliminating toxic aldehydes by catalyzing their oxidation to non-reactive acids. Mitochondrial ALDH2 plays a pivotal role in combating oxidative stress by reducing the cellular aldehyde load. This study examined protein levels of 4-HNE and ALDH2 as well as ALDH2 activity in LV myocardium of dogs with coronary microembolization-induced HF (LV ejection fraction ˜30%).
Methods: LV tissue from 7 HF dogs and from 6 normal (NL) dogs was used in the study. Using LV tissue extracts, 4-HNE-protein adducts levels were quantified using a commercially available Elisa kit and expressed as ng/mg protein. Protein levels of ALDH2 and porin, an internal loading control, were determined in isolated mitochondria by Western blotting coupled with Chemiluminescence. Band intensity were expressed in densitometric units (du). ALDH2 activity in isolated mitochondria was determined by measuring the conversion of propionaldehyde to propionic acid and the enzyme specific activity was expressed as nmol NADH formed/min/mg protein.
Results: Porin protein levels were unchanged in HF dogs compared to NL dogs (0.24 ± 0.01 vs. 0.26 ± 0.02 du, $p<0.05$). 4-HNE protein adducts levels were significantly increased in HF dogs compared to NL dogs (399 ± 35 vs. 185 ± 21 du, $p<0.05$); whereas ALDH2 protein levels were significantly decreased in HF dogs compared to NL dogs (0.49 ± 0.02 vs. 1.16 ± 0.10 du, $p<0.05$). ALDH2 activity was significantly decreased in HF dogs compared to NL dogs (51 ± 3 vs. 108 ± 4 nmol NADH/min/mg, $p<0.05$).
Conclusions: In LV myocardium of dogs with chronic HF, ALDH2 protein levels and activity are decreased in the face of elevated burden of aldehydes (e.g. 4-HNE) paving the way for enhanced cellular injury, death and progressive LV dysfunction. Drugs that increase the activity of ALDH2 may be useful in the treatment of patients with chronic HF.

Characterization of kidney function in a canine model of cardiorenal syndrome

HN Hani Sabbah[1]; RC Gupta[1]; D Lanfear[1]
[1]*Henry Ford Hospital, Detroit, United States of America*

Background: The co-existence of renal insufficiency in patients with heart failure (HF) often referred to as "cardiorenal syndrome" (CRS), carries a poor prognosis. Understanding the pathophysiology of CRS and the need to develop new therapeutics that address this complex syndrome are often hindered by lack of appropriate animal models. In the present study, we provide further characterization of kidney function in a chronic canine model of CRS developed in our laboratories to help define the differences in this model when compared to a canine model of HF with preserved renal function.

Table

	NL	HF	CRS
Baseline pCr (mg/dL)	0.81 ± 0.01	0.91 ± 0.08	1.21 ± 0.04*
Urinary Protein (ml/dL)	83 ± 8	81 ± 32	172 ± 27*
Urinary NGAL (ng/ml)	2.6 ± 0.3	2.6 ± 0.2	5.7 ± 0.3*
Urinary KIM-1 (ng/ml)	34 ± 4	33 ± 4	98 ± 12*
Plasma Cystatin-C (ng/ml)	1.5 ± 0.2	1.8 ± 0.1	3.9 ± 0.2*

*=p<0.05 vs. NL and HF

Methods: Studies were performed in 15 dogs with coronary microembolization-induced HF. In 8 of the 15 dogs, CRS was produced by performing a unilateral nephrectomy and by applying a stenosis to the contralateral renal vein to simulate elevated venous pressures. LV ejection fraction (LVEF), urinary protein, urinary kidney injury molecule-1 (KIM-1) and neutrophil gelatinase associated lipocalin (NGAL) and plasma cystatin-C were measured in all 15 dogs and in 6 normal dogs. Each dog was also given a diuretic challenge (DC) consisting of an intravenous injection of 80 mg of furosemide and pCr was measured before and one hour after the injection.
Results: LVEF was similar in HF dogs and CRS dogs (34±1 vs. 33±2 %). Urinary protein, pCr, NGAL, KIM-1 and cystatin-C were similar in NL and HF dogs but increased significantly in CRS dogs (Table). DC had no effect on pCr in HF (0.84±0.06 vs. 0.90±0.07 mg/dL) but increased significantly in CRS dogs (1.21±0.04 vs. 1.41±0.04 mg/dL, p<0.05).
Conclusions: Results of the study indicate that the canine model of CRS manifest similar abnormalities seen in patients with HF and compromised renal function. The CRS model may be useful for exploring pathophysiological aspects of CRS and can serve a tool for assessing the effects of therapeutic/pharmacologic interventions targeting patients with HF and compromised renal function.

Cardiac mitochondrial alterations in a mouse model of Fabry Disease

D Sorriento[1]; J Gambardella[1]; F Cerasuolo[1]; N Boccella[1]; C Perrino[1]; CG Tocchetti[2]; D Bonaduce[2]; P Abete[2]; B Trimarco[1]; M Ciccarelli[3]; K Valenzano[4]; G Iaccarino[5]
[1]*Federico II University, Advanced Biomedical Sciences, naples, Italy*; [2]*Federico II University of Naples, Traslational Medical Sciences, Naples, Italy*; [3]*University of Salerno, Dept. of Medicine and Surgery, Salerno, Italy*; [4]*Amicus Therapeutics, Cranbury, New Jersey, United States of America*; [5]*Federico II University of Naples, Advanced Medical Sciences, Naples, Italy*

Background: Fabry disease (FD) is a genetic disorder caused by deficiency of α-Gal A activity with intralysosomal accumulation of globotriaosylceramide (GB3). Fabry patients show cardiac involvement developing left ventricular hypertrophy and dysfunction (LVHD). However, the pathogenesis of Fabry cardiomyopathy remains unclear. Beside GB3 accumulation, impairment of energetic metabolism is hypothesized as putative mechanism for LVHD, and mitochondrial dysfunction is suggested by the reduced activity of mitochondrial respiratory chain observed in fibroblast from FD patients. Purpose: To explore the pathogenetic mechanism of cardiac dysfunction in FD evaluating the role of mitochondria. Methods: The recently described hR301Q α-Gal A transgenic (Tg)/mα-Gal A knockout (KO)] that lacks endogenous GLA but expresses a human R301Q GLA transgene under the control of the human GLA promoter was used as a model of FD. On cardiac tissue, we evaluated cell area through WGA staining. Living cardiomyocytes were isolated by Langendorff system and single cell contractility analysis was performed by MUSCLEMOTION software. The levels of BNP, SerCa, PGC-1α, Tfam and NRF1 were evaluated by Real-time PCR while the levels of Mitofusin 2 (MFN2) and Citochrome C (Cit C) by western blot on mitochondrial and cytosolic extract, respectively. Results: In cardiac tissue from FD mice (FD-M) we observed an increase of cardiac cell area compared to wild-type tissue. The size of the single cardiomyocytes (CM) isolated from FD-M was also increased, confirming the cardiac cell hypertrophy in our model. Accordingly, the transcription levels of BNP and SerCa were higher in the hearts of FD mice respect to wild type. To evaluate cardiac cell performance, single cell contractility under field stimulation was recorded. In basal condition, FD-M CM showed higher contractility than wild type cells. However, an impaired contractile response to adrenergic stimulation was recorded for FD-M CM. To verify whether the observed phenotype was linked to mitochondrial dysfunction we explored mitochondrial health. Mitochondrial biogenesis was impaired in FD-M hearts concurrently with altered expression of the master regulators PGC-1α, Tfam and NRF1. Moreover, increased levels of MFN2 on mitochondria from FD-M hearts suggest that also mitochondrial fusion is affected. In the extracts from FD-M hearts, we observed an increase cytosolic levels of Cit C, marker of a mitochondrial damage and permeabilization.
Conclusions: Cardiac cell hypertrophy was observed in FD-M hearts together with alterations in mitochondrial biology, suggesting that the LVHD could be a compensatory response to the reduced contractile force due to inadequate energy supply from dysfunctional mitochondria.

P2204

Hydrogen sulfide modulates calcium handling in cardiac mitochondria to maintain their function and helps heart to resist calcium overload

A Alina Luchkova[1]; N Strutynska[1]; V Sagach[1]
[1]*Bogomoletz Institute of Physiology, Blood Circulation, Kiev, Ukraine*

Introduction: Heart failure is a pathological condition that occurs as a result of various heart diseases and is associated with reduced cardiac pumping function and defects in excitation-contraction coupling, due to abnormal function of calcium handling and oxidative stress. Often this process is characterized by cytoplasmic and following mitochondrial calcium overload, which launches the mitochondrial pore opening, leading to dissipation of the mitochondrial membrane potential, uncoupling of oxidative phosphorylation, loss of ATP and necrosis. It is known that there are gaseous regulatory molecules that are synthesized endogenously and mediate different physiological processes in the cells. One of them is hydrogen sulfide that acts as vasodilator, antioxidant, antiapoptotic agent in cardiovascular system. But little is known about its influence on calcium homeostasis of mitochondria and cardiac resistance to calcium overload.
Methods: We used 5-7 months Wistar male rats. Cardiodynamic parameters such as LVP, dP/dT, heart rate, coronary flow and oxygen consumption were registered using Langendorf isolated rat heart. Calcium load was carried by adding of CaCl2 in perfusion solution every 10 minutes (concentration range from 1,7 to 12,5 mmol/l). Rat heart mitochondria were isolated using differential centrifugation method. Calcium accumulation in isolated organelles was studied by flow cytometry analysis and dye Fluo 4-AM. The functions of electron transport chain were estimated using oxygraph high-resolution respirometry.
Results: Exogenous NaHS (10-6 – 10-7 mol/l) increased Ca2+ accumulation in rat heart mitochondria in 1,68 and 2,54 times respectively (extramitochondrial Ca2+ concentration was 100 μmol/l). At the same time inhibitors of mitochondrial H2S synthesis enzymes led to decrease calcium accumulating capacity of isolated mitochondria. The inhibition of endogenous H2S formation in vivo impairs the function of the electron transport chain, due to the lowering of rate of oxygen consumption in the states V2, V3 and V4 by Chance, as well as indicators of RCR and ADP/O. It was also shown that inhibition of mitochondrial H2S-synthesis enzyme had a negative influence on initial cardiodynamic parameters. In particular, the LVP decreased twice and the rate of contraction and relaxation of myocardium also reduced by half. Coronary blood flow decreased by 1,12 times, while the heart rate was tended to increase. We found that the hearts of experimental animals developed less powerful reaction under the calcium overload that manifested in reduced parameters of LVP, coronary flow and heart work intensity. Also in vivo inhibition of H2S synthesis causes the increase of the rate of .O2- and .OH-radicals generation both in mitochondria and plasma, indicating an intensification of free radicals formation process with a decrease in H2S content.
Conclusion: H2S takes part in calcium handling in cardiac mitochondria which influence the heart function.

P2205

Inhibition of cystathionine gamma-lyase can prevent cardiac dysfunction after focal cerebral ischemia

N A Natali Dorofeyeva[1]; RR Sharipov[1]; VF Sagach[1]
[1]*Bogomoletz Institute of Physiology, Kiev, Ukraine*

The aim of work is to investigate the effect of inhibition of cystathionine gamma-lyase on cardiac function in focal cerebral ischemia. The study was conducted on

adult (6 months) male Wistar rats. The model of focal cerebral ischemia was as result from middle cerebral artery occlusion during 60min. The focal cerebral ischemia was confirmed by morphology. DL-Propargylglycine (inhibitor of cystathionine gamma-lyase) and L-cysteine were administered intraperitoneally before 40 minutes of focal cerebral ischemia was performed. The functional cardiohemodynamic indicators registered via microcatheter and Pressure-Volume System. It was found that the focal cerebral ischemia led to decrease in the parameters of the pumping function of the heart (the stroke volume decreased by 48,4%, cardiac output decreased by 59% after 60 min cerebral ischemia. Pretreatment of DL-Propargylglycine and L-cysteine prevents the decline of the pumping function of the heart during focal cerebral ischemia in rats: the stroke volume didn't change significantly, even increased by 16%, and the cardiac output increased by 11,6%. We demonstrate the diastolic dysfunction after focal cerebral ischemia. The end-diastolic myocardial stiffness increased by 3,8 times after 60 min focal cerebral ischemia. We have shown that pretreatment of DL-Propargylglycine and L-cysteine prevent the change of the end-diastolic myocardial stiffness and partly improved the active isovolumic relaxation of LV: dP/dt min and the time constant of isovolumic relaxation (tau) after 60 min focal cerebral ischemia.
Thus, inhibition of cystathionine gamma-lyase can prevent the pumping function disturbances and decreased diastolic heart function disorders after focal cerebral ischemia.

Myocardial iron homeostasis and hepcidin expression in a rat model of chronic heart failure at different levels of dietary iron intake

T Tereza Havlenova[1]; J Petrak[2]; M Krijt[3]; M Behounek[2]; J Franekova[1]; L Cervenka[1]; T Pluhacek[4]; D Vyoral[3]; V Melenovsky[1]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Prague, Czechia*; [2]*BIOCEV, First Faculty of Medicine, Charles University in Prague, Prague, Czechia*; [3]*Institute of Hematology and Blood Transfusion, Prague, Czechia*; [4]*Palacky University, Faculty of Science, Olomouc, Czechia*

Funding Acknowledgements: This study was supported by the Czech Science Foundation (grant 15-14200S) and Ministry of Health of the Czech Republic (grant AZV 17-28784A).

Background: Systemic iron deficiency is present in up to 50% of patients with chronic heart failure (HF) and it is associated with impaired exercise tolerance and poor prognosis. Myocardial iron deficiency (MID) in HF patients has recently been described; however, its causes and consequences remain unknown.
Purpose: We examined impact of HF and dietary iron content on systemic iron status, myocardial iron content, cardiac structure, function, expression of iron regulator hepcidin and other iron-related genes and survival in well-defined rat HF model induced by volume overload due to aorto-caval fistula (ACF).
Methods: 8-week old male Sprague Dawley rats fed defined synthetic diets with low, normal or high iron content underwent needle ACF/sham operation (HF/controls, n = 28/30). After 21 weeks, we performed echocardiography and laboratory analyses. Separate animal cohort served for survival analysis.
Results: MID developed in HF animals (myocardial iron content was 10% to 20% lower compared to healthy controls, $p<0.05$ for normal and high iron diet group). In pooled data, there was positive relation of left ventricular (LV) function (fractional shortening, r=0.40, p=0.002) and inverse relation of pulmonary congestion (lung/body weight, r=-0.47, p=0.003) to myocardial iron content. Iron suplementation did not normalize myocardial iron content; however, it improved survival (nearly 70% at 26th week in high iron diet group vs. 30% in normal iron diet group, $p<0.05$). Cardiac hepcidin was markedly upregulated in HF animals compared to controls (>3-fold, $p<0.05$). It was not related to systemic or cardiac iron levels, but strongly correlated with markers and parameters of heart injury (natriuretic peptide A, r=0.82; LV fractional shortening, r=-0.66; heart/body weight, r=0.74, $p<0.0001$ for all). Identical iron-independent pattern was observed for several iron-related gene expression.
Conclusions: In rat HF model, MID is not caused by defective iron absorption or decreased systemic iron levels, but rather by intrinsic myocardial iron deregulation. Altered cardiac hepcidin and other iron-related gene expression is driven by iron-independent stimuli. Although the mechanisms of MID development remain incompletely understood, myocardial iron content enhancement may improve cardiac function and survival.

P2207
Determination of the mechanisms of ATRA mediated suppression of cardiac hypertrophy

L Lauren Parker[1]; N Yang[1]; K Papanicolaou[1]; B O'rourke[1]; B Foster[1]
[1]*Johns Hopkins University, Baltimore, United States of America*

Funding Acknowledgements: AHA Transformational Project Award, Johns Hopkins Magic that Matters Award,

Pathway analyses of proteomic studies in guinea pig and rat hearts subjected to pressure overload-induced hypertrophy and heart failure (HF) suggest altered retinoid signaling may be a causal contributor to HF progression. This observation is bolstered by our recent studies, where we demonstrated that cardiac levels of all-trans retinoic acid (ATRA) deficient in human patients with non-ischemic HF. This led us to reconsider an old observation that ATRA blocks hypertrophy induced by the α-adrenergic agonist phenylephrine (Phe) in neonatal rat ventricular myocytes (NRVMs). With cross-sectional area (CSA) as an index of hypertrophy, we show, consistent with prior work, that ATRA suppresses Phe-induced increases in NRVM CSA by average of 70%. RT-PCR studies show that ATRA also blunts Phe-induced increases in atrial natriuretic peptide (ANP) gene expression. We then tested the pan-CYP26 inhibitor talarozole (Tala) to raise endogenous ATRA levels, and observed that Tala similarly inhibited Phe-induced increases in NRVM CSA ($p<0.001$) and ANP expression in a dose dependent manner. ATRA functions biologically through a class of ligand-dependent transcription factors called retinoic acid receptors (RARs) of which there are three isoforms, α, β and γ. To determine through which RARs ATRA and Tala mediate their anti-hypertrophic effects, we used antagonists against each RAR isoform. Initial studies show that the RARβ antagonist LE135 (1 μ M) fully blocked the action of ATRA ($p<0.0001$), while initial studies with the RARα and RARγ antagonists (BMS 195614 (1 μM) and MM 11253 (1 μM)) failed to significantly mitigate CSA suppression. This would suggest that RARβ is the primary RAR responsible for eliciting the anti-hypertrophic program. However, initial studies with NRVMs virally transduced with siRNA against RARα, β and γ support the more likely conclusion that each RAR may play a role in hypertrophy suppression. Ongoing studies aim to corroborate these findings with Tala mediated hypertrophy suppression. These studies will provide key insights into the mechanisms by which ATRA dysregulation contributes to HF pathogenesis and may aid in the development of more specific therapeutic targets.

P2208
H2S donor (NaHS) improves diastolic function during aging by oxidative stress suppression and constitutive NO synthesis stimulation

K Kostiantyn Drachuk[1]; NO Dorofeyeva[1]; VF Sagach[1]
[1]*Bogomoletz Institute of Physiology, Kiev, Ukraine*

Background. Aging is associated with diastolic dysfunction, which comes before the changes in systolic function and increases risk of heart failure. One of the mechanisms that contributes to age-dependent diastolic dysfunction is the reduction of nitric oxide (NO) bioavailability, caused by diminished NO synthesis and by augmented NO scavenging with superoxide anion (2•-) during oxidative stress.
Purpose. The purpose of the study was to investigate the effect of NaHS, an hydrogen sulfide (H2S) donor on oxidative stress, constitutive NO synthesis and diastolic function during aging.
Methods. Cardiohemodynamic parameters were studied using the Millar pressure-volume (P-V) conductance catheter system in vivo. Left ventricular diastolic function was assessed from the changes in the maximum rate of pressure decline (dP / dtmin), the time constant of active ventricular relaxation (Tau g), end-diastolic pressure (EDP), and end-diastolic stiffness (EDS). The pools of H2S, rate of 2•- -, •OH generation, level of H2O2, the activity of constitutive NO-synthesis (cNOS) and pools of nitrite anion (NO2-) were determined in heart tissue by spectrophotometric method.
Results. It was found the impaired diastolic function in old rats: 1) decrease of dp/dtmin by 33%; 2) 3-times increase of EDP; 3) increase of Tau g by 44%. In the heart tissue of old rats we found decreased pools of H2S (by 1.9 times). It was accompanied with increase of the rate of 2•- (by 3.7 times) and •OH (by 4.1 times) generation and increase pools of H2O2 (by 1.4 times). Simultaneously with oxidative stress we found the reduction of constitutive NO synthesis. It was evidenced by decrease of cNOS activity (by 2.1 times) and reduction of NO2- pools (by 1.6 times), which is the marker of constitutive NO synthesis.
The NaHS injection improved diastolic function in old rats (dP/dtmin increased by 20% and the Tau g decreased by 13%). The mechanisms of NaHS action included the increase of H2S pools (by 3.3 times), which leads to inhibition of oxidative stress, due to decrease of the rate of 2•- and •OH generation (by 7.5 and 1.7 times respectively) and decrease of H2O2 pools (by 4.1 times). Simultaneously after NaHS injection we noted the increase of cNOS activity (by 2.5 times) and NO2- pools (by 3.8 times).
Conclusions. Thus, NaHS restores H2S levels in heart tissue of old rats. It leads to inhibition of oxidative stress and increase of constitutive NO synthesis. These both effects cause the restoration of NO bioavailability and improvement of diastolic function during aging.

Funding Acknowledgements: Work was funded by Russian Science Foundation grant #16-15-10178

BACKGROUND: In heart failure (HF) metabolic alterations are detected not only in heart but also in skeletal muscle tissue that results in reduction of exercise capacity, quality of life, muscle wasting and worthening of prognosis. Exercise training is the most proved strategy to reduce muscle disorders in HF but not all patients respond to it and molecular mechanisms behind beneficial effects remain unknown.
PURPOSE: In this work RNA-Seq analysis was employed to uncover signaling pathways that contribute to beneficial effects of exercise training programs in HF patients.MEHTODS: Five HF male patients NYHA II-III functional class who responded to rehabilitation program were enrolled in the study (Table 1). The individual training intensity was determined at 90% of lactate inflection point (LIP). The skeletal muscle biopsies were taken before and after of 12 weeks of training. RNA was purified and libraries were prepared for RNA sequencing on Illumina MiSeq. Raw data were mapped using STAR 2.5 to hg38 genome. Mapped reads were count with featureCounts program, differential expression analysis was carried out using R package DESeq2, top 12,000 most expressed genes were chosen. Gene set enrichment analysis was made using the fgsea R package and GO database.
RESULTS: Transcriptome sequencing analysis revealed that exercising training results in significant upregulation of the molecular pathways that control skeletal muscle cell differentiation (NES=2,p=1.1e-04); muscle contraction (NES=1.75,p=3.9e-04); release of sequestered calcium ion into cytosol (NES=2;p=2.2e-04); potassium ion import across plasma membrane (NES=2.17;p=1.9e-05); ATP hydrolysis coupled proton transport (NES=1.99;p=3.4e-04). Downregulation of pathways that control protein neddylation (NES=-2;p=4.7-04) and hydrogen peroxide catabolic process (NES=-2;p=1.5e-04) was also detected.
CONCLUSION: Our data provide the new insight on potential targets for treatment and prevention of HF-induced skeletal muscle disorders and wasting.

Table 1

Patient	LVEF (%)	ET1(Arbitrary units)	VO_2 peak ml/min/kg	QOL(Arbitrary units)
HF-1	25/32	6/12	14,6/16,5	55/63
HF-2	20/25	12/25	13,6/12,5	82/77
HF-3	40/40	17/41	22,5/22,7	45/29
HF-4	25/40	19/27	16,2/18,4	60/44
HF-5	24/20	15/32	11/13,3	47/35

LVEF1- left ventricular ejection fraction; ET1 - exercise tolerance; before VO2 peak - peak oxygen uptake; QOL - quality of life testing (before/after training).

P2210

Gonadectomy alters the effect of preconditioning training on the development of a hypoxic pulmonary hypertension in female rats

N Pankova[1]; M Artemieva[1]; E Volynnikova[1]; N Medvedeva[1]
[1]*M.V. Lomonosov Moscow State University, Biological, Moscow, Russian Federation*

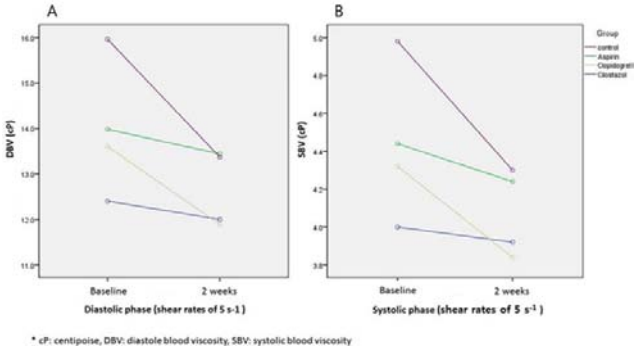
Introduction . It is known that physical activity can affect patients with pulmonary hypertension in different directions. The effect depends on gender, age, rate of disease progression, kind of exercises, etc. The purpose of this study was to study the effect of ovariectomy on the development of hypoxic pulmonary hypertension in rats with different degrees of preconditioning training.
Methods. Female Wistar rats were used. Half of rats were ovariectomized (O). After 2 weeks 2 groups ovariectomized and 2 groups with preserved ovaries rats began to undergo daily exercise preconditioning. For exercise preconditioning animals were subjected to exercise training by swimming for a period of 2 weeks to hypoxia. There were two training protocols. According to the first training protocol, rats was with aerobic swimming during 30 min/day without additional weight (hEx0). Another group undergoing training was with swimming during 15min/day with additional weight equal to 4% of body weight (hEx4). The other groups were not trained (and hC). 14 days after the start of exercises all rats except half untrained were exposed to hypoxia (h) 10h/day, 2wk. with 10% in hypobaric chamber. Two weeks after the onset of hypoxia under urethane (1,2 g/kg) systolic right ventricle pressure (SRVP) was measured as indices of hPH. Right ventricular (RV) hypertrophy was calculated as RV weight /rat b. w.
Results. Two weeks after the onset of hypoxia all groups of rats developed hPH with different extent of the disease. Hypoxia was accompanied by an increase in SRVP from 39,1±2,3 to 54,0± 2,0 mm Hg for C and hC groups and from 33,8±2,4 to 59,0±3,5 mm Hg between OC and OhC groups (p<0,05). Aerobic exercise resulted in an increase in SRVP from 54±2 (hC) to 67±4 (hEx0) mm Hg and decrease in SRVP from 59,0±3,5(OhC) to 50,6±1,5 (OhEx0) mm Hg. Thus, SRVP in OhEx0 animals was 25% lower than in hEx0 (p<0,05). The increase in training intensity (hEx4 groups) caused caused a decrease in SRVP by 40% in the hEx4 group compared to the hEx0 group (p<0,05) up to group for rats with preserved ovaries but not for gonadectomized. Thus, gonadoectomy increased SRVP in rats exercising with additional weight by 32% (p<0,05). Between hypoxic rats of all groups were not difference in RV hypertrophy.
Conclusions. Preventive effect on the increase in SRVP in female rats with hypoxic pulmonary hypertension with preserved ovaries provide an intense exercises with additional weight, but for ovariectomized rats - aerobic physical activity.

P2211

Analysis of whole blood viscosity and gastrointestinal response between low dose aspirin, clopidogrel, and cilostazol single pill in rabbit model (AGACCI trial)

SM Park[1]; MS Kim[1]; MH Jung[1]; HH Choi[1]; CW Goh[1]; KS Hong[1]; H Lee[2]
[1]*Hallym University, Chuncheon Sacred Heart Hospital, Chuncheon, Korea (Republic of)*; [2]*Gumi Cha Hospital, Cardiology, Gumi, Korea (Republic of)*

Background: Cardiovascular atherosclerotic disease is associated with hemorheologic properties such as whole blood viscosity (WBV). There are limited studies for efficacy of antiplatelet agents including aspirin, clopidogrel, and cilostazol on WBV and safety on stomach.
Objectives: This study was performed to evaluate the hemorheologic effect and gastric safety of three major antiplatelet agents.
Methods: A total of forty male rabbits (New Zealand White, 2.8-3.2kg in weight) were randomly assigned to three treatment groups and fed orally for two weeks; vehicle (carboxymethyl cellulose), aspirin (20mg/kg/day), clopidogrel (15mg/kg/day), and cilostazol controlled release (CR) (40mg/kg/day) respectively. Before and after administration of regimen, complete blood cell count (CBC), prothrombin time (PT)/activated partial thromboplastin time (aPTT), blood viscosity test, global platelet function test (PFT) were done. WBV at shear rates of 5 s-1 (diastolic blood viscosity; DBV) and 300 s-1 (systolic blood viscosity; SBV) were measured at baseline and two weeks. WBVs were adjusted to a hematocrit of 45%. At the end of experiment, stomach autopsy were performed in all scarified animals to evaluate the gastric response to drugs.
Results: WBVs in clopidogrel and cilostazol CR group were significantly decreased after 2 weeks treatment (clopidgorel [difference of DBV 0.26±1.84, p=0.013; difference of SBV 0.28±0.53 cP, p=0.007]; cilostazol [difference of DBV: 1.32±2.16, p=0.005; difference of SBV: 0.48±0.60, p=0.017] by Wilcoxon t-test, Figure 1-A and B). However, there is no change of WBV in aspirin group. In addition, the changes of CBC, PT/aPTT, and PFT were not consistent in all treatment groups. On gross inspection of stomachs, hemorrhagic spot, erosion, or ulcer lesions were more frequently observed in aspirin group than in clopidogrel and cilostazol group (ulcer lesion: 4 in aspirin, 1 in clopidogrel, 0 in cilostazol)
Conclusion: Clopidogrel and cilostazol CR treatment are associated with lowering WBV in rabbit model. Gastric response of cilostazol CR looks better than that of aspirin or clopiodgrel. Future clinical research would be warranted to validate these results.



Viscosity of diastole and systole phase

Pulmonary inflammation and vasculature remodeling in a model of heart failure with preserved ejection fraction: effects of ranolazine

A Antonella De Angelis[1]; LP Ciuffreda[1]; D Cappetta[1]; A Liparulo[1]; A Micciche'[1]; B D'agostino[1]; L Berrino[1]; K Urbanek[1]
[1]*University of Campania "Luigi Vanvitelli", Department of Experimental Medicine, Naples, Italy*

Background: Pulmonary vascular disease is gaining attention in the setting of heart failure with preserved ejection fraction (HFpEF) but the pathobiology of pulmonary hypertension (PH) in HFpEF is not clear. In HFpEF, an increase in late Na+ current (INa) in cardiomyocytes leads to increased diastolic tone. Ranolazine (RAN), by selectively inhibiting Ina, can improve myocyte relaxation and release diastolic tension.
Purpose: We aimed at studying lung involvement in HFpEF and testing the effects of RAN.
Methods: Dahl salt-sensitive rats were fed a high salt diet for 5 weeks to induce hypertension and received RAN for the following 8 weeks. Hemodynamic parameters were assessed invasively and by echocardiography. Isolated heart and lung preparation was used for lung hemodynamics.
Results: With unaltered systolic function, diastolic parameters changed in high salt animals. Decreased dP/dt min, increased LVEDP, a longer time constant and a steeper slope of the end-diastolic pressure-volume relationship were present. Analysis of pulmonary tissue showed increased levels of NF-κB, TNFα, E-selectin and VCAM-1, documenting pulmonary inflammation and endothelial activation. These effects were partly counteracted by RAN. Recruitment of inflammatory cells to the lungs is a key event of lung injury. In high salt rats the increase in myeloperoxidase levels and neutrophil infiltration were inhibited by RAN. High salt rats showed an increase in endothelin 1 expression and a reduction in endothelial NOS levels. Importantly, pulmonary vascular hemodynamics revealed pre-capillary resistance as a prominent component responding to RAN.
Conclusions: Our data point the concept that in HFpEF setting, mixed pre- and post-capillary nature of PH may represent not only an indicator of severity of underlying disease but also an attractive therapeutic target.

Clinical Case

P2214

Right ventricular assist device (RVAD): An adjuvant therapy in variety of cardiovascular procedures

M Maria Molina[1]; Y Quiaoit[2]
[1]*University of Pennsylvania, Cardiovascular Medicine and Cardiothoracic Surgery, Philadelphia, United States of America*; [2]*University of Pennsylvania, Heart Failure/Transplant, Philadelphia, United States of America*

Background: Right ventricular assist devices (RVAD) have been utilized in the treatment of post-cardiotomy right ventricular failure and as an adjunct to left ventricular assist device (LVAD) implantation with reasonable success.
Purpose: In this case series, we describe outcomes of seven patients treated at our institution with RVAD support for post-cardiotomy RV failure, as an adjunct to LVAD implantation, and as prophylactic RV support for LVAD patients undergoing elective ventricular tachycardia (VT) ablation procedures.
Methods: Retrospective analysis from 7/2017 to 9/2018 of the seven case series of patients who were supported by temporary right ventricular assist device. Laboratory findings and outcomes were analyzed using descriptive statistics.
Results: Demographics, pertinent clinical details, and outcomes are summarized in Table 1. Three patients (pts) were treated with RVAD support for post-cardiotomy RV failure; of these, one died of intracranial hemorrhage on the 6th post-operative day. The remaining 2 pts were successfully decannulated after 33 and 26 days of RVAD support, respectively, and ultimately discharged from the hospital. Two pts received RVAD support as an adjunct to LVAD implantation; both of these pts were successfully decannulated with improved RV function after 22 and 13 days. Finally, 2 pts had prophylactic RVAD placement prior to an elective VT ablation procedure; again, these 2 pts were weaned from RVAD support successfully on the 21st and 6th post-procedure days. Post-cardiotomy patients required longer duration of RVAD support (median 26 days) than LVAD pts (median 17.5 days) and pts receiving RVAD support for VT ablation (median 13.5 days). These pts also had, in general, more post-operative complications including acute renal failure and need for tracheostomy. Notably, the post-operative course of pts receiving RVAD support for elective ablation procedures was relatively uncomplicated. This anecdotal finding may support wider use of prophylactic RVAD support in this population, although certainly warrants further investigation. The peak bilirubin values were again higher for the post-cardiotomy group (4.6 mg/dL) compared to the LVAD and VT ablation groups (4.2 mg/dL and 2.7 mg/dL, respectively). This likely represents the overall higher clinical acuity of the post-cardiotomy patient population.
Conclusion: Our experience supports the notion that early or prophylactic RVAD support may be of particular benefit in certain clinical situations, as patients in our series who received RVAD support in conjunction with LVAD implant or in preparation for VT ablation had fewer complications and shorter duration of support than the post-cardiotomy group. While these findings merit further investigation, our series confirms that RVAD support is a durable, feasible option for prolonged right ventricular support in a variety of clinical scenarios, successfully bridging many patients to full recovery.

Off pump implantation of HeartMate III LVAD and closure of patent foramen ovale in patient with HIT

S Cesini[1]; S Bhagra[1]; Y Abu-Omar[1]; P Catarino[1]; S Pettit[1]
[1]*Papworth Hospital NHS Trust, Cambridge, United Kingdom of Great Britain & Northern Ireland*

A 55 year old male presented to his primary care physician with exertional breathlessness, an irregular pulse and a systolic murmur. He had no past medical history of note. He was found to be in atrial fibrillation. Echocardiography revealed severe mitral regurgitation due to P2 leaflet prolapse and preserved left ventricular systolic function. Coronary angiography was normal. He was scheduled for mitral valve surgery and was not anti-coagulated given that the anticipated waiting time for surgery was short.
In the week prior to surgery, he presented to his local hospital with an acute ST segment elevation myocardial infarction. Emergency coronary angiography revealed an occluded left anterior descending coronary artery, presumably due to thromboembolism. He underwent primary angioplasty but only TIMI-2 flow was restored. The procedure was complicated by cardiogenic shock, with renal and liver injury. He was stabilized with inotropic and IABP support, then transferred to our hospital for assessment.
He remained IABP dependent, with recurrent pulmonary oedema when augmentation was reduced. Repeat echocardiography showed severe left ventricular systolic dysfunction and severe mitral regurgitation (Fig. 1). To complicate matters, he developed heparin-induced thrombocytopenia (HIT) and was treated with Argatroban. Our cardiac surgeons felt that isolated mitral valve surgery would be unacceptably high risk.
We elected to implant a HeartMate III left ventricular assist device (LVAD) as a bridge to heart transplantation. The procedure was performed without cardiopulmonary bypass in order to avoid administration of heparin. At the time of surgery, there was evidence of a very small patent foramen ovale (PFO) on trans-oesophageal echocardiography (TOE) but this was not closed.The early post-operative period was complicated by progressive arterial desaturation and repeat TOE showed a significant right to left shunt across an enlarged PFO (Fig. 2). It was clear that the PFO required closure, but we wished to do this without cardiopulmonary bypass. A mini-thoracotomy was performed and the PFO was closed by careful placement of a suture through the inter-atrial septum from outside the heart under TOE guidance. This resulted in immediate recovery of oxygenation. The patient made an excellent recovery from this point forwards.
Conclusions: 1) LVAD may be implanted off-pump without heparin and this strategy is attractive in patients with HIT. 2) Any inter-atrial defect must be closed at the time of LVAD implantation due to the risk of post-operative right to left shunting. 3) It is possible to close a PFO from outside the heart during off-pump LVAD implantation with TOE guidance.

Interpretation of blood pressure (BP) values using noninvasive blood pressure measurement in patients with continuous-flow left ventricular assist device (LVAD) - clinical problem

M Marie Lazarova[1]; T Kara[1]; R Aiglova[1]; J Stritecky[2]; P Nemec[3]; M Taborsky[1]
[1]*University Hospital Olomouc, cardiology, Olomouc, Czechia*; [2]*Charles University in Prague, departement of biophysics, Hradec Kralove, Czechia*; [3]*Center of cardiovaslular and transplat surgery, Brno, Czechia*

Introduction The Management of hypertension in patients with LVAD is an important aspect of care due to the increased risk of fatal complications (CMP, LVAD thrombosis). However, noninvasive blood pressure measurement in patients with LVAD with continuous flow can offer many clinical pitfalls. The Doppler ultrasound method is still used in most centers, as the automated BP monitor is not successful in measuring up to 50% of cases due to the artificial reduction of pulse pressure. However, even the Doppler method is loaded with problems in interpretation of measured values (medium or systolic BP, i.e. MAP vs. SBP), which can lead to significant clinical consequences.
Case description: 69-year old patient with terminal heart failure, indicated for LVAD (HeartWare) implantation as destination therapy in May 2016. After implantation was stable, without any serious difficulties. During follow-up visits, BP values measured by Doppler were repeatedly 90-100 mm Hg. The aortic valve opening was 1:1, LVAD was with normal parameters. Since the BP values were considered as MAP, antihypertensive therapy was up-titrated. We reached the reduction of MAP to 80-85 mm Hg, the patient was asymptomatic, LVAD with normal flow again, antihypertensive medication remained unchanged. After following 2 years the patient was stable, without any complications. We did not record any major clinical or echocardiographic changes, MAP was still around 80 mm Hg. We left the antihypertensive medication unchanged. In December 2018 the patient experienced syncope with craniotrauma and underwent decompression craniotomy. In stable condition and after gradual recovery, the values of BP measured by Doppler ultrasound were repeatedly 100–110 mm Hg after previous reduction of antihypertensive therapy. Because of craniotrauma and the necessity of exact BP measurement and exact management of antihypertensive therapy, we added an invasive BP measurement. The arterial line BP values were 100-110/60-65 mm Hg. This result means that BP values obtained by Doppler method were exactly SBP in our case.
Discussion: This clinical problem (noninvasive BP measurement in patients with continuous flow LVAD and interpretation of obtained values - MAP vs. SBP) is documented in the story of our patient. It might be possible, that hypotension was one of the syncope contributing factors. We recommend that BP values in patients with LVAD should not be determined by a single isolated method, but that haemodynamics should be assessed in a comprehensive manner by a combination of several methods. The hopes are new monitors, developed specifically for non-invasive BP measurements in patients with LVAD. An individual comparison of the accuracy of each methods in a given patient at a time just before the end of the invasive monitoring of TK may be clinically beneficial.

P2217
With and without you: LVAD unplugged

F Loiacono[1]; S Sara Vazquez[1]; JM Dominguez[1]; G Spitaleri[1]; B Keller[1]; A Castel[1]; M Farrero[1]; F Perez-Villa[1]
[1]Hospital Clinic de Barcelona, Cardiology, Barcelona, Spain

We present the case of 64-year-old man previously implanted with left ventricular assist device (LVAD) for end-stage heart failure (HF), who survived three months after deliberately unplugging the device.
The patient suffered from ischemic heart disease due to anterior myocardial infarction, resulting in ejection fraction =18%. He soon developed symptoms of advanced HF, but was diagnosed with colon cancer (pT2 N0 M0) during heart transplant work-up. He underwent surgery and was considered to be free of disease 6 months later. In November 2014 he was implanted with an LVAD HeartMate 2 device, with uneventful initial course.
Later, despite psycho-social follow-up had deemed favorable previous to the implant, he developed psychopathic behavior including deliberate withdraw of medication (anticoagulants, anti-neurohormonal drugs, etc), which was later re-assumed. Besides, due to poor hygienic conditions, he soon developed exit site infection that led to multiple hospitalizations.
Four years after surgery, and despite medical warning, the patient decided to unplug device batteries, therefore causing the pump to stop. Two weeks later he was hospitalized for HF and treated with iv diurethics. Laboratory did not show a significant increase in LDH. A CT scan showed no evidence of pump thrombosis (considering the limitations of the technique); a transesophageal echo showed laminar flow into apical cannula and no thrombosis (figure 1). Despite that, due to high thrombo-embolic risk and the impossibility to definitely exclude thrombosis inside the pump, the medical team decided not to re-connect the device. According with psychiatric evaluation, we considered contraindicated HTx as well as a new surgery for substitution of the LVAD.
The patient died three months after unplugging his LVAD apparently because of progressive HF. Autopsy did not reveal any thrombosis of the device neither any sign of systemic embolism.

P2218
Idarucizumab for urgent reversal of dabigatran before orthotopic heart transplantation

M Dankova[1]; P Lesny[1]; M Luknar[1]; E Goncalvesova[1]
[1]The National Institute of Cardiovascular Diseases, Department of Heart Failure and Heart Transplant, Bratislava, Slovakia

Background: The use of dabigatran in patients with atrial fibrillation enlisted for heart transplantation has been limited by unpredictable timing of surgery and high bleeding risk.
Case presentation: A 58-year old male patient on dabigatran for atrial fibrillation was enlisted for heart transplantation due to advanced heart failure. Upon notification of suitable heart donor, we prepared patient for surgery. The last dose of dabigatran was 16 hours prior to the haemocoagulation blood tests. We recorded prolonged APTT, TT and confirmed the presence of dabigatran at 31,3ng/ml. Before general anesthesia and extracorporeal circulation we received two boluses of 2,5 mg idarucizumab. Surgery and postoperative period were without complications.
Conclusions: Idarucizumab was associated with an affective hemostasis in the setting of heart transplantation, which allows the use of dabigatran in patients with atrial fibrillation on heart transplant waiting list.

Parameters of haemocoagulation

Parameters	16 hours after dabigatran use	4.5 hours after idarucizumab administration	24 hours after idarucizumab administration	Reference values
Prothrombin test(%)	62.3	53.2	51.0	70.0 - 130.0
Prothrombin test(PT-R)	1.33	1.48	1.53	0.8 - 1.2
APTT (s)	32.2	30.3	27.1	22.0 - 28.0
APTT (R)	1.24	1.17	1.04	0.8 - 1.2
Thrombin time(s)	53.6	20.6	17.7	0.0 - 22.0
dTT (ng/ml)	31.3	n.a.	n.a.	n.a.
Antithrombin III	91.3	77.4	81.8	75.0 - 125.0

Heart transplant for acute heart failure in kearnes sayre syndrome

D Miani[1]; A Paldino[2]; G De Maglio[3]; S Pizzolito[3]; N Finato[3]; C Di Nora[1]; A Proclemer[1]; U Livi[1]
[1]Department of Cardiopulmonary Sciences, UNIVERSITY HOSPITAL, Udine, Italy; *[2]University of Trieste, Cardiology , Trieste, Italy*; *[3]University Hospital Santa Maria della Misericordia, Laboratory Department of Medical Biological Sciences, Udine, Italy*

INTRODUCTION: Acute onset of congestive heart failure is an expression of a rare form of dilated cardiomyopathy secondary to Kearnes Sayre Syndrome (KSS) (mitochondrial disease). We describe the case of a young patient affected by this syndrome, that underwent orthotropic heart transplant.
CASE PRESENTATION: a 16 year-old male has been admitted to coronary care unit for a first acute onset of heart failure on Sep 2018. He was affected by KSS, a mitochondrial disease, characterized by pigmentary retinopathy, ophthalmoplegia, epileptic seizures in therapy with levetiracetam, moderate myopathy, early stage of kidney tubulopathy and blindness, in absence of heart involvement during cardiological follow-up. He had a normal growth and development. At admission, physical examination revealed a blood pressure of 105/70 mmHg, tachycardia with heart rate of 123/bpm, jugular venous distention. Laboratory findings were significant for BNP of 988 pg/mL and troponin hs of 114 ng/L. A echocardiogram showed a dilated and hypokinetic left ventricle with an ejection fraction of 11%. In the left apex, three mobile pedunculated thrombotic masses were visible. There was also evidence of right-sided heart failure with increased pulmonary hypertension (PAPs 55 mmHg). During the hospitalization, he was treated by intravenous diuretics and heparin, and referred for heart transplant. In absence of contraindication by neurologist and nephrologist, he underwent orthotropic heart transplant, without complications. Currently, after 4 months, he has not heart transplant rejection in therapy with cyclosporin, mycophenolate and cortisone. Examination of the explanted heart revealed a dilated left ventricle with apical thrombotic material adherent to a focal thickened and activated endocardial border. The posterior wall appeared

thinned and with a greater proportion of transmural interstitial and replacement fibrosis. Cytoplasmatic vacualizations were present in subendocardial myocardiocytes. Electron microscophic examination showed heart muscle cells with attenuated myofibrils arranged in parallel arrays and separated by a proliferation of several mitochondria (interfibrillar mitochondriasis), with morphologic abnormalities as swollen mitochondria with abnormal cristae and some globular electron-dense material.
DISCUSSION: KSS is a rare disease that belongs to a group of neuromuscular disorders know as mithochondrial encephalomyopathies. Progressive cardiomyopathy is a possible cause of mortality in KSS patients. Rare cases of heart transplant in KSS patients are reported in literature, but they resulted life-saving.
CONCLUSIONS: In consideration of the multiple organs involvement, the decision for heart transplant in patients affected by mitochondrial encephalomyopathies as treatment option is arguing and should be assessed case-by-case.

Multiple cerebral infarcts in Chagas cardiomyopathy with Left Ventricular reduced Ejection Fraction : A Case report.

EJJ Eduardo Julian Jose Chuquiure[1]; L Medina-Paz[2]; C Anaya-Morales[1]; D Garcia-Romero[2]; M Balbuena-Madera[2]; C Silva-Ruz[2]; E Tapia-Lopez[2]; O Fiscal-Lopez[2]
[1]Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico; *[2]Instituto Nacional de Cardiologia Ignacio Chavez, Centro en Insuficiencia Cardiaca, Mexico City, Mexico*

Background: Chagas disease (CD) is a vector-borne illness caused by the Trypanosoma cruzi parasite that primarily affects heart and/or digestive system. It is the third most common parasitic infection worldwide. The 40% of these patients develop a chronic form of the disease, that usually generate cardiomyopathy, cardiac arrhythmias and mural thrombus. Ischemic Stroke (IS) has been linked to CD, especially in the chronic form. Stroke recurrence has been estimated at 20% of patients, and secondary prevention measures include chronic anticoagulation in cardioembolic chagasic stroke. Deaths related to these complications have been described in 31-52% of cases. No evidence exists about the use of trypanocidal drugs in patients with chagasic stroke.
Case Summary: A previously healthy male with no vascular risk factors, presented a first cerebral vascular event at 57 years old, confirmed with MRI established in right middle cerebral artery territory. Echocardiography, carotid USG, 24h Holter monitoring and hematology and rheumatology labs were performed with no abnormalities; during his evolution he had significant recovery of the symptoms; however, at 60 and 63 years old, two other episodes of IS were documented, again with undefined etiology. It remained asymptomatic until 67 years old, when he presented a fourth IS with language alterations and left hemiparesis.
When he arrived at our Institute a new approach was performed. Basic lab studies were normal, except for dyslipidemia with LDL 118 mg/dL despite of high-intensity statin therapy. EKG showed left ventricular axis deviation, 24h Holter monitoring appeared normal, Transthoracic Echo showed left ventricle dilated and inferior wall hypokinesia, LVEF was 35%. NT-proBNP was 500 pg/mL. Coronary angiography appeared normal. MRI showed extensive fibrosis with mixed pattern with LVEF 34% and RVEF 40%, increase in lateral trabeculation with third apical half predominance. T. cruzi antibodies were ordered, with positive results, two positive confirmatory ELISA against T. cruzi (4.45 and 12.04). After revealing the IS etiology, we initiated optimal medical treatment for heart failure, non-Vitamin K antagonist oral anticoagulant (NOAC) and antichagasic drug, Nifurtimox, with an incredible clinical and functional improvement.
Conclusion: Ischemic stroke can be a rare manifestation of chagasic cardiomyopathy, which is why we strongly suggest that patients from endemic regions of Chagas disease should be screened for anti-T. cruzi antibodies when there is no other explanation for cerebral thromboembolism. Although we present a case where functional and clinical improvement was achieved with medical therapy, additional future studies are needed to assess if anti chagasic treatment is beneficial on these patients to guidelines recommendations.

P2221

Stress-induced cardiomyopathy after exposure to wildfire

V Kakiouzi[1]; A Anastasia Kitsiou[1]; D Mytas[1]; P Grammata[1]; V Tzeltzes[1]; T Papafanis[1]
[1]Sismanoglio Hospital, Athens, Greece

Introduction: It has been described that intense psychological stress may result in myocardial damage and left ventricular dysfunction, known as Takotsubo cardiomyopathy.
Case presentation: An 80-year-old woman presented to the Emergency Department of our hospital due to chest pain after exposure to the wildfire in Mati, Attica, on July 23rd 2018. In addition to smoke inhalation, she had stayed in the sea for about 4 hours before she was eventually rescued.
The patient had a history of arterial hypertension and dyslipidemia (on irbesartan and atorvastatin). The physical examination did not show any abnormal findings from the heart or other organs. Blood pressure was 128/69 mmHg and heart rate was 75 bpm. The electrocardiogram showed sinus rhythm, RBBB (preexisting), ST segment elevation ≤1 mm and negative T waves in leads I and aVL. Laboratory tests showed an increase in cardiac troponin I (maximum value = 7.161 ng / ml, with a normal reference value of <0.04 ng / ml). Thansthoracic echocardiogram showed a significant reduction in left ventricular (LV) systolic function (EF≍ 35%) with severe hypokinesis of the apex, apical-mid anterior wall and apical-mid-anterior intraventricular septum. The patient underwent coronary angiography which revealed normal coronary arteries. She was discharged on medical therapy (irbesartan, metoprolol, eplerenone, atorvastatin and acetylsalicylic acid).
Conclusion-outcome: The patient remained asymptomatic. Transthoracic echocardiogram, performed one month after her discharge from the hospital, showed normal LV systolic function without regional wall motion abnormalities. It is concluded that this represents a case of cardiomyopathy caused by intense psychological stress, due to exposure to a natural disaster.

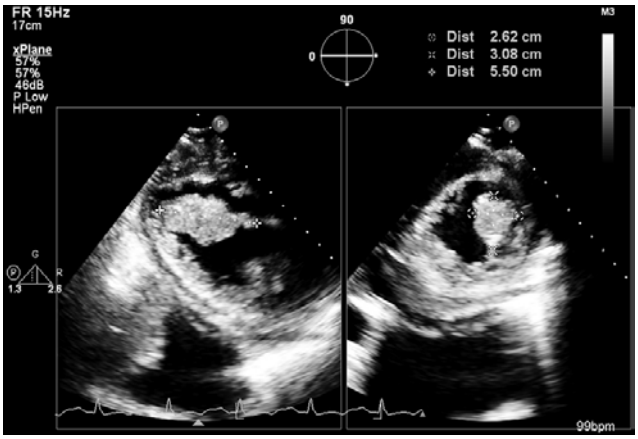
P2222

A rare and dangerous presentation of alcoholic cardiomyopathy

H Liu[1]; VK Vincent Kent Le[2]; M Sadreddini[2]
[1]University of Toronto, Toronto, Canada; *[2]Northern Ontario School of Medicine, Thunder Bay, Canada*

Introduction and case report description: A left ventricular thrombus is a serious complication that can occur after a myocardial infarction or due to cardiomyopathy. This complication is more commonly associated with a large anterior STEMI due to occlusion of the left anterior descending artery, and usually occurs five to six days after a myocardial infarction. However, it is important to remember that this complication can also occur due to cardiomyopathy and heart failure.
A 38-year-old male no past medical history presented to a rural emergency department with sudden severe chest pain, along with several months of slowly worsening peripheral edema. The patient drank 12 to 18 bottles of beer daily for the past 6 months. An electrocardiogram showed ST elevation in leads II, III, and aVF. He was given tenecteplase, along with aspirin, clopidogrel, and IV heparin, and then transported to a hospital with access to percutaneous coronary intervention. The patient developed new aphasia and right hemiparesis during his assessment on arrival to the larger hospital.
Description of the problem and differential diagnosis: A Code Stroke was called, and the patient's head CT did not show an intracranial bleed. Point-of-care ultrasound showed reduced left ventricular function with an ejection fraction of 19% and a large apical thrombus measuring 5.5 x 3.1 x 2.6 cm.
The patient's neurological symptoms resolved with anticoagulation after 5 days. Serial echocardiograms showed a decrease in thrombus size. After four weeks, the heparin was switched to warfarin and the patient was discharged in a stable condition.

The patient's significant long-term alcohol use resulted in alcoholic cardiomyopathy, as indicated by the several months of progression of lower extremity edema and severe left ventricular dysfunction on echocardiogram. The ventricular dysfunction resulted in reduced blood flow, which is one of the components of Virchow's triad, and contributed to the formation of the large apical thrombus. Eventually part of the clot broke off the thrombus, occluded the right coronary artery, and caused the inferior STEMI. Shortly after, another piece of the thrombus broke off and resulted in a cardioembolic stroke to the left middle cerebral artery.
Conclusions and implications for clinical practice: In patients who have multiple simultaneous illnesses, it is important to evaluate for a unifying diagnosis, such as in this case where the patient's alcoholic cardiomyopathy resulted in a thrombus formation, which caused both the inferior STEMI and the ischemic stroke.This case also highlights the clinical benefits of being proficient in performing a point-of-care ultrasound because a bedside echocardiogram by the receiving physician only took a few minutes and found the left ventricular dysfunction and large thrombus. This finding, along with the clinical history, resulted in a unifying diagnosis for this patient's medical condition.



Echocardiogram Showing Large Thrombus

P2223

Predominant cardiac involvement in laminopathy diagnosed at pretransplant assessment

K Katarina Hromanikova[1]; M Kubanek[1]; A Krebsova[1]; P Votypka[2]; M Macek[2]; V Melenovsky[1]; J Kautzner[1]
[1]Institute for Clinical and Experimental Medicine (IKEM), Prague, Czechia; *[2]Motol University Hospital, 2. Department of Human Biology and Medical Genetics, Prague, Czechia*

Introduction: Clinical presentation of laminopathies is variable, ranging from predominant muscular disease in Emery- Dreyfuss muscular dystrophy /EDM/ to isolated cardiac involvement with early conduction disease, progressive heart failure and ventricular tachyarrhythmias.
Case description:
A 16-year-old girl with a negative family history of heart disease was referred to our department in February 2018 due to rapid progression of left ventricular systolic dysfunction (from ejection fraction 40% to 28%) and atrial tachyarrhythmias. Previously, she was followed by pediatric cardiologists and underwent endomyocardial biopsy to exclude myocarditis, genetic testing and repeated cardioversions due to atrial tachyarrhythmias. Despite amiodarone therapy, atrial fibrillation and atypical atrial flutter persisted and the patient was repeatedly hospitalised for congestive heart failure with the necessity for inotropic support after initial examination in our department. In the search for etiology of heart failure, we noticed mild elbow contractures with otherwise normal neurological status and normal values of serum creatinkinase of 2.59 ukat/l. Genetic testing revealed pathogenic (Class 4), de novo mutation in lamin A/C gene (LMNA:c241T>G, p.Tyr81Asp). Clinical diagnosis was made of Emery-Dryefuss myopathy with predominant cardiac involvement. The patient was listed for heart transplantation in June 2018 and one month later successfully transplanted. At this period, family screening is being performed.
Conclusion: This case-report demonstrates that laminopathy should be considered in patients with progressive non-ischemic heart failure even in the absence of myopathy. The correct diagnosis may have important prognostic implications for the family of the proband.

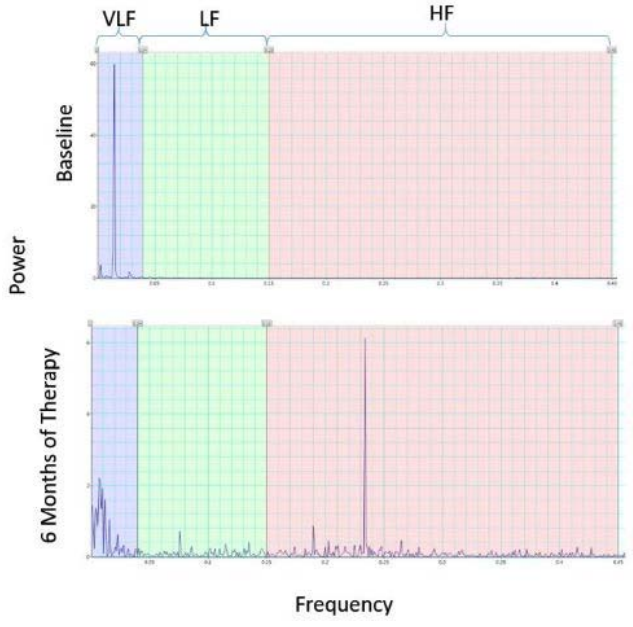
P2224

The effects of phrenic nerve stimulation on heart rate variability: a case study

AJ Coats[1]; REG Germany[2]; DW Bourn[3]; LR Goldberg[4]
[1]Monash University, Warwick, Australia; *[2]University of Oklahoma, Oklahoma City, United States of America*; *[3]Cardialen, Inc., Minnetonka, United States of America*; *[4]University of Pennsylvania, Medicine, Philadelphia, United States of America*

Funding Acknowledgements: Respicardia

Introduction: Frequency based heart rate variability (HRV) measures are one method of measuring autonomic function and sympatho-vagal balance via subtle changes in R-R interval timing. The proportions of these measures describe the autonomic function and sympatho –vagal balance of a patient and are reflected in Total Power (TP), and Very Low Frequency (VLF), Low Frequency (LF) and High Frequency (HF) power. Heart failure patients with reduced Ejection Fraction (HFrEF) exhibit high levels of sympathetic drive, depressed baroreceptor responsiveness (LF), and decreased vagal tone (HF via respiration). Central sleep apnoea (CSA), a co-morbid condition often seen in HFrEF patients, contributes to increased sympathetic drive and is manifested by increases in the VLF component. Treatment of CSA using the remedē® System has been shown to be effective in restoring a normal breathing pattern and may also contribute to improved autonomic function and sympatho–vagal balance.
Purpose: To describe changes in HRV measures after 6 months of phrenic nerve stimulation experienced by a patient with reduced ejection fraction (EF) and CSA.
Methods: The remedē® System pivotal trial assessed the effectiveness of unilateral phrenic nerve stimulation in treating moderate to severe CSA. In this analysis, overnight attended polysomnography studies performed at baseline (BL) and at 6 months of treatment (6M) were divided into 5-minute segments and the EKG was analysed by segment using an automated algorithm in Lab Chart (v8.1) HRV module. All segments were reviewed to ensure accuracy and consistency in the analysis. Here we present a single case of a trial participant that had an EF $\leq$ 40%, was in normal sinus rhythm, and demonstrated an improvement in CSA as evidenced by a reduction in the Apnoea-Hypopnoea Index from 49 to 9 events/hour at 6M.
Results: The figure below shows the median values of the 5 minute segments for the VLF, LF and HF components of the HRV Measures. At BL (n=90, 5 min. segments) the total power is dominated by the VLF content while at 6M (n=84, 5 min. segments) the total power decreases by 20% and VLF decreases by 69% (Figure 1). Additionally, LF and HF power increased by 207 and 247% respectively, demonstrating decreased sympathetic drive.
Discussion: In this case study, CSA improved at 6 months with phrenic nerve stimulation and the improvement corresponded to changes in magnitude and content of frequency domain HRV measures that suggest improved autonomic function and sympatho-vagal balance. Further analysis is required in a larger sample of patients to validate this unique finding.



Change in HRV with therapy

P2225

A rare case of heart failure with preserved ejection fraction in Erdheim Chester syndrome, at the crossroad of many possible causes

A-E Elena-Alina Patru[1]; M Anton[1]; D Coriu[2]; M Boros[2]; D Deleanu[1]; A Bardas[2]; C Ginghina[1]; BA Popescu[1]; C Jurcut[3]; R Jurcut[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, Bucharest, Romania*; [2]*Fundeni Clinical Institute, Bucharest, Romania*; [3]*Carol Davila Emergency Clinical Military Hospital, Bucharest, Romania*

Introduction We present the case of a 71 year old man, asymptomatic until 2017 when he was admitted to hospital for recurrent pleurisy. CT scan shows pleurisy and pericarditis and also bilateral periaortic and perirenal dense, fibrotic tissue, highly suggestive for Erdheim Chester disease. Perirenal biopsy was made, histological examination showing histiocyte inflitrations that expressed CD68 / PGM1 fascine and factor XII.Also,he had a history of borderline coronary atherosclerosis.
Patient management In February 2018, he develops progressive shortness of breath, fatigue and severe uncontrolled hypertension. Lab test showed progressive kidney failure (creatinine level of 2.5 mg/dl, relative to 1.5 mg value in 2017). TTE showed normal size cardiac cavities, preserved systolic function (LVEF 50-55%),inferobasal hypokinesia and infiltrated pericardial layer. Contrast angioCT reveals massive infiltration in the arterial aortic wall, significant left renal artery stenosis and no flow in the right kidney artery, with subsequent renal atrophy. Renal arteriography confirmed severe left renal artery stenosis and a 7 mm stent is implanted. At 48h after stent implantation, creatinine was 1.3 mg/dl. At discharge, arterial blood pressure values are decreasing, requiring lower dose of antihypertensive drugs, and functional capacity was remarkably improved. During followup, the patient developed severe leuco-thrombocytosis, bone marrow biopsy and genetic testing established the diagnostic of chronic myeloid leukemia. Cytoreductive treatment with hydroxyurea was started, but after two weeks, general status was not improved, with frequent episodes of paroxysmal dyspnea, elevated blood pressure, markedly high NTproBNP levels (12943 pg/ml) and an echocardiographic LVEF of 50%, with diastolic dysfunction and mild pericardial effusion. Optimization of HF therapy and stopping hydrea led to a reduction of NT proBNP levels (5292 pg/ml) and constant echocardiographic findings. However, while receiving hidroxicarbamide and imatinibe for the hematologic malignancy, several milder decompensations of heart failure episodes reoccurred.
Problems, possible differential diagnosis: Concerning the heart failure symptoms, we can make a differential diagnosis between myocardial ischemia (but with no angina, no new hypokinesia and no cardiac necrosis biomarkers), diastolic disfunction with increased filling pressure due to marked elevated arterial hypertension and chronic kidney disease, myocardial injury due to hystiocitar infiltration or cardiotoxicity of oncologic treatment for leukemia.
Conclusions : Erdheim Chester syndrome is a rare non-Langerhans cell histiocytosis that most commonly affects adults, often a fatal disease, with multi-organ damage and rapid progression, therefore diagnostic precocity is a key element. HF with preserved ejection fraction can have multiple causes in this setting (pericarditis, aortitis and medium size vasculitis, hematologic changes).

P2226

A case of infectious endocarditis associated with Laubry-Pezzi syndrome

TH Thai Hao Phan[1]
[1]*Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam*

Introduction: Charles Laubry and Cesare Pezzi described the clinical features of Laubry-Pezzi syndrome in 1921 in a patient with ventricular septal defect (VSD) with aortic regurgitation caused by aortic valve prolapse. The syndrome may eventually lead to dilatation of the aortic sinus related to the involved leaflet, resulting from a lack of continuity of the aortic media and annulus. Laubry and Pezzi syndrome is a rare but serious complication of ventricular septal defect that increase the infectious endocarditis risk. We reported a case of infectious endocarditis associated with Laubry-Pezzi syndrome.
Case Report:
A 29-year-old Vietnamese, nonsmoker, nonalcoholic, non-diabetic, normotensive man from a province presented with dyspnea on lying, two-week fever. In the physical examination, edema in both lower limbs. Crepitant rales in both lungs. Apex beat shifted outwardly and below the 5th intercostal space, in the anterior axillary line. A 3/4 grade diastolic murmur at at third left intercostal space and an holosystolic murmur of a 4/6 degree at the fourth-sixth left intercostal space level, with radiation to the right lower sternal border. Heart rate: 113 bpm. Blood pressure: 130/60 mmHg. spO2 :98% (air room).
Results: Electrocardiogarphy showed sinus tachycardia with left ventricular enlargement. Chest X-ray: cardiac shadow was large, redistribution of pulmonary blood flow. Echocardiography: left-right shunt subaortic VSD (8mm), severe aortic valve regurgitation, prolapsing of the right coronary, a ruptured abcess with diameter 12x11mm in right coronary cusp, left ventricular EF: 63%, PASP: 45mmHg. Cardiac MSCT: subaortic VSD 10mm, a ruptured abcess with diameter 12x11mm in right coronary cusp. Sinus valsalva dilation diameter # 45mm. Normal coronary arteries. Infectious endocarditis associated with Laubry-Pezzi syndrome was diagnosed. After 28 days of antibiotic of infectious endocarditis, surgical procedure modified Bentall was performed and the ventricular septal defect was closed with a Dacron patch. After operation patient's postoperative course was uneventful with improvement of heart function.
Discussion: The Laubry-Pezzi syndrome is a rare congenital hearth disease . It was reported for the first time by Laubry & Pezzi in 1921, its prevalence is 0.013 to 0.3%. Nearly always diagnosed in children and teenagers, since it is a congenital disease. In this congenital heart diaseases surgical indication, appropriate timing of surgery and operative technique are still matter of debate owing to its rare incidence among overall population.
Conclusion The Laubry-Pezzi syndrome is rare congenital heart disease leading to a significant alteration of cardiac hemodynamic. Bacterial endocarditis combined with Laubry-Pezzi syndrome have a poor prognosis needing observation and strict preventive precautions when a favoring factor is present. The surgical treatment is necessary and must be performed as soon as possible.

P2227

A case of cerebral emboli complicating infective endocarditis caused by Abiotrophia defectiva

TH Thai Hao Phan[1]
[1]*Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam*

Background: Abiotrophia defectiva is a rare cause of endocarditis. However, some studies have estimated that this organism is responsible for 5-6% of all cases of Infective endocarditis. Endocarditis caused by A.defectiva carries greater morbidity and mortality than endocarditis caused by other streptococci. It is characterized by the occurrence of certain complications such as congestive heart failure, embolization and an increased rate of surgical interventions. We report a case of cerebral emboli complicating infective endocarditis caused by Abiotrophia defectiva.
Case presentation: A 32-year-old male patient with no history of heart disease presented to the hospital with high fever over 3 weeks, fatigue and headache. On the third day of hospitalisation, left facial paralysis developed and neck stiffness. Physical examination show a holosystolic murmur 3/6 grade in apex and left side paralysis. Fundoscopic examination was normal. Laboratory investigations were as follows: WBC 10.9 x 109/L, Hemoglobin: 11.5 g/dl, Platelets: 326x109/L and CRP: 48.3mg/L. Three sets of blood cultures were obtained. Blood cultures grew a gram positive coccobacillus which was phenotypically identified as Abiotrophia defectiva.Transthoracic echocardiography revealed a 2×0.5 cm-sized vegetation on the anterior mitral valve leaflet and a 1.5x0.7cm-sized vegetation on the posterior mitral valve leaflet and severe mitral regurgitation, LV ejection fraction was 64%. Cranial computed tomography revealed an infarct in the right parietotemporal lobe. A diagnosis of cerebral emboli complicating infective endocarditis due to Abiotrophia defectiva was made. Treatment, with ceftriaxon and vancomycin, was administered for 4 weeks. Mechanical valve replacement was required after starting the antibiotic therapy. The patient had a favorable outcome on follow up.
Discussion: Abiotrophia defectiva is a rare pathogen of infective endocarditis and in some cases embolization occur. Our patient was unaware of having any cardiac

disease and the diagnosis of infective endocarditis is only considered after the development of embolic episodes. Dental procedures or dental caries are thought to be associated with the onset of infective endocarditis caused by Abiotrophia defectiva. Prompt attention to correct identification of this pathogen and surgical treatment of mitral valve must be given careful attention by the attending physican.
Conclusion: A.defectiva is a recognized cause of endocarditis. Clinicians should be aware of this organism and its pathogenic potential. Proper identification of this pathogen is important to achieve a better outcome.

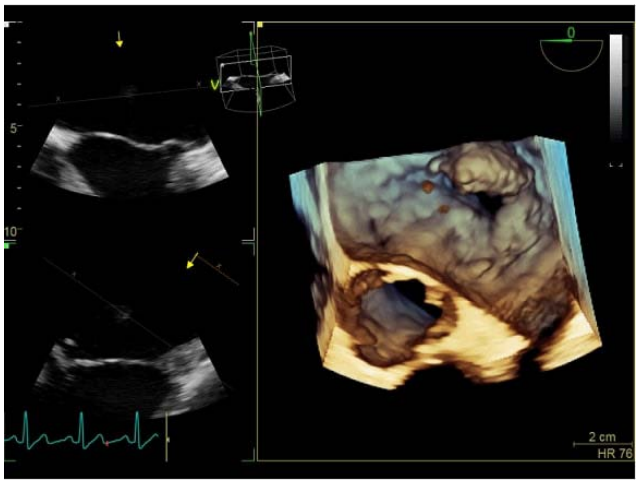
Flail mitral valve resulting in multiorgan failure

P Fountoulakis[1]; E Hamodraka[1]; A Siama[1]; A Athanasios Tsoukas[1]; AJ Manolis[1]
[1]*Asclepeion Voulas Hospital, Athens, Greece*

Funding Acknowledgements: No funding

Introduction: Mitral valve prolapse is a common echocardiographic finding affecting approximately 2,4 % of the general population and is usually asymptomatic accompanied by mild to moderate valve regurgitation. However in rare cases myxomatous degeneration can lead to severe valve regurgitation either chronically or acutely secondary to superimposed chordae tendinae rupture requiring urgent cardiothoracic management.
Case presentation: α 66 year old woman was admitted to the Emergency Department of our Hospital due to progressive paroxysmal nocturnal dyspnea and orthopnea. Her personal history included known moderate mitral regurgitation, chronic atrial fibrillation, chronic obstructive pulmonary disease under oxygen therapy, arterial hypertension and dyslipidemia. Ausculation revealed a third cardiac tone, an holosystolic murmur irradiating to the base of the heart and crackles on both pulmonary bases. The electrocardiogram depicted atrial fibrillation with increased ventricular response. Chest X-ray highlighted right moderate pleural effusion and signs of pulmonary congestion. Transthoracic echocardiography was performed and demonstrated a mitral valve with myxomatous degeneration and a flail posterior cusp accompanied by severe mitral regurgitation with an eccentric jet directed posteriorly and mild left atrial dilatation. The left ventricle manifested hyperdynamic contractibility and pulmonary pressures were only mildly elevated. Coronary angiography followed that depicted an atheromatous coronary network with non-obstructive lesions. In the following hours, the patient became hemodynamically unstable with tissue hypoxia and progressive deterioration of her renal function requiring immediate support with inotrope and vasoconstrictive agents as well as placement of an intraaortic ballon counterpulsation pump. The patient was subsequently transferred to a specialized cardiothoracic center, where she underwent successful valvuloplasty of the mitral valve. However, her general clinical status has deteriorated, thus leading to lethal multiorgan failure.
Conclusion/Discussion: Cases of myxomatous mitral valve degenaration and proptosis, even if the regurgitation is mild or moderate initially, can acuterly worsen due to chordae tendinae rupture. Acute severe mitral regurgitation imposed on chronic disease is a medical emergency with high morbidity and mortality leading to multiorgan failure and non-reversible cardiogenic shock.



Flail posterior mitral valve leaflet

P2229
Anterolateral papillary muscle rupture with non obstructive coronary artery disease

S Borges[1]; F Goncalves[1]; JP Guimaraes[1]; JJ Monteiro[1]; C Ferreira[1]; JI Moreira[1]
[1]*Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal*

BACKGROUND Papillary muscle rupture is an uncommon, potentially fatal condition that frequently results in acute severe mitral regurgitation (MR) and life-threatening cardiogenic shock. Survival depends on prompt recognition and surgical intervention.
CASE PRESENTATION A previously asymptomatic 62-years-old man with unremarkable past medical history, presented to the prehospital emergency team with acute pulmonary edema, without chest pain, less than 30 minutes long; Rapid evolution in cardiac arrest in pulseless electrical activity with return of spontaneous circulation within 6 minutes of cardiopulmonary resuscitation; Transported to the emergency room intubated with orotracheal tube, PaO2/FiO2 ratio <50, BP 86/55 mmHg. Initial
EKG showed supraventricular tachycardia with inverted T wave V4-V6; Laboratory tests revealed Urea/Creatinine 137/5.6 mg/dL, CK 317U/L, T troponin 0.272 ng/mL. Transthoracic echocardiogram showed severe mitral regurgitation (MR) due to possible flail leaflet and hyperdinamic left ventricle (LV). To better characterize the MR mechanism, it was performed a transesophageal echocardiogram that revealed papillary muscle rupture and already moderate LV systolic dysfunction, without any mass/vegetation/thrombus; After insertion of an intra-aortic balloon pump, the patient underwent emergent coronary angiography that showed nonobstructive coronary artery disease and was immediately transferred to a cardiothoracic department. Admitted for emergency surgery less than six hours after the onset of symptoms. At surgical inspection, it was observed rupture of the anterolateral papillary muscle (APM). The patient underwent mitral valve replacement with biologic valve;
Pathology demonstrated acute ischemia of the underlying myocardium. The postoperative period was complicated by the need of inotropic support, prolonged mechanical ventilation and nosocomial pneumonia. Postoperative echocardiography showed no MR. The patient was discharged 29 days later to a medical recovery unit and he is now back to his normal life, without major limitations.
DISCUSSION We have described an unusual presentation of acute MR due to isolated APM rupture in the absence of obstructive artery disease. The papillary muscles are subendocardial structures, and even a small area of myocardial infarction can cause papillary muscle ruptures. Therefore, we cannot exclude the possibility of spontaneous reperfusion, coronary spasm or embolic phenomenon as possible diagnosis hypotheses.

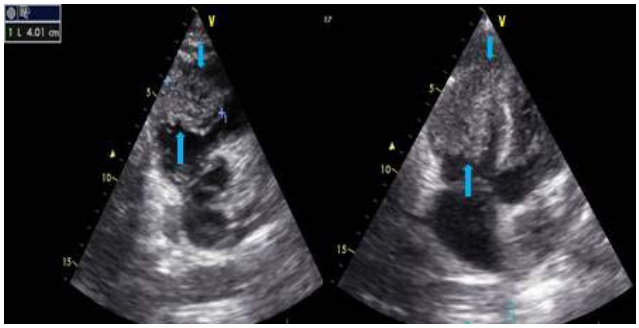
Heart metastasis of a mandibular cancer

S Antit[1]; S Chenik[1]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*

Introduction: Secondary malignant heart tumors are rare but much more common than primary tumors. These metastases affect more often the pericardium than the endocardium and generally consist of carcinomas. Owing to their topography and prevalence, carcinomas of lung and breast are the most common tumors originating cardiac metastases.
We report a rare case of cardiac metastasis of a mandibular cancer.
Observation: A 41-year-old woman had undergone surgery for left mandibular cancer followed by radio and chemotherapy. She presented to the emergency room for acute dyspnea. Physical examination found signs of right-sided heart failure. The blood pressure was 90/60 mmHg with a heart rate of 130 bpm. The electrocardiogram showed sinus tachycardia at 130 bpm associated to an incomplete right



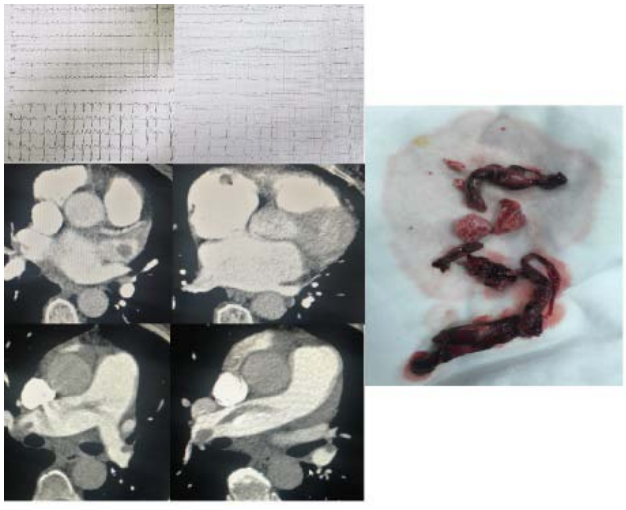
TTE : biventricular infiltration

bundle branch block with diffuse repolarization abnormalities. Cardiac echocardiography showed bi ventricular infiltration at the mid and apical segments with a large thrombus in the right ventricle partially enclosing the tricuspid valve. It has also demonstrated a circumferential pericardial effusion and pulmonary arterial hypertension. A computed tomography angiogram confirmed the bi ventricular tumor infiltration and demonstrated proximal pulmonary embolism. Lung, liver and bone metastases have also been noted. The patient was put on a palliative treatment associated to a curative heparin therapy. She died 25 days later.
Conclusion: Heart metastases are fortunately rare because of a reserved prognosis. Cardiac ultrasound is the key examination for screening and follow-up.

P2231
Acute massive pulmonary embolism treated with surgical embolectomy

I Refatllari[1]; A Banushi[1]; H Gjergo[1]; E Prifti[2]; A Veshti[2]; K Krakulli[2]; R Xhaxho[3]; A Goda[1]
[1]*University Hospital Center Mother Theresa, Cardiology, Tirana, Albania*;
[2]*University Hospital Center Mother Theresa, Cardiac Surgery, Tirana, Albania*;
[3]*Spitali i Zemres, Cardiac Surgery, Tirana, Albania*

Introduction: Massive pulmonary embolism(PE) is a life-threatening condition with a high early mortality rate despite diagnostic and therapeutic advances.A multidisciplinary approach with rapid diagnosis and early surgery is crucial in order to enhance survival in high-risk patients with acute massive PE.Case report:A 62y.o woman presented to the ER complaining of palpitations started less then 6h ago with no chest pain or dispnea and was diagnosed with high rate paroxysmal atrial fibrillation(HR¯120/min).The ECG showed AF with no specific changes,the troponin I(TPI) level was negative and a TTE revealed mildly dilated left atrium.Other lab results were within normal range(TBC and blood chemistry).Past medical history included HTN and diabetes type 2 for 10 years and 6 months respectively both on regular treatment and obesity.Also 2 months ago she was diagnosed with Hashimoto thyroiditis and close monitoring of TSH was recommended,but no treatment.An ECG performed at that visit showed sinus rhythm.Enoxaparin for anticoagulation and amiodarone i/v for cardioversion were started.After 24 h the pt was still in AF,with a controlled heart rate and no complains.However ECG changes were noticed(evolutive T negative waves in leads D1,D2,aVL,V3-V6).A D-Dimer was requested and came back negative,O2 saturation was 97%.The asymptomatic patient was transferred to the Cardiology ward for further evaluation.TPI remained negative.Due to cardiac risk factors and ECG changes,coronary angiography was performed and resulted normal.Electrical cardioversion was considered. The TSH level was undetectable. Both TEE and pulmonary angio CT were requested prior.Because of the ECG changes the CT was performed first and showed central and peripheric bilateral pulmonary artery clots present also in both atria auricles.Due to the massive thromboembolism(PE) unfractioned heparin was immediately started(aPTT 50-70s).A new TTE showed a PAP of 50 mmHg.Approximately 10h after heparin infusion,the pt developed dyspnea,tachypnea,cough,pleuritic pain and fever(temp 39.5-40C).Considering the deteriorating conditions she was consulted with a cardiac surgery team in order to perform an emergency surgical pulmonary embolectomy(ESPE) despite the high risk.Within 24h,the pt underwent ESPE of the right and left pulmonary branches after incision of the pulmonary artery,as well as a clot embolectomy of the right and left atria auricles.She was put on an iv heparin regimen and recovered well.She was discharged 2weeks later in good condition,a PAP of 40 mmHg,on acenocoumarol with persistent AF.1.5 years later she is in NYHA classI,no readmission for PE,in sinus rhythm taking rivaroxaban.Discussion:We present the case of a pt with massive PE who underwent surgical embolectomy within 24h with signs of hemodinamic instability.Despite late surgery timing,she made a good recovery with no complications.The inhospital mortality rate remains high(25-30%)even in the most specialized centers.



ECGs, angio CT and removed clots

P2232
Clinical case of cystic medionecrosis of pulmonary arterial trunk as a probable cause of thrombosis of its branches in 81-year-old woman

I A Leonova[1]; S Boldueva[1]; V Petrova[1]; I Danilova[1]
[1]*North-Western Sate Medical University named I.I. Mechnikov, St-Petersburg, Russian Federation*

At the present time, there is no clear ideas of the etiological, pathogenetic, clinical and morphological features of such a rare process as cystic pulmonary medionecrosis of the pulmonary artery.
A 81-year-old patient was hospitalized to the cardiology clinic with a diagnosis of thromboembolism of the branches of the pulmonary artery due to compliance complaints of cough, hemoptysis and dyspnoe. Patient had a long history of arterial hypertension and paroxysmal atrial fibrillation without anticoagulants. A few months before hospitalization, nausea, vomiting, sub febrile temperature and weight loss appeared, which was regarded by the family doctor as an exacerbation of chronic pancreatitis. According to the survey, an intermediate risk of developing PE on the Wells scale and the Geneva scale was revealed, an increase in the level of D-dimer. High pulmonary artery pressure, signs of right ventricular overload were found by echocardiography. According to the results of computed tomography of the lungs, there was an impression of recurrent thromboembolism of small branches of the pulmonary artery with multiple pulmonary infarctions. Cancer of pancreas was suspected after investigation. Patient was treated by anticoagulants, antibiotics, diuretics and fresh-frozen plasma due to development of disseminated intravascular coagulation. The patient died suddenly, the autopsy revealed that the probable cause of thrombosis of large and small branches of the pulmonary artery was the degeneration of the muscular fibers of the wall of the pulmonary artery by the type of cystic medionecrosis, possibly viral etiology (HSV-1 PCR positive). The disease proceeded against the background of a pancreatic body tumor 1N00 , sluggish purulent pancreatitis with the development of the syndrome of disseminated intravascular coagulation.
Patient's diagnosis was HSV-1-associatated cystic medianecrosis of pulmonary artery truncus with formation of massive sub-occlusive thrombi and invasive (-1N00) high-different pancreas body cancer (glandular papillary, squamous) with numerous intraorgan cancerous emboli

P2233
Case with successful interventional treatment with local thrombolysis for high-risk pulmonary embolism in a patient with multiple blood transfusions after gastrointestinal bleeding

K Trayanova Stoyanova[1]; R Ivanova[1]; K Karamfiloff[1]; M Shumkova[1]; TS Boneva[1]; L Vladimirova[1]; R Marinova[1]; V Pakerov[1]; D Vassilev[1]
[1]*University Hospital Alexandrovska, Sofia, Bulgaria*

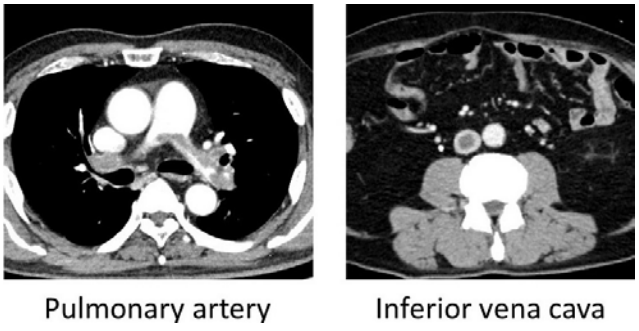
A 58 year old male was admitted in a surgery with a clinical signs of hemorrhagic shock due to gastrointestinal bleeding. From laboratory tests - hemoglobin 23 g/l (normal range 130-180 g/l). Laparotomy and sutura were performed because of bleeding gastric ulcer. In the perioperative period he received 11 bags of red blood cells and 11 bags of fresh frozen plasma. He was stabilized hemodynamically. On 12th postoperative day he presented with acute breathlessness, hypoxemia, chest pain and severe hypotension. ECG - sinus tachycardia and new right bundle branch block. Transthoracic echocardiography (TTE) showed a dilatated right ventricle, severe tricuspid regurgitation and pulmonary hypertension (mean PAP about 50 mmHg), a sign of McConnell. A Doppler ultrasound of the lower extremities ruled out deep venous thrombosis. The patient was transferred to cardiology department. Regarding diagnostic scores pulmonary embolism (PE) is most likely diagnosis. Pulmonary angiography revealed PE with thrombotic masses in bilateral main pulmonary arteries. Because of high risk for bleeding in our patient we choosed to perform a catheter-mediated thrombus fragmentation and a local thrombolysis with 50 mg of alteplase. During the hospitalization the patient was optimal anticoagulated, without bleeding, on proton-pump inhibitor. Within 1 week he recovered completely and was discharged on a DOAC (apixaban 5 mg twise/daily) for a 3-month period. One month later the patient was asymptomatic. Control TTE was with decreased pulmonary pressure and normalized right ventricle size.

Discussion: Acute pulmonary thromboembolism is a postoperative complication that is particularly common in operated patients, but in this case we may discuss also the role of the massive blood transfusions and immobilization after operation. Selecting an optimal treatment for PE is challenging. Thrombolytic therapy and catheter embolectomy are common therapeutic interventions. Although thrombolysis is effective, it can cause bleeding, especially after surgery.
Conclusion: We present a rare case of PE due to multiple blood transfusions with high risk for bleeding (recent operation and gastrointestinal bleeding within previous 3 weeks) in which percutaneous intervention with local thrombolysis is the safest and most effective treatment.

P2234
Pulmonary embolism after ablation of supraventricular tachycardia

N Narutaka Ohashi[1]; K Yamada[1]; H Taniguchi[1]; A Furukawa[1]; Y Tamura[1]; Y Aizawa[1]; T Okabe[1]; A Kawamura[1]
[1]International University of Health and and Welfare Mita Hospital, Cardiovascular center, Tokyo, Japan

Background: Radiofrequency catheter ablation has become established as an effective therapy for the treatment of supraventricular tachycardia. The risk of thromboembolism is little and anticoagulation is unnecessary in usual cases. However we experienced severe thromboembolism after catheter ablation.
Case Report: A 62-year-old man was referred for recurrent syncope. Electrophysiological study was performed from the left femoral vein using 10Fr sized Trio Sheath. Atrioventricular nodal reciprocating tachycardia was induced and a significant decrease in blood pressure occurred. Radiofrequency current was successfully delivered at the slow pathway. After catheter ablation, hemostasis at the left femoral venous access site was provided by manual compression. After a week, he felt dyspnea on walking and came to our hospital. Echocardiography showed pressure overload of the right ventricle and thrombus was seen on the branch of the pulmonary artery. Many thrombus appeared in the inferior vena cava from left femoral vein on contrast enhanced CT. There was a wide range of thrombus, thrombolytic therapy was performed. Subsequently, thrombus was reduced and right ventricular pressure overlord was improved.
Conclusion: Usually anticoagulation is unnecessary for ablation of supraventricular tachycardia. However we showed the case with severe pulmonary embolism after catheter ablation. The possibility of the thrombus must be considered in any cases.

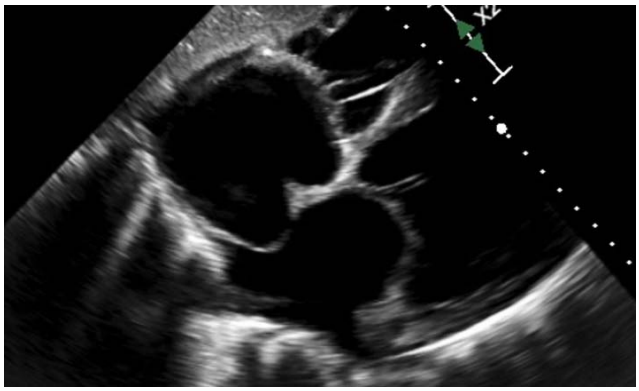


Thrombus on CT

P2235
Rare cause of desaturation in a patient with decompensated chronic heart failure

A Alexander Valerievitch Nossikoff[1]; K Angeloff[1]; N Koleva[1]; D Evrev[2]; T Donova[2]
[1]University Hospital "Lozenets", Cardiology, Sofia, Bulgaria; *[2]University Hospital "Lozenets", Cardiac and vascular surgery, Sofia, Bulgaria*

Clinical presentation. 78-year old male was admitted to our institution due to progressive shortness of breath. He had known LV dysfunction and congestive heart failure and recent hospitalisation for a previous decompensation. On admission he appeared to be drifting away, while desaturating down to 67% on pulseoxymetry. There was bilateral pitting oedema below the knees. Notably, no significant crackles were heard in the lung bases and CXR was not consistent with significant lung congestion. The patient was put on oxygen supplementation and intravenous furosemide. His BP was stable throughout the hospital stay.
Clinical investigations and diagnostic process. Labs were unremarkable except creatinine of 94 umol/L consistent with CrCl of 50ml/min and PaO2 of 50mmHg from arterial blood gases. Despite the intravenous furosemide the patient was not improving even after further dosage escalations. EKG showed LAHB and AV-block grade 1. We performed transthoracic echocardiography, which revealed a large LV with EDV of 300ml, LV EF of 30% and moderate AR and MR. There was biatrial dilation, moderate TR, dilated RV and estimated systolic PAP was nearly 100mmHg. Notably, the interatrial septum was bulging from right to left and there was a small eccentric RtoL shunt through it, which was evident on colour doppler. We performed compression ultrasound on lower limbs, which revealed bilateral femoropopliteal DVTs and confirmed our suspicion of VTE. CTPA revealed bilateral pulmonary embolism. Patient was classed as high intermediate risk by PESI score. He was put on therapeutic dosage of LMWH and remained stable and gradually improving. However, he insisted of leaving the hospital against our medical advice on day 3 from the diagnosis of PE. We decided to commence NOAC (rivaroxaban 2x15mg for 3 weeks than 20mg) and to discharge him. Several weeks later there was marked improvement in his clinical status. He was no longer limitied by shortness of breath, there was no longer evidence of pulmonary hypertension on transthoracic echocardiography and the interatrial septum was no longer bulging into left atrium.
Conclusions and implications for clinical practice. Patients with chronic heart failure are prone to thrombotic events. This is especially true during periods of prolonged bed rest and decompensations. When unexplained breathlesness, desaturation or out of proportion pulmonary hypertension are present VTE should be excluded.



IASbulgetoL

Presence of DVT on compression ultrasound in patients with suspected pulmonary embolism confirms the diagnosis at bedside. We believe that the main cause of desaturation in this case was the pulmonary embolism. The right-to-left shunt was caused by stretched PFO opened by the high right atrial pressure and had only partial contribution to the desaturation. Notably, this patient had bilateral DVT, which is rare. In such cases the usual signs of DVT can be masked or may affect both legs making the clinical diagnosis of DVT impossible.

P2236
Asymptomatic underwater swimmer with pulmonary hypertension and dilatation of right heart chambers - true or false?

K Kamilia Mekhdieva[1]; YU Zinovieva[2]; V Timokhina[1]; E Smirnov[1]; A Zakharova[1]
[1]Ural Federal University, Yekaterinburg, Russian Federation; *[2]Sverdlovsk Regional Clinical Hospital 2, Yekaterinburg, Russian Federation*

Funding Acknowledgements: The work was supported by Act 211 Government of the Russian Federation, contract #02.A03.21.0006

Background: Pulmonary hypertension (PH) is defined as increased pulmonary artery pressure (PAP) and is associated with high risk of heart failure and mortality in general population. PH may serve as an underlying condition in patients with cardiopulmonary arrest.
Problem: TTE findings of PH in asymptomatic athletes during cardiovascular screening may cause restriction from training and competitive activity. Additional invasive methods in some cases are more helpful with precise diagnostics and making decision concerning further sports career.
Clinical case: An elite 21 year old athlete specializing in underwater swimming with 12 years of sports experience was admitted to cardiac functional diagnostics department. He had no complaints, no shortness of breath, no decrease of exercise performance. He denied heart disease family history or sudden cardiac arrest cases in relatives. 12-lead ECG was normal with sinus bradycardia with HR 49 bpm, (normal finding in endurance athletes). Regular CPET in our sports lab confirmed high level of exercise performance (VO2max 62 ml/kg/min, Pmax 414 W) with no decrease during previous months. Routine cardiovascular athletes' TTE screening in 2016 revealed mild PH (rated PAP 47 mm Hg), mild RA enlargement of 60 ml,

III degree of tricuspid regurgitation with no valve or myocardium lesion. Periodical TTE studies in 2016-2017 years, conducted each 3-4 months, confirmed PH diagnosis. Measured PAP was from 40 to 54 mm Hg, right heart chambers dilatation: RA volume up to 74 ml, RV size (apical view) 47 mm. None of any other TTE abnormal findings were observed. Values of myocardium structure, global and regional segment contractile function of RV and LV were within the physiologic norm. The preliminary diagnosis, based on PAP values, was idiopathic PH. In compliance with eligibility guidelines for competitive athletes, this diagnosis is a contradiction to training and competitive activity. Athlete was deeply concerned about his future sports career, as he was preparing to important international competitions. He had been aware of possible complications and risks associated with cardiac invasive measurements before his consent was obtained. Medical consultation referred a patient to further diagnostic catheterization of PA. Follow-up catheterization of right heart chambers with Svan-Hanse catheter placement and central haemodynamics evaluation was performed. Undertaken examinations revealed normal values of PAP – 10 mm Hg. As HP diagnosis based on data from diagnostic cardiac catheterization is defined by a mean PA value of 25 mm Hg or more at rest, PH diagnosis was not confirmed. Finally, sports cardiologist admitted athlete to training and competitive activity.

Conclusions: TTE findings of PH and RA enlargement in swimmers may be explained by physiological response and specific adaptation to aquatic environment. Diagnosis of PH in experienced swimmers is better confirmed with the use of invasive methods.

P2237

Pulmonary hypertension in the setting of complex structural heart disease

A Vishnevsky[1]; P Pirlimarla[1]; NJ Ruggiero[1]; P Mehrotra[1]; A Qureshi[1]; G Reeves[1]; HT Massey[1]; R Alvarez[1]

[1]*Thomas Jefferson University Hospital, Cardiology, Philadelphia, United States of America*

Case presentationA 76 yo female with a history of HTN, HLD, NIDDM, paroxysmal AF, restrictive VSD, and severe AS presented with decompensated heart failure. Cardiac findings included RV heave and 3/6 harsh, late peaking crescendo-decrescendo murmur. There was no digital clubbing or cyanosis. TTE revealed normal EF with severe pulmonary hypertension, RV dilation with severe dysfunction, and severe AS. Her perimembranous septum was aneurysmal, with a systolic jet velocity across the defect of 4.5 m/s. There was no obstructive coronary disease. Right heart catheterization demonstrated PAP of 96/38/57 mmHg, PVR of 7.2 WU, PCWP 23 mmHg, CI of 3.04, and Qp/Qs of 1.1.

Diagnostic ChallengesThe patient's PCWP and PVR were suggestive of mixed WHO group I and II pHTN due to longstanding AS and pulmonary vascular remodeling. The degree of reversibility was unknown. Her shunt fraction and PA pulsatility index were normal, suggesting the VSD was not causing significant shunting. She was high surgical risk and her aortic valve annulus was high risk for TAVR given continuity with the VSD and deficiency of ˜25% of the annulus. Of concern was the possibility that her elevated LVEDP was masking Eisenmenger physiology, and relieving the AS may cause significant hypoxia.

Management We proceeded with balloon aortic valvuloplasty (BAV) as bridge to decision. The BAV enabled assessment of the integrity of the aortic annulus and VSD, the pulmonary pressure response to LV unloading, and development of right to left shunting after a decrease in LVEDP. Successful BAV was performed, and the patient was discharged. Following improvement in both PA pressures and her symptoms, a TAVR was offered. A self-expanding valve was selected to minimize risk of annular rupture. After successful deployment, her PAP were 78/42/54 and PCWP 23. She was diuresed and discharged.

Conclusion Significant pulmonary hypertension complicating structural heart disease leads to distinct diagnostic and management dilemmas. We present a case of severe pulmonary hypertension and RV dysfunction in the setting of perimembranous VSD and severe AS. Our case highlights important points in management of such patients. First, careful evaluation of hemodynamics, including indices of RV function is paramount in guiding decision making in these patients. In our case, the preserved PAPi with minimal shunting suggested the VSD was not significantly contributing to the severe pulmonary hypertension. Second, BAV plays an important role in such complex patients as a bridge to decision and to determine potential response to TAVR. Third, although patients with WHO II pHTN can develop an irreversible pre-capillary component, such assessment can only be made following durable reduction in LVEDP. Lastly, interdisciplinary patient care is essential. Successful management of our patient involved input from a team consisting of pulmonology, structural cardiology, critical care cardiology and heart failure.

CT Processing

P2238

Heart transplantation in a child with Ebstein's Anomaly and primary cardiomyopathy

K Chueva[1]; T Loevets[1]; T Pervunina[1]; T Vershinina[1]; P Fedotov[1]; E Vasichkina[1]; R Tatarskii[1]; D Lebedev[1]

[1]*Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation*

The patient was diagnosed with the congenital heart desease: Ebstein's Anomaly and Wolf-Parkinson-White Syndrome at the age of 2 days. For several years reicuspidal regurgitation was II grade, myocardial contractility of left ventricular was > 53 % and she have been asymptomatic. The first symptoms of heart failure such as decline of exercise capacity, cyanosis and dyspnea by physical activity appeared only at the age of 14 years. Because of the progression of symptoms, it was decided to perform tricuspid valve replacement with bioprostetic vale Carpentier Edwards 31. Until that time the patient had already underwent 3 catheter ablations of multiple right-sided accessory AV connections. But by admission a girl was presented with significant heart failure (Class III NYHA) and reduced cardiac contractility with ejection fraction of left ventricular 25%. Such rapid heart failure progression was considered not only as end stage of congenital heart disease, but as a result of myocarditis or primary cardiac cardiomyopathy. Due to anamnesis, laboratory findings and further diagnostic procedures no evidence of inflammatory cardiomyopathy was revealed, but in our patient detected novel missense mutation in gene MYPNc.458A>G (p.Lys153Arg), wich have been linked to the pathogenesis of dilated cardiomyopathy. In that case correction of Ebstein's Anomaly was associated with a poor prognosis.For this reason she was listed for heart transplantation, wich was performed after 12 months on the waiting list. Since two years after transplatation the patient have had normal heart function, she have not got limitation in physical activity and herpsychological status have become good.

Each patient with congenital heart disease and significant heart failureneed of personified approach in management. Among patients with congenital heart disease associated with primary cardiomyopathy heart transplantation could be procedure of choice and show better prognosis in comparison with surgical correction of heart lesion.

P2239

A heart failure with brilliantly preserved ejection fraction.

S Sergio Hernandez Jimenez[1]; E Rajjoub Al Mahdi[1]; G Alonso Salinas[1]; JD Sanchez Vega[1]; M Abellas Sequeiros[1]; JL Zamorano Gomez[1]
[1]*University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain*

A 85 years old woman with shortness of breath and leg edema with proggresive intensity last three weeks is admited in the cardiology department. As significant comorbidities, the patient has arterial hypertension (although last months all the medication that she needed was discontinued due to tendency toward low blood pressure) and paroxysmal atrial fibrillation. As previous surgical background, the patient only refers a carpal tunnel syndrome surgery (in both sides). In the physical exam she has a blood pressure of 110/60 Hg mm, lung crackles in the lower third of both lungs and a systolic murmur in the aortic area with a very low second sound. After being admitted in the cardiology department an echocardiography was done, showing severe left ventricle hypertrophy. As seen in the image (picture A), the myocardium, showed a characteristic granular ang bright pattern. It also showed a moderate to severe aortic stenosis. Although she was in atrial fibrillation during the echocardiography, the transmitral Doppler showed signs of significantly elevated filling pressures as for example, the presence of L waves. Finally, the exam was completed with an analysis of longitudinal deformation of the left ventricle, showing a clearly depressed global longitudinal strain, with a base-apex gradient (preserved at the apex, picture D). With these findings a Tc-PYP scintigraphy was performed, showing moderate and difuse uptake of the radioactive tracer in both ventricles (as shown in the image C). To complete the diagnosis, a cardiac magnetic resonance was performed showing a subendocardial ring pattern of delayed enhancement (image B). The diagnosis of transthyretin cardiac amyloidosis was done.
Cardiac amyloidosis is clearly underdiagnosed entity, and sometimes differential diagnosis is really hard. Patients with cardiac amyloidosis are not always so "typical" as in this case. In fact, even a 5% of patients with history of aortic stenosis surgery may have also a cardiac amyloidosis. Maybe the use of myocardial deformation study and nuclear imaging can be useful solving this problem. Several studies have shown that nuclear imaging may be useful in the early diagnosis of this disease, even before that with echocardiography or cardiac magnetic resonance. Besides, new sequences of cardiac magnetic resonance may be very useful solving the problem of the differential diagnosis in left ventricle hypertrophy: The extracellular volume mapping. In cardiac amyloidosis hypertrophy is due to the deposit of amiloid in extracellular space. Because of that, the extracellular space is significantly increased in comparison with almost every other cause of left ventricle hypertrophy, making this sequence very useful in differential diagnosis.
CONCLUSION Transthyretin cardiac amyloidosis is a rare and very under-diagnosed disease. However these problems with the advance of cardiac imaging and the development of new treatments could change very soon.

P2240

Diastolic heart failure - As bad as it gets, before it gets better

S Sidonia Albu[1]; A Dumitrache[2]; C Ginghina[1]; B Popescu[1]; R Jurcut[1]
[1]*Institute of Cardiovascular Diseases Prof. C.C. Iliescu, cardiology, Bucharest, Romania*; [2]*Medlife, Brasov, Romania*

Introduction: We report the case of a 43-year-old patient, known with professional exposure to dust, ex- smoker, who complains of fatigue, exertional dyspnea, night sweats and weight-loss for several months. The physical examination revealed axillary adenopathy and hepatosplenomegaly. His laboratory tests showed hypereosinophilia, trombocytopenia, polyglobulia and raised BNP levels. He was first evaluated by the haematologist and the suspicion of a myeloproliferative disease was raised.
Problem, patient management: His transthoracic echocardiogram revealed a cardiac mass attached to the apical and anterior wall of the left ventricle with a maximum thickness of 19 mm, a restrictive diastolic filling pattern, reduced myocardial velocities – all in favour of intrinsic cardiomyopathy. For a better evaluation, cardiac MRI was performed which showed a biventricular involvement (masses attached to the apical free wall of both ventricles- Image A, subendocardial late gadolinium enhancement of both ventricles), being highly suggestive of hypereosinophilic myocarditis. Different hematological tests in search for a possible etiology were performed (bone marrow biopsy and JAK2, BCR-ABL, PDGFR, c-MPL, CALR mutations), with negative results. A parasitologic panel obtained a positive Toxocara canis IgG result. The diagnosis of chronic eosinophilic leukemia was established by the haematologist. His treatment included corticotherapy, hydroxyurea, oral anticoagulation, betablocker and diuretics, which was well tolerated.
Questions, problems, possible differential diagnosis: The mechanism for hypereosinophilia in this case was uncertain at the beginning, with multiple possible causes : myeloproliferative syndrome/neoplastic disease (because of multiple organ involvement, laboratory tests), parasitic disease, allergic disease (previous professional exposure to dust). Also, it was decided to use a vitamin K antagonist, due to the uncertain benefits of novel anticoagulants in this setting.
Conclusions: Loeffler endocarditis is a condition resulting from various eosinophilic diseases, including parasitosis, drug hypersensitivity, systemic vasculitis or idiopathic hypereosinophilic syndromes.
"True" hypereosinophilic syndrome is considered rare. Sometimes, it proves to be challenging to ascertain the etiology, as it was in this case and it is also of great importance for establishing the prognosis.

Takotsubo syndrome masking apical hypertrophic cardiomyopathy

S Sofiya Lypovetska[1]; M Shved[1]; V Gurskyi[1]
[1]*Ternopil State Medical University, Ternopil, Ukraine*

Apical akinesis and dilation without occlusive coronary artery disease presented by acute and usually reversible heart failure are typical signs of Takotsubo syndrome. Since other diseases can be masked under certain clinical presentation.
Case report . A 63 years old white woman presented with acute chest pain, palpitation and shortness of breath, induced by unexpected emotional stress. Her medical history included hypertension (BP 140-160/90 mm Hg) with irregular usage of antihypertensive drugs, extirpation of uterus for fibro-myoma 10 years ago. She had no known coronary artery disease. Her heart rate 105 beats/min; BP 110/85 mmHg; oxygen saturation 96% on room air. Physical examination revealed tachycardia and mild pitting edema in the lower extremities. An electrocardiogram

(ECG) showed sinus tachycardia with ST elevation 5 mm in V2-V6, pathological Q wave and ST elevation 2 mm in II, III, avF. Laboratory results included an elevated troponin T level of 886.3 pg/mL (normal <14 pg/mL), creatine phosphokinase MB – 31,6 Un/l (normal < 25,0 Un/l), NT-proBNP 2234 pg/ml (normal < 300 pg/mL). A transthoracic echocardiogram (TTE) showed a left ventricle ejection fraction - 45 % with hyperdynamic basal function but with a dilated, akinetic apex and lateral wall. Results of coronary angiography were normal. Left ventriculography revealed apical ballooning dilatation with akinesis.

The diagnosis of Takotsubo syndrome was defined based on results of apical motion abnormalities of LV, preceded by a emotional stressful trigger, absence of culprit atherosclerotic coronary artery disease, new ECG abnormalities, positive troponin test and significantly elevated NT –pro BNP.

On the 12th hospital day, TTE showed no change in the apical ballooning and akinesis. The level of troponin T was decreased in dynamics: 58,0 – 22,5 -12,7 pg/mL. The ECG revealed positive dynamics: decreasing of ST elevation in anterolateral leads to 1,5 mm, absence of pathological Q wave and ST elevation in II, III, avF. The patient was discharged from the hospital on metaprolol and ramipril therapy.

The patient returned 3 weeks later for repeat TTE. The apical wall-motion abnormalities had resolved, and the LVEF had returned to normal 59 %. Newly apparent hypertrophy of the LV myocardium at the apex was onsistent with apical variant HCM. A contrast agent was administered, and no apical pouches, thrombi were found. The maximal LV wall thickness was 17 mm at end-diastole. The ECG showed repolarization changes and giant (>10 mm), inverted T waves in the anterolateral leads (particularly in leads V4 and V5). The patient was counseled in regard to the diagnosis of apical HCM. At her 2-month follow-up examination, she was asymptomatic. Apical HCM was masked by Takotsubo cardiomyopathy with apical ballooning. The apical HCM was not apparent until the apical myocardium had fully recovered and patient underwent repeat TTE.

Left ventriculography revealed apical ballooning dilatation with akinesis

Accidentally discovered aortic dissection in young patient with left ventricular hypertrophy: hypertensive heart or hypertrophic cardiomyopathy?

M Monika Gawor[1]; M Franaszczyk[2]; Ł Mazurkiewicz[1]; A Klisiewicz[3]; M Spiewak[4]; M Marczak[4]; I Michalowska[5]; J Grzybowski[1]

[1]Institute of Cardiology, Department of Cardiomyopathies, Warsaw, Poland; *[2]Institute of Cardiology, Department of Medical Biology, Warsaw, Poland*; *[3]Institute of Cardiology, Department of Congenital Heart Diseases, Warsaw, Poland*; *[4]Institute of Cardiology, CMR Unit, Warsaw, Poland*; *[5]Institute of Cardiology, Department of Radiology, Warsaw, Poland*

A 36-year-old male with positive family history of sudden cardiac death (his uncle's son died suddenly at the age of 25), hospitalized a month ago in a local hospital due to acute hypertensive cardiogenic pulmonary edema, was referred to our institution for further evaluation with suspicion of hypertrophic cardiomyopathy.

On admission patient was asymptomatic, without fatigue, exertional dyspnoea, chest pain or syncope. On physical examination his BP was significantly elevated (180/100 mmHg). The lungs were clear on auscultation, liver was not enlarged, jugular veins were normal, there was no oedema of lower extremities. Abdominal auscultation revealed vascular murmur in umbilical region.

The baseline level of NT-proBNP was 811.4 (range 0–125) pg/mL, and high-sensitivity cardiac troponin T was 20.2 (range 0–14) ng/L. The standard 12-lead electrocardiogram demonstrated sinus rhythm, left atrial enlargement and left ventricular (LV) hypertrophy with nonspecific ST segment and T-wave changes (Fig. 1A). No significant pathology was present on chest X-ray (Fig. 1B).

Transthoracic echocardiography revealed significant concentric LV hypertrophy with preserved LV ejection fraction (EF 70%) and moderately decreased global longitudinal strain (GLS-13.7%). There was mild dilatation of left atrium. Ascending aorta diameter was in normal range (Fig. 1C-D). Cardiac magnetic resonance (CMR) scan confirmed concentric LV hypertrophy with the maximal wall thickness of 18 mm at interventricular septum, and increased myocardial mass (LV mass index 124 ml/m2, range 59–92). Moreover, small areas of late gadolinium enhancement was found in LV segments (Fig. 1E-F).

Due to presence of vascular murmur in abdomen, ultrasound imaging was performed. The exam revealed abdominal aortic dissection (Fig. 1G-H). Patient was transferred to the computed tomography (CT) unit to confirm the diagnosis. Aortic dissection originated below renal arteries and involving common illiac arteries was detected (Stanford B). The presence of thrombi within the lumen created by the aortic dissection suggested chronic presentation. Patient was managed conservatively with strict blood pressure control and close follow up arranged.

We decided to perform genetic analysis. Currently we are awaiting the results in hope that it will help us to establish the diagnosis and differentiate hypertensive heart from hypertrophic cardiomyopathy.

In conclusion, aortic dissection typically presents with tearing chest pain and severe hemodynamic compromise. Painless dissection, like in this case, is relatively rare. Differential diagnosis between hypertensive heart and hypertrophic cardiomyopathy is crucial as it has direct therapeutic impact.

Hypertrophic cardiomyopathy patients with co-existing pathology: the role of heart team

K Rudenko[1]; V Lazoryshynets[1]; O Krykunov[1]; B Cherpak[1]; I Ditkivskyi[1]; O Chyzhevska[1]; L Nevmerzhytska[1]; O Trembovetska[1]; P Danchenko[2]

[1]Amosov Institute of Cardiovascular Surgery AMS of Ukraine, Kiev, Ukraine; *[2]National O.O. Bohomolets Medical University, Kiev, Ukraine*

Background. The experience of our Center shows that more and more patients with hypertrophic cardiomyopathy (HCM) require multi-disciplinary approach, e.g.

Heart Team, consisting of interventional surgeons, radiologists, cardiac surgeons and cardiologists.Introduction. 68-year-old male patient came in to the Center with complaints on chest pain, dyspnea on exertion, periodic dizziness and decrease in tolerance to physical activity. In 2013 he underwent the abdominal aneurysm repair. The data obtained from the instrumental studies are presented in Table 1. The following diagnosis was established: HOCM, moderate mitral regurgitation (MR), mild tricuspid regurgitation; ischemic heart disease, exertional angina, class II, multi-vessel coronary artery disease; thoracoabdominal aortic aneurysm, type B (DeBakey); state after abdominal aortic aneurysm repair (2013); heart failure (HF) with preserved EF, functional class II (HYHA).

The Heart Team made a decision to perform two-stage surgical correction. Stage 1 included off-pump CABG-4 of the LAD, Cx and D2 branches of the LCA with autovenous grafts, and on-pump transaortic septal myectomy of the IVS with 6 anomalous chordal attachments cutting, and mobilization of the papillary muscles. Stage 2 involved thoracoabdominal endovascular aortic repair (TEVAR) with 2 stent graft systems, 32-28 mm and 34-30 mm – 200 mm length each. The control angiography performed after surgery showed endoleak, type 1b due to kinking of the distal part of the aorta. As a result, it was decided to perform one more repair with stent graft system 36-36 mm–64 mm length. After the procedure, control angiography showed no significant paraprosthetic leak. Post-operative TEE showed: SPG on LVOT = 12 mmHg. EDV = 92 ml; ESV= 36 ml; SV= 58 ml; EF= 58%, IVS = 0,9 cm. No SAM of the anterior MV leaflet. Mild MR. No complications were observed in the post-operative period.

Conclusion. The treatment of HCM patients with co-existing diseases like coronary artery disease and thoracoabdominal aneurysm requires Heart Team. We suggest performing the surgical correction in such types of patients in two stages – off-pump CABG and on-pump septal myectomy as the fist stage, and TEVAR as the second one.

Table 1. Pre-operative results of the instrumental examination

TEE	Dilation of the thoracoabdominal aorta up to 5,6 cm. IVS = 3,2 cm, EDV=94 ml, ESV=39 ml, SV=61 ml, EF=65%, SPG on the LVOT at rest = 65 mmHg with SAM of the anterior MV leaflet
Heart catheterization	Multi-vessel coronary artery disease (atherosclerotic obstruction of LAD=75%. Cx=80%, D2=90%). SPG = 70 mmHg
Heart CT	Hemodynamically significant atherosclerosis of the coronary arteries; aneurysm of the thoracoabdominal aorta (Ø=6 cm); HOCM
MSCT of the abdominal cavity	CT-sings of fusiform aneurysm of the thoracoabdominal aorta (Ø=6 cm)

Cx - circumflex branch of the left coronary artery; D2 - diagonal branch of the left coronary artery; HOCM - hypertrophic obstructive cardiomyopathy; LAD - left anterior descending artery; MSCT - multi-spiral computer tomography; MV - mitral valve; SAM - systolic anterior motion; SPG - systolic pressure gradient.
Pre-operative results of the instrumental examination

The results of two stages of treatment

Cardiomyopathies (CM) are a heterogenous group of myocardial diseases associated with mechanical and/or electrical dysfunction due to various causes, most frequently genetic. Cardiac amyloidosis (CA) is a restrictive CM characterized by extracellular accumulation of misfolded protein fragments, most frequently classified by the amyloid precursor. Transthyretin amyloidosis (ATTR) results from accumulation of a protein (transthyretin), produced by the liver and is subdivided in 2 different types – wild type (wt) and hereditary (mt).

We present the case of a 42 yo patient with family history of heart failure (HF) and death at young age, evaluated in our clinic for aggravated dyspnea and fatigue in the last few weeks. The patient was recently diagnosed with HCM, and was started on beta-blocker (BB) therapy, which led to further worsening of his symptoms. The physical examination was unremarkable and the laboratory workup showed mild renal involvement and high levels of NTproBNP. The ECG showed synus rhythm with a 2:1 atrioventricular block (AVB), major RBBB and normal voltage, leading to interruption of BB, the patient reverting to normal conduction the next day (80 bpm). The patient had a 48 h ECG Holter monitoring that showed multiple and prolonged episodes of high grade and even complete AVB with a heart rate of 28 bpm, as well as episodes of nonsustained VT. The echocardiography showed severe biventricular hipertrophy, normal global systolic function (LVEF), but important longitudinal dysfunction with apical sparing and severe diastolic dysfunction with restrictive filling pattern.

Cardiac imaging, conduction disturbances as well as the patient's origin in a country region which has a high incidence of ATTRmt raised the suspicion of CA. Thus, his workup was completed by a neurologic evaluation that showed bilateral carpal tunnel syndrome and a bone-avid phosphate-based isotope nuclear scintigraphy with important myocardial uptake of the isotope which is highly suggestive for ATTR. The patient was implanted a bicameral ICD, with favorable evolution. He also received a low dose of furosemide and spironolactone, with no symptoms at discharge. Family screening included 2 maternal cousins with normal echocardiography.

Although a rare cause of HF, CA remains one of the main phenocopies in the differential diagnosis of HCM, patients often presenting important and dramatic symptoms. Awareness of this entity as a cause of cardiac hypertrophy is of paramount importance for following the lead. Clear recommendations for the choice between pacemaker vs ICD are not yet released, therefore the individual decision should be made based on available data and risk stratification. We stress the importance of a "red flags" based diagnosis (echocardiographic aspect, associated rhythm and conduction dysorders, poor tolerance of BB, neurologic involvement) and the importance of a careful family screening in rare genetic cardiovascular diseases.

Significance of left ventricular pronounced trabeculations in a patient with recurrent decompensated heart failure

AM Alexandra-Maria Chitroceanu[1]; N Patrascu[2]; V Vintila[2]; D Mihalcea[2]; C Stuparu[1]; D Vinereanu[2]
[1]*University Emergency Hospital of Bucharest, Cardiology, Bucharest, Romania*;
[2]*University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*

Introduction: Pronounced left ventricular (LV) trabeculations are described in dilated and hypokinetic left ventricles as well as in left ventricular non compaction (LVNC). It is unclear if this imaging findings are a distinct pathological entity, or an epiphenomena of LV remodelling.
Case presentation: A 33 year old male was admitted for recurrent decompensated heart failure, with a "wet and warm" profile. He mismanaged his diet and prescribed medications. He was diagnosed with dilated cardiomyopathy (DCM) 3 years before, when he first presented with acute heart failure and was diagnosed with a LV ejection fraction (EF) of 20% and apical thrombus considered to be secondary to myocarditis. Coronary angiography showed normal epicardial coronary arteries. Cardiac magnetic resonance (CMR), performed 4 months after the acute event, detected severely dilated LV, with an EF of 51%. CMR raised suspicion of non-compaction (LVNC), with multiple myocardial trabeculations which fulfill the LVNC criteria at the level of 7 segments, mainly at the apex, anterior, and antero-lateral walls of LV, with no thrombus, scar or fibrosis. At this admission, transthoracic echocardiography confirmed severely dilated LV, with an EDV index of 104 ml/m2, reduced ejection fraction, with an EF of 30%, and global hypokinesia. No thrombus was seen. Ratio of non-compacted /compacted layer was <2. We performed speckle tracking analysis with assessment of peak systolic longitudinal strain (PLS). PLS showed significantly reduced global longitudinal strain (-9.6%) and impaired regional PLS at the level of the anterior and antero-lateral apical and mid-segments (Figure). The patient was managed medically with improvement of symptoms.
Questions, problems or possible differential diagnosis: There is a considerable overlap between LVNC and other cardiomyopathies. Differentiation between LVNC and DCM remains challenging, being based on a careful clinical characterization and imaging (echocardiography and CMR). Complete recovery of cardiac function in a patient with LVNC is unlikely. Also, pathological conditions of volume overload are often associated with a LVNC-like phenotype. Although CMR revealed pronounced trabeculations suggestive for isolated LVNC, those criteria alone have poor specificity for LVNC being also present in asymptomatic population free from cardiovascular disease. Moreover, trabeculations are also describe in myocarditis with a regression after some time. Assessment of myocardial deformation patterns, despite overall hypokinesia with impaired global PLS, showed reduced deformation values in some segments, mimicking a post myocarditis pattern.
Conclusion and implications for clinical practice: Morphological criteria alone are necessary but insufficient for a correct diagnosis of LVNC in young patients with heart failure. Speckle tracking analysis may help to differentiate between the LVNC and pronounced trabeculations in DCM. However, a CMR follow up is mandatory.

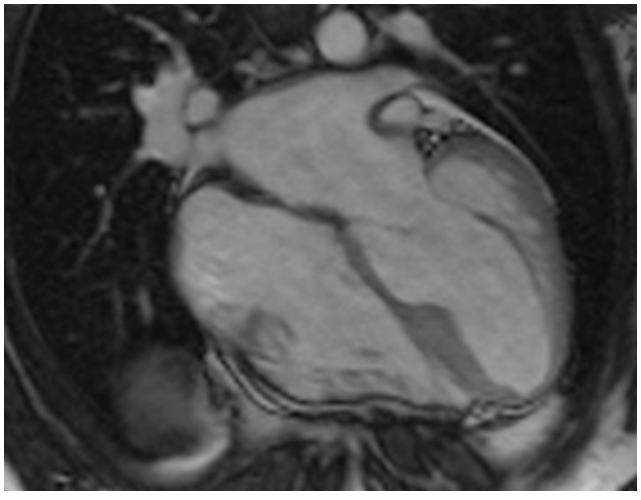
Titin mutations - a role still to unriddle

A Ana Neto[1]; D Seabra[1]; I Oliveira[1]; A Andrade[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Cardiology, Penafiel, Portugal*

Titin is the largest protein in the human body. Mutations in the titin gene (TTN) - a sarcomeric protein - cause a broad spectrum of conditions involving the muscle. Dilated cardiomyopathy (CMD) is a primary myocardial disease with a variable natural history and clinical presentation. A genetic aetiology is demonstrated in about 30% of cases with the giant muscle protein TTN being recognized as the major gene causing CMD, mostly by heterozygous truncated mutations.
The present case refers to a 61-year-old female patient (pt) previously followed in Cardiology consultation due to restrictive perimembranous ventricular septal defect with mild left ventricular dysfunction (LVD) and paroxysmal atrial flutter under rhythm control. The pt reported a positive family history of myopathy and sudden death (acknowledged consanguinity among her parents).
She was clinically stable until may 2017; at this time, the pt presented palpitations and decompensated HF having been hospitalized. Echocardiogram showed mild LV dilation, inferoposterior and posterior-septal wall akinesia and hypokinesis of the remaining segments which conditioned severe depression of LVD and new onset right ventricle (RV) dysfunction without dilation. Cardiac catheterization showed angiographically normal coronary arteries; subsequent cardiac MRI revealed extensive septal fibrosis and fibroadipose infiltration suggesting non-ischemic myocardiopathy with severe LVD (but preserved RV function). She was discharged to the HF Clinic for therapeutic optimization and further aetiology workup. Follow-up was marked by difficult drug titration due to bradycardia and hypotension. A switch from ACE inhibitors to ARNI was attempted with clear functional class improvement (despite maintaining a low dose) and a cardio-defibrillator was implanted. Due to myopathy suspicion with persistently high CPK and predominantly proximal muscle weakness at lower limbs level, the pt performed a muscle biopsy that revealed severe changes in the myopathic pattern in which myofibrillar features were prominent. Regarding genetic evaluation, she was submitted to myofibrillar myopathies panel that was negative but mendeleoma identified two variants of uncertain significance in the titin gene (exon 7 and 246). Probable titinopathy with muscular and cardiac manifestations was assumed and the therapeutic and follow-up program were instituted according to.
Some mutations in the TTN gene that predominantly affect the heart muscle, others that affect only the skeletal muscle, and some that affect both. Moreover, truncated variants of the TTN gene are also present in up to 2% of the healthy population. It is suspected that these differences may be related to the location of the mutations in the gene and consequently how they affect the versions of titin that are produced in different muscles. Thus, the actual pathogenic role of these TTN variants remains unknown.



Cardiac MRI - fibroadipose infiltration
