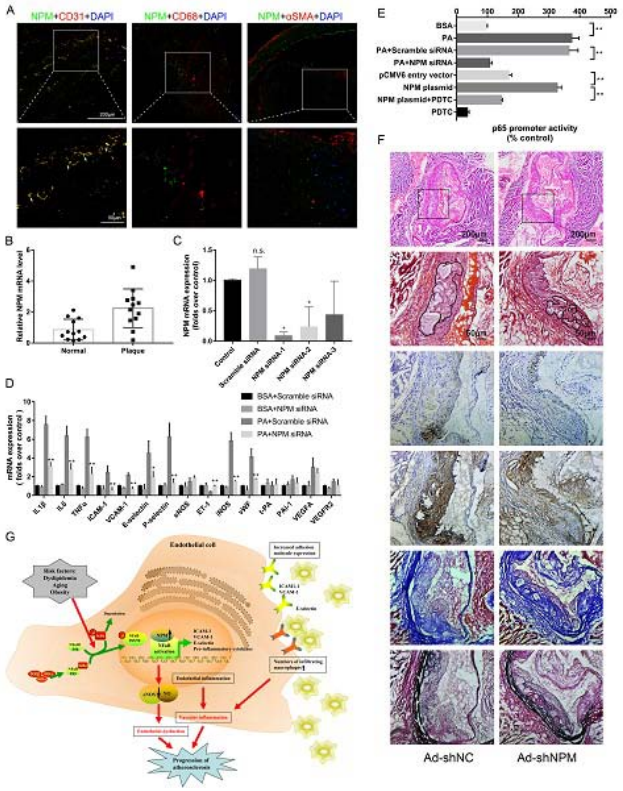
NPM accelerated vascular inflammation and endothelial dysfunction in atherosclerosis progression through NF-kappaB pathway

C Caijun Rao[1]; B Liu[2]; F Li[2]; D Huang[1]; K Huang[1]; N Dong[2]
[1]Wuhan Union Hospital, Department of Cardiology, Wuhan, China; *[2]Wuhan Union Hospital, Department of Cardiovascular Surgery, Wuhan, China*

Purpose: It was uncertain whether Nucleophosmin (NPM) participated in cardiovascular disease. The present study aims to investigate the role and underlying mechanisms of NPM in exacerbating vascular inflammation and endothelial dysfunction in atherosclerosis progression.
Methods: Levels and location of NPM in human carotid atherosclerotic plaques and healthy controls were detected by RNA-Seq and immunohistochemistry. Human primary umbilical vein endothelial cells (HUVECs) were used as in vitro model. Atherosclerotic prone ApoE−/− mice was fed with western diet for 24 weeks as in vivo model.



Results: Compared with controls, we found increased levels of NPM inatherosclerotic plaques, which mainly located in endothelial cells. In cultured HUVECs, palmitic acid induced NPM upregulation, the expression of inflammatory cytokines and monocyte adhesion, while NPM knockdown attenuated this effect. In vivo, adenovirus containing shNPM attenuated atherosclerotic leision and promoted plaque stabilization in western diet-fed ApoE-/- mice by reducing vascular inflammation, maintaining endothelial function and decreasing macrophage infiltration in atheromatous plaques. Furthermore, NPM knockdown decreased NF-Kb p65 phosphorylation . In HUVECs, NPM protein physically bind with Nuclear factor-κB (NF-κB) p65 subunits and promotes its nuclear transposition. NPM could also increase the transcriptional activity of NF-κB p65 promoter and enhance its binding to target genes including TNF-α, IL-1β, IL-6, ICAM-1 and E-selectin.
Conclusion: These data provided novel evidence that NPM promoted atherosclerosis by inducing vascular inflammation and endothelial dysfunction through NF-κB pathway, and suggested that NPM may be a novel target for atherosclerosis prevention and treatment.

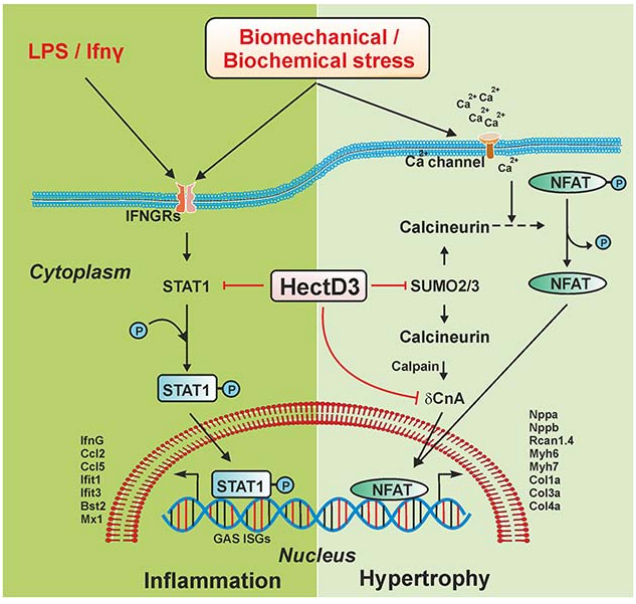
Background: We recently identified SUMO2 as a sumoylation independent inducer of cardiomyocyte hypertrophy through activation of Calcineurin-NFAT signaling via direct interaction and increased nuclear localization of calcineurin.
Purpose: In this study, we aimed at identifying cardiac-specific interactome of SUMO2 to decipher its cardiac function in depth.



Graphical abstract

Methods and results: Using Yeast two-hybrid screen, we identified HECT domain-containing E3 ubiquitin ligase 3 (HectD3) as one of the cardiac SUMO2-interacting protein. Adenovirus-mediated HectD3 overexpression significantly increased polyubiquitination and reduced protein levels of SUMO2 and its sumoylation targets in neonatal rat ventricular cardiomyocytes (NRVCMs). Presence of a proteasome inhibitor MG132, however, prevented this reduction. Moreover, inverse correlation of SUMO2 and HectD3 expression was observed in human hearts with hypertrophic cardiomyopathy. Interestingly, several proteins from interferon signaling, including signal transducer and activator of transcription-1 (Stat1), were found downregulated by HectD3 overexpression in mass-spectrometry based proteomics. Also a known SUMO2/3 target, Stat1 we found as a bona fide cardiac target of HectD3, overexpression of latter strongly attenuated LPS or interferon-mediated activation of Stat1 and downstream inflammatory signaling. Importantly, AAV9-mediated overexpression of HectD3 not only reduced cardiac SUMO2/Stat1 levels, but also significantly dissipated pathological hypertrophy, inflammation, and fibrosis induced by transverse aortic constriction or Angiotensin-II treatment.
Conclusion: In conclusion, we report here a novel mechanism of regulation of cardiac hypertrophy and inflammation by HectD3 via dual regulation of SUMO2 and one of its sumoylation targets, Stat1, establishing an important crosstalk between sumoylation and ubiquitination via a common substrate.

A translational mouse model of HFpEF

C Withaar[1]; LMG Meems[1]; C Gehlken[1]; HHW Sillje[1]; AA Voors[1]; RA De Boer[1]; CSP Lam[1]
[1]*University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands (The)*

Background Heart failure with preserved ejection fraction (HFpEF) is a heterogeneous disease with limited therapeutic options. Pathophysiology of HFpEF is complex as a large proportion of HFpEF patients have comorbidities such as obesity, diabetes and hypertension. Importance of heterogeneity and comorbidities is underscored in pre-clinical mouse models, that mostly are models with one (simple) perturbation. This mismatch in underlying pathophysiological mechanisms may contribute to the limited translational value and hinder the development of novel therapeutics. Therefore, in this study we present a heterogeneous HFpEF mouse model that closely mimics the human HFpEF phenotype.
Purpose We aimed to design a HFpEF mouse model integrating four hallmarks of human HFpEF: aging, female sex, obesity and hypertension.
Methods 18-22 months old female C57BL/6J mice (n=10) were fed a control (CTRL) or high fat diet (HFD) for 12 weeks. During the last 4 weeks, hypertension was induced with angiotensin-II (Ang) infusion (1,25mg/kg/day) (CTRL+Ang or HFD+Ang). Prior to sacrifice, echocardiographic measurements were obtained and images were used for strain analysis. Using PCR, mRNA levels of collagen, atrial natriuretic peptide (ANP), and metallopeptidase inhibitor 1 (TIMP-1) and growth and inflammatory plasma markers were determined. Histological analysis of fibrosis was performed.
Results HFD+Ang induced increased lung weights (CTRL 9.9 ± 0.5 vs. HFD+Ang 14.3±1.2 p<0.01) atrial weights(0.5±0.05 vs. 0.9±0.08 p<0.01) and increased body and fat weights. Echocardiography showed preserved ejection fraction with substantial cardiac hypertrophy in HFD and even more pronounced in HFD+Ang. Increased myocardial fibrosis was observed. mRNA levels of collagen, ANP and TIMP-1 were increased in CTRL+Ang and HFD+Ang. Plasma levels of growth factors and TIMP-1 were significantly elevated in HFD+Ang. Global longitudinal strain was impaired in HFD+Ang compared to CTRL (-21.4±1 vs. -14.1±0.6 p<0.01). During left ventricle diastolic early filling the reverse peak longitudinal strain rate is lower in the HFD+Ang compared to CTRL (10,7±0.8 vs. 7.5±0.7 p<0.01).
Conclusion We for the first time showed that by using a multifactorial approach, we were able to closely mimic the human situation. Our mouse HFpEF model uniquely recapitulates the typical human HFpEF signature: impaired movement of the myocardial endocardium, collagen deposition, fibrosis and an increase in cardiac hypertrophy and lung congestion with a preserved ejection fraction. This model is currently available for testing potential novel treatment modalities for patients with HFpEF.

8
Diastolic dysfunction and HFpEF characteristics are exacerbated with ageing in smoothelin-like 1 (SMTNL1)-deficient mice

M Murali[1]; D Belke[2]; M Chappellaz[1]; WC Cole[3]; JA Macdonald[1]

Funding Acknowledgements: Canadian Institutes of Health Research; Achievers in Medicine Scholarship-University of Calgary; Libin Cardiovascular Institute of Alberta

Background: Heart failure with preserved ejection fraction (HFpEF) has gained clinical prevalence with ~1% incidence increase per year. Clinical evidence associates HFpEF with endothelial inflammation and microvascular dysfunction, which in turn drive pathologic cardiac remodelling. With a highly comorbid HFpEF patient population and a lack of knowledge about the underlying pathophysiology, no therapeutics are yet available for improving the outcomes of HFpEF patients. Our group revealed a novel impact of the smoothelin-like 1 (SMTNL1) protein which when subjected to genetic deletion drives dramatic alterations in endothelial function and cardiovascular (CV) performance. Of note, previous cardiac hemodynamic profiling show that young male SMTNL1 knockout (KO) mice developed diastolic dysfunction as evident from increased end diastolic pressure (EDP), left ventricular (LV) relaxation time (Tau) and steeper end diastolic pressure-volume relationship (EDPVR).
Purpose: As ageing is associated with slowing of LV relaxation, and HFpEF is predominant in older patients, this study examined the impact of SMTNL1 silencing on cardiac function with increasing age in a murine transgenic model.
Methods: SMTNL1 global KO mice (3- and 12-month old, male and female) were assessed by echocardiography, followed by LV catheterization (PVR 1045, Millar Instruments) and pressure-volume loop measurements to assess the systolic-diastolic and hemodynamic parameters of cardiac function. The background strain 129S6 wildtype (WT) mice served as the control group.
Results: Like young males, aged 12-month old male KO mice developed diastolic dysfunction as evident from increased Tau (12.8±0.6 vs 11.0±0.3 ms, p<0.05), EDP (10.3±1.4 vs 6.7±0.5 mmHg, p=0.05) and EDPVR (0.46±0.03 vs 0.14±0.04, p<0.0001); along with an elevated E/E´ ratio (29.4±1.8 vs 23.2±1.9, p<0.05). However, the female KO group did not develop diastolic dysfunction even at 12-months of age. Although both male and female cohorts showed normal ejection fraction, aged male KO group showed significantly reduced E/A ratio (1.16±0.08 vs 1.56±0.15, p<0.05) in relation to their younger counterparts. Furthermore, with age the total peripheral resistance (25.6±4.5 vs 12.0±0.8 mmHg×min/µl, p<0.05) and the arterial elastance (Ea; 8.7±0.9 vs 4.8±0.9 mmHg/µl, p<0.01) was exacerbated in only male KO animals. Ageing was also associated with increased LV mass and wall thickness along with fibrotic remodelling in the KO group.
Conclusions: We have identified a potentiating effect of age on vascular and cardiac dysfunction in the absence of SMTNL1. The SMTNL1 KO model recapitulates HFpEF clinical phenotypes and represents a novel pre-clinical model to study the aetiology of HFpEF condition, in the absence of any confounding comorbidities. However, the absence of diastolic dysfunction in KO female mice potentially through the protective role of oestrogen requires further study using ovariectomized animals.

9
L-2-hydroxyglutarate dehydrogenase (L2HGDH) is a novel metabolic target protecting from cardiac hypertrophy and heart failure

A Remes[1]; L Ding[1]; B Kamlage[2]; U Rennefahrt[2]; S Hille[1]; A Jungmann[3]; K Rapti[4]; HA Katus[3]; N Frey[1]; OJ Mueller[1]
[1]*University Medical Center of Schleswig-Holstein, Kiel, Germany*; [2]*Metanomics Health GmbH, Berlin, Germany*; [3]*University Hospital of Heidelberg, Heidelberg, Germany*; [4]*University of Heidelberg, Heidelberg, Germany*

Background: Heart failure is associated with a metabolic switch to glucose oxidation while usage of long chain fatty acids (LCA) is decreased. Using transcriptional profiling in combination with untargeted metabolic profiling in mice subjected to transverse aortic constriction (TAC), we found a downregulation of L2-hydroxyglutarate dehydrogenase (L2HGDH) which is associated with accumulation of its substrate L-2-hydroxyglutarate (L2-HG). L2HGDH is involved in the energy generation process by catalyzing L-2-hydroxyglutarat (L2-HG) to α-ketoglutarate (α-KG), and therefore plays an important role in the tricarboxylic acid (TCA) cycle. However, the potential connection between L2-HG accumulation, L2HGDH down-regulation and heart failure is unclear.
Aim of our study was to investigate whether adeno-associated virus (AAV) 9-mediated cardiac expression of L2HGDH is able to ameliorate the development of heart failure in a mouse model of heart failure due to TAC.
Methods: C57BL/6N mice were randomly assigned to treatment with AAV9-L2HGDH and vector control (AAV9-luciferase) through tail vein injection. Two weeks later, mice were subjected to TAC surgery. Successful TAC was confirmed by echocardiography 2 days after TAC.
Results: 6 weeks after TAC, AAV9-luciferase control-treated mice showed progressive deterioration of contractile function and left ventricular remodeling. In contrast, over-expression of L2HGDH protein (30%) in AAV9-L2HGDH treated animals was associated with a significantly improved ejection fraction (EF) and fractional shortening (FS) at the end of the study. While AAV9-L2HGDH treated animals revealed an EF of 36.18 ± 6.63 % (n=12, mean± SD) and a FS of 16.72 ± 4.01 % (n=12, mean± SD), AAV9-luciferase treated mice showed a lower EF (20.14 ± 8.24%, n=15, p<0.001) and a reduced FS (12.66 ± 6.66 %, n=15, p<0.05). Furthermore,

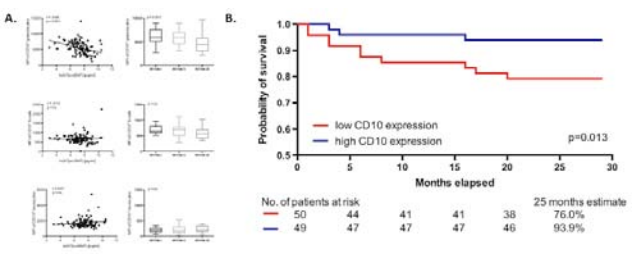
AAV9-L2HGDH-treated TAC mice revealed significantly reduced heart weight to tibia length ratios (HW/TL) as indicator of ameliorated cardiac hypertrophy and decreased lung weight to tibia length ratios (LW/TL) as indicator of decreased heart failure when compared to the vector control group (each $p<0.01$). Quantification of myocyte cross section area confirmed reduced hypertrophy in the AAV9-L2HGDH group ($p<0.001$). ANP, BNP, RCAN1.1, and RCAN1.4 as molecular markers of heart failure were also considerably decreased in AAV9-L2HGDH-treated mice ($p<0.05$). In addition, quantification of Masson's trichrom stainings revealed a significant reduction of fibrous tissue in the L2HGDH over-expression group (perivascular fibrosis, $p<0.01$ and interstitial fibrosis, $p<0.001$).
Conclusion: Cardiac over-expression of L2HGDH is able to ameliorate the development of cardiac hypertrophy and fibrosis as well as heart failure in a pressure-overload model. Therefore, upregulation of L2HGDH represents a promising approach for future therapy of heart failure.

10

Increased granulocyte neprilysin (CD10) expression is associated with better prognosis in patients with heart failure with reduced ejection fraction

H Arfsten[1]; J Novak[1]; A Cho[1]; G Goliasch[1]; PE Bartko[1]; G Strunk[2]; M Huelsmann[1]; N Pavo[1]
[1]*Medical University of Vienna, Department of Internal Medicine II, Division of Cardiology, Vienna, Austria*; [2]*Complexity Research, Vienna, Austria*

Background. The exact mechanism of action of neprilysin inhibition (NEPi) is still a subject of debate. The soluble form of the enzyme (sNEP), detectable in plasma, is discussed controversially as a potential biomarker in heart failure with reduced ejection fraction (HFrEF). NEP is present on solid tissues but identically to CD10, expressed on the surface of leukocytes under physiological conditions. The possible impact of NEP expression on peripheral leukocytes on prognosis and its association with sNEP levels have not been investigated yet.
Methods. 99 stable HFrEF patients were prospectively enrolled and clinically followed-up. Laboratory markers including NT-proBNP were assessed. NEP(CD10) expression on peripheral blood cells were measured by flow cytometry using a combination of six antibodies with fluorescence minus one samples as control [CD3(#555339),CD19(#555413),CD56(#335826),CD16(#561306),CD14(#562692), +/-CD10(#332777); BD Biosciences,USA]. sNEP levels were determined by a specific ELISA [SEB785Hu, USCN, China].Associations between NEP expression and heart failure severity, sNEP levels and all-cause mortality were determined.
Results. Median age was 65 years (IQR:55-73), 75% were male. Median NT-proBNP level was 1700pg/ml(IQR:794-4009).NEP was expressed on granulocytes with 94.8%(IQR:90.5-97.4) of CD10+cells and measurable on B-cells and monocytes with 8.5%(IQR:5.3-13.5) and 0.8%(IQR:0.4-1.5) of CD10+cells of the respective leukocyte subtype. NEP expression on T-cells was not detectable. The mean fluorescence intensity (MFI) of CD10+cells was 5461(IQR:4028-6904) for granulocytes, 640(IQR:535-740) for B-cells and 1589(IQR:1395-1975) for monocytes. Granulocyte NEP expression, but not NEP expression on B-cells or monocytes, correlated inversely with heart failure severity reflected by NT-proBNP level ($r=-0.46, p<0.001$) and NYHA class ($p=0.013$)(FigureA). sNEP concentrations correlated weakly with NEP expression on granulocytes ($r=0.22$, $p=0.030$) as well as the MFI of CD10+granulocytes ($r=0.31$, $p=0.003$). 15% of the patients died during a median FUP of 24 (IQR:23-28) months. Increased NEP expression on granulocytes was indicative for better overall survival even after adjustment for age and kidney function [adj.HR per 1-IQR increase of MFI 0.41 (95%CI:0.18-0.94),$p=0.035$]. Kaplan-Meier analysis illustrates the impact of granulocyte NEP expression on outcome graphically(FigureB).
Conclusions. Albeit beneficial effects of NEPi by ARNI therapy, NEP expression on granulocytes is inversely correlated with heart failure severity and mortality. The results support the inverse relationship between BNP and plasma NEP activity reported for a mixed population of heart failure patients. The positive correlation of granulocyte NEP expression and sNEP indicates a possible contribution of shed membrane NEP molecules to plasma NEP levels as a surrogate marker. The utility of granulocyte NEP expression or sNEP as biomarkers in HFrEF have to be further evaluated.



11

The role and mechanism of Kir6.1 in diabetic cardiomyopathy

Q Qinglei Zhu[1]; JINXIN Wang[1]; YANG Li[1]; PENG Duan[1]
[1]*China PLA General Hospital, Department of Cardiology, Beijing, China*

On behalf of: Qinglei Zhu
Funding Acknowledgements: This study was funded by the National Natural Science Foundation of China (grant nos. 81570349 and 81200157

Background: Diabetic cardiomyopathy (DCM) seriously plagues the health of diabetic patients. A previous study have showed that the expression and function of mitoKATP was significantly reduced in the mouse model of type 1 diabetes. However, in type 2 DCM, whether its expression and function have changed and what role it plays in DCM has not been reported.
Objective To study the role and mechanism of Kir6.1 in DCM.
Methods We generated transgenic mice including specific cardiac Kir6.1 knockout mice and Kir6.1 overexpressing mice. The cardiac function of mice was analyzed with echocardiography and serum BNP respectively. The cardiomyocyte cell area and apoptosis rate of mice were analyzed with HE staining and TUNEL. The heart mitochondrial structure of the mice was analyzed with transmission electron microscope. The cardiac function and mitochondrial function of cardiomyocyte were analyzed with serum BNP and Seahorse XFe96respectively. The expression of Kir6.1 in mRNA and protein level was analyzed with RT-QPCR and WB, respectively. The expressions of T-AKT, P-AKT, T-FOXO1, and P-FOXO1 in protein level were analyzed with WB respectively.
Results Specific Kir6.1 knockout decreased the cardiac function, mitochondrial function and the phosphorylation of AKT and FOXO1. Moreover, the cardiac function, mitochondrial function and the phosphorylation of AKT and FOXO1 in heart-specific Kir6.1 knockout mice model are decreased more than the group control. Overexpression of Kir6.1 reduces cardiac function and mitochondrial dysfunction and upregulates the phosphorylation of AKT and FOXO1 in mice model of diabetic cardiomyopathy. Furthermore, overexpression of Kir6.1 reduces cardiomyocyte function and mitochondrial dysfunction and upregulates the phosphorylation of AKT and FOXO1 in cardiomyocyte insulin resistance.
CONCLUSIONS: Kir6.1 plays an important role in improving cardiac and mitochondrial function via AKT-FOXO1 signaling pathway in DCM, and may therefore be a new potential therapeutic target for DCM.

Regulatory effect of enoyl coenzyme a hydratase 1 on left ventricular remodeling and dysfunction after acute myocardial infarction

L Liu Baoqing[1]; C Rao[2]; F Li[1]; N Dong[1]
[1]*Wuhan Union Hospital, Department of Cardiovascular Surgery, Wuhan, China*; [2]*Wuhan Union Hospital, Department of Cardiology, Wuhan, China*

Objective: Acute myocardial infarction (AMI) is one of the major causes of mortality and health care cost in the world. Altered lipid metabolism has been observed in patients with AMI. Enoyl coenzyme A hydratase 1 (Ech1), the second enzyme in the pathway of lipids degradation, has been demonstrated playing a critical role in inflammation, tumor development and metastasis. However, the causal relationship between Ech1 and AMI remains scarcely explored. This study aims to identify the functional significance of Ech1 in cardiac remodeling after AMI and the underlying mechanisms of its effect.
Methods: Ech1 level in human cardiac tissue from ischemic cardiomyopathy patients undergoing heart transplantation was evaluated using immunohistochemical staining and immunoblotting. Age matched male C57BL/6 mice and Ech1-knockout (Ech1-/-) mice were subjected to ligation of LAD coronary artery to simulate human AMI. Adeno-associated virus carrying Ech1 plasmid was injected via tail vein to see the effect of Ech1 overexpression on cardiac remodeling after AMI. Cardiac structure and function were serially assessed by echocardiography at baseline (4d before AMI) and 48h, 7d, 14d as well as 28d after AMI. Mice were sacrificed after 28d for histological and biochemical assessments. Primary cardiomyocyte culture was used as in vitro model.
Results: Ech1 were down-regulated in cardiac tissue from patients with ischemic cardiomyopathy undergoing heart transplantation. In addition, similar results were observed in myocardial infarction area and border zone of mouse post-infarction hearts. At 48h post-AMI, left ventricular ejection fraction (LVEF) was similar and significantly reduced in wild type and Ech1-/- mice compared with baseline, indicating that the ischemic injury was similar in the two groups. However, 28d after AMI, Ech1-/- mice developed larger infarct sizes, reduced survival rates, and more severe LV dysfunction, compared with wild type mice. Furthermore, Ech1-/- mice had more cardiomyocyte apoptosis and inflammatory cell infiltration in the infarct border zone. Conversely, overexpressing Ech1 ameliorated AMI-induced mortality and phenotype change compared with wild type mice. Attenuated LV remodeling was observed in the overexpressing Ech1 hearts after AMI, with reduced cardiac hypertrophy and fibrosis. Similar results were observed in cultured neonatal

mice cardiomyocytes exposed to hypoxia. Moreover, we discovered that the Ech1-mediated cardio-protective effects of AMI were associated with NF-κB and p38 signaling cascades.
Conclusion: These novel findings demonstrate that Ech1 may have a favorable effect on ventricular remodeling after AMI via the regulation of the NF-κB and p38 signaling. Thus, modulation of Ech1 probably has therapeutic potential for patients after AMI at risk for adverse remodeling and development of heart failure.

Purified exosome product and extracellular vesicles: treatment for acute myocarditis, dilated cardiomyopathy and heart failure

K Katelyn Bruno[1]; DN Diflorio[1]; AR Hill[1]; PG Stalboerger[2]; LT Cooper Jr[1]; A Behfar[2]; D Fairweather[1]
[1]*Mayo Clinic, Cardiovascular Diseases, Jacksonville, United States of America*; [2]*Mayo Clinic, Rochester, United States of America*

Funding Acknowledgements: Mayo Clinic Center for Regenerative Medicine

Background: Myocarditis is an important cause of heart failure and sudden cardiac death in children and young adults with no targeted treatment to reduce/prevent disease.
Purpose: We wanted to determine whether purified exosome product (PEP) or premenopausal PEP (pmPEP) could improve and/or prevent myocarditis and prevent dilated cardiomyopathy (DCM) using a preclinical mouse model of myocarditis/DCM. We looked at pmPEP because estrogen protects women from myocarditis and heart failure. We also investigated if Adipose Derived Extracellular Vesicles (AEV) was a more effective and efficient treatment product.
Methods: We administered PEP, pmPEP or AEV vs. control ip to male BALB/c mice at day -1, 0 and +1 with virus inoculation on day 0 to induce myocarditis, and harvested mice at day 10 post infection (pi) during the peak of acute myocarditis. Next we treated male BALB/c mice with PEP, pmPEP, AEV or control ip on day 7, 8 and 9 pi (a clinically relevant timepoint) and harvested on day 10 pi during acute myocarditis or day 35 pi during DCM.
Results: We found that the dose and exposure route were successful. pmPEP and AEV, but not PEP, significantly decreased acute myocarditis based on histology (ANOVA p=0.0009) and decreased total immune cells (CD45 p=0.008). Importantly, CR1, the central inhibitor of the complement cascade, was significantly increased by pmPEP (p=0.004). Visual qualitative observations in AEV treated mice indicated improved health in mice receiving regenerative treatment. Body weight was also significantly increased in mice treated with AEV indicating improved health. When assessing clinically relevant dosing timepoint we that found that both PEP and pmPEP treatment given during myocarditis significantly reduced inflammation compared to PBS (ANOVA PEP p=0.006, pmPEP p= 0.005) and decreased fibrosis when assessed at day 35pi
Conclusion: These findings suggest that regenerative medicine treatments; PEP, pmPEP and AEV, could be administered to patients who present with acute onset myocarditis to decrease the severity of disease and potentially prevent heart failure and sudden death.

14
Impact of environmental factors on heart failure decompensations

V Vanessa Escolar Perez[1]; A Lozano[1]; N Larburu[2]; G Artola[2]; R Alvarez[2]; B Juez[3]; J Kerexeta[2]; A Artetxe[2]; A Echebarria[2]; A Azcona[2]
[1]*Hospital de Basurto, Cardiology, Bilbao, Spain*; [2]*Vicomtech Research Centre, San Sebastián, Spain*; [3]*Hospital de Basurto, Bilbao, Spain*

Introduction: The association of environmental pollution and weather changes in the development and decompensation of heart failure (HF) is not well studied.
Objectives and methods: The objective is to determine the impact of various environmental factors on the decompensation of heart failure. The following data have been collected: 1. Hospital admissions for heart failure in our hospital from January 2012 to August 2017. 2. Weather registry (wind, temperature, humidity, rainfall, atmospheric pressure) in that period (data from Euskalmet, the Basque agency of meteorology). 3. Air quality (% of carbon monoxide, nitric oxide, nitrogen oxide and dioxide, pollution and particulate matter -PM10-, sulphur dioxide, benzenes and toluenes) (data from Open Data Euskadi website).
Results: The database contains 8338 hospitalizations of 5343 different patients (average of 4.02 admissions per day). In the warmer months (June to October) there are significantly fewer hospital admissions due to worsening HF than in the colder months (December to March). The parameter that best predicts HF decompensation is a previous hospital admission due to the same cause (table 1). Within environmental factors, the attribute that best correlates with HF decompensations is temperature, so the lower the temperature, the greater the risk (inverse correlation - Figure 1). The concentrations of sulphur dioxide and nitrogen oxide have a positive correlation with decompensations. Humidity, precipitation and PM10 parameters have not shown significant correlation or relevant p values.
Conclusions: There is a clear relationship between environmental factors and heart failure decompensations. The most relevant being factors are temperature (inverse relationship) and air composition (percentage of sulphur dioxide and nitrogen oxide).

Table 1. Measured parameters and their c

	Correlation	P value
Previous hospital admissions	0.7075	0.002
Temperature	-0.3794	0.014
Humidity	0.0469	0.238
Precipitation	0.0795	0.046
SO2	0.23	0.007
NOX	0.2196	<0.001
NO	0.1733	<0.001
NO2	0.1876	<0.001

Acute intravenous infusion of the beta-3 adrenergic receptor antagonist APD418 improves left ventricular function in dogs with advanced heart failure: a dose escalation study

HN Hani Sabbah[1]; K Zhang[1]; J Xu[1]; RC Gupta[1]; J Adams[2]
[1]*Henry Ford Hospital, Detroit, United States of America*; [2]*Arena Pharmaceuticals, Inc., San Diego, United States of America*

Background: Unlike β1 and β2-adrenergic receptors (ARs), β3-AR stimulation inhibits cardiac contractility and relaxation through links to inhibitory G proteins. In the failing left ventricular (LV) myocardium, β3-ARs are upregulated, a maladaptation that can contribute to LV dysfunction. This study examined the effects of acute intravenous (i.v.) infusions of the β3-AR antagonist APD418 on LV

systolic and diastolic function by conducting a doseescalation study in dogs with chronic heart failure (HF) (LV ejection fraction, EF˜35%).
Methods: Studies were performed in 7 dogs with coronary microembolizations-induced HF. After baseline measurements, 0.9% NaCl (vehicle) was administered as a continuous i.v. infusion for 30 min. This was followed by infusions of 3 escalating doses of APD418 (0.696, 1.407 and 2.814 mg/kg) with each dose maintained for 30 min. Heart rate (HR), mean aortic pressure (mAoP), LV end-diastolic (EDV) and end-systolic (ESV) volumes, EF, stroke volume (SV) cardiac output (CO), LV end-diastolic pressure (EDP) and systemic vascular resistance (SVR) as well as the diastolic function measures Ei/Ai and mitral inflow velocity deceleration time (DCT) were measured at end of each 30 min period.
Results: Infusion of APD418 had no effects on HR, mAoP, or EDV but significantly decreased ESV, LVEDP and SVR and significantly increased EF, SV, CO Ei/Ai and DCT in a dose-dependent manner (Table).
Conclusions: Acute i.v. infusions of APD418 in HF dogs elicit positive inotropic and lusitropic effects along with modest preload and afterload reductions. The findings support the development of APD418 for the in-hospital treatment of patients with exacerbation of chronic HF.

Table

	Baseline	Vehicle	APD418 (0.696 mg/kg)	APD418 (1.407 mg/kg)	APD418 (2.814 mg/kg)
LV EDV (ml)	62±1	63±1	62±2	62±2	61±2
LV ESV (ml)	41±1	41±1	38±1*	38±1*	36±1*
LV EF (%)	34±1	35±1	38±1*	39±1*	41±1*

Background: Myocardial fibrosis is a hallmark of various heart diseases and is associated with a worse outcome ultimately promoting heart failure (HF) development. Recently, we demonstrated that adipose-tissue-specific deletion of adipose-triglyceride-lipase (ATGL) has complex effects on the cardiac lipidome and prevents pressure-mediated HF in mice. In this study, we investigate the effects of a pharmacological inhibitor of ATGL, Atglistatin (ATGLi), predominantly targeting ATGL in adipose tissue and liver, on the development of cardiac fibrosis.
Methods: Male 129/Sv mice received repetitively high-dose injections of Isoproterenol (ISO, 25 mg/kg BW) to induce myocardial fibrosis, or saline as vehicle (VEH). Five days prior to ISO-application, oral ATGLi (2 mmol kg-1 diet) or control treatment was started. Cardiac function was analyzed by echocardiography twelve and two days after the last ISO-injection. Myocardial deformation was evaluated using speckle-tracking-technique. The results were complemented by histologic/qRT-PCR-based analysis performed on cardiac tissue.
Results: Twelve days after the last ISO-injection, echocardiographic analysis revealed a markedly impaired global longitudinal strain (GLS) due to ISO (VEH vs. ISO, -15.6±1.1% vs. -11.2±0.6%; p≤0.01), which was significantly improved by ATGLi-treatment (ISO vs. ISO/ATGLi, -11.2±0.6% vs. -16.6±0.8%; p≤0.001). ISO had no impact on systolic function. Additionally, ISO-injection led to pronounced fibrotic lesions in the subendocardial layer (VEH vs. ISO, 4.1±1% vs. 21.3±3.8%; p≤0.001). Subendocardial fibrosis was closely associated with GLS and was potently diminished by ATGLi (ISO vs. ISO/ATGLi, 21.3±3.8% vs. 11.2±1.6%; p≤0.05). Accordingly, the ISO-induced increase in mRNA-expression of collagen I and III was significantly reduced by ATGLi.
Mechanistic investigations early (two days) after the final ISO-injection revealed that cardiac pro-apoptotic ISO-induced BAX expression was significantly attenuated upon ATGLi. Moreover, ATGLi ameliorated an increase in mRNA-expression of macrophage marker CD68, indicating a lower migration of macrophages into cardiac tissue.
Conclusion: The present study demonstrates antifibrotic and cardioprotective effects of ATGLi involving anti-apoptotic and/or anti-inflammatory actions. These data suggest a therapeutic potential of ATGLi in the context of myocardial fibrosis. Interestingly, ATGLi´s cardioprotective effects are mediated by non-cardiac actions supporting the concept that pharmacological targeting of remote organs such as adipose tissue may provide an effective way to treat heart diseases.

Funding Acknowledgements: SUPPORTED BY THE ÚNKP-18-3-III-DE-209 NEW NATIONAL EXCELLENCE PROGRAM OF THE MINISTRY OF HUMAN CAPACITIES

Omecamtiv mecarbil (OM) is a promising first-in-class direct myosin activator, under clinical development to improve cardiac contractility. Clinical studies with OM confirmed positive inotropy, but also shed light on potential side-effects, such as hypotension and myocardial ischaemia.
We tested OM on rat, dog and human cardiac contractility. OM was administered intravenously to the rat. We confirmed the dose-dependent improvement of systolic cardiac function (building up from 600 μg/kg, reaching maximum at 1,200 μg/kg) by echocardiography and left ventricular (LV) pressure-volume analysis. However, we also observed novel (so far unreported) overlapping side-effects at the same dose. We found (1) a severe drop in blood pressure to 40% of initial value at 1,200 μg/kg (invasive blood pressure measurement); (2) a disturbed diastolic heart function from 600 μg/kg, reaching maximum at 1,200 μg/kg by echocardiography: decreased E/A, increased IVRT and LA diameter; (3) impaired diastolic performance by pressure-volume recordings: decreased dP/dtmin, increased Tau, LVEDP and slope of EDPVR; (4) depressed relaxation: lower maximal force generation, increased pCa50 value, slower kinetics of contraction and relaxation in human cardiomyocytes, in vitro; (5) occasional (n=23 out of the total 30 rats), transient electromechanical alternans: normal systole alternating with diminished contraction without major differences on the ECG; (6) this was associated by disturbances of intracellular Ca2+ handling in canine cardiomyocytes, in vitro.
OM was found to have deleterious effects on cardiac performance, besides improving systolic function. In particular, here we identified OM as a pharmaceutical tool to evoke electromechanical alternans and diastolic dysfunction. These effects may limit its clinical effectiveness.

Funding Acknowledgements: National Institute of Health [PI16/01627, PI17/01925, PI17/01232], Consorcio Centro de Investigación Biomédica en Red, M.P. [CB16/11/00261], and FEDER

Background: Nowadays the detection of heart transplant rejection by non-invasive methods represents a challenge. Changes in sarcoplasmic reticulum calcium ATPase 2a (SERCA2a) serum levels occur in cardiac allograft rejection, demonstrating a good potential for detection. Although many SERCA2a-related genes and

proteins involved in the regulation of myocardial Ca2+ fluxes have been explored, its related metabolites remain poorly studied.
Purpose: Our objective was to identify circulating SERCA2a-related metabolites altered in cardiac allograft rejection and to determine whether these could serve as non-invasive biomarkers.
Methods: Sixty plasma samples from adult heart transplant recipients (15 without allograft rejection and 45 with diagnosis of biopsy allograft rejection: 15 Grade 1R, 15 Grade 2R, 15 Grade 3R) were included in a metabolomic analysis.
Results: We identified thirteen differential metabolites and focused on sphingosine-1- phosphate (S1P), metabolite closely related with SERCA. S1P plasma levels were increased in patients with cardiac rejection ($p<0.0001$). A receiver-operating characteristic analysis showed that S1P strongly discriminated between patients with and without rejection: non-rejection grafts vs. all rejecting grafts (AUC=0.911, $p<0.0001$), non-rejection grafts vs. Grade 1R (AUC=0.819, $p<0.01$), non-rejection grafts vs. Grade 2R (AUC=0.911, $p<0.0001$), non-rejection grafts vs. Grade 3R (AUC=0.996, $p<0.0001$).
Conclusions: This metabolomic study reveals that circulating S1P determination could be a novel approach to detect cardiac rejection, even at lower grades, showing a robust capability for detection that improve gradually with the severity of rejection. The alteration of this SERCA-related metabolite demonstrates once again the implication of calcium regulation on the pathophysiology of transplant rejection.

Genome-wide gene expression analysis reveals pathomechanisms in patients with heart failure and preserved ejection fraction (HFpEF) - Insights from the Leipzig Heart Study

KP Karl-Philipp Rommel[1]; H Kirsten[2]; C Beser[1]; F Schlotter[1]; M Von Roeder[1]; A Teren[1]; F Beutner[1]; U Ceglarek[2]; J Thiery[3]; H Thiele[1]; R Burkhardt[3]; M Scholz[2]; P Lurz[1]
[1]Heart Center of Leipzig, Internal Medicine / Cardiology, Leipzig, Germany; *[2]University of Leipzig, Institute of Medical Informatics, Statistic and Epidemiology, Leipzig, Germany*; *[3]Leipzig University Hospital, Institute of Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, University of Leipzi, Leipzig, Germany*

Background: Heart Failure with preserved Ejection Fraction (HFpEF) is an urgent medical challenge without proven therapy to date. A lack of understanding of the pathophysiology and heterogeneity of the HFpEF syndrome hinders translation into novel therapeutic approaches. Genome-wide gene expression analysis may provide insights into novel mechanisms, associated with disease states and may identify biomarkers for diagnosis, prognosis and therapeutic monitoring of disease activity.
Methods and Results: 719 HFpEF patients and 1106 controls were identified in the Leipzig Heart Study (n=6995). Peripheral mononuclear cell (PBMC) gene-expression was investigated using the HT-12v4 Expression BeadChip (Illumina, USA), quantifying 14,239 unique genes.
We identified 17 differentially expressed genes between HFpEF and controls at a false discovery rate of 5% using fully adjusted linear regression models. Top genes included genes encoding for glutathione peroxidase 3 ($p<0.001$), Ras-related GTP binding protein D ($p<0.001$) and all three subunits of the Fc-γ-receptor ($p<0.001$). Differentially expressed genes were related to several canonical pathways like cellular oxidant detoxification ($p<0.01$), epithelial cell differentiation ($p=0.02$) and interferon-γ signaling ($p<0.01$).
Functional pathway analyses predicated increased downstream activation of mechanisms related to the maintenance of cell viability (z-score 1.3). Enriched upstream factors included the enzyme O-linked N-acetylglucosamine ($p<0.001$) and activated beta-estradiol (z-score 1.9).
Conclusions: In this largest study to date differential gene-expression analysis in PBMCs confirmed several mechanisms known to be involved in the cellular HFpEF pathophysiology, validating our findings. Furthermore, we identified novel potential mechanisms and therapeutic targets that may contribute to the heterogeneity and pathophysiology of the HFpEF syndrome, which require further evaluation to develop novel therapeutic strategies.

Acute myocardial infarction in cardiogenic shock: beyond coronary anatomy

S Sofia Alegria[1]; T Silva[2]; A Ferreira[2]; I Cruz[1]; A Marques[1]; AR Pereira[1]; A Briosa[1]; D Sebaiti[1]; I Rangel[1]; O Simoes[1]; H Pereira[1]
[1]Hospital Garcia de Orta, Cardiology, Almada, Portugal; *[2]Hospital Garcia de Orta, Endocrinology, Almada, Portugal*

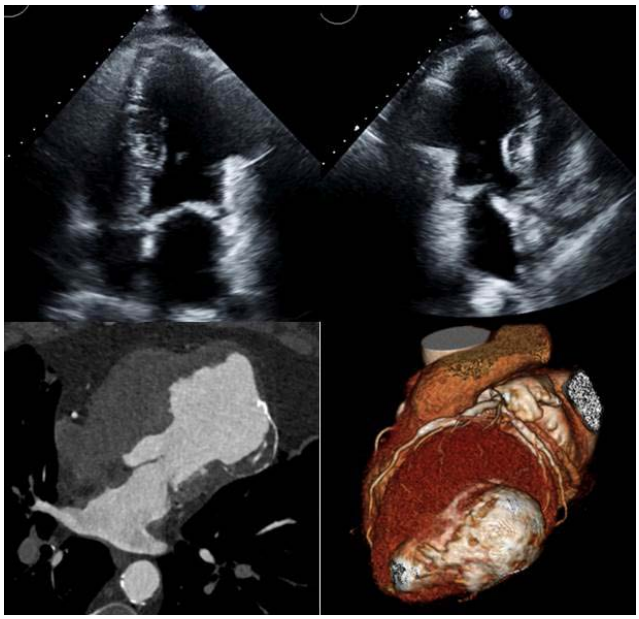
We present the case of a 76 year-old male patient with a history of arterial hypertension, dyslipidemia, non-insulin-treated type II diabetes mellitus, non-ST-segment elevation acute myocardial infarction (NSTEMI) in 2001 submitted to percutaneous coronary intervention (PCI) of the right coronary artery, and Parkinson's syndrome.He presented to the Emergency Department due to chest pain with two hours of evolution, associated with elevated blood pressure (BP), vomiting and headache.On admission he was hypertensive with a blood pressure (BP) of 185/89 mmHg and with an heart rate of 93 bpm. The remaining physical exam was unremarkable.
The electrocardiogram documented sinus rhythm, with a frequency of 92 /minute and ST-segment depression in the precordial leads. Laboratory evaluation showed high-sensitivity troponin T of 600 ng/l.
Transthoracic echocardiography (TTE) documented left ventricle with hypokinesia of the infero-lateral wall and of the medium and apical segment of the anterior wall; global systolic function was at the lower limit of normality. He was admitted with a diagnosis of NSTEMI in Killip-Kimball class I. In the following hours he became hypotensive and with signs of systemic hypoperfusion and repeated TTE documented severe biventricular dysfunction.
In this setting the patient was submitted to emergent coronary angiography that revealed a left anterior descending (LAD) artery with a proximal lesion of 90%; first diagonal of small caliber with an ostial lesion of 80%; right coronary artery with anomalous origin in the LAD, with non-significant restenosis of the stent in the proximal segment, diffuse disease of the mid segment with maximum stenosis of 50 to 70% and distal occlusion; there was contralateral filling of the posterior descending artery. PCI was performed in the LAD, with implantation of a drug-eluting stent.After the intervention the patient presented with marked blood pressure variation, alternating periods of shock requiring vasopressor support with noradrenaline, with hypertensive peaks (maximum BP of 270/130 mmHg), accompanied by vomiting and headache, requiring nitrate infusion. For this reason, the diagnosis of pheochromocytoma was considered, and abdominal computed tomography (CT) was performed, which documented a right retroperitoneal hypervascular mass suggestive of paraganglioma, with a dimension of 65 x 35 mm. The remaining study also showed a positive urinary metanephrine assay, and PET demonstrated hypercaptation at the localization previously described, compatible with secretory paraganglioma. Alpha-adrenergic blocking therapy was initiated with tansulosin and amlodipine, with control of the hypertensive spikes and remission of paroxysms.TTE at discharge documented recovery of biventricular function.Four months after hospitalization the patient underwent excision of the paraganglioma, without complications.

35

Ischemic cardiomyopathy late complication, an unusual aspect.

J Jose Pedro Alves Guimaraes[1]; F Goncalves[1]; S Borges[1]; JJ Monteiro[1]; J Trigo[1]; S Carvalho[1]; JI Moreira[1]
[1]CHTMAD - Vila Real, Vila, Portugal

We present the case of a 77-year-old man with hypertension, dyslipidemia, type II diabetes mellitus, smoking history (100 pack-years) and chronic obstructive pulmonary disease. He had history of chest pain and syncope 10 years ago, however he did not go to the emergency department. In the same year he was referred to Cardiology. The echocardiogram had akinesia of the medial and apical segments of the lateral and inferolateral walls; a mildly depressed left ventricular (LV) ejection fraction (EF) and mild aortic stenosis. He underwent percutaneous coronary intervention of the left anterior descending artery and of the proximal circumflex artery. He was then lost to follow-up.
In 2018, he was referred to Cardiology consult after complaints of stable effort dyspnea. He was in NYHA class II/III and had no chest pain or syncope. His physical examination was remarkable for a grade II/VI aortic systolic murmur and bilateral diffuse crackles. The EKG had a left bundle branch block.
The echocardiography showed a probable large aneurysm of the medial and distal segments of the lateral and inferolateral walls with acoustic shadowing artifacts. The LV was non dilated, moderately hypertrophied and had a mild to moderately depressed EF (qualitative evaluation). He also had a probable severe aortic stenosis (aortic valve area 0.9cm2; mean gradient 33mmHg, velocity ratio 0.25, stroke volume 37 mL/m2). For better characterization a cardiac CT was done that showed a LV aneurysm with a wide neck (44mm) with largest dimensions of 44*44mm in the medial and distal segments of the lateral and inferolateral walls. It had calcified walls and an associated organized mural thrombus. The aortic valve Agatston calcium score was 2550 (severe aortic stenosis likely). Given the LV aneurysm he did not underwent dobutamine stress echocardiography. His surgical risk was deemed too high and the patient is currently under evaluation for transcatheter aortic valve implantation.
The development of LV aneurysms is not infrequent after myocardial infarction, however, the development of calcified walls as in this case is rarer and it may difficult echocardiogram evaluation due to acoustic artifacts. It also adds to the complexity of an eventual TAVI procedure.



Echocardiogram and cardiac CT

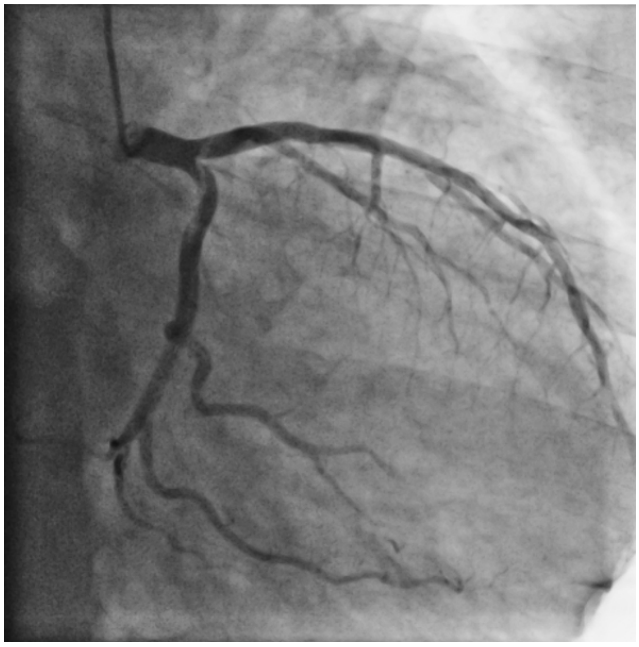
The early onset of heart failure caused by myocardial infarcton that is thrombus masquarade ballet

D Poluszynska[1]; R Romanek[1]; T Wnuk[1]; P Grzelakowski[1]; Ł Kafarski[1]; A Goch[1]
[1]10th Military Hospital, Bydgoszcz, Poland

On behalf of: Department of Invasive Cardiology
Funding Acknowledgements: There was no financial support.

A 75 year old male with a history of diabetes mellitus type 2, hypertension and prostate cancer hospitalized for a few days in Department of internal medicine due

to acute inflammation of pancreas, drug induced acute renal failure requiring temporary hemodialysis,and toxic liver damage. He had also low hemoglobin rate (77g/L) and melaena that temporary occured.Gastroscopy did not reveal any hemorrhage. The patient needed red blood cells transfusion. Due to suspicion of early heart failure onset and significant dynamics of myocardial biomarkers suggesting myocardial infarction, he was referred to our Department for further evaluation including coronarography. On admission to our Department patient suffered from progressive weakness. He denied chest pain, dyspnea or any episode of syncope. On physical examination patient was normotensive. Auscultation of heart valves revealed diastolic murmur at the Erbs point. The liver was not enlarged,jugular veins were normal, there was no oedema of lower extremities.The baseline level of CRP was 80,87mg/l (normal range: <5mg/l), first taken high sensitivity cardiac Troponin I was 8535,41 ng/l and the second one taken 3 hours later was 22815,06 (normal range : less than 46,47 ng/l).The standard 12-lead electrocardiogram demonstrated atrial fibrillation with ventricular rate around 100 beats per minutes ,non specific ST segment and T-wave abnormalities and also low QRS voltage in limb leads. Transthoracic echocardiography revealed local hypokinesis in the areas supplied by circumflex artery , ejection fraction 48%,and pericardial effusion. Due to suspicion of myocardial infarction invasive coronarography was performed. The coronarography revealed thrombus in circumflex artery which moved rapidly “dancing at artery” while contrast was given into the coronary arteries. The cause of myocardial ischemia was proven. Because of high risk of hemorrhage eptifibatyde was not introduced. The pharmacological treatment consisted of a single antiplatelet therapy- acetylsalicylic acid 75mg per day and unfractioned heparin intravenous infusion dosed according to activated partial thromboplastin time. During hospitalization hs Troponin I decreased 177,77ng/l. The patient was discharged on low dose of apixaban 2,5mg twice a day and acetylsalicylic acid 75mg per day. CONCLUSIONS: Early onset of heart failure can be caused by myocardial infarction secondary to thrombus in coronary arteries and it needs different , well balanced treatment, focused on the trigger of early onset heart failure-lets say –personalized treatment.

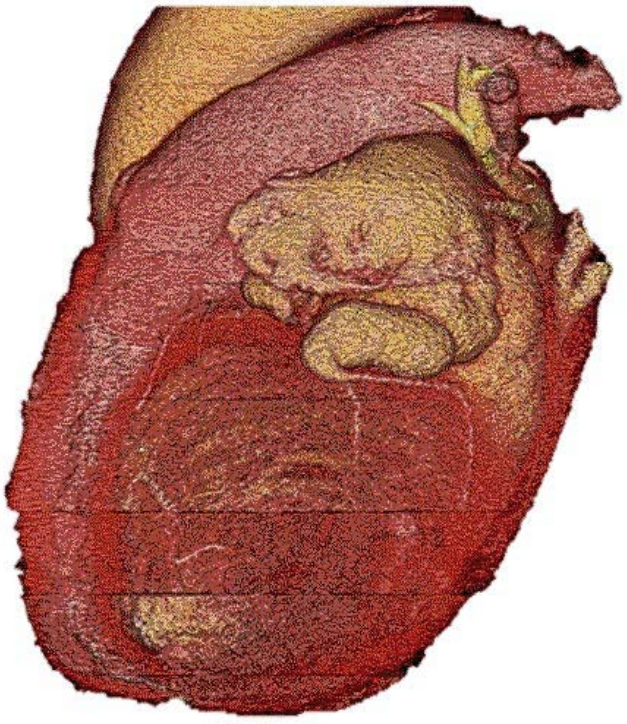


37

Heart failure as an acquired coronary fistula manifestation in the adulthood: a rare case of a coronary arterial fistula

MJ Rodriguez[1]; EJ Pardo Aparicio[2]; LA Medina[3]; MD Ocampo Gonzalez[3]
[1]Foundation Cardioinfantil, Cardiology, Bogota, Colombia; *[2]universidad de Santander, Medicina General, bucaramanga, Colombia*; *[3]Fundación Cardiovascular de Colombia, Santander, Bucaramanga, Colombia*

Coronary artery fistula is a direct precapillary connection between a branch of a coronary artery with the lumen of a cardiac chamber or with one of the vessels located around it (1). Coronary fistulas correspond to 0.002% of the general population and 0.4% of all cardiac malformations. (2). The other variant is due to acquired fistulas that occur as a result of coronary angioplasty, coronary revascularization, after a heart transplant, a rare myocardial biopsy, they can be secondary to trauma with the passage of transcutaneous catheters. (1) (3) Located mainly in the right coronary artery (55%), in the left coronary artery (35%) (4) with the most common drainage site, the right ventricle (45%), the right atrium (25%), the pulmonary artery (15%)) and the left atrium or left ventricle in less than 10% of cases (5). The majority of fistulas are isolated, tend to be asymptomatic and incidentally detected, they can be associated to different manifestations depending on the physiopathological mechanism as the short circuit from left to right, which often causes congestive heart failure due to volume overload (6) or in other cases a coronary "steal" syndrome with myocardial ischemia and possible angina or ventricular arrhythmias. (7) (8)68-year-old male patient, first time in our heart failure department, chest pain, arterial hypertension, unidentified heart failure, permanent atrial fibrillation, dextrocardia-levocardia, wound by left thoracoabdominal firearm and a traumatic diaphragmatic hernia, three years ago had been presenting heart failure required hospitalizations, disease modifying therapy, its etiology an incidental finding. Transthoracic echocardiography with presence of coronary fistula with continuous flow at the trunk level, the left coronary to the left atrium was dilated and a dilated left ventricle with moderate eccentric parietal hypertrophy and preserved systolic function with ejection fraction of 55%, arteriography showed the right coronary as a single vessel due to the collaterals to the anterior descending and Circumflex, which are not filled by antegrade circulation and the left coronary artery presents a giant fistula that starts from the trunk of the left coronary artery and it is connected to the left atrium, Angio-Tac was asked for; but not done because of atrial fibrillation, tac with three-dimensional reconstruction was done, left coronary trunk is dilated, as the proximal portion of the first diagonal, the circumflex artery which is connected to the inferior aspect of the left auriculilla, anterior descending artery, first and second diagonal and marginal obtuse artery, are small caliber, with filiform opacification. Based on the findings we conclude that the heart failure episodes are due to coronary steal syndrome in a patient with an acquired fistula after a gun shot, so it was proposed to perform coronary revascularization of the DA and circumflex with ligature of the left main coronary artery.



computed tomography coronary fistula

38

ICD and heart transplantation in a child with ARVC

A Mikhaylov[1]; R Tatarskiy[1]; D Lebedev[1]; I Nikitina[1]; E Vasickina[1]; K Chueva[1]
[1]Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation

Introduction Arrhythmogenic right ventricular cardiomyopathy (ARVC) is predominantly a genetically determined cardiac disease that is characterized by fibrofatty replacement of the right ventricular (RV) myocardial tissue and by high incidence of ventricular arrhythmias (VA) that can lead to sudden cardiac death (SCD).

Case report A 12-year-old asymptomatic female patient presented with a pathological ECG at an annual school check-up (repolarization abnormalities, PVCs). Right heart chamber enlargement (RV from parasternal position 47mm, 4-chambers position 50mm, RA 63/64mm), and reduction of both ventricles' ejection fraction (EF) - LVEF 40%, TAPSE 1,0 cm - were observed upon further examination.
Various types of arrhythmia started taking place: atrial flutter, polymorphic PVCs, and VT episodes with syncope and a heart rate of up to 240 beats per minute. At the age of 13, a single-chamber ICD was implanted. Genetic testing marked 859R and 23321 mutations in the PKP-2 gene. Endomyocardial biopsy (EMB) showed fibrofatty replacement of tissue with residual myocytes < 40%.
Further on, the patient has been hospitalized multiple times due to hemodynamic instability caused by various arrhythmias and heart failure (HF) progression. HF medication, antiarrhythmics and anticoagulants were administered. ICD was also helpful – there were 6 effective ATP-therapies.
The patient was put on the heart transplant list at the age of 14 due to the severe deterioration of her HF, further reduction of both ventricles' EF, life-threatening cardiac arrhythmias, and ineffectiveness of drug treatment.
While on the waiting list, her condition deteriorated further.
Echocardiography had been consistently registering gradual enlargement of right heart chambers (RV from parasternal position 58mm, 4-chambers position 67mm, RA 77/89mm), pericardial effusion. The frequency of atrial flutter episodes was increasing. At the age of 15 the patient received mechanical circulatory support system due to the increasing severity of biventricular dysfunction (LVEF up to 20%, TAPSE 0,3 cm).
The patient was hemodynamically stable during the use of EXCOR. After 8 months, an orthotopic heart transplantation was performed using the bicaval technique. The ICD lead was dissected together with vena cava superior; the ICD itself was removed along with the remaining part of the lead.
Conclusion This case shows the efficacy of the complex approach that included various diagnostics and treatment methodologies.
Diagnostic procedures, such as genetic study and EMB allowed us to confirm the diagnosis and determine the further treatment strategy. The implanted ICD prevented SCD from VT. Further systematic follow up and timely optimization of antiarrhythmics and HF drugs helped maintain a stable condition for a certain period. EXCOR served as a bridge to the heart transplantation.
Currently, the patient is being supervised in our center for close follow up and therapy optimization.

39

Mechanical circulatory support before and after heart transplantation

N Natallia Piatrovich[1]; L Shestakova[1]; Y Ostrovsky[1]
[1]Republican Scientific and Practical Centre of Cardiology, Department of extracorporeal blood circulation, Minsk, Belarus

Background: Mechanical circulatory support (MCS) is a surgical method of treatment severe heart failure, in which central hemodynamics supported by the work of implantable or external pump. MCS is used as 'mechanical bridge' to heart transplantation or as a rescue in the development of complications in post-transplant period.
Methods: A 64-year-old man with ischemic cardiomyopathy after coronary artery bypass using internal mammary artery (2007), implantation of cardioverter-defibrillator (2013) was bridged to LVAD (Heart Mate II; 2014) and was listed for heart transplantation. In 2018 LVAD system was stopped due to thrombosis. Term of work was 1249 days. There was a certain remodeling of LV, it´s pumping function was preserved without deterioration. 5 months later he underwent well cross-matched orthotopic heart transplantation. Donor cold ischemia time was 301 min. During 288 min of reperfusion patient developed signs of poor cardiac output and worsening lactic acidosis requiring escalating doses of cardiotonic drugs (dobutamine 6 mcg / kg / min, noradrenaline 0,2 mcg / kg / min). LVEF 25%, RVEF 40%, the inability to disable CPB, AP 69/61 mm Hg, CVP 12 mm Hg, PAP 17/10 mm Hg, SpO2 80-83%. CI 1,0 l / min / m^2, LVSWI 8,2 g * m / m^2, RVSWI 0,29 g * m / m^2. Due to depressed biventricular function patient was subsequently connected to peripheral veno-arterial ECMO with a distal leg perfusion system.
Results: Successful wean off ECMO after 73 hours. Stay in ICU was 22 days, in hospital -31 days. Complications: encephalopathy with coordination disorders, psychoorganic syndrome, pneumothorax, esophageal bleeding, erosive tracheitis, bilateral diffuse-focal bronchitis. The patient was discharged with improvement of condition.
Problems: 1) Irregular evaluation of the effectiveness of anticoagulant and disaggregant therapy during LVAD can be a reason of massive thrombosis or bleeding. 2) Absence of round-the-clock technical and clinical support to patients with MCS can lead to untimely troubleshooting and deterioration of the patient´s condition. 3) Choosing the best option of mechanical support for primary graft dysfunction.
Discussion: 1) It is very important to carefully monitor the patient´s condition and to evaluate the functions of all organs and systems. 2) It is necessary to select the optimal anticoagulant and antiplatelet therapy. 3) High qualified and coordinated work of all specialists (surgeon, perfusiologist, resuscitator, cardiologist and rehabilitologist) significantly increases hospital survival rate.
Conclusions: Mechanical circulatory support is the only effective method of treating patients with end-stage chronic heart failure and contraindications to direct heart transplantation. This is especially significant in conditions of shortage of donors. In case of primary graft failure MCS provides preservation and restoration of function of donor heart. It improves in-hospital survival in perioperative period of heart transplantation.

Extracorporeal support life support. Insights form ventricular support with ecmo, levitronix and heartmate 3 in a patient with fulminant myocarditis and poor prognostic indicators

GC German Camilo Giraldo[1]; L Salazar[2]; A Figueredo[2]; C Pizarro[2]; LE Echeverria[2]
[1]Valle del Lili Foundation, Cali, Colombia; *[2]Industrial University of Santander, Ventricular assistance, Bucaramanga, Colombia*

Introduction: Extracorporeal Life Support can provide an opportunity to maintain life in patients who are not candidates for heart transplant. However, circulatory assistance is not available worldwide. A 22-year-old Ukrainian sailor was working on a cargo ship that travelled from Panama in Central America to Santos in Brazil. When the ship was returning to Central America, he developed general malaise and flu-like symptoms, progressive oedema and dyspnea to NYHA 4. The cargo ship stopped in the coast of Colombia (South America) 4 weeks later in a terciary health centre in Barranquilla, Colombia. He had a cardiorespiratory arrest and was resuscitated for 20 minutes, returning to spontaneous circulation. The shock persisted, a diagnosis of fulminant myocarditis was made. The medical team contacted the cardiovascular surgery team in Floridablanca (Colombia). The ECMO team travelled to collect the patient in an air ambulance. Veno-arterial cannulation with ECMO system was performed prior to patient transfer. Problems: Haemodynamic monitoring showed a raised Pulmonary Capillary Wedge Pressure (PCWP), high central venous pressure and a very low cardiac index and output. ECMO support improved cardiac index and lowered the requirement of vasopressors, however, severely raised PCWP was noted with left ventricular end-diastolic pressure of 30 mmHg. A levitronics Centrimag device was implanted, achieving improvement with PCWP and central venous pressure to near normal levels. Additionally, it allowed early endotraqueal extubation, nutritional recovery and physical therapy. Despite the extracorporeal assistance, the level of bilirrubin continued to rise, peaking at 30.9 mg/dl at the seventh day with lactate 4 mmol/L, but returned to normal levels after a week. After 4 weeks, weaning from hemodynamic support was not possible so a heartmate 3 device was implanted, as foreign, he could not be heart transplanted in Colombia. Implications: Myocarditis has different clinical presentations, from mild symptoms, to death, and its prognosis ranges from full clinical recovery to advanced heart failure. A published retrospective analysis of mortality in mechanical supported patients, found that high lactate levels (≥ 2.25 mmol/L), and bilirubin ≥10mg/dl were associated with high mortality and especially higher predictive accuracy, when at least two out of three markers were increased. Bilirubin levels higher than 10 mg/dl were associated with survival probability around 10% to 180 days. Conclusion: a comprehensive reference center for mechanic circulatory support is needed and not yet worldwide available. In Colombia, cardiovascular foundation in Floridablanca Colombia has experience wit short, middle and long term support, greater than other latin american countries.

41

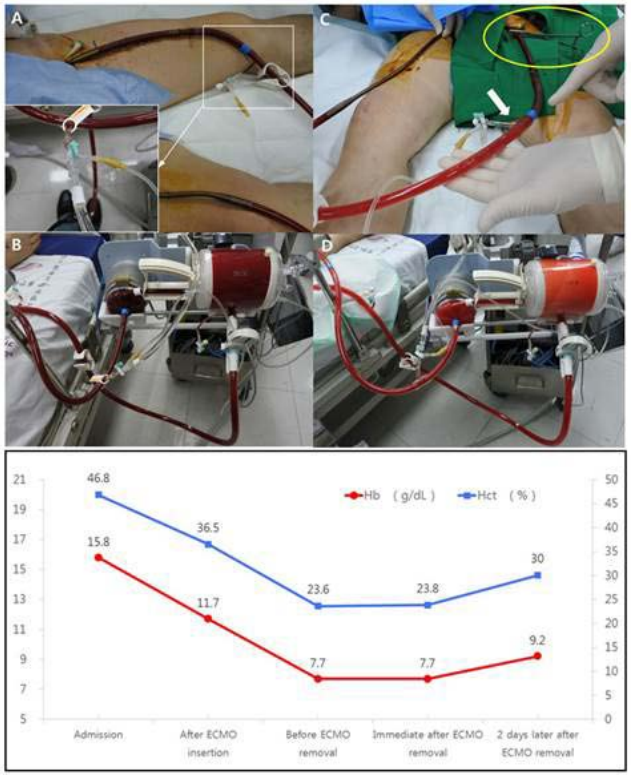
Blood-loss minimizing removal technique of extracorporeal membrane oxygenation circuit in a patient unable to receive blood transfusions because of religious belief

SM Park[1]; MH Jung[1]; MS Kim[1]; HH Choi[1]; KS Hong[1]; H Lee[2]
[1]Hallym University, Chuncheon Sacred Heart Hospital, Chuncheon, Korea (Republic of); *[2]Gumi Cha Hospital, Cardiology, Gumi, Korea (Republic of)*

Background: Extracorporeal membrane oxygenation (ECMO) has been widely used to maintain cardiac and/or pulmonary functions in patients with cardiopulmonary collapse. If the patient doesn't accept the blood transfusion even at the risk of death due to any cause, medical team could not help taking up the challenging clinical situation for the patient.
Case: A 61-year-old male came to the emergency room (ER) complaining loss of consciousness and severe dyspnea. In social history, his religion is Jehovah's witness. On arrival at ER, he developed a generalized seizure and cardiac arrest. The cardiac rhythm was recovered 3 minutes after CPR. However, hypoxia was not improved despite mechanical ventilation with high oxygen flow while his vital signs looked stable without any inotropic support. The level of hemoglobin (Hb) and hematocrit (Hct) was 15.8 mg/dL and 46.8% respectively. A chest computed tomography (CT) scan to evaluate the cause of sudden collapse revealed massive

pulmonary thromboembolism. We decided to apply ECMO (Capiox EBS®, Terumo, Tokyo, Japan) for respiratory support. The guardian strongly refused any type of blood transfusion according to his religious belief. Emergency veno-venous (VV) type ECMO was applied. Simultaneously performed coronary angiography showed no significant lesion. At the 3 days of hospitalization, global oxygenation was improved with minimal support by ECMO and the level of Hb and Hct was decreased to 7.7mg/dL and 23.6%. We removed ECMO using blood loss minimizing technique during decannulation as follows; after first venous access cannula was clamped, total 600cc of saline was continuously and slowly infused to EMCO circuit till the whole circuit was fulfilled with saline. Then, return venous cannula was clamped and both cannulae were carefully removed at zero motor speed. The level of Hb and Hct was increased up to 9.2mg/dL and 30.0% respectively 2 days later. There is no significant hemodynamic change after ECMO removal.

Conclusion: Our blood loss minimizing ECMO removal technique with careful and continuous saline infusion into circuit would be greatly helpful in critical patients who cannot accept blood transfusion due to any reason.



Circuit removal and change of hemoglobin

42

Clinical case of multiple thrombi in amphetamine-associated cardiomyopathy

N Nataliia Dovganych[1]; S Kozhukhov[1]
[1]*National Scientific Center 'M.D. Strazhesko Institute of Cardiology', Kyiv, Ukraine*

Background. Cardiotoxicity after amphetamines use has been presented mainly by acute coronary syndrome, arrhythmias, hypertension, cardiomyopathy, however its thromboembolic complications are rare. We describe a case of amphetamine cardiomyopathy resulting in heart failure (HF) and complicated by multiple thrombus. Case description. A previously healthy 32-year-old male without cardiac risk factors was admitted with progressive dyspnea on minimal exertion tachycardia, edema and a preliminary diagnosis of dilated cardiomyopathy with HF. There was no evidence of a familial dilated cardiomyopathy. He denied any drug abuse initially, but later confessed oral consumption of amphetamine-type stimulants during the last 3 years in a non-specified quantity. 2-D echocardiography displayed cardiac dilatation, left ventricle (LV) severe systolic dysfunction (ejection fraction (EF) 26%) with total hypokinesis, apical LV thrombus (2.4×1.7 cm), multiple thrombi in right ventricle and atrium, pulmonary hypertension. Chest X-ray revealed cardiomegaly with right-sided pleural effusion. Anticoagulants (low-molecular-weight heparin and warfarin) and heart failure treatment (diuretics, angiotensin receptor II blocker and b-blockers) were started. On day 2 of in-hospital stay - progressive worsening with chest pain, tachycardia and polypnea. A thorax contrast T scan showed signs of pulmonary embolism and confirmed thrombi in right and left heart chambers. During in-hospital stay patient demonstrated liver insufficiency (10-fold increase of transaminases) and coagulopathy with anticoagulant's dose correction. On the 10th day patient was discharged home in stable condition. At 2 month follow-up patient presented asymptomatic, with HR 75 bpm; 2D-echocardiography showed partial LV thrombus resolution and no RV thrombus, though LV function was not recovered (EF 29%).
Conclusion. Amphetamine toxicity on myocardium should be taken into account as a possible risk of cardiomyopathy with LV dysfunction and thromboembolism in young patients with symptoms of acute dyspnea, tachycardia and thoracic pain. In this case early and optimal anticoagulation therapy decreased risk of thrombosis progression. Prolonged HF treatment and long-term monitoring are required to achieve LV function recovery and coagulation control.

Discussion: - Could right-heart thrombi be equal to diagnosis of pulmonary embolism?
- Should early anticoagulation therapy be started even in asymptomatic patients?

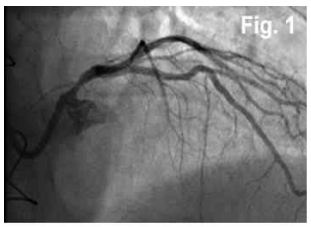
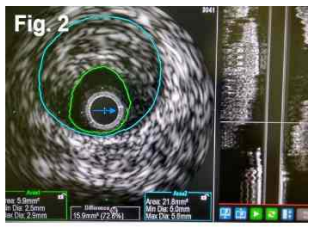
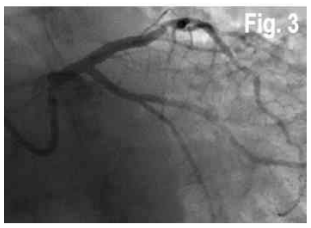
Intravascular Ultrasound As An Effective Tool Of The Left Main Critical Lesion Detection In A LVEF-preserved Allograft Within Cardiac Allograft Vasculopathy Surveillance. PCI Management Of The Case.

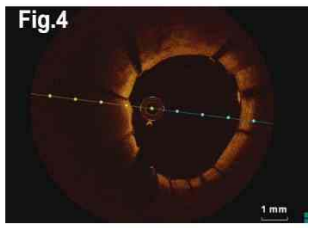
A Aliaksei Barysevich[1]; O Polonetsky[1]; V Stelmashok[1]; A Zakharevich[1]; A Zatsepin[1]; N Strygo[1]; E Kurlianskaya[1]; L Rachok[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Introduction And Background: early detection and treatment of transplant coronary arterial vasculopathy is of vital significance as it is a major cause of death among long-term outcomes after heart transplantation. Classic symptoms of myocardial ischemia are usually absent due to allograft denervation. As many noninvasive modalities and invasive coronary angiography are proven to be relatively insensitive the role of intravascular imaging is hard to overestimate.









A 57 years old patient was admitted to the hospital because of progressing dyspnea and weakness on minimal physical exertion. According to anamnesis he had orthotopic heart transplantation due to dilated cardiomyopathy (08.2010), diabetes mellitus 2 type, gouty arthritis, mild arterial hypertension, latent chronic renal failure. Initial assessment included ECHO which showed preserved LVEF (69%) with normokinesis of the LV wall. Coronary angiography via transradial access (fig.1) showed intermediate stenosis of the distal part of LM. Then the patient proceeded

to intravascular ultrasound (IVUS) of the LM which showed minimum lumen area of 5.9 mm2 (73% stenosis) (fig.2). After a Heart team presentation between the options of CABG, PCI and retransplantation we decided to switch to PCI of the Left Main coronary artery. We used single stent technique. Optimal drug eluting stent apposition to the vessel wall was achieved with balloon postdilatation within proximal optimization technique under optical coherence tomography (OCT) control with final minimum lumen area of 15 mm2. (fig.3)
The patient was discharged on the day 2 without any complications. The telephone follow-up 4 months after the procedure showed significant clinical improvement.

Conclusion: - patients with previous heart transplantation need regular routine surveillance in order for early cardiac allograft vasculopathy detection because of frequent atypical clinical manifestation
- in medium to long-term follow-up invasive intravascular assessments contribute much to evaluation of "intermediate" angiographic lesions
- PCI is the adequate and effective mode for revascularization in case of local critical lesion of the main coronary vessels including LM due to CAV
- final high pressure in-stent postdilatation with non-compliant balloon leads to optimal stent expansion especially followed by OCT-control (fig.4)

Moderated Poster Session - Acute heart failure

External validation and comparison of the CardShock and IABPII shock risk scores in real-life cardiogenic shock patients

M Mercedes Rivas Lasarte[1]; J Sans-Rosello[1]; E Collado Lledo[2]; V Gonzalez Fernandez[3]; J Fernandez Martinez[1]; F Noriega Sanz[4]; F Hernandez Perez[5]; J Segovia[5]; A Viana[4]; RM Lidon[3]; A Ariza[2]; A Sionis[1]
[1]Hospital de la Santa Creu i Sant Pau, Cardiology Department, Barcelona, Spain; *[2]University Hospital of Bellvitge, Cardiology, Barcelona, Spain*; *[3]University Hospital Vall d'Hebron, Cardiology, Barcelona, Spain*; *[4]Hospital Clínico San Carlos, Cardiology, Madrid, Spain*; *[5]University Hospital Puerta de Hierro Majadahonda, Cardiology, Madrid, Spain*

Funding Acknowledgements: Instituto de Salud Carlos III, CIBERCV

Background: The recently published CardShock and the IABPII-Shock scores have shown a good performance in predicting short-term mortality. To date, they have not been compared in a large cohort of real-life patients.
Methods: This is a multicenter retrospective cohort study of CS patients.
Results: The 696 patients with complete data were analyzed. Acute Coronary Syndrome (ACS) was the main cause of shock in 62% of patients. The main characteristics of patients are summarized in the table. The Cardshock risk score and the IABPII risk score were good in-hospital mortality predictors with similar Areas Under the ROC Curve in ACS patients (AUC: 0.742 vs 0.752, p=0.551). The discrimination performance dropped when the scores were applied to non-ACS patients (0.648 vs 0.619, respectively p=0.310). Calibration was acceptable for both scores (non-significant Hosmer-Lemeshow test).

Characteristics of the study population

	ACS434 patients62%	Non-ACS262 patients38%	p-value
Age (years), mean (SD)	68 (13)	61 (16)	<0.0001
Hypertension	281 (65%)	133 (51%)	<0.001
Diabetes	183 (42%)	100 (38%)	0.298
Smokers	159 (37%)	71 (27%)	0.028
Renal insufficiency	61 (14%)	61 (23%)	0.002
Previous myocardial infarction	77 (18%)	63 (24%)	0.044
Previous heart failure	46 (10%)	151 (58%)	<0.001
Cardiac arrest	119 (27%)	25 (13%)	<0.001
CardShock risk score, mean (SD)	5 (2)	4 (2)	<0.0001
IABPIIshock risk score, mean (SD)	2.8(1.8)	2.0 (1.6)	<0.0001
Dobutamine	392 (90%)	237 (90%)	0.953
Invasive mechanical ventilation	275 (63%)	156 (60%)	0.314
Renal replacement therapy	80 (18%)	53 (20%)	0.543
IABP	245 (56%)	82 (31%)	<0.001
LVAD or BiVAD (Levitronix)	14 (3%)	28 (11%)	<0.001
In-hospital mortality	198 (45%)	112 (43%)	0.460

Conclusions: The Cardshock and the IABPII shock risk scores were good predictors of in-hospital mortality. The lower ability of both scores to predict the short-term prognosis in non-ACS patients may be related to their marked heterogeneity.

45

Adverse Dose Dependent Effects of Morphine Therapy in Acute Heart Failure

O Oren Caspi[1]; NR Naami[2]; EA Halfin[2]; DA Aronson[1]
[1]Rambam Health Care Campus, Cardiology, Haifa, Israel; *[2]Technion - Israel Institute of Technology, Haifa, Israel*

Aims: Morphine has been a pivotal therapy in acute heart failure (AHF) for more than a century. The evidence for morphine therapy in AHF remains controversial. This study sought to assess the therapeutic effect of morphine on patients with AHF.
Methods and Results: The study used a cohort of 13,788 patients admitted with a primary diagnosis of AHF. Propensity-score-matching was generated using 26 clinical variables. Primary endpoints included in-hospital mortality and invasive mechanical ventilation. Secondary endpoints included non-invasive ventilation, need for inotropes and acute kidney injury (AKI). 761 (5.5%) patients were treated with morphine in the first day following hospital admission. Propensity score matching yielded 672 patient pairs. The incidence of invasive ventilation was higher in the morphine-treated patients (7.4%) than in matched patients in the no-morphine cohort (3.6%), OR 2.13 (95% CI 1.32-3.57, P=0.007). In-hospital mortality was also higher in the morphine group (17.4%) than in the matched no-morphine group (13.4%), OR 1.43 (95% CI 1.05 to 1.98, P=0.024). For both the endpoint of invasive ventilation (Ptrend=0.005) and mortality (Ptrend=0.004), there was a significant linear dose-response relationship for the adverse effect of morphine. Morphine was associated with a significant increase in all secondary outcomes: Non-invasive ventilation (OR 2.78, 95% CI 1.95–3.96); Inotrope use (OR 3.50, 95% CI 2.10–5.82) and AKI (OR 1.81, 95% CI 1.39–2.36). A landmark analysis demonstrated no difference in post-discharge survival between cohorts.
Conclusions: Morphine administration in is associated with significant dose-dependent risk for in-hospital mortality and need for mechanical ventilation.

46

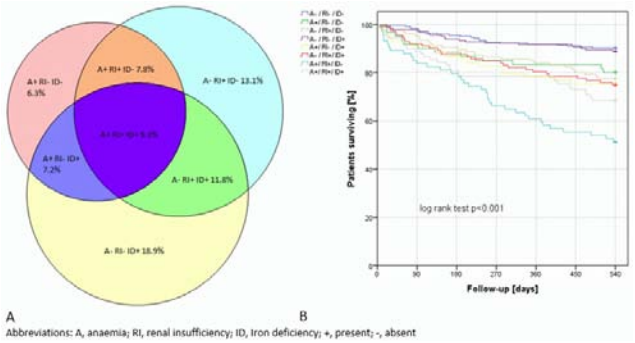
Prevalence and prognostic impact of anaemia, renal insufficiency, and iron deficiency in patients discharged from hospital after decompensation for systolic heart failure

M Maren Kordsmeyer[1]; G Gueder[2]; C Morbach[2]; M Kaspar[1]; S Brenner[2]; S Stoerk[1]; G Ertl[2]; CE Angermann[1]
[1]Comprehensive Heart Failure Center (CHFC), Wurzburg, Germany; *[2]University Hospital of Wurzburg, Wurzburg, Germany*

On behalf of: INH Study Group

Background: Anaemia (A), renal insufficiency (RI), and iron deficiency (ID) are common in heart failure (HF) and associated with adverse outcomes.
Purpose: This study investigated the prevalence of A, RI, and ID and their individual and cumulative impact on 18-month all-cause mortality (ACM) in patients discharged from hospital after admission for decompensated HF with reduced ejection fraction (HFrEF).
Methods: This post-hoc analysis was performed with participants of the Interdisciplinary Network for HF (INH) program. Out of 1022 consecutive patients, 953 patients (68.0±12.3 years, 28.3% female) had laboratory values to define A, RI, and ID available at baseline and were thus included into the current analysis. Follow-up was 18 months (100% complete). Participants were divided into eight groups according to the presence/absence of A (defined as haemoglobin <13/12g/dL in men/women), RI (estimated glomerular filtration rate <60mL/min/1.73m^2), and ID (ferritin <100μg/L or ferritin 100-299 μg/L plus transferrin saturation <20%). For survival analyses log rank tests and multivariable Cox regression models (not shown) were used.

Results: Overall, the baseline prevalence of A was 30.6%, of RI 42.0%, and of ID 47.2%. 74.4% of patients had at least one comorbidity and 9.3% showed all three comorbidities. The figure shows the prevalence of the three comorbidities alone and combined (A) and the individual and cumulative impact on ACM (B). Hazard Ratios indicated that isolated ID had no significant impact on ACM. The risk for ACM was highest in patients with A and RI with or without ID. When only the latter two groups were compared, patients with A and RI without ID appeared to be at higher risk for ACM.
Conclusions: Our findings in this large cohort of survivors of the in-hospital phase demonstrate, that A, RI, and ID are common and often coincide in patients after acutely decompensated HFrEF. Patients with A and RI with or without ID had the highest risk of ACM. The prognostic role of ID after acute cardiac decompensation requires further evaluation.

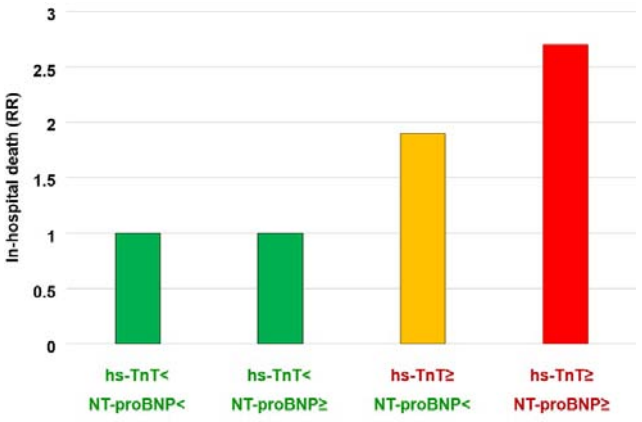


47

Admission high-sensitivity troponin T and NT-proBNP for outcome prediction in acute heart failure

A Aimo[1]; JL Januzzi[2]; C Mueller[3]; O Miro[4]; D Pascual Figal[5]; J Jacob[4]; P Herrero-Puente[4]; P Llorens[6]; D Wussler[3]; N Kozhuharov[3]; Z Sabti[3]; T Breidthardt[3]; G Vergaro[7]; C Prontera[7]; M Emdin[8]
[1]Azienda Ospedaliero-Universitaria Pisana, Scuola di Specializzazione Malattie dell'Apparato Cardiovascolare, Pisa, Italy; *[2]Massachusetts General Hospital, Boston, United States of America*; *[3]University Hospital Basel, Basel, Switzerland*; *[4]University Hospital of Bellvitge, Barcelona, Spain*; *[5]University of Murcia, Murcia, Spain*; *[6]General University Hospital of Alicante, Alicante, Spain*; *[7]Gabriele Monasterio Foundation, Pisa, Italy*; *[8]Sant'Anna School of Advanced Studies, Pisa, Italy*

Background: High-sensitivity troponin T (hs-TnT) reflects the severity of ongoing myocardial damage and is a predictor of outcome in chronic heart failure (HF), while its prognostic value in the acute setting is unclear.
Purpose: To assess hs-TnT as predictor of prognosis in acute HF (AHF).
Methods: The study was a retrospective analysis of individual data of 1449 patients with AHF with hs-TnT measured on admission, deriving from 3 cohorts (2 Spanish, 1 Swiss). Patients received Guideline-recommended treatment for HF. In-hospital death and post-discharge outcome (all-cause and cardiovascular mortality, HF hospitalization, composite of cardiovascular mortality and HF hospitalization at 6, 12 and 24 months) were evaluated.
Results: Patients were aged 78±10 years, 51% were men, and 45% had an history of coronary artery disease. Median left ventricular ejection fraction was 50% (interquartile interval 33-60). The index hospitalization was the first manifestation of HF in 31% of patients. Median hs-TnT and NT-proBNP concentrations were 43 ng/L (26-69) and 5660 (2693-12466), respectively. Patients experiencing in-hospital death (n=187, 13%) had significantly higher hs-TnT and NT-proBNP on admission (both p<0.001). The risk of in-hospital death increased by 45% per each doubling of hs-TnT (HR 1.45, 95% confidence interval - CI 1.31-1.59, p<0.001), and by 32% per each doubling of NT-proBNP (HR 1.32, 95% CI 1.17-1.50, p<0.001). Patients with hs-TnT ≥43 ng/L and NT-proBNP ≥5660 ng/L had a 2.7-fold higher risk of in-hospital death (relative risk - RR 2.7, 95% CI 1.7-4.5). Among the 1262 patients discharged, 1024 deaths occurred over a median 11-month follow-up (4-22). hs-TnT ≥43 ng/L was a strong, independent predictor of all-cause death at 6, 12 and 24 months, and the composite of cardiovascular death or HF hospitalization at 6 and 24 months. hs-TnT ≥43 ng/L also improved risk reclassification.
Conclusions: The risk of in-hospital death is almost 3 folds higher with admission hs-TnT ≥43 ng/L and NT-proBNP ≥5660 ng/L, and hs-TnT ≥43 ng/L holds strong independent prognostic significance for post-discharge outcome. Admission hs-TnT may help identify patients at higher risk needing an enhanced, individualized therapeutic effort during hospital admission and after discharge.



48

Increased NT-proBNP levels most significantly predict 30-day mortality in admitted out-of hospital-cardiac-arrest (OHCA) patients

A Andreja Sinkovic[1]; KM Novak[2]; M Martincic[2]
[1]University Medical Centre Maribor, Maribor, Slovenia; *[2]University of Maribor, Medical faculty, Maribor, Slovenia*

Background. After cardiac arrest (CA) complex post-resuscitation syndromes develope such as brain injury, global cardiac dysfunction, systemic ischemia/reperfusion injury, etc. Brain injury accounts for the majority of deaths, but severe acute post-CA heart failure – in particularly shock - affects more than two-thirds of OHCA patients. Mortality from post-CA shock and brain injury share similar risk factors, which are related to the quality of the rescue process. Shock after CA, requiring vasopressor support is consistently associated with an adverse outcome after CA and is the result of pre-existing cardiac pathology, ischemia/reperfusion injury with activated inflammatory cytokine and catecholamines, etc. Hemodynamic stabilization after CA aims to reverse the effects of myocardial dysfunction and to improve systemic perfusion. Purpose. To evaluate the less clear association between acute heart failure and 30-day mortality of admitted OHCA patients.
Methods. We retrospectively included 110 OHCA patients, admitted in 2013 to 2016 (72.7% men, mean age 65.6±13,8 years, age ≥ 65 years 72.7%) to the medical ICU. We registered their clinical and laboratory data, treatments, 30-day mortality and predictors of 30-day mortality.
Results. In admitted OHCA patients witnessed CA was observed in 71.8%, ventricular fibrillation or pulseless ventricular tachycardia (VF/VT) as the cause of OHCA in 63.6%, asystole in 35.5%, resuscitation ≥20 minutes in 21.8%, admission lactate ≥ 6 mmol/L in 30%, acute coronary syndromes (ACS) in 55.5%, PCI in 40%, admission mechanical ventilation (MV) in 87.3%, in-hospital peak NT-proBNP ≥ 400pmol/l in 23.6%, in-hospital acute heart failure 82.7% and shock in 75.5%, ischemic brain injury in 62.7% and acute kidney injury (AKI) in 32.7%. 30-day mortality of admitted OHCA patients was 48.2%. 30-day mortality in comparison to survival was associated significantly with age ≥ 65 years (54.6% vs 29.8%, p=0.02), with asystole as the cause of CA (56.6% vs 15.8%, p<0.001), resuscitation ≥ 20 minutes (32.1% vs 12.3%, p=0.017), admission MV (98.1% vs 77.1%, p=0.001) and lactate ≥ 6 mmol/l (45.3% vs 15.8%, p=0.005), in-hospital acute heart failure (98.1% vs 68.4%, p<0.001), shock (84.9% vs 66.7%, p=0.029), AKI (47.2% vs 19.3%, p=0.002), brain injury (96.2% vs 31.6%, p<0.001), peak NT-proBNP ≥ 400pmol/L (30.2% vs 17.5%, p=0.003), but significantly less likely with ACS (43.4% vs 66.7%, p=0.042), VF/VT as the cause of CA (43.4% vs 82.5%, p<0.001) and admission EF ≥ 35% (24.5% vs 43.9%, p=0.031). Logistic regression (forward Wald) demonstrated that peak hospital NT-proBNP ≥ 400pmol/l was most significant independent predictor of 30-day mortality (OR 29.8, 95% CI 2.377-372.762, p=0.009).
Conclusions. Acute heart failure was present in more than 80% of admitted OHCA patients – in particular in early non-survivors. Increased levels of NT-proBNP, reflecting acute heart failure, most significantly predicted 30-day mortality in admitted OHCA patients.

49

The clinical use of bioactive adrenomedullin and proenkephalin A in detecting congestion, renal dysfunction and clinical outcomes in two independent acute heart failure cohorts

J Molvin[1]; A Jujic[2]; S Navarin[3]; O Melander[2]; G Zoccoli[3]; O Hartmann[4]; A Bergmann[4]; J Struck[4]; E Bachus[2]; S Di Somma[5]; M Magnusson[1]
[1]Skane University Hospital, Dept of Cardiology, Malmo, Sweden; [2]Lund University, Dept of Clinical Sciences, Malmo, Sweden; [3]Sapienza University of Rome, Rome, Italy; [4]Sphingotec GmbH, Hennigsdorf, Germany; [5]GREAT Network, Rome, Italy

Background: In an acute heart failure (AHF) setting, proenkephalin A 119-159 (PENK) has emerged as a promising prognostic marker for predicting worsening renal function (WRF), while biologically active adrenomedullin (bio-ADM) has been proposed as a potential marker for congestion.
Aims: We examined the diagnostic value of bio-ADM in congestion and PENK in WRF, and investigated the prognostic value of bio-ADM and PENK regarding mortality, rehospitalisation, and length of hospital stay in two separate European AHF cohorts.
Methods: Bio-ADM and PENK were measured in 530 subjects hospitalized for AHF in two cohorts: the Swedish Heart and Brain Failure Investigation study - Malmö (HARVEST- Malmö) (n=322, 30.1% female; mean age 75.1 years; 12-months follow-up) and the GREAT Network Rome study (n=208, 54.8% female; mean age 78.5 years; no follow-up).
Results: PENK was associated with WRF (AUC 0.65, p<0.001). In multi-variable logistic regression analysis of the pooled cohort, PENK showed an independent association with WRF (adjusted odds ratio [aOR] 1.74, p=0.004).
Bio-ADM was associated with peripheral oedema (AUC 0.71, p<0.001) which proved to be independent after adjustment (aOR 2.30, p<0.001).
PENK was predictive of in-hospital mortality (OR 2.24, p<0.001).
In the HARVEST-Malmö cohort, both PENK and bio-ADM were predictive of one-year mortality (aOR 1.34, p=0.038 and aOR 1.39, p=0.030). Furthermore, bio-ADM was associated with rehospitalization (aOR 1.25, p=0.007) and length of hospital stay (β 0.702, p=0.005).
Conclusion: In two European AHF cohorts, bio-ADM and PENK perform as suitable biomarkers for early detection of congestion severity and WRF occurrence, respectively, and are associated with pertinent clinical outcomes.

50

Heart failure day treatment centre (HFDTC), a novel service design

T Teresa Castiello[1]; G Williams[2]; A Krakowiak[2]
[1]Croydon Health Services NHS Trust and Kings College Hospital, London, United Kingdom of Great Britain & Northern Ireland; [2]Croydon Health Services NHS Trust, Cardiology , London, United Kingdom of Great Britain & Northern Ireland

BACKGROUND: Heart Failure (HF) is one of the most common causes of acute hospital admissions and bed occupancies. A local Audit was carried out to analyse the HF population in a London borough and to investigate the causes of non-elective HF admission, in order to prevent them and to promote a more effective management. The Audit identified a fragile population, insufficiently referred to HF specialists (51%), with poor compliance (21%) and in sub-optimal therapy (27%) suggesting a large number of preventable admissions. The majority of non-elective admission had sub-acute presentation with relatively mild symptoms or signs of failure. The key objective of the Audit was to guide a novel service design. The Heart Failure Day Treatment Centre (HFDTC) was suggested.
AIM AND HYPOTHESIS: The aim was to design a service to improve quality and reduce admission rate and costs. We hypothesised that the HFDTC would reduce non-elective admission by 10% and readmission rate within 30 days by 30%, increasing patients access to specialised care, with significant reduction of in-patient bed demand.
SERVICE DESIGN: The HFDTC has been established by the multi-disciplinary HF team to operate as a HF specialist nurse (HFSN) run and HF-consultant led facility. The HFDTC aims to provide timely access to specialist care and better patient experience, in line with national and international benchmark.
Inclusion and exclusion criteria identify a sub-acute group of HF population (main inclusion: patients in threatening admission mode, already under HF Team). Patients who meet criteria receive a 'business card' with contact details and opening times; patients are enabled to self-refer to the service or be referred by general practitioner or hospital clinician. The first point of contact with the patient is the HFSN, who can escalate to the HF physician. The HFDTC offers a full range of hospital treatment, such as imaging, bloods and medical therapy. Patients can have single or multiple accesses to the HFDTC until they are ready to be discharged back to community.CHALLENGE: Service design implies a delicate balance between quality and cost-effectiveness. Funding limitation, agreement among 'Providers' and 'Commissioners', estimation of demand and capacity and coordination with the co-existing teams are the most relevant challenges.
SERVICE EVALUATION: Economic evaluation, key performance indicators, data monitoring and quality data will be collected and analysed with a specifically designed Audit Tool and through patient questionnaires.
CONCLUSION: The HFDTC is the first of its kind in the UK and acts effectively as day hospital for patients with established diagnosis of HF. It guarantees prompt assessment and treatment by the HF Team with the aim to reduce acute HF admissions which will result in a decrease in costs and improvement in patients quality of life. The cost-effectiveness of this model will be analysed with the support of a designed Audit Tool.

5-year outcome of acute heart failure in korea: results from the korean acute heart failure registry (KorAHF)

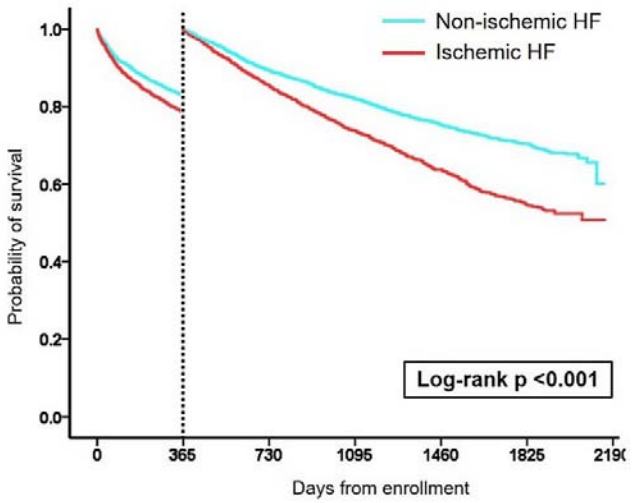
GC Oh[1]; HJ Cho[1]; HY Lee[1]; MC Cho[2]; BH Oh[3]
[1]Seoul National University Hospital, Cardiology, Seoul, Korea (Republic of); [2]Chungbuk National University Hospital, Cardiology, Cheongju, Korea (Republic of); [3]Mediplex Sejong Hospital, Cardiology, Incheon, Korea (Republic of)

On behalf of: KorAHF
Funding Acknowledgements: This research was supported by the Korea Centers for Disease Control and Prevention

Background: Heart failure (HF) is associated with high mortality and cost, and even with current advances in medicine, the prevalence of HF is on a steady increase.Purpose: The Korean Acute Heart Failure registry (KorAHF) evaluated the clinical characteristics, treatment, and long-term outcome of patients hospitalized for acute HF.

Baseline characteristics	Ischemic (n=2113)	Non-ischemic (n=3512)	p
Age (years)	71.9 ± 10.9	66.5 ± 15.9	<0.001
Male (%)	61.5	48.2	<0.001
Diabetes	56.2	30.2	<0.001
LVEF≤40%	68.7	55.9	<0.001
ACEI/ARBs at discharge	67.1	65.2	0.147
Beta-blockers at discharge	54.7	47.0	<0.001
MRAs at discharge	39.6	48.1	<0.001
In-hospital mortality (%)	6.5	4.1	<0.001

LVEF, left ventricular ejection fraction; ACEI, angiotensin converting enzyme inhibitor; ARB, angiotensin receptor blocker; MRA, mineralocorticoid receptor blocker.



Survival according to etiology

Methods: Patients were prospectively enrolled in 10 university hospitals nationwide from March 2011 to February 2014. A total of 5 625 patients were followed up for up to 5.9 years. Primary outcome was death and readmission due to HF. Total

outcome of hospitalized HF patients, along with outcomes in relation to etiology and left ventricular ejection fraction (LVEF) were analyzed. The proportion of patients adhering to guideline-recommended therapies were additionally assessed.
Results: The mean age of patients was 68.5 (14.5) years, and 53.2% were male. De novo HF compromised 52.2% of the patients, and 37.6% of total enrolled patients had ischemic etiologies. Acute HF due to ischemic etiologies showed poorer in-hospital, 1-year, and long-term outcomes compared with non-ischemic HF. In relation to LV systolic function, 57.4% of the patients were classified as heart failure with reduced ejection fraction (HFrEF). For these group of patients, there were no differences in survival compared to either heart failure with mid-range or preserved ejection fraction. Regarding oral treatment, guideline-based therapies such as renin-angiotensin system blockers, beta-blockers, and mineralocorticoid receptor blockers were used in 73, 55, and 51% of patients with HFrEF.
Conclusion: This registry provides information on the current status and prognosis of acute HF in Korea. Although the proportion of ischemic HF is lower than previous global registries, these patients have worse outcome, suggesting that closer monitoring and treatment is needed.

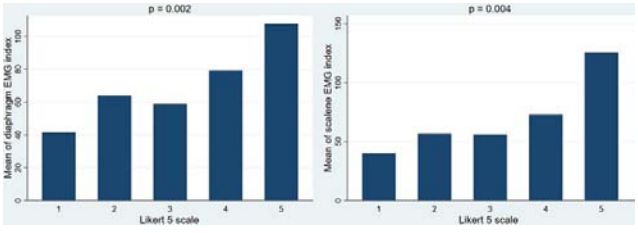
Surface respiratory electromyography and dyspnea in acute heart failure patients

D Luiso[1]; JA Villanueva[2]; LC Belarte-Tornero[1]; A Fort[3]; Z Blazquez-Bermejo[4]; S Ruiz[1]; R Farre[2]; J Rigau[5]; J Marti-Almor[1]; N Farre[1]
[1]Hospital del Mar, Department of Cardiology, Barcelona, Spain; *[2]University of Barcelona, Biophysics and Bioengineering Unit, School of Medicine, Barcelona, Spain*; *[3]University Hospital de Girona Dr. Josep Trueta, Department of Cardiology, Girona, Spain*; *[4]University Hospital 12 de Octubre, Department of Cardiology, Madrid, Spain*; *[5]Research, Development, and Innovation Department, Sibel S.A.U., Barcelona, Spain*

Background/Introduction Dyspnea is the most common symptom among hospitalized patients with heart failure (HF) and represents a therapeutic target. Despite this, there is no instrument that allows an objective evaluation of dyspnea. Studies performed in respiratory patients and mechanically ventilated patients suggest that the measurement of electromyographic (EMG) activity of the accessory muscles with surface electrodes correlates well with dyspnea and offers prognostic information. However, no data is available about the usefulness of this technique in HF.
Purpose Our aim was to demonstrate a relationship between respiratory muscles EMG activity and dyspnea severity in acute HF patients.
Methods Prospective and descriptive pilot study carried out in adult patients admitted for acute HF at the Emergency department. Measurements were carried out with a cardio-respiratory portable polygraph including nasal prongs to assess ventilation, pulse oximetry and EMG surface electrodes for measuring the activity of accessory (scalene and pectoralis minor) and main (diaphragm) respiratory muscles. After the sensors were in place, the patient was asked about his/her dyspnea sensation by means of the Likert 5 questionnaire. Then, data were recorded during 3 min of spontaneous breathing and after immediately asking the patient to breathe at maximum effort for several cycles. This assessment was carried out within the first 24 hours of admission, at 24 hours and at day 5. Clinicians were blinded to the EMG measurement, which was analyzed offline following patient discharge. An index to quantify the activity of each respiratory muscle was computed. A higher EMG index was expected as dyspnea intensity increased.
Results The study was carried out in 28 patients. Dyspnea score with Likert 5 scale decreased along the three measured days: from a median 2 (1.5-3) in day 1 to a median 1 (1-2) in day 5 (p=0.011). Out of the total 84 possible measurements per muscle (28 patients x 3 days/patient), reliable EMG results were obtained in 74 cases (88%) for pectoralis minor and diaphragm and in 63 cases (75%) in scalene. Diaphragm and scalene EMG index showed a significant direct relationship with dyspnea score: the higher the Likert 5, the higher EMG index (p=0.002 and p=0.004 respectively). The pectoralis minor muscle did not show a significant linear relationship with Likert 5 scale (p=0.075).
Conclusion(s) In our pilot study, diaphragm and scalene EMG activity was linearly associated with increasing severity of dyspnea. Surface respiratory EMG could be a useful tool to objectively quantify dyspnea in acute HF patients.

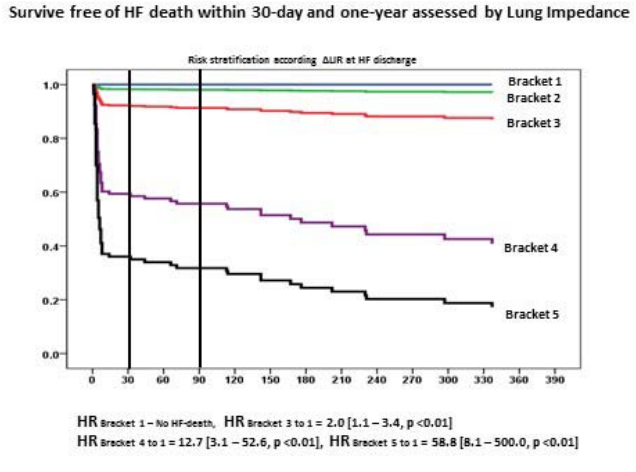


EMG index along Likert 5 scale

53
Residual congestion on discharge for Heart Failure assessed by impedance technique predicts 30-day and one-year Heart Failure death. Results of IMPEDANCE-HF extended trial

M Michael Kleiner Shochat[1]; D Kapustin[2]; M Fudim[3]; M Kazatsker[1]; Y Levy[1]; A Asif[1]; I Kleiner[4]; JM Weinstein[4]; G Panjrath[5]; A Roguin[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]University of Toronto, Internal disease , Toronto, Canada*; *[3]Duke University Medical Center, Cardiology, Durham, United States of America*; *[4]Saroka Medical Center, Cardiology, Beer Sheva, Israel*; *[5]George Washington University School of Medicine and Health Sciences, Cardiology, Washington, United States of America*

The aim of secondary analyses of the IMPEDANCE-HF extended trial was to find out if residual congestion on discharge for HF could predict 30-day and one-year Heart Failure death.
The analysis of IMPEDANCE-HF extended trial was based on the data collected during the index hospitalization for HF. The IMPEDANCE-HF extended trial was a randomized controlled single-blinded trial of HF with reduced LVEF patients. Inclusion criteria were LVEF $\leq$ 45%, NYHA class II-IV and patients were hospitalized for HF within 12 months (ClinicalTrials.gov NCT01315223). Half of the patients (N=145) were assigned to the active Lung Impedance (LI)-guided treatment arm where clinicians were based therapy on LI level. The other half was assigned to the control arm where LI values were recorded but not conveyed to the clinical treatment team. In the case of hospitalization, LI was recorded in all patients at discharge. The decisions regarding discharge and choice of treatment were at the discretion of the hospital staff.
A non-invasive impedance device was used in this study to assess the lung fluid content. Unlike the existing impedance devices, the present device has the ability to differentiate a true signal from the lungs from the noise signal of surrounding chest wall. Such approach enables to measure a small change in lung fluid content. A method to determine individual "dry" baseline LI (BLI) for each HF patient has been reported. BLI for each patient was used to calculate a new parameter, the LIR= [(current LI/BLI)-1] $\times$100%, which determinate the degree of pulmonary congestion in time of measurement.
Method. Degree of pulmonary congestion at discharge for HF hospitalization was divided into 5 brackets. (1) LIR= 0 to – 18% - minimal interstitial edema (IE), (2) LIR= - 18.1 to -28% - mild IE, (3) LIR= -28.1 to – 38 – moderate IE, (4) LIR= -38.1 to -48% - severe IE to mild alveolar edema (AE) and (5) LIR < -48.1% - moderate AE.
Results: LI-guided patients were followed for 61.9.4$\pm$39.6 months and control patients for 46.7$\pm$33.3 months (p<0.01) accounting for 269 and 470 HF hospitalizations, respectively (p<0.01). Twenty-five (38%) and 57 (66%) HF-associated deaths were recorded during follow-up (p<0.01) representing a mortality rate of 0.03 and 0.1 per patient×year follow up in the LI-guided and control group, respectively (p<0.01). Probability of HF death within 30-day and one year is presented on figure. Conclusion The degree of pre-discharge pulmonary congestion as assessed by LI is a very robust and reliable predictor for 30-day and one-year HF death.



Heart Failure associated death

Rapid Fire 2 - Biomarker: present and future

Role of neprilysin in myocardial tissue Renin-Angiotensin-System (RAS) of the failing heart

N Noemi Pavo[1]; H Arfsten[1]; G Goliasch[1]; PE Bartko[1]; S Prausmueller[1]; G Spinka[1]; JF Novak[1]; A Cho[1]; R Wurm[1]; M Poglitsch[2]; M Huelsmann[1]
[1]Medical University of Vienna, Vienna, Austria; *[2]Attoquant Diagnostics, Vienna, Austria*

Background. Prognosis of patients with HFrEF remains poor despite recent advances in pharmacologic therapy as the introduction of angiotensin-receptor neprilysin-inhibitor (ARNI). The Renin-Angiotensin-System (RAS) is dysregulated in HF with elevated AngII levels as a central driver of disease progression. The myocardium is capable of synthesizing all RAS components resulting in tissue specific angiotensin levels. Neprilysin (NEP), among other tissue enzymes, is implicated in the RAS peptide cascade, catalyzing the generation of Ang1-7 which counteracts the deleterious effects of AngII. The specific role of neprilysin in myocardial tissue RAS of the failing heart and has not been investigated yet.
Methods. Angiotensin metabolite levels (RAS-fingerprints), enzyme regulation and metabolic activities were investigated in myocardial samples of end-stage HFrEF patients undergoing heart transplantation with a mass-spectrometry based method.
Results. Eighteen patients were included (n=10 with ACE-I and n=8 without RAS-blockade). Median age was 54(IQR:45-61) years and 83% of patients were male. Median NT-proBNP levels were 4572(IQR:1559-10684) pg/ml. Myocardial AngI, Ang1-7, Ang1-5 and AngIV levels were below the detection limit for all samples. AngII and AngIII levels were comparable between the ACE-I and no-RAS-blocker group [AngII: 72.4(IQR:54.6-139.1) vs 45.7(IQR:22.5-123.8),p=ns and AngIII 19.0(IQR:5.0-46.5) vs 23.4(IQR:5.0-64.5),p=ns]. Moreover, there were no significant differences in angiotensin metabolization patterns between patients receiving ACE-I compared to no RAS-blocker therapy, indicating similar regulation of tissue RAS enzymes between the groups (Figure1A). The formation of AngII from AngI was mainly chymase dependent with conversion rates of 99.4(IQR:77.0-254.1) (pg/µg protein)/h for the ACE-I and 141.8(IQR:67.9-369.2) (pg/µg protein)/h for the no RAS-blockade group, whereas ACE-related generation of AngII was under the detection limit. The formation of Ang1-7 from AngI was mediated by both NEP and propel-endopeptidase (PEP), however the contribution of NEP was significantly higher [5022(IQR:5002-5286) (pg/µg protein)/h vs 3555(IQR:3351-3849) (pg/µg protein)/h,p=0.005 for the ACE-I group and 4729(IQR:4438-6135) (pg/µg protein)/h vs 3601(IQR:3052-4182) (pg/µg protein)/h,p=0.012 for the no RAS-blockade group]. Interestingly, there were no differences in tissue enzymatic activities between the different therapy groups, as already indicated by the metabolization patterns.

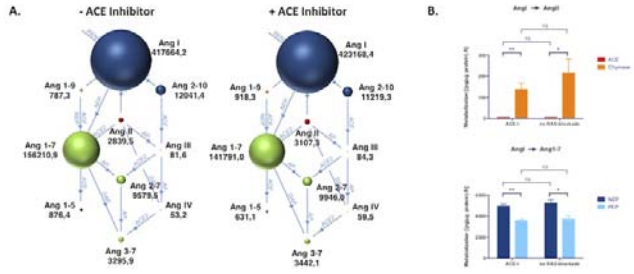

Figure 1

Conclusions. AngII levels are high in the failing heart and levels are independent of an established RAS-blocker therapy with ACE-I. In contrast to plasma, AngII formation of the tissue is mainly chymase dependent, whereas ACE seems to play an unsignificant role. Neprilysin has a substantial role in the generation of beneficial Ang1-7 from AngI. The impact of NEP inhibition by ARNI on tissue RAS and mechanism of action have to be further investigated.

The value of tubular maximum phosphate reabsorption capacity, a functional proximal tubular parameter in heart failure

JE Emmens[1]; MH De Borst[2]; K Damman[1]; AA Voors[1]; JM Ter Maaten[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The); *[2]University Medical Center Groningen, Nephrology, Groningen, Netherlands (The)*

Funding Acknowledgements: BIOSTAT-CHF was funded by the European Commission [FP7-242209-BIOSTAT-CHF; EudraCT 2010-020808-29].

Introduction Renal proximal tubule cells are early and essential sensors of kidney injury. We aimed to study the clinical determinants of tubular maximum phosphate reabsorption capacity (TmP/GFR), a functional proximal tubular parameter, as well as its association with renal and cardiovascular outcome in patients with heart failure (HF).
Methods In 2,085 HF patients (BIOSTAT-CHF), we established determinants of TmP/GFR (calculated using the formula originally devised by Bijvoet), and its association with worsening renal function (WRF; defined as >25% eGFR decrease), tubular damage (defined as plasma Neutrophil Gelatinase-Associated Lipocalin [NGAL] doubling between baseline and 9 months), and outcome independent of confounders.

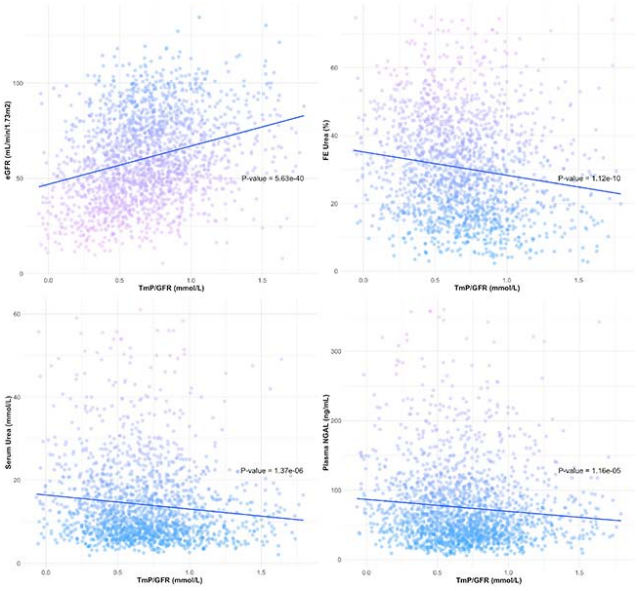

Figure 1. Correlation plots of TmP/GFR

Results Low TmP/GFR (<0.80 mmol/L) was observed in 1,392 (67%) patients. Patients with lower TmP/GFR had more advanced HF, lower eGFR, and signs of increased tubular damage. Lower TmP/GFR was strongly associated with lower serum phosphate, and to a lesser extent with higher fractional urea excretion, higher serum urea, lower haemoglobin, higher urinary creatinine, and lower plasma NGAL (all P<0.001). TmP/GFR was independently associated with tubular damage (OR 2.36 [1.20–4.67], P=0.014 per log TmP/GFR decrease), but not with WRF. Decreased TmP/GFR was independently associated with increased mortality (HR per log

decrease 3.05[1.52–6.13], P=0.002), HF hospitalisation (HR per log decrease 2.17 [1.05–4.50], P=0.036), and the combined endpoint (HR per log decrease 1.83 [1.04–3.22], P=0.035) after adjustment for the BIOSTAT risk model, serum phosphate, and eGFR.
Discussion TmP/GFR is a novel marker for proximal tubular function that is associated with severity of HF, and with glomerular and tubular function. TmP/GFR predicts tubular damage, as well as poor outcome, suggesting that TmP/GFR might be a suitable, novel parameter to monitor proximal tubular function in HF.

56
The risk of bias of current novel circulating biomarker studies for the detection of HFpEF and left ventricular diastolic dysfunction

M Henkens[1]; S Remmelzwaal[2]; AJ Ballegooijen Van[2]; E Robbinson[3]; A Barandiaran Aizpurua[1]; AG Raafs[1]; JAJ Verdonschot[1]; MR Hazebroek[1]; S Sanders-Wijk Van[1]; VPM Empel Van[1]; R Vos[4]; HP Brunner-La Rocca[1]; JWJ Beulens[2]; SRB Heymans[1]

Funding Acknowledgements: Cardiovasculair Onderzoek Nederland (CVON)

Background: Diagnosing Heart Failure with preserved Ejection Fraction (HFpEF) remains a major challenge. Natriuretic peptides lack positive predictive value for diagnosing this heterogenous syndrome, giving rise to a multitude of research investigating novel circulating biomarkers within this field. However, large variation in methodological quality possibly introduced bias, hindering the potential implementation of novel biomarkers into the clinics.
Purpose: To determine the risk of bias of papers evaluating novel circulating biomarkers for the diagnosis of HFpEF or left ventricular diastolic dysfunction (LVDD).
Methods: Extensive literature searches using the PubMed and Embase databases until February 2018 were performed for this systematic review. Inclusion criteria were: (i) use of novel blood/urine biomarker for the detection of HFpEF or LVDD in humans (ii) use of a control population (e.g. healthy controls or heart failure with reduced ejection fraction) (iii) use of Dutch or English language. Studies were excluded if they: (i) did not state a diagnostic performance measure (ii) studied an acute HF population (iii) were a (systematic) review, meta-analysis, editorial or conference abstract. Two reviewers independently screened titles, abstracts and full-text and evaluated the methodological quality using the QUADAS-2 checklist. This checklist determines the risk of bias within four domains: patient selection, index test, reference standard, and patient flow & timing. The risk of bias was rated low, intermediate or high individually for the four domains. Inconsistencies in the quality assessment between the reviewers were resolved by discussion and consensus between all authors.
Results: A total of 1978 articles derived from the search, 260 papers were analyzed as full text. Finally, 18 papers were eligible. These included a wide range of HFpEF-related biomarkers (Figure 1a). The risk of bias within the different domains is presented in Figure 1b. A total of 6 papers showed high risk of bias within all four domains and all papers had at least one domain with high risk of bias. Main determinants of bias included the wide use of case-control designs, excluding difficult to diagnose patients, not making use of a pre-specified cut-off value for the index test without performing external validation, and the use of an inappropriate reference standard.
Conclusions: The majority of current diagnostic HFpEF and LVDD papers have a high risk of bias. This indicates that standardized research methodologies (e.g. avoidance of case control designs, performance of external validation and making use of the same reference standards) are urgently needed to determine the incremental value of novel biomarkers within this field.

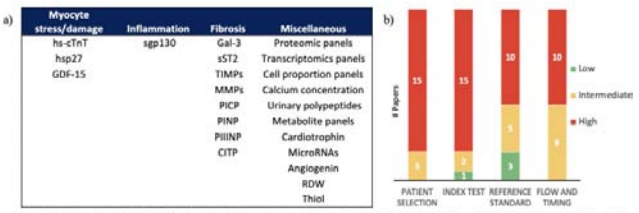

Figure 1 a) Biomarkers included within this study: High-sensitive cardiac troponin T(hs-cTnT), Heat shock protein 27 (hsp27), Growth differentiation factor 15 (GDF-15), Soluble glycoprotein 130 (sgp130), Galactin-3 (Gal-3), Soluble ST2 (sST2), Tissue inhibitors of MMP levels (TIMPs), Matrix metalloproteinases (MMPs), Serum carboxy (PICP) amino (PINP) and carboxytelo (CITP) peptides of procollagen type I, Amino peptide of procollagen type III (PIIINP), red cell distribution width (RDW). b) Overview of risk of bias of current studies that focus on the diagnostic value of novel blood/urine biomarkers for the detection HFpEF or LVDD subdived in the domains: Patient Selection, Index test, Reference standard and Flow and timing.

57
The effect of liraglutide on natriuretic peptides and copeptin in heart failure patients

R Roni Nielsen[1]; A Jorsal[1]; RS Tougaard[1]; J Rasmussen[2]; M Schou[3]; L Videbaek[4]; I Gustafsson[5]; A Flyvbjerg[6]; H Wiggers[1]; L Tarnow[7]; C Kistorp[8]

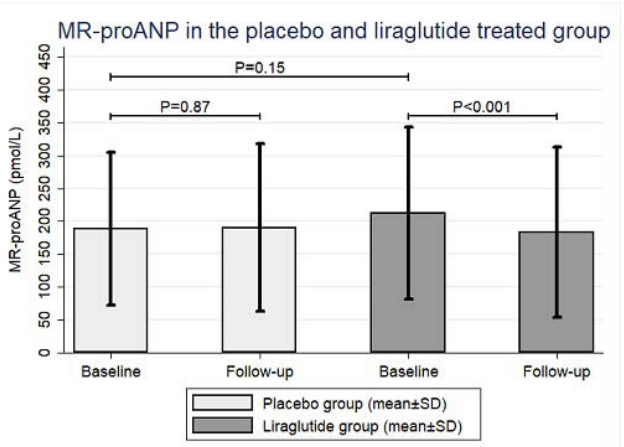
Funding Acknowledgements: Unrestricted grant from Novo Nordisk A/S

Background: Treatment with the anti-diabetic therapy GLP-1 analogue liraglutide improves the prognosis in patients with type 2-diabetes (T2D). Despite this, two randomized trials enrolling more than 500 heart failure patients with reduced ejection fraction (HFrEF) did not demonstrate any effect of liraglutide on left ventricular ejection fraction (LVEF) or B-type natriuretic peptide. However, liraglutide treatment may be associated with changes in other parameters of neurohormonal activation as midregional-pro-atrial natriuretic peptide (MR-proANP), midregional-pro-adrenomedullin (MR-proADM) and copeptin, being part of a system controlling fluid and hemodynamic homeostasis.

Table 1

	Liraglutide (n=104)	Placebo (n=104)	Delta	P-value
MR-proANP (pmol/L)	-22.6±5.9	0.7±4.7	-23.4 (-38.2, -8.5)	0.002
MR-proADM (nmol/L)	0.00±0.01	0.03±0.01	-0.03 (-0.07, 0.01)	0.10
Copeptin (pmol/L)	0.30±0.83	0.91±0.42	-0.61 (-2.45, 1.24)	0.52
E/e'	-0.72±0.48	0.68±0.44	-1.39 (-2.68, -0.11)	0.03
LAVI (ml/m2)	-2.5±0.9	1.8±1.0	-4.2 (-6.9, -1.5)	0.002

Changes from baseline to follow-up in each study group



MR-proANP levels

Purpose: To investigate the effect of liraglutide treatment on MR-proANP, MR-proADM and copeptin in HFrE patients, and to evaluate the possible association with changes in diastolic function.
Methods: The LIVE-study investigated the effects of liraglutide in HFrEF patients. In a double blinded clinical trial, 241 patients with LVEF ≤ 45 % were randomized to receive liraglutide (1.8 mg. daily) or placebo for 24 weeks. For this substudy, MR-proANP, MR-proADM and copeptin were analysed at baseline and after 24 weeks.
Results: LVEF was 34±9% and 31 % had T2D with no difference between study groups (P=0.13, P=0.67 respectively). At baseline, MR-proANP was 201±124 pmol/L, MR-proADM 0.90±0.29 nmol/L and copeptin 9.8 [5.6, 16.4] pmol/L with no difference between study groups (P>0.05 for all). At follow-up,

MR-proANP decreased by approximately 10% (P<0.001) in the liraglutide treated group as compared to no change in the placebo group (P=0.87) with a significant difference in changes between groups (P=0.002, Table 1, Figure 1). Changes in MR-proADM (P=0.10) and copeptin (P=0.52) did not differ between groups. A decrease in E/e' (P=0.03) and left atrial volume index (LAVI) (P=0.002) was observed in the liraglutide treated group as compared to the placebo group. The observed effect on MR-proANP was confined to HF patients with T2D (P=0.003).
Conclusion: Treatment with liraglutide decreased the levels of MRproANP and improved parameters of diastolic function in patients with T2D and heart failure with reduced ejection fraction.

58
Improvement of existing strategies to prevent heart failure after myocardial infarction: a potential role for thrombopoietin

L Malinova[1]; N Furman[1]; P Dolotovskaya[1]; N Puchinyan[1]; T Denisova[2]
[1]Saratov State Medical University, Research institute of cardiology, Saratov, Russian Federation; *[2]Saratov State Medical University, Saratov, Russian Federation*

Patients who survived myocardial infarction represent an extremely high-risk group for heart failure development. Currently existing strategies to prevent heart failure (HF) after myocardial infarction include early completed revascularization, optimal medication to prevent rethrombosis, atherosclerosis progression, fibrosis and myocardial remodeling, and biomarker approach to identify patients with increased risk of HF development. Thrombopoietin (TPO) is primarily known as the principle regulator of thrombopoiesis. However, recent studies suggest that TPO possesses pleotropic effects. For instance, several animal model studies provided evidence that TPO reduced cardiac damage caused by doxorubicin.
The purpose of the study was to investigate possible cardioprotective effects of thrombopoietin (TPO) in patients with ST-segment elevation myocardial infarction (STEMI) undergoing percutaneous coronary intervention (PCI), as to improve existing strategies to prevent HF after myocardial infarction.
Methods. 118 male patients with STEMI undergoing PCI were involved in the study. TPO and TPO receptor (MPL) levels were measured serially at admission, after PCI and on the 7th day. At these points, we also measured myoglobin (MYO), troponin I (TNI), creatine kinase MB (CKMB) and brain natriuretic peptide (BNP). Platelet function was assessed by impedance and luminescence aggregometry. Follow-up period was 18 months.
Results. In 57.5 % of patients TPO level at admission exceeded 250 pg/mL (TPO high). Low and high TPO subgroups were comparable by age 59 (46; 68) vs 58 (48; 65) y.o., p = 0.613, frequency of antiplatelet pretreatment (p = 0.694), total ischemic time (p = 0.089) and incidence of comorbidities. Collagen-induced aggregation was weaker in high TPO patients: 2 (1; 5) vs 5(3; 9) ohms, p = 0.049. CKMB, TNI and BNP were significantly lower in high TPO subgroup with p levels = 0.023; 0.050; and 0.032 respectively. This distinction maintained through all period of observation. At baseline patients with high TPO seemed to present more severe course of STEMI: incidence of cardiogenic shock, pulmonary edema, malignant arrhythmias was 28% vs 9%, but at discharge frequency of mid-range and reduced ejection fraction in combination with elevated BNP level was significantly higher in low TPO subgroup (p = 0.014). TPO at admission revealed positive correlation with BNP level at discharge (p = 0.047). There was weak but significant correlation between TPO and time before end-point (HF manifestation, rethrombotic event; R = 0.3, p=0.023). Low TPO indicated higher risk of HF manifestation within follow-up period (OR 1.8 CI 1.1 to 2.3). Conclusion. Received data support hypothesis that TPO possesses cardioprotective effects, and could improve heart failure risk stratification in STEMI patients. Our results encourage further investigation of TPO role in postinfarction heart failure, and the development of TPO and related compounds as cardiac protective agents.

Funding Acknowledgements: National Institute for Health Research Leicester Cardiovascular Biomedical Research Centre overall project Grant (IRS_BRU_0211_20033)

Background: Tenascin-C is reportedly associated with adverse outcomes in heart failure with reduced ejection fraction but its role in heart failure with preserved ejection fraction (HFpEF) is unknown.
Purpose To assess whether plasma Tenascin-C is related to prognosis in HFpEF.
Methods Prospective, observational study of age and sex-matched HFpEF n=130 and controls n=42 (age 73±9, males 50%) who underwent comprehensive phenotyping with plasma biomarkers, cardiovascular magnetic resonance imaging, echocardiography and 6-minute-walk-testing (6MWT).
Results Tenascin-C was higher in HFpEF (13.7 vs 11.1 ng/ml [controls], p<0.0001). During follow-up (median 1428 days), there were 61 composite end-points (21 deaths, 40 HF hospitalizations). 28 univariable predictors were noted (p<0.1). In multivariable Cox regression, Tenascin-C (adjusted hazard ratio [HR] 1.755, 95% confidence interval [CI] 1.305–2.360; p<0.0001) and indexed extracellular volume (HR 1.465, CI 1.019-2.106; p=0.039) were the only parameters that remained significant when added to a base prognostic model comprising age, prior HF hospitalization, diastolic blood pressure, lung disease, NYHA, 6MWT distance, haemoglobin, creatinine, BNP and E/E'.
Conclusions Tenascin-C is a strong prognostic marker in HFpEF

Phosphodiesterase 9A - novel biomarker or potential therapeutic target in patients with heart failure and preserved ejection fraction?

KP Rommel[1]; C Besler[1]; J Moerbitz[1]; H Kirsten[2]; M Scholz[2]; K Kingel[3]; J Thiery[4]; R Burkhardt[4]; P Buettner[1]; V Adams[5]; H Thiele[1]; P Lurz[1]
[1]Heart Center of Leipzig, Internal Medicine / Cardiology, Leipzig, Germany; *[2]University of Leipzig, Institute of Medical Informatics, Statistic and Epidemiology, Leipzig, Germany*; *[3]University Hospital, Institute for Pathology and Neuropathology, Department of Molecular Pathology, Tuebingen, Germany*; *[4]Leipzig University Hospital, Institute of Laboratory Medicine, Clinical Chemistry and Molecular Diagnostics, University of Leipzi, Leipzig, Germany*; *[5]University Hospital Dresden, Dresden, Germany*

Rationale:
Increasing cyclic guanosine monophosphate (cGMP) levels in cardiomyocytes has been suggested as a potential therapeutic approach in patients with heart failure (HF) with preserved ejection fraction (HFpEF). Phosphodiesterase 9A (PDE9A) was recently identified as a novel nitric oxide-independent regulator of cGMP in murine models of hypertrophic heart disease.
Objective: We aimed to characterize PDE9A expression in endomyocardial biopsies (EMB) and peripheral blood mononuclear cells (PBMNC) from patients with different HF phenotypes.
Methods and Results: EMB and PBMNC were obtained from a derivation cohort of patients with HFpEF (n=24), HF with reduced ejection fraction (HFrEF, n=22), inflammatory cardiomyopathy (iCMP, n=24) and patients without HF (n=5). PDE9A expression was increased in EMB and PBMNC from patients with HFpEF as compared to other HF phenotypes or subjects without HF. Endomyocardial PDE9A expression correlated with the inflammatory cell count on EMB, but not with cardiac fibrosis or left ventricular diastolic wall stress. PDE9A expression in PBMNC was increased in patients with higher hsCRP levels and in response to pro-inflammatory stimulation. As a validation cohort, 719 patients with HFpEF and 1,106 subjects without HF were identified from the LIFE-Heart study. PDE9A expression data in PBMNC from this cohort were obtained from a gene expression array and displayed an age-dependent distribution. Following age adjustment, PDE9A expression in PBMNC conferred increased risk for HFpEF with a lower confidence interval for the main effect of 5.9. Notably, lower PDE9A expression in PBMNC was associated with worse survival in patients with HFpEF.
Conclusion: The present findings suggest an inflammation-associated increase in PDE9A expression in EMB and PBMNC from HFpEF patients, with higher PDE9A expression in PBMNC being associated with disease risk after age adjustment, but lower mortality. Whereas PDE9A appears as a marker of prognostic and potential pathophysiological relevance in HFpEF, its role as a treatment target requires further investigations.

Evolution of low risk natriuretic peptide to higher risk - Do we have a phenotype?

N Blake[1]; J Gallagher[2]; C Watson[2]; E O' Connell[2]; M Ledwidge[2]; K Mc Donald[2]
[1]St Vincent's University Hospital, Cardiology Department, Dublin, Ireland; *[2]St Vincent's University Hospital, STOP HF Service, St Vincent's Healthcare Group., Dublin, Ireland*

On behalf of: STOP HF
Funding Acknowledgements: Heartbeat Trust, Ireland

INTRO Natriuretic Peptide (NP) is a strong independent risk factor and predictor of cardiovascular (CV) events. Being a surrogate marker of risk and inherently one of ventricular stretch it also provides assurances related to lower risk once values remain low. The natural history of NP in low NP patients has yet to be defined. Establishing when to retest NP may be a useful way of mapping risk in a sub-population with CV risk factors. PURPOSE Using the STOP-HF cohort we examined the natural history of patients with initially low values of NP to determine the transition frequency to higher risk status and thereby determine retest intervals. METHODS In our retrospective study we utilised the STOP-HF population. Low risk patients (LPs) were defined as those with an initial NP<40 pg/ml, a choice reflecting a value significantly below the cut-off used for intervention in high risk patients in STOP-HF. Transitioners (Ts) were defined by a NP of <40 with a NP >50pg/ml upon repeat annual reassessment. We compare Ts to LPs with a focus on retest intervals and a comparison of hospitalisations for CV and nonCV events. RESULTS Population total of 661 LPs and 171 Ts. Ts were older (54 vs 65, p<0.001), 43% were male (p=0.521). Comorbidity was similar between the groups; DM 22%, HTN 62%, stroke/TIA 4%, atrial fibrillation 1%. NP levels were higher in Ts (11 vs 23 p<0.001). Ts had lower mean heart rate (73 vs 69, p<0.001), but were more likely to be on a beta blocker (15 vs 26%, p<0.001). Ts were prescribed more non-RAAS BP lowering medications (39 vs 49%, p<0.019) with no difference in RAAS medications (ACE/ARB, p=0.768). LAVI was higher in Ts (23 vs 26, p<0.001). Otherwise there were similar ECHO parameters (LVEF>55%). Approximately 4% of patients with an initial BNP<40 transitioned (any BNP>50) each year. From our cox-proportional hazards model, transition potential was dependent on baseline BNP. Those in 10-20 group were 2.5 times more likely versus <10 group. Those in 20-40 group were 7.5 times more likely versus <10 group. To keep the percentage of Ts under 5% at follow-up, recheck BNP should occur at 4 years for those with BNP <10, at 2 years for those with BNP 10-20 and at 1 year for those with BNP 20-40. Event rates were measured from the time of initial NP measurement. Via basic non parametric testing CV (p<0.036) and nonCV admissions (p<0.048) were more frequent in Ts. Events become less significant when correcting per 1000 patient-years and controlling for covariates of age, sex and BNP at baseline. CONCLUSIONS Transition to higher NP occurs in 4% of the population annually. Ts had higher baseline NP, were older, were more frequently on non-RAAS BP medication or beta blockers and had higher LAVI on ECHO. Retest frequency should be pursued at 1, 2, or 4 years respective of baseline BNP to keep the percentage of Ts under 5% at follow up. Retest intervals have been defined to allow for effective re-screening of this changing risk status population.

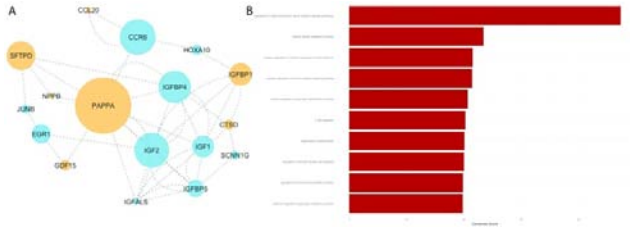
Biomarker correlates of coronary microvascular dysfunction and diastolic dysfunction in heart failure with preserved ejection fraction

J Jasper Tromp[1]; C Hage[2]; S Sanders-Van Wijk[3]; S Svedlund[4]; A Saraste[5]; UL Faxen[2]; M Lagerstrom Fermer[6]; LM Gan[4]; LH Lund[2]; SJ Shah[7]; CSP Lam[1]
[1]National Heart Centre Singapore, Cardiology, Singapore, Singapore; *[2]Karolinska Institute, Stockholm, Sweden*; *[3]Cardiovascular Research Institute Maastricht (CARIM), Maastricht, Netherlands (The)*; *[4]University of Gothenburg, Gothenburg, Sweden*; *[5]Turku University Hospital, Turku, Finland*; *[6]AstraZeneca, Gothenburg, Sweden*; *[7]Northwestern University, Chicago, United States of America*

Background. Limited data is available on the pathophysiological mechanisms and the role of underlying coronary microvascular (CMD) in heart failure with preserved ejection fraction (HFpEF). Therefore, we studied biomarker profiles associated with CMD and associations between left ventricular systolic and diastolic dysfunction and structural derangements in HFpEF.
Methods. We measured 268 biomarkers from different pathophysiological domains (e.g. inflammation, oxidative stress) in 192 patients with stable HFpEF from the prospective PROMIS-HFpEF study. Coronary flow reserve (CFR) was measured with adenosine stress transthoracic Doppler echocardiography. Elastic net regression analyses combined with network and pathway overrepresentation analyses were used to identify key pathophysiological biomarkers and mechanisms associated with CFR as well as global longitudinal strain (GLS), lateral E' and left atrial volume indexed to body surface area (LAVi).
Results. In total, 11 biomarkers were significantly associated with CFR with the strongest predictors being N-terminal pro B-type natriuretic peptide (NT-proBNP),

growth differentiation factor 15 (GDF15), insulin-like growth factor binding protein 1 (IGFBP1) and surfactant protein D (PSPD). Only NT-proBNP was significantly associated with both CFR, LAVi, lateral E' and GLS (P <0.001 for all). Network analyses showed that Pappalysin-1 (PAPPA) was an important hub (Figure A). Insulin-like growth factor receptor pathways and T-cell migration were most strongly associated with CFR (Figure B) in pathway overrepresentation analyses.
Conclusions. In HFpEF, CMD is associated with a unique biomarker profile, related to T-cell migration and insulin-like growth factor receptor signaling. These data highlight IGF signaling and immune cell trafficking as distinct pathophysiological correlates of CMD in HFpEF



63

Serum endotrophin levels in heart failure patients with reduced ejection fraction; a preliminary study

G Gazi Capar[1]; H Eruzun[2]; Y Arman[2]; İ Toprak[2]; U Yilmaz[2]; O Kutlu[2]; İ Aslan[2]; Ş Aydin Yoldemir[2]; Y Kutlu[2]; M Ozcan[2]; S Irmak[2]; G Guven[2]; T Tukek[1]
[1]Istanbul University , Istanbul, Turkey; *[2]Okmeydani Training and Research Hospital, Istanbul, Turkey*

Introduction: Endotrophin, a type VI collagen cleavage product, induces fibrosis, insulin resistance and has tumour-promoting effect. Collagen VI plays a role in cardiac fibrosis. In this study, we aimed to investigate the role of endotrophin in the pathogenesis of cardiac fibrosis by determining its levels in heart failure patients with reduced ejection fraction. We also aimed to determine the possible association between endotrophin and treatment that prevent ventricular fibrosis.
Materials and Methods: Sixty heart failure patients with reduced ejection fraction and twenty-seven volunteers with no cardiac failure were included in this study. In both groups, complete blood count, creatinine, triglyceride, total cholesterol, low density lipoproteins cholesterol, high density lipoproteins cholesterol, glucose, ejection fraction and endotrophin levels were measured. Body mass indexes were calculated. In the determination of Endotrophin levels Enzyme-Linked Immuno Sorbent Assay (ELISA) was performed.
Results: There was no significant difference between the patient and the control groups in endotrophin levels (p:0.35). Participants in the study were divided into three groups according to their ejection fractions: 30% and less, 30-50% and >50% (the control group). These three groups were again divided into two groups, seperately according to usage of renin-angiotensin-aldosterone system blocking drugs. In %30-50 EF Group (p:0,04) and >50% EF Group (p: 0.03), endotrophin levels were significantly statistically lower in patients using renin angiotensin aldosterone system blockers than the patients not using renin angiotensin aldosterone system blockers.
Conclusion: This study is the first study evaluating the relationship between endotrophin and heart failure in the literature. Endotrophin levels were found to be low in the patients using the renin-angiotensin-aldosterone system blockers with heart failure. This may suggest that renin-angiotensin-aldosterone system blockers may affect endotrophin levels and it could have a role of remodelling prevention.

64

Global longitudinal strain predicts future cardiovascular hospitalizations and death in patients with non-ischemic cardiomyopathy and recovered left ventricular ejection fraction: a multicenter study

L Luigi Adamo[1]; M Merlo[2]; F Clemenza[3]; A Perry[1]; E La Franca[3]; L Ajello[3]; D Bellavia[3]; A Boscutti[2]; M Gobbo[2]; A Kraja[1]; G Romano[3]; D Stolfo[2]; J Gorcsan[1]; G Sinagra[2]; D Mann[1]
[1]Washington University School of Medicine, Cardiovascular Division, Department of Medicine, St. Louis, United States of America; *[2]University of Trieste, Cardiovascular department, Trieste, Italy*; *[3]Mediterranean Institute for Transplantation and High Specialization Therapies (IsMeTT), Department for the Treatment and Study of Cardiothoracic Diseases and Cardiothoracic Transplantation, Palermo, Italy*

Background: Patients with recovered left ventricular ejection fraction (LVEF) remain at increased risk for adverse outcomes but we currently have very limited tools to risk stratify them. A prior single center analysis showed that in this patient population an absolute Global Longitudinal Strain (aGLS) ≥ 16 correlates with a decreased risk of redeveloping a depressed LVEF (<50%). However, it is unknown whether this translates into a reduced risk of adverse outcomes.
Purpose: To test the hypothesis that in patients with non-ischemic cardiomyopathy (NICM) and recovered LVEF, aGLS ≥ 16 is predictive of future cardiovascular hospitalizations and all-cause mortality.
Methods: We combined databases from 3 tertiary centers in 2 different countries and identified patients with NICM who initially had a reduced LVEF (<50%), but whose LVEF had increased by at least 10% and normalized (LVEF >50%). Speckle tracking GLS was quantified at the time of LVEF recovery and studied in relation to cardiovascular hospitalizations and death during follow-up.
Results: We identified 222 patients meeting inclusion criteria. Mean reduced LVEF was 31 ± 9%, mean LVEF at the time of EF recovery was 55% (Range 50 to 72), mean aGLS at the time of EF recovery was 13.6 (range 4.1 to 22.7). During a mean follow up of 5.5± 2.74 years, 80 patients had at least one hospitalization for cardiac causes and 39 patients died. During follow up, patients with aGLS ≥ 16 at the time of LVEF recovery had a lower probability of experiencing cardiovascular hospitalizations or death (Odds Ratio 0.50, 95% CI 0.28-0.90, p=0.02). In a time to event analysis, patients with aGLS ≥ 16 had also a lower risk of death for any cause in the first 5.5 years since normalization of LVEF (Log-Rank p<0.01, Fig 1). The reduction in mortality risk persisted with longer follow up but lost statistical significance (p=0.22).
Conclusions: GLS has important prognostic significance in HF patients with non-ischemic cardiomyopathy and recovered LVEF. An abnormal GLS in the setting of recovered LVEF portends an increased risk of cardiovascular hospitalizations and death.

An unusual case of giant cell myocarditis managed with immunosuppression and left ventricular assist device

J Fallon[1]; A Parker[1]; SP Dunn[1]; JLW Kennedy[1]
[1]*University of Virginia Health System, Charlottesville, United States of America*

We describe the case of a 55-year-old female presenting with symptoms of chest tightness and palpitations. Evaluation revealed low-level troponin elevation, non-sustained ventricular tachycardia, and reduced left ventricular ejection fraction. Cardiac catheterization performed during her initial evaluation ruled out coronary artery disease. During a subsequent admission for ventricular tachycardia, she underwent cardiac magnetic resonance imaging, which showed diffuse patchy transmural delayed hyperenhancement compatible with infiltrative cardiomyopathy with a left ventricular ejection fraction of 32.8%, and received a dual chamber implantable cardioverter-defibrillator. Due to concern for myocarditis she underwent endomyocardial biopsy, which revealed a predominantly lymphocytic infiltrate in the cardiac interstitium with no eosinophils or granulomas and multiple areas of myocyte damage suggestive of Lyme carditis, though serologies were negative. She progressively declined over the following year and underwent implantation of a left ventricular assist device (LVAD) as a bridge to transplant. During surgery, a left ventricular apex core biopsy was performed with findings consistent with giant cell myocarditis (GCM) as shown in Figure 1. Unfortunately, she developed high levels of preformed antibodies as a result of surgery, which limited donor availability. She was initially treated with mycophenolate to reduce the antibody burden, it was not effective and she developed leukopenia so was discontinued after a year. She was then treated with rituximab, intravenous immunoglobulin, and plasma exchange for the 4-year interval until transplant. During this time, she experienced a reduction and then stabilization of symptoms and an increase in systolic function, however she was unable to tolerate wean of LVAD support. She was ultimately transplanted at age 60, she is now four years post transplant without evidence of recurrent GCM.

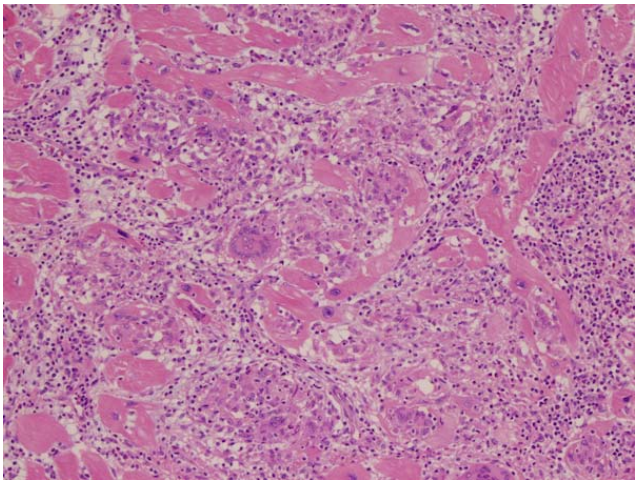

Figure 1

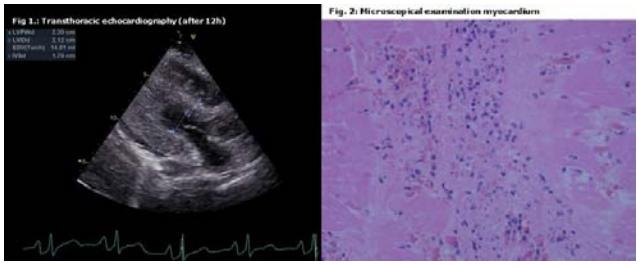
The search is ongoing for accurate and timely ways to diagnose and effectively treat GCM. Randomized clinical trials evaluating immunosuppression regimens to manage GCM face challenges in enrollment due to the rare nature of the disease. This case describes an atypical presentation of giant cell myocarditis, where cardiac function deteriorated over more than a year. Management with LVAD and immunosuppression resulted in significant improvement in cardiac function, though insufficient to allow device explant. This benefit was observed in the setting of using an alternative immunosuppression regimen to what has often been reported for GCM. This case adds to the evidence of alternative treatment modalities outside of immunosuppression that may support functional and symptomatic recovery as well as prolonging time to transplant.

158

Sudden cardiac death: a case of fulminant myocarditis

E Evelyne Meekers[1]; R Achten[1]; R Cartuyvels[1]; P Koopman[1]; E Benit[1]; P J Timmermans[1]
[1]*Jessa Hospital, Hasselt, Belgium*

Introduction: A 31-year-old man collapsed while driving his car, without any warning signs. His co-driver immediately started basic life support. The first documented rhythm was ventricular fibrillation (VF). Repeated external defibrillation was unsuccessful and resuscitation was continued while patient was transported to the hospital.
Management: Veno-arterial extracorporeal life support was initiated after a resuscitation time of 90 minutes. Quick-look transthoracic echocardiography (TTE) displayed an akinetic heart without major signs of hypertrophy. Coronary angiography demonstrated normal coronary arteries. TTE 12 hours later showed extensive wall thickening and a depressed systolic function (EF<10%, fig. 1). Despite optimal medical treatment and circulatory support, brain death was diagnosed 48 hours after admission and the patient died after withdrawal of life support.
There was no relevant medical or family history. Autoimmune and toxicological screening came back negative. At necropsy, the heart weighed 520 grams. The left ventricular wall was thickened. The myocardium had grey-yellow streaks due to hemorrhagic and necrotic tissue. Microscopical examination revealed fulminant lymphocytic infiltration and myocytolysis (fig. 2). Postmortem viral PCR on the myocardial tissue was negative.
Differential diagnosis: Sudden cardiac death (SCD) is usually caused by an acute coronary syndrome (ACS). However, the patient had no risk factors and coronary angiogram ruled out ACS. Structural heart disease can also cause SCD, but TTE on admission showed normal ventricular dimensions. Nevertheless, pronounced myocardial hypertrophy was documented on TTE 12 hours after admission. Given the autopsy results, this is likely due to severe myocardial edema caused by fulminant myocarditis, which likely caused the VF. Underlying genetic cardiac conditions are possible, but genetic examination is still ongoing.



Conclusion: Myocarditis is a not uncommon cause of SCD. Patients mostly have symptoms such as chest pain or heart failure. Rarely, SCD may be the first presenting symptom. Echocardiographic signs suggestive of myocarditis can be absent on admission, but can evolve quickly. TTE is necessary in the workup for myocarditis and should be repeated if there is a high index of suspicion. Current guidelines advocate endomyocardial biopsy when myocarditis is complicated by life-threatening arrhythmias. In this case, the lack of structural myocardial abnormalities on

admission was deemed sufficient to withhold myocarditis as a possible cause of SCD. PCRs for cardiotropic viruses were negative, but tissue was obtained after patient passed away.
This case should alert clinicians to the possibility of myocarditis as cause of SCD and repeat TTE if no definite diagnosis has been made. There should be a low threshold to perform an endomyocardial biopsy and start cardiogenetic work-up in the acute setting if coronary atherosclerosis is ruled out in patients with VF.

159
Constrictive pericarditis secondary to prior Mycobacterium tuberculosis infection: the use of multimodality imaging to guide pericardectomy

A Salem[1]; C Nunn[1]; A Kardos[1]
[1]Milton Keynes Hospital NHS Trust, Milton Keynes, United Kingdom of Great Britain & Northern Ireland

A 66-year-old Somalian lady, with regular non-attendances to cardiology follow up, presented to the Emergency Department with decompensated right heart failure symptoms. Her past medical history was significant for congestive cardiac failure (diagnosed in 2001), previous pulmonary Mycobacterium tuberculosis infection, fully treated in 1990. On examination, she had significant bilateral pitting peripheral oedema up to the sacrum area, as well as evidence of moderate ascites. Her JVP was elevated at 10cm, and a third heart sound as well as a pericardial knock was present with positive Kussmaul sign. Initial bloods demonstrated a Brain Natriuretic Peptide (BNP) of 437pg/ml, the admission chest x-ray showed cardiomegaly and pericardial calcification. Transthoracic echocardiography demonstrated a constrictive physiology with a good systolic left ventricular function. The RV longitudinal function was reduced with moderate tricuspid, and elevated pulmonary artery pressure estimated at 50-55 mmHg.
She was established on a high dose of diuretics, and her heart failure medications were optimised as her fluid balance normalised over the course of a few weeks.
As her symptom burden had decreased, further investigations were undertaken to confirm the aetiology of the heart failure and to discuss her further management.
Coronary angiogram with right and left cardiac catheterisation was undertaken. The right heart catheterisation showed equalization of the diastolic pressure in both left and right ventricles with square root sign and interventricular dependence on deep inspiration (Fig 1. D) . The left ventricular rapid filling wave was noticed to be very deep. The right atrium showed M shape morphology with prominent X and Y descent. and the left heart catheter showed non-obstructive coronary arteries.
Following this, she underwent a functional ECG gated cardiac CT angiography to identify the relationship of the pericardial calcification with the myocardium. The scan demonstrated extensive pericardial calcification surrounding predominantly the right ventricle with some calcified protrusion into the right ventricle free wall (Fig 1. A pre-operative CCTA).
As a result, pericardiectomy was offered with an accepted mortality of 8-12% and an acknowledgement of the potential difficulty in resecting the entire pericardium due to local calcific infiltration of the myocardium into the right ventricle. The patient made an informed decision to proceed and had an uncomplicated partial pericardiectomy and a subsequent marked reduction in symptom burden (Fig 1. C post-operative CCTA).
In conclusion, multimodality imaging techniques not only have an important role to play in the diagnosis of constrictive pericarditis and planning of pericardiectomy, but also in helping clinicians to better determine the peri- and intra-operative risks to allow the patient to make a better informed decision.

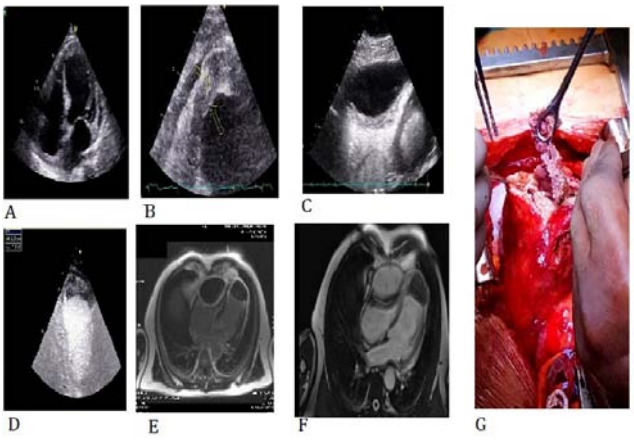
Double trouble: when a thrombus save your life

L Moderato[1]; S Binno[1]; MF Piepoli[2]; R Giacalone[2]; B Borrello[3]; G Pastorini[1]; GQ Villani[2]
[1]University of Parma, Parma, Italy; *[2]Guglielmo da Saliceto Hospital, Piacenza, Italy*; *[3]University Hospital of Parma, Cardiology Department, Parma, Italy*

Funding Acknowledgements: No financial support.

We report a case of a 72-year-old man, who was admitted to intensive care unit from cardiac rehabilitation institute for dizziness and acute onset of pericardial effusion. He had suffered from subacute anterior wall myocardial infarction one month earlier, underwenting unsuccesful revascularization of left anterior descending coronary artery (and succesful PTCA on RCA). The patient was discharged on DAPT and oral anticoagulant for apical thrombosis (figure A-B), with moderate systolic dysfunction and no pericardial effusion.
The patient was asymptomatic at rest, hemodinamically stable; no heart murmurs were audible and no paradoxical pulse was found.Echocardiography showed severe pericardial effusion causing compression of right ventricle free wall (maximal diameter 5.2cm) associated with persistence of left ventricle apical thrombosis; contrast administration showed no pericardial blush excluding a communication with ventricular cavity (Figure C-D).
We performed cardiac magnetic resonance that showed a "double trouble" (Figure E – F): Cine images confirmed the presence of severe hematic pericardial effusion with compression of mid and basal right ventricle free wall and massive left ventricle apical thrombosis (5.09x3,27cm).
The patient was referred to heart surgeon; during surgery a communication between left ventricle apical wall and pericardium was found, closed by a large apical thrombus. The surgeon succesfully performed left ventriculoplasty and pericardial drainage (Figure G).
Surgery confirmed our pathophysiological hypotesis of a sudden left ventricle rupture with pericardial hemorrage, which was immediately closed by apical thrombosis.



161
The price of emulating Hercules: mephentermine associated cardiomyopathy (MAC)

AK Singal[1]; S Deepti[1]; G Sharma[1]; SS Kothari[1]
[1]All India Institute of Medical Sciences (AIIMS), Department of Cardiology, New Delhi, India

PRESENTATION: A 32-year-old professional bodybuilder presented with acute decompensated heart failure preceded by progressively worsening exertional dyspnea for 3 months. He gave history of anabolic androgenic steroids (AAS) use for more than 2 years and mephentermine use for the past 3 months (coinciding with the symptom onset). Examination revealed features of decompensated heart failure - tachycardia (HR 116/min), tachypnea (RR 26/min), hepatomegaly, pedal edema and elevated jugular venous pressure. Auscultation revealed left ventricular (LV) third heart sound and bilateral crepitations.
INVESTIGATIONS: He had polycythemia (Hb 18.2 gm/dL), neutrophilic leukocytosis (TLC 13400) and raised SGOT/SGPT levels. NT-proBNP level was increased (3280 pg/mL). Troponin-I and CPK-MB levels were within normal limits. Chest radiograph showed cardiomegaly with pulmonary venous hypertension (Figure 1A). Electrocardiogram showed sinus tachycardia and LV enlargement, with no evidence

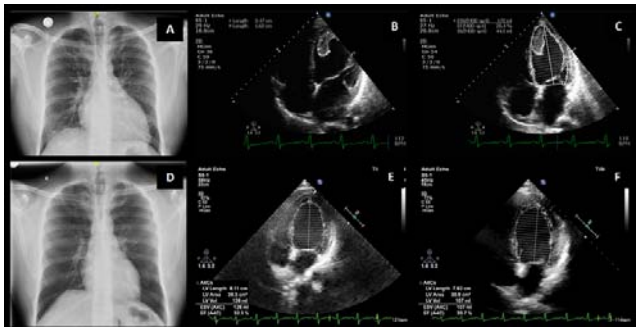
of ischemia/infarction. Transthoracic echocardiograph showed a large pedunculated, mobile thrombus (3.47x1.62 cm) attached to the ventricular apex with severe biventricular dysfunction (LVEF 20.4%) (Figure 1B-1C).

CLINICAL COURSE: He had an embolic stroke during hospital stay, with complete neurological recovery within 6 hours. MRI brain done later showed infarcts in left parietal lobe and right cerebellum. Over the next 2 weeks of hospital stay, his functional status improved to NYHA class II. At discharge, his LVEF was 25%, with significant reduction in the clot size. He was discharged on torsemide, eplerenone, ramipril, carvedilol and warfarin.

Following cessation of mephentermine use, there was steady improvement in his functional status along with resolution of chest radiograph changes (Figure 1D) and LV function improvement over a follow-up of 2 months (LVEF 32.3%) (Figure 1E). At the next follow-up (3 months), his ventricular function showed deterioration (EF 20.7%) (Figure 1F). On repeated questioning, he confessed to have started mephentermine reuse for 2 weeks. He was referred to Psychiatry department for mephentermine deaddiction.

MAC HYPOTHESIS: Though AAS abuse by athletes leading to such a presentation has been documented, similar role of mephentermine has not been reported. Deterioration of cardiac function in rat model with nor-epinephrine infusion, in humans by methamphetamine (which bears structural and physiological resemblance to mephentermine) use and in pheochromocytoma (a hyperadrenergic state similar to that created by mephentermine use) provide proof of concept for Mephentermine Associated Cardiomyopathy (MAC). Because of strong biological plausibility and temporal correlation, we conclude that in our patient, mephentermine caused the reversible cardiomyopathy.

CONCLUSION: Mephentermine addiction potential is being increasingly recognised, and increased awareness regarding the entity of Mephentermine Associated Cardiomyopathy (MAC) is warranted.



Chest radiograph and 2D Echocardiograph

Rapid Fire 3 - Acute heart failure

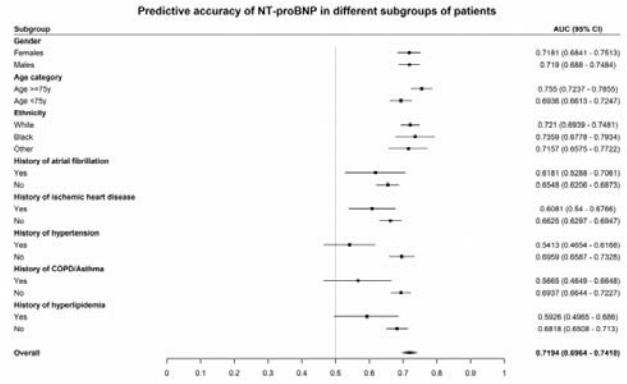
The discriminative power and optimal diagnostic thresholds of NT-proBNP in patients admitted with acute heart failure-related signs and symptoms: a prospective observational study

P Simitsis[1]; J Webb[2]; J Draper[2]; S Piper[1]; T Jackson[2]; S Claridge[2]; TA Mcdonagh[1]; S Kapetanakis[2]; R Razavi[2]; G Carr-White[2]
[1]Kings College Hospital, Department of Cardiology, London, United Kingdom of Great Britain & Northern Ireland; *[2]St Thomas' Hospital, Department of Cardiology, London, United Kingdom of Great Britain & Northern Ireland*

Background: A prompt diagnosis of acute heart failure (AHF) is challenging in patients presenting to Emergency Department (ED) with AHF-related signs and symptoms and plasma NT-proBNP has been shown to be effective as a rule-out test. However, few non-UK studies have explored the discriminative power of this test.
Purpose: We sought to determine the diagnostic power of NT-proBNP in patients presenting acutely with HF-related symptoms in a UK hospital setting.
Methods: This is a prospective single-center observational study of 1995 consecutive patients who attended the ED with AHF-related symptoms during 12 months. They all had NT-proBNP measured and the diagnosis of AHF versus other conditions was adjudicated by the multidisciplinary Heart Failure Team. Receiver operating characteristic (ROC) curves analysis was used. The area under the curve (AUC) and its respective 95% confidence intervals (CI) was used to assess the discriminative power of NT-proBNP. Optimal NT-proBNP thresholds for each ROC curve were estimated based on the F1 score.



Predictive accuracy of NT-proBNP

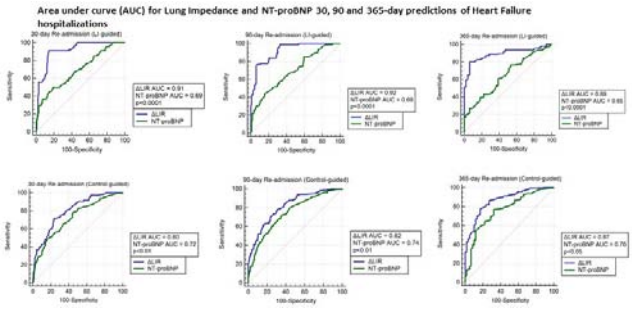
Results: Among 1995 patients presenting with AHF-related symptoms 730 had a final diagnosis of AHF and a median NT-proBNP 4223pg/ml (IQR: 8670pg/ml) while 1265 were diagnosed with other conditions and had a median NT-proBNP 1257pg/ml (IQR: 3056pg/ml). The test had a fair discriminative power for AHF [AUC: 0.7194 (95%CI: 0.6964 - 0.7418)] acute decompensation of chronic HF (CHF) [AUC: 0.7135 (95%CI: 0.6837 - 0.7437)] and denovo AHF [AUC: 0.7238 (95%CI: 0.6976 - 0.7494)] versus other conditions. The same was true for HF with reduced ejection fraction (HFrEF) and HF with mid-range ejection fraction (HFmrEF) versus other conditions [AUC: 0.7738 (95%CI: 0.7473 - 0.7997) and 0.7302 (95%CI: 0.691 - 0.7669) respectively]. However, for patients with HF with preserved ejection fraction (HFpEF) the test did not perform well [AUC: 0.6341 (95%CI: 0.5993 - 0.6669)]. The optimal NT-proBNP threshold for AHF was 955pg/ml (specificity: 43.87%, sensitivity: 85.62%, accuracy: 59.15%, negative prognostic value: 84.09%, F1 score: 0.605). The test had significantly higher predictive power for patients over 75 years vs younger (AUC: 0.755 vs 0.6936, p= 0.0064) but there was no difference in gender, ethnicity, history of atrial fibrillation (AF) or ischemic heart disease (IHD). It had no discriminatory capacity for patients with hypertension or COPD/asthma. Males had higher optimal threshold than females (1258 vs 874pg/ml) and black patients lower than white (508 vs 955pg/ml).
Conclusions: In a large sample of UK patients who attended the ED with AHF-related symptoms, NT-proBNP was helpful in discriminating between AHF and other conditions, but its predictive power was not satisfactory (AUC<0.80). Its power was significantly higher in older patients but did not differ by gender or ethnicity. Finally, the optimal NT-proBNP threshold was significantly higher than the proposed 300pg/ml in the entire cohort and across all subgroups.

198

Compeering of predictive accuracy for 30, 90 and 365-day Heart Failure readmission assessed by impedance technique and NT-proBNP. Results of IMPEDANCE-HF extended trial

M Michael Kleiner Shochat[1]; D Kapustin[2]; M Fudim[3]; M Kazatsker[1]; Y Levy[1]; A Levy[1]; I Kleiner[4]; JM Weinstein[4]; G Panjrath[5]; A Roguin[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]University of Toronto, Internal disease , Toronto, Canada*; *[3]Duke University Medical Center, Cardiology, Durham, United States of America*; *[4]Saroka Medical Center, Cardiology, Beer Sheva, Israel*; *[5]George Washington University School of Medicine and Health Sciences, Cardiology, Washington, United States of America*

The aim of secondary analyses of the IMPEDANCE-HF extended trial was to find out if residual congestion on discharge for HF could predict 30-day and one-year Heart Failure death.
The analysis of IMPEDANCE-HF extended trial was based on the data collected during the index hospitalization for HF. The IMPEDANCE-HF extended trial was a randomized controlled single-blinded trial of HF with reduced LVEF patients. Inclusion criteria were LVEF ≤ 45%, NYHA class II-IV and patients were hospitalized for HF within 12 months (ClinicalTrials.gov NCT01315223). Half of the patients (N=145) were assigned to the active Lung Impedance (LI)-guided treatment arm where clinicians were based therapy on LI level. The other half was assigned to the control arm where LI values were recorded but not conveyed to the clinical treatment team. In the case of hospitalization, LI was recorded in all patients at discharge. The decisions regarding discharge and choice of treatment were at the discretion of the hospital staff.
A non-invasive impedance device was used in this study to assess the lung fluid content. Unlike the existing impedance devices, the present device has the ability to differentiate a true signal from the lungs from the noise signal of surrounding chest wall. Such approach enables to measure a small change in lung fluid content. A method to determine individual "dry" baseline LI (BLI) for each HF patient has been reported. BLI for each patient was used to calculate a new parameter, the LIR= [(current LI/BLI)-1] ×100%, which determinate the degree of pulmonary congestion in time of measurement.



Area under curve

Method. Degree of pulmonary congestion at discharge for HF hospitalization was divided into 5 brackets. (1) LIR= 0 to – 18% - minimal interstitial edema (IE), (2) LIR= - 18.1 to -28% - mild IE, (3) LIR= -28.1 to – 38 – moderate IE, (4) LIR= -38.1 to -48% - severe IE to mild alveolar edema (AE) and (5) LIR < -48.1% - moderate AE.
Results: LI-guided patients were followed for 61.9.4±39.6 months and control patients for 46.7±33.3 months (p<0.01) accounting for 269 and 470 HF hospitalizations, respectively (p<0.01). Predictive accuracy of 30, 90 and 365-day readmission was assessed by calculating area under curve for Lung Impedance method and for NT-proBNP for both groups separately. Results are presented on figure.
Conclusion The degree of pre-discharge pulmonary congestion as assessed by LI is a better predictor than pre-discharge values of NT-proBNP for 30, 90 and 365-day HF readmission.

Improving diuresis and dropsy with elamipretide in advanced heart failure (IDDEA-HF); a multi-centre, double-blind, placebo-controlled trial

JGF Cleland[1]; J Carr[2]; P Pierpaolo Pellicori[1]; B Merkely[3]; A Voors[4]; M Kruk[5]; T Kostic[6]; N Pontaga[7]; D Raev[8]; L Almenar[9]; M Robertson[1]; I Ford[1]; JJ Mcmurray[1]; B Pitt[10]
[1]*University of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland*; [2]*Stealth BioTherapeutics, Newton, United States of America*; [3]*Semmelweis University Heart Center, Budapest, Hungary*; [4]*University of Groningen, Groningen, Netherlands (The)*; [5]*Institute of Cardiology, Warsaw, Poland*; [6]*Clinical Center of Nis, Nis, Serbia*; [7]*Daugavpils Regional Hospital, Daugavpils, Latvia*; [8]*UMHAT 'Sveta Anna' , Sofia, Bulgaria*; [9]*Hospital Universitario y PolitÇcnico La Fe, Valencia, Spain*; [10]*University of Michigan, Ann Arbor, United States of America*

Background: Most trials of 'acute' heart failure have focussed on dyspnoea as the primary symptom but many patients are admitted to hospital for increasing peripheral oedema reflecting both deteriorating cardiac function and renal water and salt retention. The myocardium and kidney are metabolically active and produce a substantial amount of ATP. However, defective mitochondrial electron-transport chain (ETC) function impairs ATP production and increases oxygen free-radical production. Elamipretide is designed to repair the cardiolipin scaffold on which the ETC sits, which might improve function and ATP production and thereby therapeutic response to conventional therapy for heart failure.
Purpose: to discover whether administration of Elamipretide enhances the resolution of congestion in patients with worsening heart failure.
Methods: a randomised, double-blind, placebo-controlled trial of Elamipretide 20mg given as a one hour infusion repeated daily for up to seven days to patients with heart failure and an LVEF ≤40% within 48 hours of an admission for worsening peripheral oedema. The primary endpoint was the slope of the decline in logNT-proBNP from baseline to Day 8.
Results: of 306 randomised patients, 22% were women, median (IQR) age was 70(63-78) years and LVEF was 30(24-35)%. The primary aetiology of ventricular dysfunction was ischaemic heart disease in 45%, dilated cardiomyopathy in 27%, hypertension in 14% and other in 13%; 52% were in a rhythm other than sinus. Treatment at baseline included loop diuretics (100% - median dose in 24 hours before randomisation in furosemide equivalents - 480mg/day), MRA (78%), ACEi (73%), ARB 14%, beta-blockers (89%), digoxin (22%) and hypoglycaemic therapy (37%). At randomisation, respiratory rate 20(18-23)bpm, heart rate 76(68-86)bpm, systolic blood pressure 120(108-130)mmHg, haemoglobin 13.2(11.6-14.6)g/dL and eGFR 51(40-66)ml/min/1.73m2 were similar for each group. NT-proBNP [5,333(2,855-11,337)ng/L] and CA125 [92(31-224)U/mL] were grossly elevated.
Over eight days, the decline in NT-proBNP was similar (p = 0.414) in patients assigned to placebo [from 6,653(3,085-10,586) to 3,639(1,990-7,922)ng/L] and Elamipretide [from 5,236(2,562-10,210) to 3,486(1,771-6,402)ng/L]. Weight declined by 4.7(6.7-2.5)Kg, median eGFR did not change [+1(-5-7) ml/min/1.73m2] and congestion score improved markedly but changes were similar for placebo and Elamipretide. Doses of diuretic during the study were also similar for each group.
Median length of admission was similar [9 (8-10) versus 10 (8-12)days]. Within 40 days of randomisation, 16 patients assigned to placebo and 10 assigned to Elamipretide were re-hospitalised for heart failure or had a cardiovascular death [HR 0.66(0.29-1.5); p=0.317].
Conclusions: This trial suggests that short-term administration of Elamipretide does not substantially enhance the effects of conventional treatment for congestive heart failure.

BIS equation of glomerular filtration rate in the prediction of hospitalization and mortality in older patients with heart failure

M I Maria Ines Pires[1]; H Antunes[1]; ML Goncalves[1]; JM Santos[1]; JG Goncalves Pereira[1]; J Correia[1]; J Costa Cabral[1]; I Almeida[1]
[1]*Hospital Sao Teotonio, Cardiology, Viseu, Portugal*

Introduction: Renal dysfunction (RD) is a predictor of adverse outcomes in heart failure (HF). There are several equations to estimate glomerular filtration rate (eGFR), namely the recent Berlin Initiative Study creatinine-based (BIS) formula, developed in ≥70 years old patients; the chronic kidney disease epidemiology collaboration creatinine-based (CKD-EPI) formula; and the Modification of Diet in Renal Disease (MDRD) formula. This study compares different eGFR equations in the prediction of adverse outcomes in older patients with HF.
Methods: All patients with ≥70 years admitted for acute HF in a Cardiology Department during 7 years were included. Admission creatinine levels were used to calculate eGFR, using BIS, CKD-EPI and MDRD formulas. Patients were classified into normal renal function/mild RD if eGFR≥60mL/min/1.73m2 or moderate/severe RD if eGFR<60mL/min/1.73m2. The follow-up (FU) was of 24 months. The primary endpoint (EP) was a composite of all-cause mortality or hospitalization for HF. Statistical analysis used chi-square, Mc Nemar and Mann-Whitney U tests; Kaplan-Meier curves and log-rank tests; Cox proportional hazards regression; and ROC curves to estimate the area under the curve (AUC) for the 3 eGFR formulas.
Results: 815 patients were studied (54.2% female, mean age 81.1±6.2 years). eGFR mean values as measured by the BIS, CKD-EPI and MDRD formulas were 45.95±16.59, 50.85±21.37 and 56.57±25.73 mL/min/1.73m2, respectively. The prevalence of eGFR<60mL/min/1.73m2 was different with the 3 formulas: 80.6% with BIS, 66.7% with CKD-EPI and 60% with MDRD (p<0.001).
Mortality during FU was 9.6%, and was associated with older age (p<0.001); chronic obstructive pulmonary disease (p<0.001); lower systolic blood pressure (p=0.005); lower hemoglobin (p=0.027) and albumin (p=0.021) levels; higher urea (p=0.049), potassium (p=0.012) and blood natriuretic peptide (p<0.001) levels. Mortality was associated with lower eGFR calculated with BIS (p=0.035), but not with CKD-EPI (p=0.096) or MDRD (p=0.152) equations. In survival analysis, there was a significant decrease in primary EP in patients with eGFR≥60 mL/min/1.73m2 using BIS (p=0.002), CKD-EPI (p<0.001) and MDRD (p=0.001) formulas. The unadjusted hazard ratio for reduction in primary EP was 0.984 (p<0.001) for BIS, 0.988 (p<0.001) for CKD-EPI and 0.991 (p=0.001) for MDRD. The BIS equation showed the best discriminatory power of the 3 formulas for prediction of both primary EP (AUC 0.609, 95% CI 0.566-0.650) and mortality during FU (AUC 0.574, 95% CI 0.531-0.616), and outperformed all other equations (p<0.001 in all comparisons).
Conclusion: In this study, BIS eGFR equation was a predictor of primary EP and mortality during FU in older patients with acute HF, and had the best predictive power, when compared to other commonly used formulas. Therefore, BIS should be considered to estimate renal function in these patients, as its use could translate into better risk prediction.

Incident hyperkalemia and RAAS-inhibition during an acute heart failure hospitalization

JC Beusekamp[1]; J Tromp[1]; AA Voors[1]; P Van Der Meer[1]
[1]*University Medical Center Groningen, Groningen, Netherlands (The)*

Background: Hyperkalemia is common in patients with heart failure but data on the association between incident hyperkalemia during AHF hospitalizations and up- or down-titration of renin–angiotensin–aldosterone-system (RAAS) inhibitors are scant.
Methods: Serum potassium levels were measured daily from admission until discharge or day 7 in 1589 patients from the PROTECT trial. Incident hypokalemia was defined as at least one episode of potassium <3.5 mEq/L and incident hyperkalemia >5.0 mEq/L. Primary outcome was all-cause mortality at 180 days.
Results: Mean serum potassium levels increased from 4.3±0.6 mEq/L at admission to 4.5±0.6 mEq/L at discharge or day 7 (p<0.001). Patients developing incident hyperkalemia (564 patients (35%)) were more often on mineralocorticoid antagonists (MRAs) prior to hospitalization and MRAs were more often down-titrated during hospitalization, independent of confounders. Down-titration of MRAs during hospitalization was independently associated with increased risk of 180-day mortality (HR 1.70; 95%CI 1.15-2.53). Incident hyperkalemia was not associated with increased risk of 180-day mortality. There was no interaction (Pinteraction>0.1) between incident hyperkalemia and up-titration of MRA during hospitalization for the primary outcome. Compared to normokalemia, patients with incident hyperkalemia and constant MRA doses or up-titration throughout hospitalization showed a better survival (HR 0.67; 95%CI 0.46-0.99). This was similar for ACE-I/ARB therapy (HR 0.70; 95%CI 0.50-0.99).

Conclusion: Incident hyperkalemia occurs in a third of patients hospitalized for AHF and is independently associated with down-titration of MRAs. Patients who maintained or increased their dose of MRA and/or ACE-I/ARB during hospital admission had a better 180-day survival.

Concurrent Initiation of Intra-aortic Balloon Pumping with Extracorporeal Membrane Oxygenation Reduced In-hospital Mortality in Postcardiotomy Cardiogenic Shock

K Kai Chen[1]; HW Tang[1]; JF Hou[1]; SS Hu[1]
[1]*Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, department of cardiac surgeon, Beijing, China*

Purpose: We analyzed the outcomes, predictive factors and complications of veno-arterial extracorporeal membrane oxygenation (VA-ECMO) use for postcardiotomy cardiac shock (PCS).
Methods: A total of 152 adult subjects who received VA-ECMO (24 hours) for PCS in our hospital were consecutively included. Baseline characteristics were compared between survivors with non-survivors, and logistic regression was performed to identify predictive factors for in-hospital mortality.
Results: The mean age of the subjects was 49.5±14.1 years. The main surgical procedures were heart transplantation (32.2%), coronary artery bypass graft (17%) and valvular surgery (11.8%). Intra-aortic balloon pumping(IABP) was initiated concurrently with ECMO in 32.2% subjects and sequentially in 18.4% subjects. The ECMO weaning rate was 56.6%, and the in-hospital mortality was 52.0%. When compared with non-survivors, survivors had less hypertension (15.1% vs. 35.4%, p=0.004), pre-ECMO secondary thoracotomy (19.2% vs. 39.2%, p=0.007), pre-ECMO cardiac arrest/ventricular fibrillation (11.0% vs. 34.2%, p=0.001), bedside implantation of ECMO (11.0% vs. 41.8%, p0.001), and more transplant procedure (45.2% vs. 20.3%, p=0.001), concurrent IAPB initiation with ECMO (41.1% vs. 24.1%, p=0.025). Multivariate logistic regression indicated concurrent IABP initiation with ECMO was the only independent protective factor for in-hospital mortality (OR=0.375, p=0.041, 95% CI: 0.146-0.963). Concurrent IABP initiation with ECMO had less need for continuous renal replacement therapy (30.6% vs. 49.3%, p=0.039) and less neurological complications (8.2% vs. 22.7%, p=0.035), but more thrombosis complications (18.4% vs. 2.7%, p=0.007).
Conclusion: Concurrent initiation of IABP with ECMO provides better short-term survival for PCS, with reduced peripheral perfusion complications.

Cardiac autonomic nerves stimulation improves hemodynamics and clinical status in advanced heart failure patients

MPC Michael Cuchiara[1]; CM Marin Y Kall[2]; JB Boehmer[3]; MC Cowie[4]; AM Mebazaa[5]; TD Diaz[6]
[1]*NeuroTronik, Clinical Research, Durham, United States of America*; [2]*University of Miami, International Medicine Institute, Miami, United States of America*; [3]*Milton S. Hershey Medical Center, Hershey, United States of America*; [4]*Imperial College London, London, United Kingdom of Great Britain & Northern Ireland*; [5]*University Paris Diderot , Paris, France*; [6]*Pacífica Salud Hospital Punta Pacífica, Panama City, Panama*

Despite therapy advances in the management of HF, symptomatic congestion and low cardiac output in acute heart failure is a leading cause of mortality and morbidity. The purpose of this study was to investigate transvenous cardiac autonomic nerve stimulation (CANS) effects on in-hospital hemodynamics and signs and symptoms of congestion.
The study was a single-center, observational, clinical investigation of CANS. Twelve subjects with left ventricular ejection fraction (LVEF) < 40% and at least two signs and symptoms of congestion were consented and enrolled. A purpose-built electrical stimulation catheter was placed in the left brachiocephalic vein via left subclavian vein access. A purpose-built neurostimulator was then connected to the catheter and used to deliver CANS therapy in-hospital for up to 96 hrs.The subjects presented symptomatic, had a mean baseline NT-proBNP of 10,915 pg/mL, a LVEF of 24%, and a pulmonary capillary wedge pressure (PCWP) of 19 mmHg. CANS therapy was provided for a mean duration of 59 hrs. and was well tolerated. There were no device or study related adverse events reported.
During CANS therapy average cardiac index increased (1.7 to 2.1 L/min./m2), systemic vascular resistance decreased (25 to 20 WU), and PCWP decreased (19 to 14 mmHg) with little change in MAP or HR. Clinical status improved during CANS therapy and at 30 day follow-up. On average, patients were fluid net negative 1.3 L, edema pitting score improved 2 points, and 6 minute hall walk distance (6MHW) increased 54 m. At 30 day follow-up, edema pitting score improved 3 points, 6MHW increased 106 m and the KCCQ-12 summary score improved 37 points from baseline.
Hemodynamic and clinical improvements occurred in the presence of stable medical management. Patients received at least 80 mg/day of furosemide, had minimal change to existing HF medical management, received no new vasoactive therapies, and a majority of the patients (9/12) received no furosemide dose uptitration during CANS therapy.
Alongside concomitant medical therapy, CANS holds promise as a tool to improve in-hospital hemodynamics and relieve congestion.

CANS Therapy Hemodynamic Profile	
CardiacIndex	+22%(p=0.03)
Rightventricular stroke work index	+29%(p=0.06)
PulmonaryCapillary Wedge Pressure	-28%(p<0.01)
SystemicVascular Resistance	-22%(p=0.04)
MAP	-3%(NS)
HR	+1%(NS)

Paired, single tail t-test of the mean, n=12, NS= not significant.

Lung ultrasound in acute heart failure: prevalence of pulmonary congestion and associated short- and long-term outcomes

E Platz[1]; R Campbell[2]; B Claggett[1]; E Lewis[1]; J Groarke[1]; K Docherty[2]; M Lee[2]; A Merz[1]; M Silverman[1]; V Swamy[1]; M Proplesch[1]; J Rivero[1]; S Solomon[1]; J Mcmurray[2]
[1]Brigham and Women's Hospital, Boston, United States of America; *[2]Cardiovascular Research Centre of Glasgow, Glasgow, United Kingdom of Great Britain & Northern Ireland*

Funding Acknowledgements: National Heart, Lung and Blood Institute (K23HL123533) (EP) and British Heart Foundation (PG/13/17/30050) (RTC/JJM)

Background: Pulmonary congestion in acute heart failure (AHF) is both a common and important finding. However, current methods for its detection, such as auscultation and chest x-ray, are insensitive.
Purpose: To assess the prevalence and prognostic importance of pulmonary congestion, with a simplified lung ultrasound (LUS) method, and examine changes of LUS findings ('B-lines') with treatment for AHF.
Methods: In a two-site, prospective, observational study 4-zone LUS was performed early during hospitalization for AHF (LUS1) and at discharge (LUS2). B-lines were quantified offline, blinded to clinical findings and outcomes by a core laboratory.
Results: Among 349 AHF patients (median age 75, 59% men, mean EF 39%) the sum of B-lines in 4 zones ranged from 0 to 18 (median 6) (LUS1). The risk of an adverse in-hospital event increased with rising B-line number on LUS1: odds ratio for each B-line tertile 1.82 (95% CI 1.14-2.88, P=0.011). B-line count decreased from a median of 6 on LUS1 to 4 on LUS2; P<0.001) over a median of 6 days. In 132 patients with LUS2 images, the risk of HF hospitalization or all-cause death increased with increasing B-line number at discharge (LUS2). This relationship was stronger closer to hospital discharge: unadjusted HR comparing the first to the third B-line tertile for the first 90 days: 2.94, 1.46-5.93, P=0.003; for 180 days: 2.01, 1.11-3.64, P=0.021 (Figure). The association between B-line number and short and long-term outcomes persisted after adjusting for other important clinical variables, including NT-proBNP.
Conclusion: Pulmonary congestion using a simplified 4-zone lung ultrasound method was found to be common in AHF and improved with therapy. A higher number of B-lines at baseline and discharge identified patients at increased risk for adverse in-hospital and longer-term events.

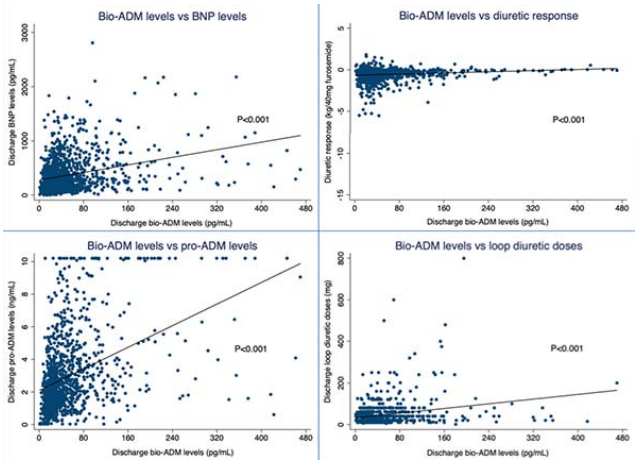
The value of discharge bio-ADM as a marker of residual congestion, discharge loop diuretic doses and clinical outcomes in patients with acute heart failure

P Pandhi[1]; JE Emmens[1]; J Struck[2]; JM Ter Maaten[1]; AA Voors[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The); *[2]Sphingotec, Henningsdorf, Germany*

On behalf of: PROTECT

Background: Recently, bio-adrenomedullin (bio-ADM) was implicated to be a congestion marker in acute heart failure (AHF) patients. As a result, there is potential interest in the use of this biomarker in patients with AHF before discharge to provide additional information on (residual) congestion status, titration of diuretic doses and to predict the risk of death and hospital re-admission.
Objectives: We evaluated the association between discharge bio-ADM levels and clinical variables, congestion status and discharge loop diuretic doses. Furthermore, we investigated the combined value of bio-ADM and loop diuretic doses to predict the risk of 60-day HF rehospitalization and 180-day mortality.
Methods: Plasma bio-ADM levels were measured in 1,236 acute HF patients at day 7 or discharge in the randomized controlled PROTECT trial. Clinical congestion score (CCS) was defined as a composite score (range 0 to 8) comprising of jugular venous pressure, orthopnoea and peripheral oedema.
Results: Median plasma bio-ADM concentration was 33.7 pg/mL [IQR 21.5-61.5] at day 7 or discharge. Patients with higher discharge levels of bio-ADM had a longer length of hospitalization, more residual congestion at discharge, higher BNP levels, and a poorer diuretic response (all P<0.001). Bio-ADM was the strongest predictor of residual congestion at discharge (defined as CCS>3) (OR=4.35, 95%CI: 3.37-5.62, P<0.001). In a multivariable regression model, oedema at the time of discharge was one of the strongest predictors of bio-ADM levels (b=0.240, P<0.001). Higher discharge loop diuretic doses were independently associated with a poorer diuretic response during hospitalization (b=0.187; P<0.001) and higher discharge bio-ADM levels (b=0.084; P=0.020). High bio-ADM levels combined with higher use of loop diuretics at discharge were independently associated with greater risk of 60-day HF rehospitalization (HR=4.02, 95%CI: 2.23–7.26; P<0.001), but not 180-day mortality (P=0.247).
Conclusions: Elevated discharge bio-ADM levels reflected residual congestion and were associated with higher loop diuretic doses at discharge. Patients with higher bio-ADM levels and higher loop diuretic doses at discharge had an increased risk of HF rehospitalization. Assessment of bio-ADM at discharge could therefore be a readily applicable marker to identify patients with residual congestion who are at higher risk of early hospital re-admission after discharge.



Bio-ADM and clinical variables

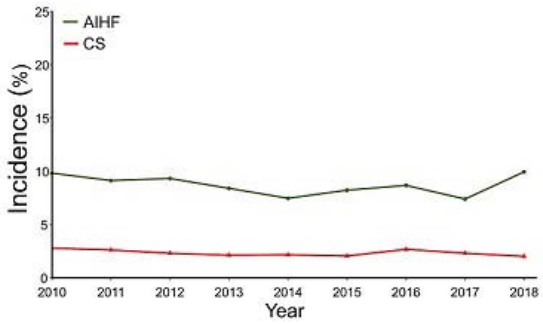
Trends in outcomes in patients with acute ischemic heart failure: a report from Swedish Angiography and Angioplasty Registry

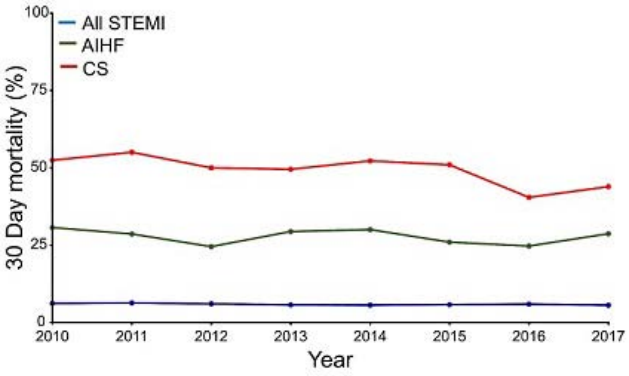
B Bjorn Redfors[1]; S Volz[1]; O Angeras[1]; D Ioanes[1]; J Odenstedt[1]; S Koul[2]; I Haraldsson[1]; C Ljungman[1]; C Dworeck[1]; O Frobert[3]; S James[3]; A Ulvenstam[4]; T Jernberg[5]; D Erlinge[2]; E Omerovic[1]
[1]Sahlgrenska Academy, Univ. of Gothenburg, Dept of Molecular & Clinical Medicine/Cardiology, Gothenburg, Sweden; *[2]Skane University Hospital, Lund, Sweden*; *[3]Uppsala University Hospital, Uppsala, Sweden*; *[4]Ostersund Hospital, Ostersund, Sweden*; *[5]Danderyd University Hospital, Stockholm, Sweden*

Background: Acute ischemic heart failure (AIHF) is the most common cause of death for patients with ST-elevation myocardial infarction (STEMI). The most severe form of AIHF, cardiogenic shock, carries a particularly poor prognosis.
Purpose: We sought to determine whether the incidence and prognostic impact of AIHF and CS in STEMI have been reduced over the last eight years.
Methods: Using the nationwide Swedish Angiography and Angioplasty Registry (SCAAR) we identified patients who underwent primary PCI due to STEMI in Sweden between January 2010 and April 2018. We defined IAHF as Killip class ≥2 and cardiogenic shock as Killip class 4. The primary endpoint was mortality at 30 days.
Results: We identified 40,701 patients who underwent primary PCI during the study period with known vital status at 30 days, for whom Killip class was reported for 40,365 (99.2%). AIHF occurred in 3,456 (8.6%) of these patients, and 955 (2.4%) developed cardiogenic shock. Thirty-day mortality for the overall STEMI cohort was 5.9%, whereas 30-day mortality for patients with AIHF and CS were 27.7% and

48.8%. respectively. The incidence of AIHF decreased somewhat (ptrend=0.006), whereas the incidence of CS did not (ptrend=0.77)(Figure). In contrast, we observed an improvement over the study period in the prognosis of CS (ptrend=0.004) but not AIHF (ptrend=0.065) (Figure).

Conclusions: The incidence and prognostic implications of AIHF among patients with STEMI have improved slightly over the eight years. However, AIHF, and particularly CS, is still associated with a very high risk of dying.





Poster Session 1

Atrial Fibrillation

P232

The relationship between epicardial adipose tissue and atrial fibrillation

L-L Lan-Linh Truong[1]; F Erthal[1]; H El Mais[1]; Y Yam[2]; D Dey[3]; BJ Chow[1]
[1]University of Ottawa Heart Institute, Cardiac Imaging, Ottawa, Canada; *[2]University of Ottawa Heart Institute, Cardiovascular Research Methods Centre, Ottawa, Canada*; *[3]Cedars-Sinai Medical Center, Biomedical Imaging Research Institute, Los Angeles, United States of America*

Introduction: Atrial fibrillation (AF) is the most common arrhythmia affecting approximately 2% of the general population and 25% of those over the age of 75. Recently, epicardial adipose tissue (EAT) has been associated with AF prevalence. Our study sought to understand the relationship between EAT and AF by comparing EAT volumes in matched patients with and without AF.
Methods: A total of 781 AF patients undergoing cardiac computed tomography angiography (CCTA) between January 2006 and June 2016 were included and matched to propensity score-matched controls without AF. The entire study comprised 1,562 CCTA patients. Non-contrast enhanced images were analyzed using QFAT. Epicardial fat borders were traced for each axial image starting at the level of the bifurcation of the pulmonary arteries and ending at the level of the diaphragm. Total EAT volume was measured and differences between AF and non-AF patients were compared.
Results: 1,562 were analyzed (mean age 59.0±11.3 years, 996 (63.76%) men, mean BMI 29.14±5.42 kg/m2) (Table 1). Patients with AF had higher overall EAT volumes than those without (125.75±57.5 cm3 and 118.3±55.7cm3 respectively, p=0.016).
Conclusion: Our study confirms, in a large cohort, that EAT is associated with AF.

Decreased left atrial reservoir function can predict new onset atrial fibrillation in patients with acute heart failure

JH Jae-Hyeong Park[1]; JJ Park[2]; JH Lee[3]; JB Park[4]; GY Cho[2]
[1]Chungnam National University Hospital, Daejeon, Korea (Republic of); *[2]Seoul National University Bundang Hospital, Cardiovascular Center and Department of Internal Medicine, Seongnam, Korea (Republic of)*; *[3]Chungbuk National University Hospital, Cardiology, Cheongju, Korea (Republic of)*; *[4]Seoul National University College of Medicine, Cardiology, Seoul, Korea (Republic of)*

Background: Atrial fibrillation (AFib) is one of major cardiovascular disease associated with worsening heart failure (HF) and embolic events. Early detection of AFib can prevent future cardiovascular events. We studied that decreased left atrial (LA) strain can predict new-onset AFib (NOAF) in patients with acute heart failure (AHF).
Materials and Methods: In our STRATS-AHF (STrain for Risk Assessment and Therapeutic Strategies in patients with AHF) registry, we included all consecutive patients with AHF admitted to 3 tertiary hospitals in Korea from January 2009 to December 2016. Of them, we measured LA global longitudinal strain (LAGLS) in 4010 patients with suitable echocardiographic images.
Results: In a total of 4312 patients in STRATS-AHF registry, we excluded 1338 patients with AFib, 209 patients without LA strain and 65 patients with AFib during the index hospitalization. Thus, we included total 2700 patients (1439 males, mean age: 70±14 years old) with LAGLS and sinus rhythm. The mean LVEF was 39.2±15.5%, LA diameter was 42.7±8.2mm, LA volume index was 42.5±23.1ml/m2 and LAGLS was 16.1±10.0%.
During follow-up, 250 patients (9.3%) had NOAF. Age (HR=1.029, P<0.001), hypertension (HR=1.555, P=0.001), diabetes (HR=0.720, P=0.018), total cholesterol (HR=0.995, P<0.001), LV end-diastolic dimension (HR=0.985, P=0.033), LV end-systolic dimension (HR=0.975, P<0.001), LV end-diastolic volume (HR=0.997, P=0.019), LV end-systolic volume (HR=0.996, P=0.007), LVEF (HR=1.015, P<0.001), LA diameter (HR=1.046, P<0.001), LA volume index (HR=1.010, P<0.001), LAGLS (HR=0.966, P<0.001), HFpEF (HR=1.691, P<0.001) and use of RAS-inhibitor at discharge (HR=0.708, P=0.011). The best cut-off value of LAGLS in the detection of NOAF was 18.0%. Patients with LAGLS<18.0% had significantly higher incidence of NOAF (HR=1.931, P<0.001). In the multivariate analysis, hypertension (HR=2.423, P=0.004), diabetes (HR=0.616, P=0.036), mitral E-velocity (HR=1.009, P=0.009), LA diameter (HR=1.043, P=0.010), RV systolic pressure (HR=0.967, P<0.001) and LAGLS<18.0% (HR=2.498, P=0.001). Conclusion: LAGLS<18.0% was a powerful predictor of future NOAF in AHF patients.

P234

Impact of obesity and age on left atrial function in patients with paroxysmal atrial fibrillation undergoing catheter ablation

A Asim Katbeh[1]; T De Potter[1]; P Geelen[1]; G Di Gioia[1]; E Stefanidis[1]; Z Balogh[1]; K Iliodromitis[1]; E Barbato[1]; M Vanderheyden[1]; G Van Camp[1]; M Penicka[1]
[1]Olv Hospital Aalst, Aalst, Belgium

Background: Obesity and older age are associated with increased risk of atrial fibrillation (AF) and heart failure. Previous studies assessing the efficacy of catheter ablation in obese and elderly patients have shown conflicting data.
Purpose: We thought to assess the impact of obesity and age on left atrial (LA) phasic function in patients with paroxysmal AF undergoing the first catheter ablation.
Methods: We prospectively enrolled 112 consecutive patients (age:63±21 years; 32% female) with symptomatic paroxysmal AF and preserved left ventricular ejection fraction (≥50%) undergoing the first catheter ablation during sinus rhythm, and 23 healthy controls. Patients with valvular AF or in AF at the time of ablation were excluded. All patients underwent comprehensive echocardiography at one day pre and at one day post ablation, and after three months. The LA reservoir, conduit and contractile strain and strain rate (SR) were assessed using the two-dimensional speckle tracking echocardiography as average of segmental values in apical views.
Results: A total of 36 (32%) patients had normal weight (BMI <25 kg/m^2), while 50 (45%) overweight (25≤BMI<30kg/m^2), and 26 (23%) obesity (BMI≥30kg/m^2). A total of 42 (38%) individuals were elderly (≥ 65 years old). Pre-ablation, all groups of patients with paroxysmal AF had significantly lower magnitude of all three components of LA strain and SR compared with controls (all p<0.01). Obese patients showed significantly lower magnitude of reservoir strain, contractile strain and SR compared with normal-weight patients (all p<0.05). Reservoir but not contractile strain was also significantly lower in over-weight versus normal-weight individuals . Middle-age compared with elderly patients had significantly higher magnitude of reservoir strain, reservoir and contractile SR (all p < 0.05). Post ablation, LA strain and SR significantly decreased in all groups of patients regardless of BMI or age (all p<0.05) (Figure 1AB,2AB). At three-month follow-up, LA strain

and SR showed almost complete recovery to pre-ablation values in all groups of patients. Yet, LA function remained significantly lower compared with controls (all p<0.01). Moreover, individuals with obesity remained to have significantly lower LA function than patients with normal weight. Elderly patients with overweight tended to have lower follow-up LA function compared with middle-age patients with normal weight (p 0.06). Out of the all indices of phasic LA function, reservoir strain showed to be the most clinically useful to monitor LA function throughout the study.

Conclusion: Obese patients with paroxysmal AF had significantly lower LA function both pre and post catheter ablation. This may imply a higher AF recurrent rate and risk for development of heart failure. Reservoir LA strain appears to be the most useful parameter to monitor LA function.

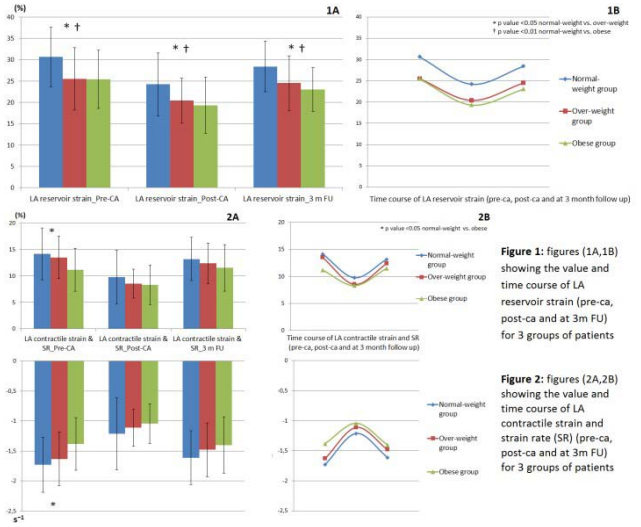

Figure 1: figures (1A,1B) showing the value and time course of LA reservoir strain (pre-ca, post-ca and at 3m FU) for 3 groups of patients

Figure 2: figures (2A,2B) showing the value and time course of LA contractile strain and strain rate (SR) (pre-ca, post-ca and at 3m FU) for 3 groups of patients

P236

Sex differences in the effects of class III antiarrhythmic drugs on left ventriculoatrial remodeling in atrial fibrillation patients with diastolic dysfunction

E Kokhan[1]; G Kiyakbaev[1]; A Shavarov[1]; ZH Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: The association between gender and atrial fibrillation (AF) is poorly understood. Some studies have revealed that women with AF seem to have a higher risk of stroke, death and poorer results of rhythm control strategy compared to men. The origin of these differences may lie in a sex-specific variability of the left atrial (LA) and ventricle (LV) remodeling.

Purpose: This study sought to evaluate the impact of sex on the effects of class III antiarrhythmic drugs on left ventriculoatrial remodeling in AF patients with diastolic dysfunction (DD).

Methods: The study included 27 men and 28 women (median age of 65 [60;72]) with recurrent non-valvular AF, hypertension, coronary artery disease, mild to moderate LV DD and preserved ejection fraction (>50%) treated with amiodarone or sotalol. All patients underwent conventional and speckle tracking echocardiography at baseline and after 3 months. Global peak LA longitudinal strain (PALS, %) in the reservoir (r) and contractile (c) phases was assessed using 6 segments in the 4-chamber and 2-chamber views.

Results: No difference was observed between LA structural and functional parameters in men and women at baseline. However, in women LV diastolic function was worse [E/E' (13 vs 11.2; p=0.03) and E/E'/LV-end diastolic volume (LVEDV) (0.13 vs 0.09 ml-1; p=0.001)]. Despite comparable changes () in heart rate and blood pressure, LA volume index (: -4 vs -1 ml/m2; p=0.03) as well as PALSr (: 2 vs 0.7; p=0.001) and PALSc (: -1.8 vs -1.6; p=0.02) improved more significantly in men. Significant improvements of diastolic function were observed in male patients only. However, only women had intergroup differences in E', E/E', E/E'/LVEDV, LV global longitudinal strain with complete and partial antiarrhythmic response.

Conclusion: During the treatment, structural and functional LA and LV parameters of male patients improved more significantly. However, the association between antiarrhythmic efficacy and diastolic function at the end of treatment was observed only in women.

P237

Impact of gender on the relation between heart rate and left atrial remodeling in patients with recurrent atrial fibrillation and preserved ejection fraction

E Kokhan[1]; G Kiyakbaev[1]; A Shavarov[1]; ZH Kobalava[1]
[1]*RUDN University, Moscow, Russian Federation*

Background: In contrast with patients with reduced ejection fraction, the benefit of heart rate (HR) reduction in patients with preserved ejection fraction has not yet be proven. Lower HR is associated with higher augmentation index and late systolic load on the left ventricle (LV) which could lead to deterioration of diastolic function and, therefore, left atrial (LA) remodeling. Some studies have also found that diastolic dysfunction (DD) is more frequent in women than in men. But the data concerning the relationship between HR and LA remodeling depending on gender is scarce.

Purpose: To evaluate the impact of gender on the association between HR and LA remodeling in patients with recurrent AF, hypertension and preserved ejection fraction

Methods: Twenty seven men and 28 women (median age of 65 [60;72]) with paroxysmal or persistent AF, hypertension and preserved ejection fraction (>50%) were enrolled in this study. Beyond conventional echocardiographic protocol, global peak LA longitudinal strain (PALS, %) in the reservoir (r) and contractile (c) phases was measured using two-dimensional speckle tracking echocardiography. We used the diastolic index [(E/E')/LV-end diastolic volume] as a measure for LV stiffness.

Results: There were no significant differences between women and men in most clinical and demographic parameters including mean HR (63 vs 63; p=0.21), duration of hypertension (65 vs 67 moths, respectively; p=0.88) and AF (37 vs 42 moths, respectively; p=0.83). Despite the fact that DD was significantly more pronounced in women than in men [E/E' (13 vs 11.2; p=0.03); diastolic index (0.13 vs 0.09 ml-1; p=0.001)], both groups had similar LA volume index (41 vs 41 ml/m2; p=0.97). Compared to men, women also had higher median of LV relative wall thickness (0.53 vs 0.4; p=0.03). Diastolic index was not significantly related to mean HR both in women (r=-0.27; p=0.08) and men (r=-0.11; p=0.61). However, in women as distinct from men, we observed significant association between LA volume index and mean HR (r=-0.49; p=0.01 vs r=0.06; p=0.74; z=-1.67, p=0.048).

Conclusion: Only in women was lower mean HR significantly related to increased LA volume index. Accordingly, HR lowering strategy might not be beneficial or could even be harmful for women with preserved ejection fraction. However, this fact needs to be proved in prospective studies.

P238

Immediate recovery of atrial mechanical function after electrical cardioversion in patients with persistent atrial fibrillation is predictive of maintenance of sinus rhythm

DG Dae-Gyun Park[1]; W-W Seo[1]; S-E Kim[1]; J-H Lee[1]; K-R Han[1]; D-J Oh[1]
[1]*Hallym University Kangdong Sacred Heart Hospital, Seoul, Korea (Republic of)*

Background: Electrical or structural degeneration in left atrium (LA) occur after long period of atrial fibrillation (AF). This change of left atrium lead to increase of LA size and might be related to success rate of sinus conversion and relapse of AF after cardioversion. Purpose: We investigated whether recovery of left atrial mechanical function over time after electrical cardioversion in patients with persistent AF is related to relapse of AF, using serially measured echocardiographic parameters. Methods: We included 20 patients with persistent AF who have no valvular or structural heart disease and unsuccessful in pharmacological cardioversion. After electrical cardioversion, we recorded tans-mitral and pulmonary vein flow to evaluate mechanical function of LA at 30 min, 1 day, 7 days, and 30 days in each patient. We evaluated clinical parameters such as age, sex, duration of AF, presence of heart failure, risk factors, and antiarrhythmic agents; and echocardiographic parameters such as chamber size, left ventricular ejection fraction, and Doppler measurements, including estimated right ventricular pressure. Results: Mean age is 59 ± 12 years old (male, n=12, 60%). Duration of AF is 47 month (median: 22 month). Hypertension was most prevalent risk factor (55%). Electrical cardioversions were successful in 16 patients (80%). In cardioverted patients, AF recurred in 8 patients (50%) and AF relapse occurred within 15 days in 6 patients among them. Left ventricular ejection fraction decreased transiently after electrical cardioversion and left atrial size decreased over time. In all converted patients, A wave of trans-mitral flow was more than 0.35 m/sec at 7 days during follow-up. Early S wave and reverse a wave of pulmonary vein flow appeared during follow-up in most patients. Trans-mitral flow and pulmonary vein flow were normalized at 30 days after electrical cardioversion. AF relapse was not related to age and duration of atrial fibrillation. Maintenance of sinus conversion is associated with earlier elevation of mitral A wave and earlier detection of early S wave and revere a wave of pulmonary vein flow. Muscle enzymes such as isoenzyme of creatine kinase and lactate dehydrogenase were elevated in 7 patients.

Conclusions: Systolic and diastolic function of left atrium were much improved at 7 days after electrical cardioversion for patients with persistent atrial fibrillation and were normalized at 30 days. Immediate recovery of atrial mechanical function using

trans-mitral flow and pulmonary flow might be useful predictor for maintenance of sinus rhythm after cardioversion of atrial fibrillation.

Left atrial enlargement predicts 1-year mortality in patients with atrial fibrillation and heart failure

A Samaras[1]; G Fotos[1]; G Dividis[1]; D Vasdeki[1]; E Paschou[1]; I Goulas[1]; A Kartas[1]; E Forozidou[1]; V Tsoukra[1]; H Karvounis[1]; A Tzikas[1]; G Giannakoulas[1]
[1]Ahepa University Hospital, 1st Cardiology department , Thessaloniki, Greece

On behalf of: MISOAC-AF investigators

Background Enlargement of the left atrium (LA) appears to portend poor outcomes in the general population. Atrial fibrillation (AF) and heart failure (HF) have been known to be separately associated with increased LA dimensions; yet the association between the LA size and the risk of death among patients with both AF and HF remains still largely unexplored.
Purpose This study sought to evaluate the prognostic value of the left atrial size as a predictive tool for death among hospitalized patients with AF and HF.
Methods Transthoracic or transesophageal echocardiogram was used for the measurement of the LA area in consecutive patients who were hospitalized at our cardiology department with any diagnosis and coexisting AF and HF. LA area was defined as normal (≤20 cm^2), mildly enlarged (21-30 cm^2), moderately enlarged (31-40 cm^2) and severely enlarged (>40 cm^2) as measured in the 4-chamber view. The outcome measure was all-cause mortality after 1 year of follow-up.Results We reviewed 441 patients with AF and HF aged 18 years or older (mean age 75.5 ± 9.0 years, 57% men). In total, 101 (23%) patients died. The crude cumulative 1-year survival among patients with normal left atrial size, mild enlargement, moderate enlargement and severe enlargement was 93.4%, 82.9%, 71.2% and 60.2%, respectively (p=0.001) [Picture 1]. After adjustment in multivariable Cox proportional hazard analysis, LA area remained a predictor of all-cause mortality in both sexes (HR 1.03 per 1 cm^2 increase, 95% CI 1.01–1.05, p = 0.001 in men, and HR 1.06 per 1 cm^2 increase, 95% CI 1.02–1.11, p >0.001 in women) [Table 1].

Table 1

Risk factors for men	p value	HR (min-max)
RBBB (on the ECG)	0.002	3.04 (1.35-6.83)
Dyspnea (as the main symptom on admission)	0.009	2.75 (1.31-5.77)
LA area (per 1cm^2increase)	0.001	1.03 (1.01-1.05)
Risk factors for women	p value	HR (min-max)
History of Cardiac arrest	0.019	4.71 (1.29-8.12)
LA area (per 1cm^2increase)	<0.001	1.06 (1.02-1.11)
GFR at discharge (per 1 mL/min/1.73 m^2 decrease)	0.004	1.03 (1.02-1.04)

Independent predictors of all-cause mortality in both sexes among hospitalized patients with AF and HF

Conclusions Nearly 1 out of 4 patients with AF and HF will die during 1 year of follow-up after a hospitalization for cardiac reasons. LA area has a graded and independent association with all-cause mortality in both sexes among hospitalized patients with AF and HF. Further research is suggested to refine the prognostic value of this echocardiographic parameter.

P240

Sinus rhytm restore in patients with atrial fibrillation and heart failure

G Dussekeyeva[1]; RR Rekvava[1]; AK Abdymomunov[1]
[1]Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan

Atrial fibrillation (AF) and heart failure (HF) the two major syndromes in cardiology and they frequently coexist. HF increases mean right and left atria (LA) pressures, contributing their progressive dilatation. Such remodeling promotes atrial fibrosis and electrical heterogeneity and eventually induces AF. Otherwise, AF episode immediately induces loss of atrial contraction, increases mean heart rate and pdecrease the heart's pump function. Mortality and morbidity are higher among patients with AF and HF than among those with HF or AF alone. Restoration of sinus rhythm (RSR) using catheter ablation (CA) may be useful treatment tool in this group. But not all patients with HF will RSR, because most of them with longstanding AF and markedly dilated LA.CA for atrial fibrillation can improve outcomes among this group of patients, if it made to correctly selected patients.
Objective: Estimate the efficacy of CA for RSR in patients with HF and AF.
Methods: We identified 350 patients with AF and divided them either with HF and preserved ejection fraction (EF)- AF-HFpEF (n = 130, 37%), HF and reduced EF-AF-HFrEF (n = 150, 43%) and HF and moderately reduced EF–AF-HFmrEF (n = 70, 20%).Compared to the patients with AF-HFrEF, those with AF-HFpEF were older. For RSR 35% underwent radiofrequency ablation and 65% cryobaloon ablation. The levels of NT-proBNP and LA and left ventricular (LV) function echocardiographic parameters were estimated. LA volume measurements were done at the time of mitral valve opening, at the onset of atrial systole (p wave at the electrocardiogram=Vp) and at mitral valveclosure. All volumes were indexed for body surface area, and the following left atrial emptying functions were calculated. Follow-up was made after 3,6,9,12 months after CA.
Results: In all cases restoring of RSR was achieved using electrical cardioversion after ablation. After 12±3 months, 49% of the patients with HF remained in sinus rhythm and had significant improvement in left ventricular function (increases in the ejection fraction and fractional shortening of 19±12 percent and 9±5 percent, respectively; P<0.001 for both comparisons), LV dimensions (decreases in the diastolic and systolic diameters of 3.5±2 mm and 2.7±3 mm, respectively; P=0.03 and P<0.001, respectively). Also, there was significant reduction of mitral regurgitation level in 25% from 3 to 2 degree, 37% from 2 to 1 degree. Those patients who recurred AF after ablation had higher levels of NT-proBNP than in group with RSR (470.2 ± 180.7 and 230.7 ± 175.8 retrospectively, P<0.001). Among the patients with RSR 38% was patients with AF-HFmrEF, among patients who recurred AF was the prevalence of AF-HFrEF. It is important to notice,that patients who recurred AF initially had lower LA EF.
Conclusion: Catheter ablation for AF is useful treatment tool in HF patients. It needs further research to develop correct selection criteria of patients with AF and HF undergoing catheter ablation.

P241

Low albumin level is one of the strongest predictors for cardiovascular mortality in reduced ejection fraction heart failure patients with atrial fibrillation in both genders

G Guliz Kozdag[1]; D U[2]; K Karauzum[1]; I Karauzum[1]; T Sahin[1]; J Wiley[3]; C Sanina[3]; A Vural[1]; U Celikyurt[1]; A Agacdiken Agir[1]

[1]Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey; *[2]Koc University, Cardiology, Istanbul, Turkey*; *[3]Albert Einstein College of Medicine, Cardiology, New York, United States of America*

BACKGROUND: Even though atrial fibrillation (AF) is common in reduced ejection fraction heart failure (HFrEF), the predictors for cardiovascular mortality according to gender are not clear. The aim of this study was to evaluate the predictors for cardiovascular mortality in the male and the female patients with AF in HFrEF who were discharged on optimal medical therapy.

METHODS AND RESULTS: 172 patients (mean age 67± 11 years, 106 male, 66 female, and mean ejection fraction (EF) 27 ± 9%) with atrial fibrillation in HFrEF who were hospitalized due to worsening heart failure were included to the study. 34 male patients (32%) and 26 female patients (39%) of the cohort died during a median follow-up (FU) duration of 76 months. Patients who died during FU were older and hospitalized more than the patients who survived during FU. Hepatic functions in both genders who met the study endpoint were worse than the patients who survived during FU (Table). Both genders had the same predictors for CVS mortality in multivariate analysis (In the male patients: Albumin [HR, 0.561 (95% CI 0.449-0.701), P < 0.001] and age [HR, 1.058 (95% CI 1.044-1.073), P < 0.001] and in the female patients: Albumin [HR, 0.524 (95% CI 0.424-0.648), P < 0.001] and age [HR, 1.059 (95% CI 1.045-1.073), P < 0.001]) .

CONCLUSION: Although there were some differences for predictors of CVS mortality in the males and the females with AF in HFrEF in univariate analysis both genders had the same predictors in multivariate analysis. Older age and decreased albumin were the most powerful predictors for CVS mortality for both genders in this study.

Low heart rate at follow up predicts improvement of ejection fraction in a large-volume cohort of women with wearable cardioverter defibrillator

L Lore Schrutka[1]; J W Erath[2]; V Kutiyfa[3]; B Assmus[4]; A Burch[5]; A M Russo[6]; D Bonderman[1]

[1]Medical University of Vienna, Cardiology, Vienna, Austria; *[2]JW Goethe University, Department of Cardiology, Frankfurt am Main, Germany*; *[3]University of Rochester, Rochester, United States of America*; *[4]University of Giessen, Giessen, Germany*; *[5]Department of Cardiovascular Sciences, East Carolina University, Greenville, United States of America*; *[6]Cooper University Hospital, Camden, United States of America*

Background. Wearable cardioverter defibrillators (WCD) are effective in short-term therapy of ventricular arrhythmias and serve as diagnostic tools with continuous heart rate (HR) monitoring. Previous studies highlighted the importance of HR control in heart failure. Women at risk for sudden cardiac death are not well studied. The objective was to evaluate the impact of HR on improvement of ejection fraction (EF) in women provided with WCDs.

Methods. Data from women fitted with WCD from 2015 to 2018 were obtained from the manufacturer's database. Quartiles of HR were compared between patients showing improvement of EF and patients who either had indication for implantable cardioverter defibrillators (ICD) or died.

Results. A total of 15 321 women with mean age of 66 ± 13 years were included. Mean time of WCD use was 96 ± 50 days. Patients with improvement of EF had significantly lower HR compared to patients who died or received an ICD. Univariable logistic regression showed that lower HR was predictive for improvement, with nighttime HR at follow up showing strongest predictive power with OR of 2.06 (95%CI 1.90-2.23, p<0.001). Multivariable adjustment revealed that daytime, nighttime and delta nighttime HR at the end of WCD use was predictive for improvement.

Conclusion. HR was significantly lower in patients showing improvement of EF. Absolute daytime, nighttime and delta nighttime HR at follow up showed predictive ability for recovery.

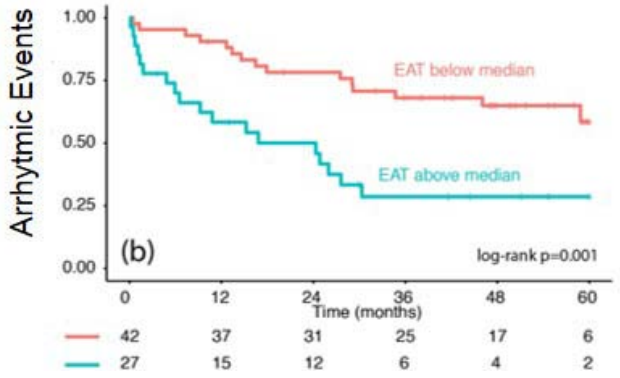
Epicardial adipose tissue echocardiographic thickness predicts arrhythmic outcome in heart failure patients.

L Ferrante[1]; L Petraglia[1]; FV Grieco[1]; M Conte[1]; C Napolitano[1]; M Russo[1]; L Gioia[1]; L Visaggi[1]; P Campana[1]; D Bruzzese[2]; V Parisi[1]

[1]University of Naples Federico II, Department of Translational Medical Sciences , Naples, Italy; *[2]Federico II University of Naples, Department of Public Health, Naples, Italy*

Background: We previously demonstrated that epicardial adipose tissue (EAT) thickness is increased in patients with heart failure with reduced ejection fraction (HFrEF). In HFrEF EAT is a marker of cardiac denervation and is a local source of catecholamines, both predictors of arrhythmic events and sudden death. EAT is also strongly associated with atrial fibrillation.

Purpose: in this study we investigated the predictive value of EAT thickness on arrhythmic events in a HFrEF population undergoing implantable cardioverter defibrillator implantation (ICD) for primary and secondary prevention.
Methods: We prospectively enrolled 104 patients (mean age 68.7 ± 6.5 years) with HFrEF, undergoing ICD implantation and followed up (FU) them for a maximum of 5 years (median FU of 17.2 months). At baseline, demographic, clinical and laboratory data were collected. At the time of enrollment, all patients underwent complete echocardiography with the measurement of the maximal EAT thickness. Sustained atrial and ventricular tachyarrhythmic events were recorded at the time of each ICD check, including appropriate DC-shocks.
Results: Median EAT thickness was 9.3±3.3 mm. At FU, 36 atrial events and 29 ventricular events, were recorded. Of interest, EAT did not correlate with left ventricular ejection fraction (LVEF) (p =0.3), which drives ICD implantation. EAT predicted arrhythmic events at univariate analysis (p<0.001). At multivariate analysis, including LVEF and betablockers therapy, EAT was an independent predictor of arrhythmias (p <0.001). The figure shows Kaplan Meier curves dividing patients for EAT median value.
Conclusions: EAT thickness significantly predicts the arrhythmia occurrence in patients with HFrEF, becoming a new prognostic marker. The correlation of this parameter with cardiac denervation in patients with heart failure, previously demonstrated by our group, suggests that EAT contributes to the pathogenesis and progression of heart disease. It is therefore desirable to include the EAT measurement in the standard echocardiographic examination.



P244
The prevalence of anxiety among patients with implantable cardioverter-defibrillator, does it change with decades of implementations?

P Zegarow[1]; M Manczak[1]; R Robert Olszewski[1]
[1]*National Institute of Geriatrics Rheumatology and Rehabilitation, Warsaw, Poland*

INTRODUCTION: Currently, it is believed that implantable cardioverter-defibrillator (ICD) is the most effective method of primary and secondary prevention of sudden cardiac death due to ventricular arrhythmias. Although ICD saves lives, it can lead to psychological disturbance in many patients including anxiety and other forms of psychological distress.
AIM: The aim of this meta-analysis was to assess the prevalence of anxiety among adults with an implantable cardioverter-defibrillator. A more accurate estimate of anxiety prevalence than what is currently available is needed to gauge the potential impact of anxiety management among patients with implantable cardioverter-defibrillator.
METHODS: A comprehensive search of articles that were published between 1999 and October 2018 was conducted using MEDLINE, PubMed, Web of Science, Scopus and Google Scholar. Data extraction was carried out by two independent researchers. The severity of anxiety symptoms in the included studies was measured by self-report questionnaires; Hospital Anxiety and Depression Scale (HADS). The quality of the included studies was assessed using the Newcastle-Ottawa Scale. A random-effects model was used to estimate the pooled mean difference of these values between patients with ICD and the controls. The eligible publications were divided into two parts depending on the decade in which they were carried out; the first decade 1999-2008 and the second decade 2009-2018.
RESULTS: 20 studies of the 591 search results met the inclusion criteria with data from 7352 patients (77 % male, mean age 59 years) with implantable cardioverter -defibrillator. Patients with ICD implanted in the first decade have reported a higher prevalence of anxiety symptoms (HADS index ≥ 8) compared to the patients with ICD implanted in the second decade, respectively (25.5% vs 19.6 %, p < 0.001). Fig. 1.

CONCLUSION: Based on existing data, the prevalence of contemporary anxiety in patients with ICD is high as 19.6% but significantly lower than in the previous decade. This requires further research on the cause and the possibility of treatment. This may be related to the dissemination of information about this modern method of treatment in society.

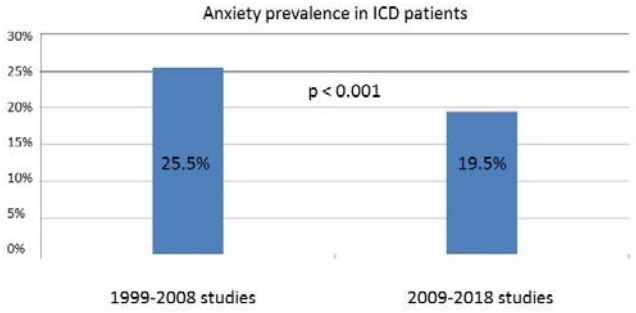


Fig. 1.

P245
Single lead implantable cardioverter-defibrillator lead system with a atrial sensing dipole (Dx-AICD technology): 1-year follow-up

P Parin Sangoi[1]; R Deep Chandh[1]; A Mullasari[1]; U Pandurangi[1]
[1]*Madras Medical Mission, CARDIOLOGY, Chennai, India*

Background: Atrial sensing ability is supposedly useful for discrimination of arrhythmias. A lead incorporating an atrial electrode, theoretically, can discriminate tachy-arrhythmias better. Atrial oversensing can also at times miss ventricular tachycardia (VT). Atrial sensing (VDD mode) is also useful in patients with AV block, where sinus node function is preserved. However data regarding atrial electrograms, battery longevity and lead performance of the Dx-ICD system is lacking.
Methods: We retrospectively analysed the data of 34 patients who had undergone ICD implantation at our center in the period from April 2017 to April 2018. Of these patients, 22 (64%) were implanted with Itrevia 5 VR-T Dx AICD with either Protego Dx or Linox Smart Dx MRI compatible leads using the SMART algorithm (BIOTRONIK). The baseline characteristics, implant characteristics and follow-up pacemaker records of the patients including the remote transmissions were analysed.
Results: Among the 22 patients, mean age was 61.5 ± 16 years, males were 92%, diabetics and hypertensives were 43% and 64% respectively. The etiology of underlying cardiomyopathy was ischemic, idiopathic dilated, hypertrophic, valvular cardiomyopathy in 43%, 36%, 14% and 7% respectively. The mean LVEF was 35± 16%. ICD was implanted for secondary and primary prevention in 72% and 28% patients respectively. 14.3% patients had underlying AV block. Radiofrequency ablation for documented VT was performed before the implant in 64% patients. Remote monitoring was installed in 79% patients.
Extrathoracic left subclavian vein was used for lead implant at the RV apex in all the patients. The mean fluoroscopic time was 67 ±12 minutes. There were no procedural complications. The mean follow-up was 14 ± 8 months. The mean P wave amplitude, sensed R wave, pacing threshold, pace/sense lead impedance and mean defibrillation lead impedance at follow-up were 6.3±5.2 mv (2.1 to 13 mv), 15.1± 4.2 mv, 0.9± 0.3 Volts, 748± 136 Ohms and 69 ± 4.1 Ohms. The mean ventricular pacing rate was 2%. The battery life expectancy was satisfactory. Lead failure as defined by atrial undersensing or oversensing events or inappropriate therapies or failed detection of ventricular tachyarrhythmias, was not detected in any patient. Appropriate therapies were recorded in 15% patients, atrial AT/AF episodes were detected appropriately in 22% patients. ATP and DC shock reverted the underlying VT successfully in 14 and 7% patients respectively.
Conclusions: Dx-ICD systems provide reliable atrial and ventricular signals and superior arrhythmia discrimination, in the follow-up recordings as well as transmitted remote data. They bear significant advantages over dual chamber ICD systems by avoiding lead and procedural complications due to dual leads. Atrial dipole sensing did not encroach upon the battery life.

P246
Appropriate and inappropriate ICD therapy in patients with ischemic and non-ischemic cardiomyopathies according remote monitoring data.

D Denis Losik[1]; V Shabanov[1]; I Peregudov[1]; R Zhizhov[1]; A Filippenko[1]; I Mikheenko[1]; E Fisher[1]; E Morzhanaev[1]; N Elemesov[1]; D Elesin[1]; E Pokushalov[1]; A Romanov[1]
[1]*National Medical Research Center named after E.N.Meshalkin, Novosibirsk, Russian Federation*

Background: Implantable cardioverter–defibrillator (ICD) in patients with symptomatic systolic heart failure is indicated for prevention of the sudden cardiac death. The Danish study demonstrated no benefits from ICD in patients with non-ischemic cardiomyopathy in all cause death, but many patients died suddenly without ICD therapy. Also, the problem of inappropriate ICD therapy is still remained.
Purpose: To test the frequency and reasons of anti-tachy pacing (ATP) and ICD shocks between patients with ischemic and non-ischemic cardiomyopathies using remote monitoring data.
Methods: The retrospective analysis included data of 198 patients with an ICD. Remote monitoring data with Discovery Link system were analyzed. All patients were included in CareLink system (Medtronic, LTD) after ICD implantation. Active transmissions for assessing arrhythmic events were recommended every 3 months after implantation.
Results: The mean period of follow up was 36±5 months. Data were analyzed from 42 (21%) single chamber ICD, 30 (15%) dual chamber ICD and 126 (64%) CRTD. The 1860 (mean 73±35 per month) active transmissions were performed at the end of follow up with and without events. The number of patients with treated events was 34(17.1%). In 16 (45%) cases ICD therapy was inappropriate and appropriate therapy was occurred in 18 (55%) patients. In cases with inappropriate therapy, most of the patients had non-ischemic cardiomyopathy: 12(80%) vs 3(20%) ischemic cardiomyopathy ($p<0.001$). In cases with appropriate therapy, most of the patients had ischemic cardiomyopathy: 12(66.7%) vs 6(29%) non-ischemic cardiomyopathy ($p<0.001$).
Conclusion: Patients with non-ischemic cardiomyopathy had significantly more inappropriate ICD therapies as compared with ischemic cardiomyopathy based on remote monitoring. More data needs to assessed necessity of the ICD implantation for patients with non- ischemic cardiomyopathy.

P247

Frequency and patterns of implantable cardiac defibrillator therapies in patients with left ventricular assist devices

A Aggeliki Gkouziouta[1]; D Miliopoulos[1]; A Kostopoulou[1]; M Spartalis[1]; M Bonios[1]; TH Livanis[1]; S Adamopoulos[1]; N Kogerakis[1]
[1]*Onassis Cardiac Surgery Center, Athens, Greece*

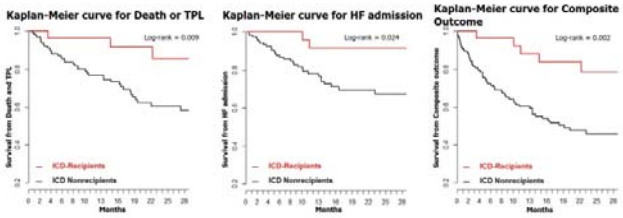
Purpose: Durable ventricular assist devices (VADs) use is a life-saving therapy in patients with end-stage heart failure. These patients are at high risk for ventricular arrhythmias. The pattern of ICD therapies in these patients is not well characterized.
Methods: Our Hospital, in Athens is the only centre in Greece for VAD and Heart Transplantation. We have implanted more than 160 VADs since 2003. BiVADs being the majority of the VADs implanted due to advanced biventricular failure of the patients and the late referral for advanced heart failure treatment. Our single-center retrospective cohort included 90 patients with ICDs and VADs followed at our centre. Not all the patients treated with VADs had previously ICD. According to our Hospital Guidelines patients planned to receive BIVAD were not supposed to have an ICD. On the other hand, for all the patients treated with LVAD ICD implantation was mandatory. Data collected included frequency of ICD therapies, type of therapy (appropriate vs. inappropriate; shocks vs. anti-tachycardia pacing (ATP)), and time-course of therapies.
Results: There were 105 episodes (2,9 episodes/patient) and 379 arrhythmias were treated, 61,4% of which were appropriate. 36 episodes (46%) required ICD shocks with the remaining requiring ATP. LVAD pts who received ICD therapy were all hospitalized due to our Hospital Guidelines in order to protect the RV function. Only one patient had sustained VT and needed temporary RV support with ECLS. VF when detected in BiVAD patients was treated only once and when recurrent episodes were occurred were left untreated if no hemodynamic compromise was occurred. ICD therapies were all switched off in BiVAD pts after the first treatment and no battery change was performed in the BiVAD cohort. All VAD pts were treated with heart failure treatment and some LVAD pts received antiarrhythmic therapy with amiodarone and mexiletine. Ablation of ventricular tachycardia was proposed by EP physicians in 2 LVAD patients with recurrent episodes of ventricular tachycardia.
Conclusions: Analysis of our VAD cohort revealed three important findings: a) ICD therapy is very common (42%) in the first year especially after LVAD implantation; b) Ventricular arrhythmias are highly clustered in this cohort, especially VF in the very sick BiVAD patients; c)ATP is frequently effective. These findings have important implications on device follow-up and programming for this expanding patient population. New data from our hospital are available including follow up of 5 years support for LVAD and BiVAD patients in a low organ donation environment.

P248

Low guideline adherence of physicians for primary prevention of sudden cardiac death with implantable cardioverter defibrillator implantation despite prenotification system

IK Inki Moon[1]; EK Choi[1]; EJ Lee[1]; MJ Cha[1]; SI Oh[1]
[1]*Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea (Republic of)*

Background: Implantable cardioverter defibrillators (ICD) is known to improve survival of patients with heart failure by preventing sudden cardiac death. Although the guideline and reimbursement system have been expanded, there is a gap between the guideline recommendation and real-world practice.
Purpose: We sought to find the impact of prenotification system of candidate for ICD implantation and the adherence to guideline in tertiary hospital.
Methods: Patients were screened based on echocardiography (less than 35% of left ventricular ejection fraction, LVEF) and medical records from 2015 January to 2018 April. If the patients were or could be met to the guideline and reimbursement criteria, prenotification with e-mail was sent to physicians to recommend ICD implantation. We evaluated the implantation rates, the cause of non-implantation, and outcomes after prenotification.
Results: Total 156 of patients (mean age 67.4 years, male 68.6%) were screened, and 26 (16.7%) of patients were referred to electrophysiologists and performed device implantation (15 of ICD and 11 of cardiac resynchronization therapy defibrillator [CRT-D]). Among those without ICD implantation (n=130), 61 (46.9%) of patients did not receive optimal medical therapy, 21 (16.2%) of patients refused procedures, and other following reasons; candidate for cardiac transplantation (TPL, n=13), prescribed new drugs and observed (n=21), and other reasons (n=14). Among those with ICD implantation (n=26), one patient received TPL because of heart failure aggravation and two were expired. During a mean follow-up of 1.8 years, 3 (11.5%) of ICD implanted patients occurred sustained ventricular tachycardia (n=2) and fibrillation (n=1) and treated by anti-tachycardia pacing therapy and shock. In the non-implantation group, 42 (32.3%) patients were deceased and seven received TPL. Patients with ICD implantation showed better survival compared to those without ICD implantation in all-cause death and TPL (adjusted hazard ratios [HR] 0.3, 95% confidence interval [CI] 0.13-0.65).
Conclusions: Substantial number of patients didn't receive guideline recommended therapy and effect of e-mail letter for activating referral system was unfavorable. New methods for appropriate treatment should be sought.



P249

The follow-up of patients with chronic heart failure and implantable cardioverter defibrillator in primary prevention

M Michal Kerekanic[1]; S Misikova[1]; E Komanova[1]; J Sedlak[1]; J Farkas[1]; B Stancak[1]
[1]*East-Slovak Institute of Cardiovascular Diseases, Department of Arrhythmias, Kosice, Slovakia*

Background: The aim of the study was to examine the occurrence and predictors of appropriate and inappropriate shocks and all cause mortality in patients with chronic heart failure who had received an implantable cardioverter defibrillator (ICD) in primary prevention of sudden cardiac death.
Methods: We have retrospectively included 454 consecutive ICD patients (mean age 61 ± 10 years, 388 men) received single- or dual-chamber ICD. Two hundred forty-five patients (54 %) were in NYHA class III and the mean left ventricular ejection fraction (LVEF) was 27 ± 5 %. ICD shock was defined as an appropriate when delivered for ventricular tachycardia or ventricular fibrillation and as an inappropriate when delivered for other arrhythmias or for an abnormal sensing.
Results: During a mean follow-up of 1578 ± 876 days, 87 patients (20 %) had ≥ 1appropriate ICD shock and 55 patients (12 %) had ≥ 1 inappropriate ICD shock. Causes of an inappropriate ICD shock were atrial fibrillation or atrial flutter (65 %), an abnormal sensing (24 %) and sinus tachycardia (11 %). The mean time from the ICD implantation was 790 ± 643 days to the first appropriate ICD shock and 873 ± 794 days to the first inappropriate ICD shock. Logistic regression analysis showed that digoxin therapy (OR 1,72, 95 % CI 1.03 - 2.87, p = 0.037) was significantly associated with an appropriate ICD shock and NYHA class III (OR 1.97, 95 % CI 1.06 - 3.66, p = 0.032), history of atrial fibrillation (OR 2.34, 95 % CI 1.31 - 4.19, p = 0.004) and mineralocorticoid receptor antagonist (MRA) therapy (OR 0.47, 95 % CI 0.25 - 0.86, p = 0.016) were significantly associated with an inappropriate ICD shock.

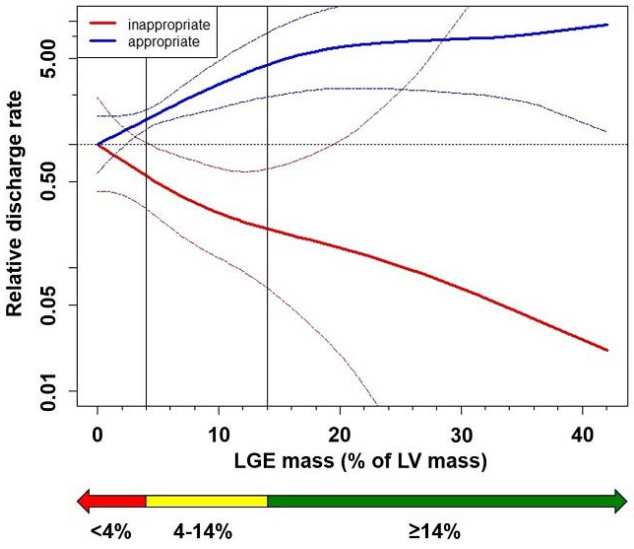
The death from any cause occurred in 193 patients (43 %). The mean time from the ICD implantation to death from any cause was 1010 ± 687 days. Cox regression analysis showed that diabetes mellitus (HR 1.58, 95 % CI 1.13 - 2.20, p = 0.006), LVEF ≤ 27 % (HR 1.64, 95 % CI 1.19 - 2.25, p = 0.002) and creatinine level ≥ 1.2 mg/dl (HR 1.48, 95 % CI 1,08 - 2.03, p = 0.013) increased and statin therapy (HR 0,71, 95 % CI 0.51 - 0.98, p = 0.041) decreased the occurrence rate of all cause mortality.
Conclusion: In the present study, 20 % of patients received appropriate ICD shock and 12 % of patients received inappropriate ICD shock during 4 years after implantation ICD. The digoxin therapy was independent predictor of appropriate ICD shock and NYHA class III, history of atrial fibrillation and MRA therapy were independent predictors of inappropriate ICD shock. Four-year all cause mortality was 43 %. Independent predictors of all cause mortality were diabetes mellitus, LVEF, creatinine level and statin therapy.

P250

Late gadolinium enhancement mass to predict shocks of defibrillators implanted for primary prevention in patients with non-ischaemic heart failure

A Aimo[1]; A Barison[2]; A Barison[2]; A Barison[2]; V Castiglione[1]; V Castiglione[1]; V Castiglione[3]; G Mirizzi[2]; G Mirizzi[2]; G Mirizzi[2]; A Ripoli[2]; A Ripoli[2]; A Ripoli[2]; GD Aquaro[2]; GD Aquaro[2]; GD Aquaro[2]; M Piacenti[2]; M Piacenti[2]; M Piacenti[2]; C Passino[4]; C Passino[4]; A Giannoni[2]; C Passino[4]; M Emdin[4]; M Emdin[4]; M Emdin[4]
[1]Azienda Ospedaliero-Universitaria Pisana, Scuola di Specializzazione Malattie dell'Apparato Cardiovascolare, Pisa, Italy; *[2]Gabriele Monasterio Foundation, Pisa, Italy*; *[3]Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy*; *[4]Sant'Anna School of Advanced Studies, Pisa, Italy*

Background: Implantable cardioverter defibrillator (ICD) is recommended for patients with non-ischaemic heart failure (HF) and left ventricular ejection fraction (LVEF) ≤35% despite optimal medical therapy. No solid evidence exists to support this recommendation, and most patients will not experience any appropriate ICD intervention. Cardiovascular magnetic resonance (CMR) may allow a tailoired and more effective strategy of ICD implantation.
Methods: From our institutional dataset we retrieved the data of all patients with non-ischaemic HF receiving an ICD for primary prevention, and undergoing CMR within 1 month before implantation.



Results: 183 patients were evaluated (men 73%, median age 66 years, LVEF 24%, N-terminal fraction of pro-B-type natriuretic peptide 1217 ng/L, atrial fibrillation, flutter or atrial ectopic rhythm 21%). They received single-chamber (n=21, 12%), dual-chamber (n=34, 19%), or cardiac resynchronization therapy devices (n=127, 69%); 1 patient (1%) received a subcutaneous defibrillator. Twenty patients (11%) experienced a shock for ventricular tachycardia or fibrillation (VT/VF) over 2.5 years (0.8-5.4), and 13 (7%) had an inappropriate shock over 2.7 years (0.9-5.4). At CMR examination, late gadolinium enhancement (LGE) accounted for a very limited percentage of the LV mass (4% [2-11%]). LGE mass and posterior wall LGE emerged as univariate predictors of shocks for VT/VF, LGE mass being also an independent predictor (hazard ratio - HR 1.90, 95% confidence interval - CI 1.19-3.03; p=0.007). LGE mass ≥14% (the best cut-off at receiver operating characteristics analysis) independently predicted shocks for VT/VF (HR 3.82, 95% CI 1.51-9.68; p=0.005). LGE mass <4% was the only univariate predictor of inappropriate shocks (HR 4.82, 95% CI 1.07-21.76; p=0.041). As visually represented by spline curves, patients with LGE mass ≥14% (n=27, 15%) had a high likelihood of shocks for VT/VF and a low likelihood of inappropriate shocks, while the opposite was true for patients with LGE mass <4% (n=88, 48%).
Conclusions: Among patients with non-ischaemic HF receiving an ICD for primary prevention, those with LGE mass ≥14% benefit most from ICD in terms of prevention of SCD, while those with LGE mass ≤4% display mainly inappropriate shocks. A therapeutic strategy informed by LGE quantification is then worth considering.

P251

Etiology of dilated cardiomyopathy as the leading predictor of efficiency of implantable cardioverter-defibrillators in prevention of sudden cardiac death

E A Elena Solovyova[1]; OV Blagova[1]; VP Sedov[1]; EA Kogan[1]; EV Zaklyazminskaya[1]; AV Nedostup[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Purpose: to study the predictors of efficiency of ICD/CRTD in prevention of sudden cardiac death (SCD) in patients with dilated cardiomyopathy (DCM).
Methods: 275 patients with DCM syndrome were included (185 males; 46.8±12.5 years). Inclusion criteria were left ventricular end-diastolic diameter (LV EDD) more than 5.5 cm and LV ejection fraction (EF) less than 50%.The average EF 37.8±11.6% and EDD 6.5±0.8 cm. Patients with coronary artery stenoses more than 50% were excluded. Cardioverter-defibrillators were implanted in 78 (28. 4%) of patients (54 males, 48.8±12.8 years): 43 ICD, 35 CRTD. The follow-up was 14 [6; 120] months.
Results: defibrillators were implanted in patients with more severe dysfunction: EDD (6.7±0.8 vs 6.4±0.8 cm in patients without devices, <0.005), EF (32.5±9.5 vs 40.1±11.8%, <0.001), RV (3.4±0.8 cm vs 3.1±0.8 cm, <0.05), pulmonary artery systolic pressure (45.4±16.6 vs 49.6±15.0 mmHg, =0.02), mitral regurgitation (2.0 vs 1.5, <0.005). The following causes of DCM syndrome have been identified: the isolated myocarditis (n=137, 49.8%), the primary (genetic) DCM (n=54, 19.6%), the genetic basis with myocarditis (n=68, 24.7%) and anthracycline-induced cardiomyopathy (n=4, 1.5%). Genetic forms of DCM were represented by non-compact myocardium (n=64), ARVC (n=12), TTR-amyloidosis (n=1), myopathy (n=6). The pathogenic mutations in the genes LMNA (n=1), DES (n=2), DSP (n=2), EMD (n=2), PKP2 (n=1), MUH7+MyBPC3 (n=2), MyBPC3 (n=4) were detected. The appropriate shocks rate (ASR) was 21. 8%. The only reliable predictor of ASR was identified the genetic nature of DCM syndrome (in combination with myocarditis in 67% or isolated in 30% in comparison with 35/20% in patients without ASR, p<0.005, AUC 0.733, RR 1.66, 95% CI 0.711-3.885). In patients with shocks were detected the higher frequencies of stable/unstable VT (22 / 67%) in comparison with patients without shocks (1.7 / 73%, =0.06), a low QRS voltage (39 vs 13%, <0.05), absence of LV hypertrophy signs on the ECG (83% vs 53%, =0.07). The average LVEF was higher in patients with ASR (34.4±9.4%) in comparison with patients without ASR (25.9±9.0%), <0.003. There were no differences of NYHA class, the sizes of cardiac chambers. The mortality in patients with DCM was 18.9% (n=52), death + transplantation 22.5% (n=62), SCD 2.9% (n=8); in patients with defibrillators – 23.0%, 31.0%, 2.6%; in patients without devices – 17.3%, 19.3%, SCD 3.1%. There were no differences between the groups.
onclusion. Due to effective ICD therapy, death rate did not exceed those of less severe patients without devices. As criteria for ICD implantation, it is necessary to use the genetic nature of DCM, sustained / unsustained VT, the low QRS voltage, and the absence of LV hypertrophy (ECG). The genetic nature of DCM syndrome (alone or in association with myocarditis) is the more important predictor of appropriate shocks than EF.

P252

Are women being offered an ICD compare to men ?

S Serge Lepage[1]; C Ahnadi[1]; C Allard[1]; S Pigeon[1]
[1]Sherbrooke University, Sherbrooke, Canada

Funding Acknowledgements: supported by a grant fron société quebecoise insuffisance cardiaque

BACKGROUND: Guidelines supporting the use of implantable cardioverter-defibrillator (ICD) for primary prevention of sudden cardiac death (SCD) in patients diagnosed with heart failure have been established for many years. We suspected discordance between Canadian Cardiovascular Society's recommendations and current clinical practice. Our goal was to establish the difference between current guidelines and clinical practice as well as the factors, such as sex, that significantly influence prescription of an ICD.
METHODS: This retrospective study included 903 consecutive patients that were followed by cardiologists in a specialized heart function clinic. Our electronic medical

record (Vision C+) collected data from patients seen between May 2005 and February 2017. Patients had to have a documented left ventricular ejection fraction of 35% or less and be followed for at least one visit over a period of at least 90 days. All patients fulfilling these criteria were included except patients with a latest documented New York Heart Association functional class of 4. We described the use of ICD within our group of patients, considering the selected patients were potentially eligible for ICD in primary prevention of SCD. All variables available such as age, sex, medication and comorbidities were analyzed.
RESULTS: Of our 903 patients group, 195 (21,6%) were women. Mean age on was 72 years. The use of ICD was reported for 367 (40,6%) patients. CAD was labeled has the cause of HF in 607 (67,2%) of patients. In a logistic regression, factors such as age (OR=1,03, p<0,001), female sex (OR=1,6, p=0,011) and diagnostic of cognitive impairment (OR=3,45, p=0,004) were showed to negatively influence the prescription of an ICD.
CONCLUSIONS: As expected, clinical practice differs to national recommendations. We agree that the prescription of an ICD should be approached individually according to the age, comorbidities and wishes of each patient. The present study indicated that women, independently of age and comorbidities, were to receive significantly less ICD then men. Our group included only 21,6% of women which can possibly be a source a bias. We cannot know for sure if the difference noted is related to wishes and beliefs in our group or if there really is a sex bias within clinical practice. This concern would benefit further evaluation in future studies.

Chronic Heart Failure - Pathophysiology and Mechanisms

P253
Relationship between functional capacity, haemodynamic response to exercise and quality of life in chronic heart failure

Background/Aim: Heart failure is associated with high mortality rate. Diminished functional capacity, haemodynamic response to exercise and quality of life are strong independent determinants of prognosis and mortality in chronic heart failure. The aim of the present study was to assess the relationship between functional capacity, haemodynamic response to exercise and quality of life in patients with chronic heart failure.
Methods: A single-centre, prospective, cross-sectional study recruited 42 patients (31 males, 11 females, age 60±10 years, body mass index 29±4 kg/m2) with stable chronic heart failure due to left ventricular systolic dysfunction (LVEF=25±7%) and the New York Heart Association Functional Class II (45%) and III (55% of patients). All patients completed a maximal graded cardiopulmonary exercise stress testing using cycle ergometer with non-invasive gas exchange and haemodynamic measurements to assess peak oxygen consumption and cardiac response to exercise. Cardiac power output, expressed in watts, was calculated as the product of mean arterial blood pressure and cardiac output. Quality of life was assessed using Minnesota Living with Heart Failure Questionnaire (MLHF).
Results: The average value (±SD) for functional capacity i.e. peak O2 consumption was 14.3±4.3 ml/kg/min, peak exercise haemodynamics i.e. heart rate 105±21 beats/min, mean arterial blood pressure 95±18 mmHg, cardiac output 13.9±3.6 L/min, cardiac power output 2.87±0.83 watts, and MLHF quality of life score 27±18. There was a significant negative relationship between the MLHF quality of life score and peak O2 consumption (r= -0.50, p=0.01) and heart rate (r= -0.30, p=0.05). There was however no significant relationship between the MLHF quality of life score and other exercise haemodynamic measures including peak cardiac power output (r= 0.15, p=0.38), cardiac output (r= 0.22, p=0.15), and mean arterial blood pressure (r= -0.09, p=0.57).
Conclusion: The major finding from the present study suggests that functional capacity, represented by peak exercise oxygen consumption, is a strong determinant of quality of life in patients with chronic heart failure. Results further reveal that the MLHF quality of life score may not be influenced by overall function and pumping capability of the heart.

Background Cardiac rhythm disturbances are common in heart failure, and likely to play a significant role in adverse clinical outcomes. Despite this, they have not been systematically studied, because until recently it has not been possible to undertake prolonged, continuous cardiac monitoring.
Purpose To investigate the role of arrhythmias and conduction disturbances in adverse clinical outcomes in patients with heart failure and to determine the cause and mode of death.
Methods Patients are recruited during an index admission for decompensated heart failure and receive an injectable cardiac monitor (ICM) prior to hospital discharge. Patients are then followed-up remotely for between two and four years, or until death. Cardiac rhythm data are collected via home transmission and are analysed for their temporal association with subsequent clinical events, including readmission for heart failure and stroke, and all-cause mortality. In an optional sub-study, patients are prospectively consented to an autopsy examination in the event of their death before the end of the study. Amongst these patients, the mode and cause of death will be characterised utilising both autopsy data and the terminal electrocardiographic rhythm captured via interrogation of their implanted ICM. In a further optional sub-study, patients undergo cardiac magnetic resonance (CMR) imaging during their index hospitalisation, to inform correlation of CMR data at baseline with subsequent novel ICM-defined arrhythmic outcomes (eg. new-onset, subclinical, ICM-detected atrial fibrillation; or ICM-documented arrhythmic sudden death). Study recruitment commenced in August 2017 and follow-up will end on 31/07/2021. We will enrol up to 500 patients.
Results/Conclusion RHYTHM-HF is a novel, contemporary, natural history study which aims to investigate the association of arrhythmias and conduction disturbances to adverse clinical events in patients with heart failure, and to characterise the cause and mode of death in heart failure. It is anticipated that the results of this study will inform the design of several new randomised, interventional trials directed at preventing these adverse events.

Heterogeneity of cardiac macrophages in patients with of ischemic ADHF

EV Ekaterina Kruchinkina[1]; YV Rogovskaya[2]; RE Batalov[1]; VV Ryabov[3]
[1]Cardiology Research Institute Tomsk National Research Medical Center Russian Academy of Sciences, Tomsk, Russian Federation; *[2]National Research Tomsk State University, Tomsk, Russian Federation*; *[3]Siberian State Medical University, Tomsk, Russian Federation*

The role of the inflammatory reaction in the pathogenesis of HF is a well-known fact. However, there are no methods that affect myocardial inflammation. This is due to the lack of laboratory and clinical criteria for the phenotyping of HF. Macrophages play an important role in the inflammation. Identification of macrophage subpopulations in different types of inflammation in patients with HF will allow filling the lack of knowledge.
Aim: To study the heterogeneity of cardiac macrophages in patients with cute decompensation of ischemic chronic heart failure (ADHF).
Methods: This open-label, nonrandomized, single-center, prospective trial was registered at clinicaltrials.gov (#NCT02649517). This trial included 25 patients (84% men, left ventricular ejection fraction 29.17±9.4%) with ADHF and ischemic systolic dysfunction. Inclusion criteria were ADHF not earlier than six months after optimal surgery (percutaneous coronary intervention or/and coronary artery bypass graft) and optimal drug treatment for ADHF according to ESC guidelines. All patients underwent invasive angiography and endomyocardial biopsy with immunohistochemistry (n=25) and immunofluorescent analysis (n=21). Immunohistochemical criteria of myocarditis were at least 14 leukocytes per sq. mm in the myocardium including up to 4 monocytes and 7 or more CD3+ T lymphocytes per sq. mm. After that they were divided into four groups: group 1 (viral and autoimmune inflammation), group 2 (viral inflammation), group 3 (cardiotropic virus without inflammation), group 4 (cardiotropic virus with antibodies to cardiomyocytes without inflammation). We used CD68 as a marker for the cells of the macrophage lineage, while CD80 was considered as M1-like macrophage and CD163, CD206, stabilin-1 were considered as M2-like macrophage biomarkers. We used CD19, Cq1, MHL II as a marker for autoimmune process.

Results: The most common phenotype of inflammation according to the results of immunohistochemical analysis is viral inflammation (40%). Cardiotropic virus without signs of inflammation in the myocardium was revealed in 16% of patients. Viral and autoimmune inflammation and a cardiotropic virus with antibodies to cardiomyocytes were found in 12% and 8% of cases, respectively. The number of CD68+CD80+ cells in group 1 was significantly higher than in group 2 (p=0.0429). In addition, we observed an increased number of macrophages CD68+CD206+ in group 2 compared with group 3 (p=0.0085). We noted a slight increase stabilin-1 in group 4.
Conclusions: We found the heterogeneity of cardiac macrophages in patients with ADHF. It was revealed the predominance of CD68+CD80+ cells in patients with viral and autoimmune inflammation and CD163-CD206+ cells predominate in patients with viral inflammation.

On behalf of: Heart "OMics" in AGEing (HOMAGE) investigators
Funding Acknowledgements: This work is supported by the European Union: HEALTH-F7-305507 HOMAGE

Background: Heart failure (HF) is common in both men and women, however disease pathophysiology, presentation and progression differ between sexes. These sex differences may cause differences in circulating biomarkers, but studies investigating sex-specific biomarker profiles in prediction of new onset HF are scarce.
Purpose: To identify and validate sex-specific proteomic biomarkers and the underlying mechanistic pathways associated with development of new onset HF.

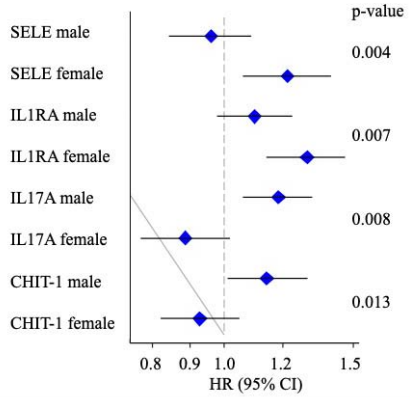

Figure 1: Forest plot showing hazard ratio's with 95% confidence intervals and p-values of the sex-interaction of 4 sex-specific protein biomarkers in relation to new onset HF

Figure 1

Methods and results: A matched case control design was used with cases (new-onset HF) and controls selected out of different international cohorts within the HOMAGE consortium (>20,000 individuals). Incident HF was defined as first hospitalization for HF. Controls were matched on cohort, follow-up time and age. Two independent sample sets were used to discover and replicate the findings: a 'discovery' set with 300 cases and 600 controls (phase 1a) and a replication set with 315 cases and 315 controls (phase 1b). Circulating proteins in the plasma were studied (n= 252) using O-link technology, and were manually clustered into 9 functional clusters based on the ConsensusPath database. Cox regression analysis was performed to look for sex-specific biomarkers related to HF development in the different sample phases as well as the pooled phases, correcting for matched factors and clinical factors (heart rate, systolic and diastolic blood pressure, BMI, HDL, LDL, history of coronary artery disease, diabetes mellitus, creatinin and smoking status). Four protein biomarkers consistently revealed (a trend to) significant sex differences in the prediction of new onset HF (figure 1) in the pooled data: E-selectin (SELE) and interleukin-1 receptor antagonist (IL1RA) being more predictive for females; and interleukin-17A (IL17A) and Chitotriosidase-1 (CHIT1) being more predictive for males. All 4 proteins are involved in the immunological response. Moreover, both female biomarkers (SELE and IL1RA) also play a role in energy metabolism or fibrosis (SELE).
Conclusions: IL17A and CHIT1 in male and SELE and IL1RA in female are sex-specific protein biomarkers for the prediction of new onset HF in the HOMAGE study. Further studies are required for validation in other independent cohorts and to investigate the clinical value of these proteins.

Functional mitral regurgitation in pts with HFrEF, HFmrEF and HFpEF: the good, the bad and the ugly ?

T Castelein[1]; M Beles[1]; S Verstreken[1]; M Goethals[1]; W Heggermont[1]; R Dierckx[1]; J Bartunek[1]; M Marc Vanderheyden[1]
[1]OLV Hospital Aalst, Cardiovascular Center, Aalst, Belgium

Background: The 2016 heart failure(HF) guidelines introduced a new classification of heart failure based on ejection fraction – HFrEF, HFmrEF and HFpEF. The aim of this study was to evaluate and compare the prevalence and evolution of functional(F) mitral(M) regurgitation(R) in HFrEF, HFmrEF and HFpEF pts admitted with an episode of acute decompensated heart failure .
Methods:We retrospectively analyzed data of 1453 de novo heart failure(HF) patients consecutively admitted with an acute episode of heart failure in a tertiary HF center (mean length of stay: 18 ± 16 days) . Ejection fraction was measured during index hospitalization and functional mitral regurgitation(FMR) was assessed at time of discharge. Severe FMR ≥ 2 was present in 40 % of pts. Mean age of the patients was 74 ± 12 years, 52% of them were men. After a mean FU of 1045 ± 702 day, 63 % of pts were still alive. According to ESC criteria we identified 45.3 % patients with HFrEF, 18.8 % patients with HFmrEF and 35.9 % patients with HFpEF.
Results: Pts with HFpEF were younger (p<0.001), had lower NTproBNP (p<0.001), less cardiac readmissions (p<0.001) and better RV function as evidenced by TAPSE(p=0.003). HFrEF pts had significantly higher incidence of severe FMR ≥ 2 at time of discharge (50.8 % vs 33.1% vs 38.8%; p > 0.001) and had higher LVEDD (60 ± 9 mm vs 54 ± 8 mm vs 48 ± 7mm; p < 0.05) compared to HFpEF, HFmrEF pts. Interestingly in HFrEF as well as in HFpEF pts optimisation of the HF therapy resulted in a significant improvement in FMR. Although no difference in early survival was noted between HFpEF, HFmrEF and HFrEF pts, HFpEF patients had worse long term survival compared to HFmrEF and HFrEF
However, only in the HFrEF group a significant difference in survival was noted beween those pts with and without severe FMR (p < 0.001).
Conclusion: Interestingly in HFrEF and HFmrEF but not in HFpEF pts optimisation of HF therapy resulted in a significant improvement in MR. Although FMR is prevalent in pts with HFpEF and HFmrEF it only bears prognostic information in HFrEF pts. Therefore we speculate that HFrEF pts with persistent severe FMR after recompensation should be followed intensively in a dedicated heart failure clinic.

Funding Acknowledgements: National Institute for Health Research Leicester Cardiovascular Biomedical Research Centre overall project Grant (IRS_BRU_0211_20033)

Background The pathophysiology of heart failure with preserved ejection fraction (HFpEF) remains incompletely defined.
Purpose To characterize HFpEF compared to heart failure with reduced ejection fraction (HFrEF) and controls and gain pathophysiological insights.
Methods Prospective, observational study of HFpEF n=140, HFrEF n=46 and controls n=48; age (73±8) and sex-matched (males 49%). Subjects underwent intense phenotyping with cardiovascular magnetic resonance imaging, echocardiography, 6-minute-walk-testing (6MWT) and plasma biomarkers of myocardial fibrosis (ST2, galectin-3, GDF-15, pentraxin-C, TIMP-1, TIMP-4, MMP-2, MMP-3, MMP-7, MMP-8, MMP-9), cardiomyocyte stress/damage (Troponin-I, BNP, pro-BNP, NTpro-ANP), myocardial hypertrophy (Renin), inflammation/oxidative stress (MPO, hs-CRP, TNFR-1, IL-6) and renal dysfunction (cystatin-C and NGAL).

Results The HFpEF group was characterized by a high burden of co-morbidity: obesity (body mass index 34±7), hypertension (91%), diabetes (54%) and atrial fibrillation (31%). Both HFrEF and HFpEF groups when compared to controls had worse exercise capacity (6MWT distance: 210 vs 180 vs 380m), lower left ventricular (LV) EF (28 vs 56 vs 58%), higher LV filling pressures (E/E': 15 vs 13 vs 9, BNP: 387 vs 135 vs 33 ng/L), greater proportion of right ventricular (RV) systolic dysfunction (defined as RVEF <45%): 46 vs 19 vs 0%, more left atrial (LA) remodeling/dysfunction i.e. higher LA volumes: 59 vs 53 vs 35 ml/m2 and lower LA ejection fraction (LAEF): 29 vs 32 vs 51%, greater proportion of focal fibrosis i.e. myocardial infarction: 57 vs 23 vs 0% and non-ischaemic: 41 vs 35 vs 10%, greater burden of diffuse fibrosis i.e. extracellular volume fraction: 31 vs 28 vs 25% and higher levels of all plasma markers tested; p<0.0001 for all above.
LV remodeling i.e. mass/volume ratio was different between HFpEF (0.68 - concentric) and HFrEF (0.47 - eccentric); p<0.0001. Compared to HFpEF, HFrEF patients had lower LVEF, increased LV volumes, greater burden of focal and diffuse fibrosis, more RV remodeling, lower LAEF and higher LA volumes; p<0.05 for all. Plasma markers of LV cardiomyocyte stretch: BNP (387 vs 136 ng/L), pro-BNP (2.3 vs 1.6 pg/ml) and NTpro-ANP (7814 vs 6443 pg/ml) were also higher in HFrEF; p<0.05. In contrast, highly sensitive-C reactive protein was highest in HFpEF (43 vs 25 mg/L); p=0.06.
Conclusions HFpEF exists as a distinct pathophysiological entity compared to age- and sex-matched HFrEF and controls, providing differing targets for treatments. Inflammation (hs-CRP) is possibly more prominent in HFpEF compared to HFrEF in which cardiomyocyte stretch/stress is greater.

Effects of sympathetic modulation by renal denervation in patients with heart failure and preserved ejection fraction

K-P Kresoja[1]; K-P Rommel[1]; K Fengler[1]; M Von Roeder[1]; C Besler[1]; S Desch[1]; H Thiele[1]; P Lurz[1]
[1]*Heart Center of Leipzig, Department of Cardiology, Leipzig, Germany*

Background: Heart failure with preserved ejection fraction (HFpEF) is associated with significant morbidity and mortality and up to now no treatment has proven effective. Amongst many pathophysiological derangements studies have indicated that HFpEF might be linked to increased sympathetic activity. Modification of the sympathetic nervous system through renal sympathetic denervation (RDN) is associated with reduction of blood pressure variability, which is an indicator of sympathetic nervous activity and effective circulating volumes. We therefore hypothesised that RDN might pose a possible treatment option in HFpEF through modifying sympathetic activity.
Purpose: The aim of the present analysis was to investigate the effects of RDN on patients with HFpEF.
Methods: Patients ≥18 years who underwent RDN, either in a prospective randomized clinical trial or in clinical routine in a single high-volume centre, were retrospectively included in the current analysis. Patients with a LVEF < 50% (n=9) were excluded. Patients were stratified into a "HFpEF" or no heart failure "non-HF" group according to ESC recommendations from 2016.
Results: Between November 2011 and September 2018, 76 HFpEF (median age, 66 [IQR 61-74] years, 39.5% ♀) and 48 non-HF patients (age 60 [54-66] years, 18.8% ♀) were included in the current analysis. RDN reduced systolic ambulatory blood pressure (BP) in both HFpEF (Fig. 1a) and non-HF patients at three-months (-8.5 ± 11.7 and -7.4 ± 10.4, both p<0.001; respectively) and six months (-8.1 ± 11.8 and -8.2 ± 8.4, both p<0.001; respectively). Frequencies of BP response ≥5 mmHg were not different between HFpEF and non-HF patients (p=0.663).
BP variability (BPV) as indicated by day- or night-time 24-h ambulatory BP standard deviation (SD) tended to be higher in HFpEF as compared to non-HF patients at baseline (SDday 17.0 [13.6-20.2] vs. 14.7 [12.4-17.3], p=0.055 and SDnight 15.5 [12.4-20.4] vs. 12.6 [11.3-15.0], p=0.003). RDN reduced BPV at three and six months in HFpEF patients (Fig. 1b) to equivalent levels of non-HF patients.
Compared to baseline values, NT-proBNP levels at the three months follow-up were decreased in HFpEF (348 [216-679] vs. 326 [164-689] pg/mL, p=0.010) (Fig. 1c) but not in non-HF patients (54 [34-90] vs. 67 [41-114] pg/mL, p=0.006), while renal function as assessed by estimated glomerular filtration rate did not improve in either group.
Conclusion: Sympathetic activity and stressed volume might be increased in HFpEF patients as indicated by higher BPV when compared to non-HF patients undergoing RDN. RDN in HFpEF patients reduced ambulatory BP. Additionally BPV was reduced to values of non-HF patients, which was accompanied by a decrease in NT-proBNP levels. Modification of sympathetic activity through RDN might be a promising therapeutic approach in HFpEF, which merits further investigations.

Evaluation of left intraventricular synchrony in asymptomatic left bundle branch block patients by non-invasive parameters obtained from radionuclide ventriculography

A Agustin Pastor Fuentes[1]; R Mata Caballero[1]; J Perea[1]; A Nunez Angulo[1]; B Alcon[1]; M Alcocer[1]
[1]*Hospital Universitario Getafe, Getafe (Madrid), Spain*

Background: Radionuclide ventriculography (RNV) has been used to assess left ventricular ejection fraction (LVEF) and ventricular synchrony by means of phase and amplitude parametric images and their quantitative-derived parameters, where mean phase angle (PA) represents mean time of ventricular contraction onset and the standard deviation (SD) of the PA relates to synchrony of ventricular contraction. Objective: To study global and regional LVEF data as well as LV synchrony parameters obtained by RNV in patients (P) with asymptomatic left bundle branch block (LBBB)
Methods: Global and regional LVEF and LV synchrony data obtained from a RNV in 18 normal ECG P, were compared with the same parameters in 46 asymptomatic LBBB P with no previous cardiac history, who were referred for evaluation because of the abnormal ECG finding. SD of PA was derived from the phase histogram obtained

in the best left anterior oblique view, and expressed both in grades (°) or milliseconds (ms). Regional LVEF was derived from each of the four segments that ventricular blood pool was divided (Septal, Apex, Inferior-Lat, Post-Lat) in the same left anterior oblique view.

Results: In 19 LBBB P, mean LVEF was < 50% and > 50% in the remaining 27 P (40±7% vs 60±5%p < .001). Other results are expressed in the table below. In the whole LBBB group, a weak but good and inverse correlation between SD of PA and LVEF was found (r=-0.53, p<0.001), so the greater SD of PA, the less LVEF.

Conclusions: 1. Abnormal LV systolic function is encountered in 41% of asymptomatic ambulatory P with LBBB. 2. All LBBB P, showed left intraventricular mechanical asynchrony data estimated by RNV parameters when compared to controls, although higher in those P with depressed LVEF.

3. We may speculate that this abnormal LVEF in 41% of LBBB group is due to an undiagnosed primary cardiomyopathy since regional wall motion is globally affected in this group compared with control P and those LBBB P with preserved EF or due to a LV remodeling because of LBBB-dependent electrical asynchrony itself

The impact of regulatory T lymphocytes on long-term survival in patients with ischemic heart failure with reduced ejection fraction

P Patrick Sulzgruber[1]; L Koller[1]; S Blum[1]; M Huelsmann[1]; J Wojta[1]; A Niessner[1]
[1]*Medical University of Vienna, Cardiology, Vienna, Austria*

Background: Heart failure with reduce ejection fraction (HFrEF) constitutes a global health issue representing a prevalent clinical syndrome. While pro-inflammatory cytokines proved to have a pivotal role in the development and progression of HFrEF, less attention has been paid to the cellular immunity. Regulatory T lymphocytes (Tregs) seem to have an important role in the induction and maintenance of immune homeostasis especially in patients after acute coronary syndrome and coronary vessel disease. Therefore we aimed to investigate the impact of Tregs on the outcome of patients presenting with ischemic HFrEF.

Methods: We prospectively enrolled 112 patients with HFrEF defined by New York Heart Association (NYHA) functional class >II and left ventricular ejection fraction (LVEF) <40%. Patients were stratified in ischemic (iHFrEF, n=57) and dilated etiology (dHFrEF, n=55). Cells from fresh heparinized blood were stained and analyzed using BD FACS Canto II flow cytometry. Cox regression hazard analysis was used to assess the influence of Tregs on survival. The multivariate model was adjusted forage and gender.

Results: Comparing patients with iHFrEF to dHFrEF we found a significantly lower fraction of Tregs within lymphocytes in the ischemic subgroup (0.42% vs. 0.56%; p=0.009). After a mean follow-up time of 4.5 years 32 (28.6%) patients died due to cardiovascular causes. We found that Tregs were significantly associated with cardiovascular survival in the entire study cohort with an adjusted HR per one standard deviation (1-SD) of 0.60 (95% CI 0.39-0.92; p=0.017). Interestingly while there was no association with cardiovascular survival independently in the dHFrEFsubgroup (adj. HR per 1-SD of 0.62 (95% CI 0.17-2.31); p=0.486), we found a significant inverse association of Tregs and cardiovascular survival in patients with iHFrEFwith an adj. HR per 1-SD of 0.59 (95% CI 0.36-0.96; p=0.034).

Conclusion: Our results indicate a potential influence of Tregs in the pathogenesis and progression of iHFrEF, fostering the implication of cellular immunity in iHFrEF pathophysiology and proving Tregs as a predictor for long-term survival among iHFrEF -patients.

P263

Prognostic role of ST2 in heart failure patients with carbohydrate metabolism disorders

K Kristina Kopeva[1]; EV Grakova[1]; AT Teplyakov[1]; MV Soldatenko[1]; ON Ogurkova[1]; AA Garganeeva[1]
[1]*Cardiology Research Institute, Tomsk National Research Medical Centre, Tomsk, Russian Federation*

Objective. The objective of this study was to evaluate prognostic value of sST2 biomarker in the development of adverse cardiac events during the 12-month follow-up period in heart failure patients with carbohydrate metabolism disorders (impaired glucose tolerance (IGT) and type 2 diabetes mellitus (DM)). Methods. A total of 118 patients (83.9% men, median age of 62.5 [57; 68] years) with stable coronary artery disease and baseline LVEF of 60% [46; 64]% were enrolled in the study. At baseline evaluation, heart failure patients were of New York Heart Association (NYHA) class I (7.7%), class II (61.0%), and class III (31.3%). Serum levels of sST2 and NT-proBNP were measured using an enzyme immunoassay. Results. Depending on the presence of carbohydrate metabolism disorders (CMD), the patients were divided into 3 groups: group 1 (n = 65) comprised patients without CDM, group 2 (n = 30) comprised patients with IGT, and group 3 (n = 23) comprised patients with type 2 DM. Serum levels of sST2 in patients with CMD were (p = 0.011) higher than in patients without CMD, but in subgroups of patients with IGT and type 2 DM the concentrations of sST2 did not differ. The median values of baseline sST2 were 30.51 [26.38; 37.06] ng/mL in group 1, and 37.97 [33.18; 47.48] and 41.45 [35.27; 50.37] ng/ml in group 2 and 3, respectively. During the 12-month follow-up period in group 1 the rate of adverse cardiac events was 29.7% cases, and 55.2% and 52.2% in group 2 and 3, respectively. Odds ratio for ST2 were 3.06 (95% CI 2.89–3.17; p <0.0001) in patients with CMD and 2.11 (95% CI 1.93–2.15; p <0.001) in patients without it for adverse cardiac events. CMD did not impact the predictive value of sST2 biomarker, but in patients with CDM, sST2 levels were significantly higher than in those without CDM that was associated with a higher rate of adverse cardiac events during the 12-month follow-up period (p<0,001). The cut-off values predicting adverse cardiac events in ischemic heart failure patients with CDM were determined based on receiver operating characteristic curve analysis. Baseline sST2 concentration of 34.14 ng/mL was identified as a cut-off value with the sensitivity of 73.3%, specificity of 75.0%, and AUC of 0.77 (95% CI 0.59-0.89, p=0.002). Conclusion. Our data suggest that ST2 may be considered a non-invasive biomarker for prediction of adverse cardiac outcomes during the 12-month follow-up period in heart failure patients with CMD.

INTRODUCTION: Obesity is a major risk factor for the development of heart failure (HF). In patients with overt HF, the amount of fluid retention contributing to the apparently higher body weight may be difficult to assess. In order to understand the pathophysiologic mechanisms and trigger factors of a failing heart, profound knowledge on normal physiology is key. A novel echocardiographic method to non-invasively determine myocardial work based on speckle-tracking derived longitudinal strain and blood pressure has recently been validated. We assessed the association of body mass index (BMI), total body water (TBW), and extracellular water (ECW) with myocardial work.

METHODS: The Characteristics and Course of Heart Failure STAges A/B and Determinants of Progression (STAAB) cohort study carefully characterized a representative sample of the population of a medium-sized town in Germany, aged 30-79 years and free from HF. Weight, TBW, and ECW were assessed using a

bioimpedance scale, respectively. Off-line analysis (EchoPAC®, Version 202, GE) of the standardized, quality-controlled transthoracic echocardiograms regarding myocardial work yields i.e. the following parameters: global constructive work (GCW): work performed during shortening in systole and adding negative work during lengthening in isovolumic relaxation; global wasted work (GWW): negative work performed during lengthening in systole adding work performed during shortening in isovolumic relaxation; and global work efficiency (GWE): constructive work / (constructive work+ wasted work).
RESULTS: From the sample of the first planned STAAB interim analysis, myocardial work analysis could be performed in 1838 (74%) individuals (49.5% female; 54±12 years). In simple linear regression, GCW was significantly associated with BMI (B=−10.76 [−15.5; −6], p<0.001), TBW (B=−9.3 [−12; −6.61], p<0.001) and ECW (B=-19.2 [−26.42; −12], p<0.001). No significant association was found with GWW and GWE.
CONCLUSION: In subjects free of HF sampled from the general population, we observed that higher BMI, TBW and ECW were associated with lower GCW. This implies a negative impact of subclinical fluid retention on constructive myocardial work, while wasted work and work efficiency seemed unaffected by these variables. The individual contribution of these factors to reduced cardiac performance deserves further validation in patients with HF.

Impact of renal function and serum electrolytes on myocardial work - Results from the STAAB cohort study

C Morbach[1]; F Sahiti[2]; T Tiffe[3]; V Cejka[2]; M Breunig[1]; F Eichner[3]; G Gelbrich[3]; PU Heuschmann[3]; S Stoerk[1]
[1]University Hospital Wuerzburg, Comprehensive Heart Failure Center and Dept. of Medicine I, Wuerzburg, Germany; *[2]Comprehensive Heart Failure Center (CHFC), Wurzburg, Germany*; *[3]University of Wuerzburg, Institute of Clinical Epidemiology and Biometry and Comprehensive Heart Failure Center, Wuerzburg, Germany*

Funding Acknowledgements: German Ministry of Research and Education BMBF 01EO1004 and 01EO1504

INTRODUCTION: In order to understand the mechanisms and trigger factors of a failing heart, profound knowledge on normal physiology is key. A novel and invasively validated echocardiographic method allows to non-invasively quantify constructive and wasted myocardial work based on speckle-tracking derived longitudinal strain and blood pressure. Here we assessed the association of serum electrolytes and renal function with myocardial work.
METHODS: The Characteristics and Course of Heart Failure STAges A/B and Determinants of Progression (STAAB) cohort study phenotyped a representative sample of the population of a medium-sized town in Germany, aged 30-79 years. Off-line analysis of standardized, quality-controlled transthoracic echocardiograms yields the following aspects describing myocardial work: global constructive work (GCW): work performed during shortening in systole and adding negative work during lengthening in isovolumic relaxation; global wasted work (GWW): negative work performed during lengthening in systole adding work performed during shortening in isovolumic relaxation; global work efficiency (GWE): constructive work / (constructive work+ wasted work). Glomerular filtration rate (GFR) and serum electrolytes were assessed at the same study visit.
RESULTS: Myocardial work analysis was performed in 1838 (74%) individuals (49.5% female; 54±12 years). In simple linear regression, GCW was significantly associated with sodium (B= +18.0 [8.4; 27.6], p <0.001), potassium (B=−79.7 [−132.7; −24.6], p=0.004), and GFR (B=−3.2 [−4.6; −1.9], p<0.001). GWW was significantly associated with GFR (B=−0.365 [−0.516; −0.215], p<0.001). Regarding GWE, we found a significant association with potassium (B=−0.362 [−0.603; −0.120], p=0.003) and GFR (B=+0.013 [+0.007; +0.019], p<0.001).
CONCLUSION: In individuals free from heart failure, increasing GFR was associated with both, a decrease in constructive but also in wasted work which resulted in a significant increase of net myocardial work efficiency. Further, increasing serum sodium was associated with a slight increase in constructive work but no significant change in work efficiency. In contrast, increasing serum potassium was associated with a significant decrease in constructive work which resulted in a significant decrease of work efficiency. These findings are worth further evaluation in patients with heart failure to investigate whether this pattern can be reproduced in patients with heart failure, and, importantly, whether these novel echo-measures may be used to determine individual target ranges for electrolytes to improve myocardial function in patients with heart failure.

Urinary sodium profiling in chronic heart failure to detect the development of acute decompensated heart failure.

P Pieter Martens[1]; M Dupont[1]; K Damman[2]; J Penders[1]; J Testani[3]; WHW Tang[4]; W Mullens[1]
[1]Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium; *[2]University Medical Center Groningen, Groningen, Netherlands (The)*; *[3]Yale University, New Haven, United States of America*; *[4]Cleveland Clinic Foundation, Department of Cardiovascular Medicine, Heart and Vascular Institute, Cleveland, United States of America*

BACKGROUND
No data is available about the dynamics of urinary sodium (Una)-concentration in patients with chronic heart failure (CHF), including its temporal relationship with acute heart failure hospitalization (AHF).
OBJECTIVE To determine the relationship between Una-concentration and the pathophysiologic interaction with the development of AHF.
METHODS We prospectively included stable CHF-patients with either reduced or preserved ejection fraction to undergo prospective collection of morning spot Una-samples for 30 consecutive weeks. Linear mixed modeling was used to assess the longitudinal changes in Una-concentration. Patients were followed for the development of the clinical endpoint of AHF.
RESULTS A total of 80 CHF-patients (age=71±11years, NT-proBNP=771[221-1906], LVEF 33±7%) prospectively collected weekly pre-diuretic first void morning Una-samples for 30 weeks. A total of 1970 Una-samples were collected, with mean Una=81.6±41mmol/l. Sodium excretion remained stable over time on a population level (time-effect p=0.663). However, inter-individual differences revealed the presence of high (n=39, Una=88mmol/l) and low (n=41, Una=73mmol/l) sodium-excreters. Only a younger age was an independent predictor of high sodium excretion (OR=0.91; CI=0.83-1.00; p=0.045 per year). During 587±54 days of follow-up, 21 patients were admitted for AHF. Patients who developed AHF had significantly lower Una-concentrations (F[1.80]=24.063;p<0.001; figure panel A). The discriminating capacity of Una-concentration to detect AHF, persisted after inclusion of NT-proBNP and eGFR as random-effects (p=0.041). Additionally, Una-concentration further dropped (Una=46±16mmol/l vs. Una=70±32mmol/l; p=0.003) in the week preceding the hospitalization, and returned to the individual baseline (Una=71±22mmol/l; p=0.002) following recompensation (figure panel B). While such early longitudinal changes in weight and dyspnea scores were not apparent in the week preceding decompensation.
CONCLUSION Overall Una-concentration remains relatively stable over time, but large inter-individual differences exist in stable CHF-patients. Patients who develop an AHF-admission exhibit a chronically lower Una-concentration and exhibit a further drop in Una-concentration the week preceding hospitalization. Ambulatory Una-sample collection is feasible and might offer additional prognostic and therapeutic information.

Arterial stiffness in heart failure patients after an acute episode of acute decompensation : preliminary results

M Feola[1]; M Testa[1]; C Ferreri[2]; GL Rosso[3]; A Rossi[2]; G Ruocco[1]
[1]Ospedale Regina Montis Regalis, Cardiology Division, Mondovi, Cuneo, Italy, Italy; *[2]University of Turin, Geriatry, Turin, Italy*; *[3]University Hospital S. Giovanni Battista, Emergency Department, Regione Piemonte, Turin, Italy*

Background: The role of arterial stiffness in the pathogenesis and clinical outcome in heart failure (HF) patients should be elucidated yet. Preliminary data demonstrated an increased pulse wave velocity (PWV) in HF patients in comparison with healthy subjects and patients with cardiovascular risk factors. Moreover, growth differentiation factor-15 and soluble ST2 (sST2), biomarkers of cardiac stress and validate prognostic tools of HF , seemed to be strictly related to PWV.

Purpose: The aim of this observational experience was to analyze the arterial stiffness in HF patients in comparison with a healthy control population trying to correlate it with functional parameters.
Methods: consecutive patients admitted for acute decompensation underwent clinical examination, echocardiogram, biomarkers dosage and evaluation of arterial stiffness by measuring the PWV (expressed in meter/second from the pressure wave transit and the distance between carotid and femoral artery) and the augmentation index (AIX75) (using the manufacturer's proprietary software) with a Sphygmocor applanation tonometer system according to the established protocol. The arterial stiffness was also calculated in a control group formed by healthy volunteers.
Results: 59 hospitalized HF patients (40 males; age 73.3±11.5 years) with mean LVEF 38.5±12.2% and NT-proBNP (10765.7± 10096.4 pg/ml) entered the study. Twenty-seven (47.5%) had a coronary artery disease (CAD), in 27 (45.7%) the aetiology was dependent from a valvular disease and the others are hypertensive of idiopathic. The HF population were compared with 42 subjects [25 healthy controls (11 males, age 54.8±13.6 ys) and 17 patients (11 males, age 71.9±8 ys) with cardiovascular risk factors (CVRF) but in absence of heart failure]. The control group was formed by younger subject in comparison to CVRF group and HF patients ($p<0.001$ for both groups). The analysis of PWV demonstrated a velocity of 10±1.68 m/sec , 12.41±2.18 m/sec and 10.94±2.19 m/sec in controls, CVRF and HF patients, respectively (HF vs CVRF p=0.03; HF vs controls p=0.14; CVRF vs controls p=0.001). Aix75 (corrected for heart frequency) demonstrated to be higher in CVRF group vs HF patients (35.12±9.21 vs 23.28±13.22, p=0.004) so as central systolic pressure resulted higher in CVRF than in others (CVRF 63.23±14.50 mmHg, HF 54.16±14.09 mmHg, controls 50.08±8.94 mmHg: CVRF vs HF p=0.03; HF vs controls p=0.40; CVRF vs controls p=0.005).
Conclusion: CVRF patients seemed to present a worst arterial stiffness in comparison to healthy subjects and HF patients hospitalized. These preliminary results deserve future investigation on a larger population.

INTRODUCTION: Patients with heart failure (HF) often exhibit left ventricular (LV) hypertrophy or dilation. Nevertheless, the individual effect of LV dimensions on LV function is not well understood. A novel echocardiographic method to non-invasively determine myocardial work based on speckle-tracking derived longitudinal strain and blood pressure has recently been invasively validated.
We aimed to assess the relationship of LV dimensions on myocardial work.
METHODS: The Characteristics and Course of Heart Failure STAges A/B and Determinants of Progression (STAAB) cohort study carefully characterized a representative sample of the population of a medium-sized town in Germany, aged 30-79 years. We defined a subsample of "healthy" individuals in sinus rhythm and free from cardiovascular disease and risk factors, and designated the remaining subjects "at risk". Off-line analysis (EchoPAC®, Version 202, GE) of the standardized, quality-controlled transthoracic echocardiograms regarding myocardial work yields; global constructive work (GCW): work performed during shortening in systole and adding negative work during lengthening in isovolumic relaxation; global wasted work (GWW): negative work performed during lengthening in systole adding work performed during shortening in isovolumic relaxation; global work efficiency (GWE): GCW / (GCW + GWW). Further, LV volume and mass were measured and indexed to body surface area.
RESULTS: We analysed 1838 individuals (49.5 % female; 54±12 years, n=432 healthy). Mean values of GWE, GCW, and GWW are given in the table. In linear regression, GCW was associated with LVEDVi (B=−2.07 [−3.95; −0.195], p= 0.031) and LVMi (B=+1.51 [0.349; 2.67], p= 0.011); GWW with LVMi (B=+0.457 [0.328; 0.585], p <0.001); and GWE with LVEDVi (B=−0.011 [−0.019; −0.003], p=0.01). An association of GWE with LVMi (B=−0.023 [−0.029; −0.017], p <0.001) was only observed in the at risk group.
CONCLUSION: Although both an increase in LV volume and in LV mass were associated with lower myocardial work efficiency, only LV volume was associated with reduced constructive work (but not wasted work). Particularly in subjects at risk, higher LV mass was associated not only with higher constructive but also wasted work, and thus with a decrease in net efficiency. The clinical utility of this concept deserves further investigation in heart failure patients.

	Healthy (n=432)	At risk (n=1404)	p
GWE %mean (SD)	96.05 (1.5)	95.4 (±2)	<0.001
GCW mmHg%mean (SD)	2443 (343)	2529 (455)	<0.001
GWW mmHg%mean (SD)	82 (39)	96 (51)	<0.001

P269

Cardiovascular risk factors are associated with constructive but not with wasted myocardial work, Insights from the STAAB cohort study

F Sahiti[1]; C Morbach[2]; T Tiffe[3]; V Cejka[2]; M Breunig[2]; F Eichner[3]; G Gelbrich[3]; PU Heuschmann[3]; S Stoerk[2]

INTRODUCTION: A novel echocardiographic method to non-invasively determine myocardial work based on speckle-tracking derived longitudinal strain and blood pressure has recently been validated against invasive reference measurements and is considered a less load-depend parameter than LVEF and strain. We aimed to assess the relationship of cardiovascular risk factors (CVFR) on the individual indices of non-invasively measured myocardial work.
METHODS: The Characteristics and Course of Heart Failure STAges A/B and Determinants of Progression (STAAB) cohort study comprehensively characterized a representative sample of the population of a medium-sized town in Germany, aged 30-79 years. Using off-line analysis of the standardized, quality-controlled transthoracic echocardiograms, several indices describing myocardial work could be derived. Global constructive work (GCW): sum of positive work performed during systolic shortening plus negative work during lengthening in isovolumic relaxation; global wasted work (GWW): sum of negative work performed during systolic lengthening plus work performed during shortening in isovolumic relaxation; global work efficiency (GWE): GCW / (GCW+GWW).
RESULTS: From the sample of the first planned STAAB interim analysis (n=2473; 51% female; 54±12 years), myocardial work analysis could be retrieved in 1838 (74%) individuals. Mean values and results of the multiple regression including CVRF and age are given in the table. Hypertension was significantly associated with higher levels of GCW and GWW but lower GWE. We found an adverse association of smoking and dyslipidemia with GCW, but not with GWW. Obesity was associated with lower GCW, but not with GWE. Diabetes mellitus had no significant relationship on myocardial work.
CONCLUSION: Our results from a representative sample of the general population suggest an adverse effect of smoking, dyslipidemia and obesity on constructive, but no effect on wasted myocardial work. Only the effect of hypertension and dyslipidemia might be dominant enough to significantly reduce global work efficiency as parameter integrating constructive and wasted myocardial work.

	Mean (SD)	Hypertension	Smoking	Diabetes	Dyslipidemia	Obesity
		B	B	B	B	B
GWE [%]	96 (2)	-0.66***	ns	ns	-0.34**	ns

Sleep disordered breathing, neurocognitive impairment and diastolic function in acute heart failure patients with preserved ejection fraction

E D'elia[1]; CA Stamerra[1]; M Gori[1]; V Duino[1]; G Balestrieri[1]; B Pierangelo[1]; AL Vecchi[1]; A Iacovoni[1]; A Ghirardi[2]; A Gavazzi[2]; C Ferri[3]; M Senni[1]
[1]Ospedale Papa Giovanni XXIII, Cardiovascular, Bergamo, Italy; *[2]Ospedale Papa Giovanni XXIII, FROM Research Foundation, Bergamo, Italy*; *[3]University of L'Aquila, Life, Health and Environmental Sciences, L'Aquila, Italy*

Background: Sleep disordered breathing (SDB) and neurocognitive impairment (NI) are typical features of heart failure (HF), especially HF with preserved ejection fraction (HFpEF).
Purpose: To investigate changes in the severity of SDB, the degree of NI, and the diastolic function in an acute phase of hospitalization and in a stable period at home after discharge.
Methods: We enrolled 24 AHF patients (12 HFrEF and 12 HFpEF) with SDB and compared them to a matched population of 12 non-HF patients hospitalized for other cardiovascular causes. A complete echocardiogram, a set of NI tests, and a polysomnography were performed in the acute phase and after 3 months follow-up.
Results: Improvements in diastolic and right ventricular function were observed at 3 months compared to baseline, with a greater extent in HFpEF vs HFrEF, probably due to the higher volume load dependence of these echocardiographic indexes in HFpEF than HFrEF: respectively E/E' from 15.52 ± 6.90 to 13.28 ± 5.67 in HFpEF ($p < 0.05$) and 12.57 ± 4.49 to vs 13.56 ± 5.57 in HFrEF (p= 0.2); LAVI- left atrial volume index- from 63.49 ± 41.94 ml/m2 to 54.08 ± 34.20 ml/m2 (p = 0.04) vs 55.59 ± 17.01 ml/m2 to 54.60 ± 24.55 ml/m2 (p 0.2); PAPs -pulmonary artery pressures- from 34.57 ± 7.73 mmHg to 25.02 ± 14.94 mmHg (p = 0.04) vs 31.65 ± 10.99 mmHg to 25.36 ± 10.25 mmHg (p 0.02); TAPSE – tricuspid annular plane systolic excursion- from 20.57 ± 4.40 mm to 25.14 ± 10.14 mm (p = 0.03) vs 16.90 ± 3.21 mm to 21.70 ± 6.15 mm (p 0.03). At baseline SDB were present in both HFpEF and HFrEF, and a significant reduction of apneic events was observed at follow up (AHI-apnea hypopnea index-: 25.0 ± 16.9/h to 16.6 ± 10.7/ h and 33.7 ± 21.6/ h to 19.2 ± 14.1/h, $p < 0.05$; mean SaO2 –oxygen saturation-: 91.7 ± 4.4 % to 92.8 ± 2.1% vs 91.6 ± 2.4% vs 92.8 ± 2.3%, p = NS). Moreover, compared to non HF and HFrEF patients, lower baseline scores at NI tests were observed in HFpEF, but a more significant improvement was assessed at 3 months in this group.
Conclusion: Our study seems to suggest that in AHF patients with SDB the achievement of a better compensation could lead to important beneficial effects not only on echocardiographic parameters and nocturnal respiratory profile, but also on NI, especially in HFpEF.

P271

Atrial fibrillation and heart failure with non reduced ejection fraction: can biomarkers make the difference?

A Merino Merino[1]; JA Perez Rivera[1]; R Saez De La Maleta Ubeda[2]; R Salgado Aranda[1]; V Pascual Tejerina[1]; J Martin Gonzalez[1]; J Garcia Fernandez[1]; D Al Kassam Martinez[2]
[1]University Hospital of Burgos, Cardiology, Burgos, Spain; *[2]University Hospital of Burgos, Clinical Analysis, Burgos, Spain*

BACKGROUND: Atrial fibrillation (AF) and Heart Failure (HF) share similar symptoms and echo findings. The overlap of AF and HF with preserved (HFpEF) or mid-range ejection fraction (HFmrEF) usually delays the use of the appropriate therapies in each case. Biomarkers (BM) are commonly determined in these patients and could be used to differentiate both diseases.
PURPOSE: We design a study to assess the differences in BM between both diseases.
METHODS: We designed a cross sectional study in a population of 101 patients with symptomatic persistent non-valvular AF. We excluded patients with clinical instability or ejection fraction < 40%. We defined HF as the presence of diastolic dysfunction in echo (left atrium indexed volume >34 ml/m2 or e/é>8) or ejection fraction between 40 and 50%. According to this definition, we detected 72 patients with HF (14 with HFmrEF and 58 with HFpEF) and 29 without HF. We compared the plasmatic levels of 7 BMs between the 2 groups. The BMs studied were proBNP, C reactive protein (CRP), galectin 3, ST2, fibrinogen, urate, and ultrasensible troponin T (trop). We used t-student for normal variables or U Man Whithney for non normal quantitative variables and Chi square for qualitative ones to compare the values between the 2 groups. We performed a ROC curve to detect the best cut off point in the variables that presented statistical differences.
RESULTS: In table 1 we summarized the baseline characteristics of both groups. The only BM that showed statistical difference was proBNP that was higher in patients with HF (118.93 ± 876.46 vs. 847.45 ± 837.74 pg/ml; $p<0.05$). The area under the curve was 0.67 and the best cut off point was 524.5 pg/ml (sensitivity 84% and specificity 52%).
CONCLUSIONS: The levels of BMs in patients with AF with or without HF are similar. Only proBNP was significantly higher in patients with HF, so its measurement could be useful to suspect HF in symptomatic patients with AF in order to modify their clinical management. We suggest higher cut off points than usually recommended in this clinical scenario.

Table 1

Variable	With HF (n=72)	Without HF (n=29)	P
Age (years)	65 ± 8	60 ± 11	0.01
Male	49 (68.6 %)	24 (82.7 %)	NS
Hypertension	43 (59.7%)	14 (48.3 %)	NS
Diabetes	10 (13.8 %)	3 (10.3 %)	NS
Smoking	13 (18 %)	4 (13.8 %)	NS

Matrix metalloproteinase-2,9 activity, galectin-3 and systemic inflammation in patients with postinfarction heart failure with preserved ejection fraction

O Oksana Sirenko[1]; O Kuryata[1]; A Zabida[1]
[1]Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine

Objective: study was designed to evaluate the serum level of MMP 2,9, galactin-3 and C- reactive protein (CRP) in postinfarction heart failure with preserved ejection fraction (HFpEF) patients. Methods: We divided all included patients into two main groups: 1st group- 40 patients with HFpEF and history of myocardial infarction. 2nd group- 38 patients with HFpEF and stable angina. Standard laboratory blood tests, CRP, haematological parameters, lipid profile, glucose, renal and liver function tests were performed for all patients. MMP activity assay and galectin- 3 serum level was detected for all patients.
Results: It was established significant differences between study groups in MMP-2, MMP-9 levels. Particularly, patients with HFpEF with MI in anamnesis had significantly higher MMP-2, MMP-9 levels on 21.8 % and 20.7 % respectively. The C-RP and leucocytes levels were significantly higher in 1st group pts. Significant differences in MMP-2, MMP-9 were established in 1st group patients in different age groups ($p < 0.05$). The MMP 2 level was positively correlated with MMP 9 level ($R=0.73$, $p < 0.05$), the MMP 9 level – with age ($R=0.68$, $p < 0.05$). There were no significant differences between galectin-3 level in study group. But we estimated significant differences in galectin-3 level between 1st and 2nd subgroups ($p < 0.05$). Conclusion: Serum MMP-2, MMP-9, CRP and galectin-3 were significantly increased in pts with postinfarction heart failure with preserved ejection fraction compare to pts without myocardial infarction in anamnesis.

P273

Increased inflammatory state can be a predictive marker for acute kidney injury in acute decompansated heart failure patients with preserved ejection fraction

U Kocabas[1]; H Altay[1]; F Ozkalayci[1]; E Kulah[2]; O Yildirimturk[3]; S Pehlivanoglu[1]
[1]Baskent University Faculty of Medicine, Cardiology, Istanbul, Turkey; *[2]Baskent University Faculty of Medicine, Nephrology, Istanbul, Turkey*; *[3]Dr. Siyami Ersek Thoracic and Cardiovascular Surgery Center, Cardiology, Istanbul, Turkey*

Background: Acute kidney injury (AKI) is an independent risk factor for mortality in acute decompansated heart failure (ADHF). The purpose of this study is to determine the predictors and prognostic impact of AKI in ADHF patients with preserved ejection fraction.
Methods: Fifty-three patients with ADHF with preserved ejection fraction (29 male; mean age 79 ± 10 years) who were hospitalized at our intensive cardiac care unit (ICCU) during January 2016 – April 2018 were retrospectively investigated. All patients received prespecified standardized decongestive heart failure therapy as a part of "ICCU - Acute Heart Failure Treatment Protocol". AKI is defined as an increase in serum creatinine ≥0.3 mg/mL during the hospitalization.
Results: AKI developed in 37.7% of patients with ADHF with preserved ejection fraction. The baseline demographic characteristics, co-morbidities, medical therapies and laboratory analyses were similar between patients with and without AKI, except for higher N-terminal pro-brain natriuretic peptide (NT-proBNP) levels in the AKI group (13879 ± 12534 vs 7422 ± 8924; p = 0.03) (Table 1-2). Baseline C-reactive protein (CRP) levels were increased in both groups on admission. CRP increase during hospitalization period (CRPΔ: maximal CRP baseline CRP), but not CRP value on admission, was found to be an independent risk factor for AKI [odds ratio (OR): 1.07, 95% confidence interval (CI): 1.01–1.14, P = 0.01] despite clinically diagnosed infection was not different between the groups. AKI was associated with increased

lenght of hospital stay (9.9 ± 10.2 vs 5.4 ± 2.8; p = 0.02) and also increased risk of in-hospital mortality (Table 2). Conclusion: Increased inflammatory state (i.e. CRP levels) may be a marker of uncontrolled incidious infection which is associated with AKI leading to longer hospital stay and higher in-hospital mortality in ADHF patients with preserved ejection fraction.

P274

Therapeutic approaches via blood transfusion in anemic patients with diastolic heart failure.Role of bone morphogenetic protein 11 from young (<30age) blood donors in diastolic dysfunction reverse.

I Ilias Kanellos[1]; G Kaiafa[2]; M Petridou[3]; A Antoniou[4]; A Vomvas[3]; G Rampidis[5]; S Daios[4]; K Diplaris[6]; S Papaioannou[7]; A Gogakos[8]; S Lampropoulos[9]; G Krassas[10]; S Handanis[11]; H Karvounis[5]; C Savopoulos[3]

Background/Introduction Heart failure (HF) represents a clinical syndrome of symptoms and sings, with structural or functional alterations of myocardial systolic or diastolic properties or mixed. HF is correlated with anemia (AN), since 30% of HF patients (HFP) will develop AN and vice versa AN is a risk factor for HF. Annual risk of death is higher in anemic than in normoanemic HFP and reduction of 1% in hematocrite (Ht) increases 10% the death risk in HFP. Since normal levels of Ht are correlated with lower HFP death risk, in our study we examine if blood transfusion (BT) is a possible optimum treatment in diastolic HFP (DHFP). Also we examine the hypothesis from evidence in animal models that BT from young blood donors (YBD) reverses HF, due to high levels of plasma bone morphogenetic protein 11 (BMP-11) (BPM-11 levels are high only in plasma of young subjects and decreases with age).
Purpose Investigate whether; the BT could improve HF outcomes in anemic DHFP and also the existence of possible existence correlation between BT from YBD and HF reversing.
Methods 2 groups of 30 DHFP with anemia (due to chronic disease), (15 males, 15 females, average age 80 years old, without chronic kidney disease and with eligibility criteria for BT [hemoglobin (Hb) <7g/dl]. The first group (15 subjects) where treated for AN receiving BT from YBD (<30years old) and the second from donors >30 years old. The mean transfusion frequency was 1 BT/ 4 months and the total study period was 4 years. At the start and at the end of the study diastolic echo parameters [maximal velocity (Vmax) of both early and late diastolic left ventricular filling, deceleration time (DT) of early diastolic filling, left atrial diameter (LAD)] were measured and compared statistically.
Results In both groups we found a statistically significant negative and mild correlation between Hb and Vmax (r=0.61, p<0.05), DT (r=0.54, p<0.05) and LAD (r=0.64, p<0.05) indicating evidence that AN correction with BT is possible related with diastolic dysfunction improvement. However the echo findings regarding diastolic dysfunction were optimum in the first group compared with the second group [statistically significantly (p<0.05) lower values in Vmax, DT and LAD in the first group (BT from YBD)], suggesting indirect evidence of possible correlation between high plasma levels of BMP-11 and diastolic HF reverse.
Conclusion(s) a)There is evidence that treatment of AN in DHFP with BT, improves diastolic dysfunction lowering intracardiac pressures.b)Also emerging indirect evidence that circulated blood-borne signals (BMP-11) from a YBD, during anemic DHFP treatment via BT, maybe reverses heart diastolic dysfunction.Our study has serious limitations, sample is small and more specific studies (with direct measurements of BPM-11) must be conducted, in order to clarify if the diastolic HF reverse observed in anemic DHFP treated via BT, is a result of Hb normanization and/or BPM-11 effect.

P275

Effect of long-term remote ischemic conditioning on inflammatory and cardiac remodeling parameters in patients with chronic ischemic heart failure

Background: Remote ischemic conditioning (RIC) protects against acute ischemia-reperfusion injury and may also have beneficial effects in patients with stable cardiovascular disease. We investigated the effect of long-term RIC treatment in patients with chronic ischemic heart failure (CIHF).
Methods: In a prospective, exploratory and outcome-assessor blinded study, 21 patients with compensated CIHF and 21 matched controls without heart failure or ischemic heart disease were treated with RIC once daily for 28±4 days. RIC was conducted as 4 cycles of 5 minutes upper arm ischemia followed by 5 minutes of reperfusion. We evaluated circulating markers of inflammation and cardiac remodeling at baseline and following long-term RIC.
Results: RIC reduced C-reactive protein from 1.5 (0.6-2.5) to 1.3 (0.6-2.1) mg/l following long-term RIC treatment (p=0.02) and calprotectin from 477 (95% CI 380 to 600) to 434 (95% CI 354 to 533) ng/ml (p=0.03) in patients with CIHF, but not in matched controls. Overall, RIC did not affect circulating markers related to adaptive or innate immunology or cardiac remodeling in patients with CIHF.Among patients with CIHF and N-terminal pro-brain natriuretic peptide (NT-proBNP) plasma levels above the geometric mean of 372 ng/l, long-term RIC treatment reduced soluble ST2 (n=9) from 22.0 ± 3.7 to 20.3 ± 3.9 ng/ml following long-term RIC treatment (p=0.01).
Conclusion: Our findings suggest that long-term RIC treatment have mild anti-inflammatory effects in patients with compensated CIHF and anti-remodeling effects in those with increased NT-proBNP levels. This should be further investigated in a randomized sham-controlled trial.

P276

Usefulness of comprehensive cardiac assessments for early detection of subclinical chemotherapy-related cardiac dysfunction in breast cancer patients -A prospective pilot study-

Y Terui[1]; K Sugimura[1]; H Ota[2]; H Tada[3]; H Sato[1]; K Nochioka[1]; S Tatebe[1]; S Miyata[1]; Y Sakata[1]; T Ishida[3]; K Takase[2]; H Shimokawa[1]
[1]Tohoku University Graduate School of Medicine, Department of Cardiovascular Medicine, Sendai, Japan; *[2]Tohoku University Graduate School of Medicine, Department of Diagnostic Radiology, Sendai, Japan*; *[3]Tohoku University Graduate School of Medicine, Department of Surgical Oncology, Sendai, Japan*

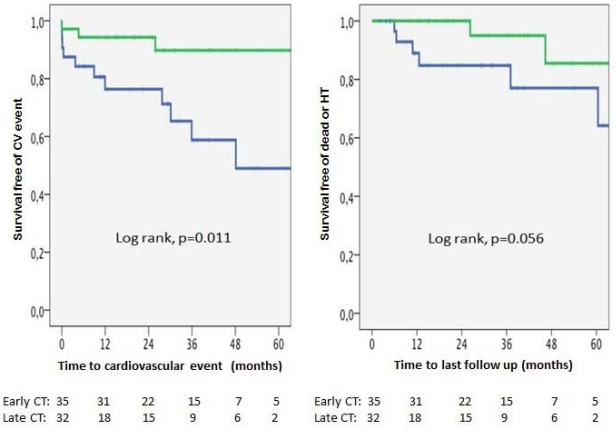
Background: Long-term prognosis of cancer patients has been dramatically improved along with the progress in cancer chemotherapies with anti-cancer agents. However, chemotherapy-related cardiac dysfunction (CTRCD) is an emerging serious adverse effect because it deteriorates long-term prognosis of those patients and severely limits their quality of life. Thus, early detection of subclinical CTRCD is one of the important emerging issues in the management of cancer patients.
Purpose: In this pilot study, we examined whether the comprehensive cardiac assessments, including cardiac magnetic resonance (CMR), echocardiography, and biomarkers, are useful for early detection of CTRCD. We performed a prospective pilot study to evaluate the usefulness of comprehensive cardiac assessments, including novel imaging modality and biomarkers, in breast cancer patients treated with chemotherapies.
Methods: A total of 94 consecutive patients with breast cancer (all female) were registered in this study from August 2017 to December 2018. To evaluate CTRCD in those patients treated with chemotherapies, we performed CMR (at baseline and/or 6 months), and 12-lead electrocardiogram (ECG), echocardiography, biomarkers analysis including cardiac troponin T (cTnT) and BNP (at baseline and every 3 months during chemotherapies.). CTRCD was defined as a reduction in left ventricular ejection fraction (LVEF) >10% from baseline and below 53% without symptoms
Results: In the 94 patients, 52(mean age, 53.0±12.7 yrs.)completed cardiac assessment at 6 months. Among them, 40 (77%) were treated with anthracycline and 6 (12%) developed CTRCD. In patients with CTRCD (CTRCD group), as compared with those without it (non-CTRCD group), both native T1 value on CMR and QTc interval on ECG were significantly prolonged after chemotherapy (1,322±22 vs. 1,303±32 msec at 6 months, P=0.03; 461±22 vs. 441±18 msec at 6 months, P<0.0001, respectively). Plasma levels of cTnT at 3 months were also higher in the CTRCD group compared with the non-CTRCD group [0.022 (IQR 0.015-0.026) vs. 0.01 (0.006-0.014) ng/mL, P=0.024], whereas there was no difference in BNP values. In patients whose plasma levels of cTnT at 3 months were higher than 0.014, LVEF at 6 months was significantly decreased at 6 months from the baseline (62.7±2.6% at baseline to 59.0±6.0% at 3 months, P=0.042).
Conclusions: These results indicate that early detections of the changes in native T1 value, QTc interval, and cTnT are useful to identify CTRCD among breast cancer patients treated with chemotherapies. Based on these preliminary findings of the presentpilot study, we have started multicenter prospective study with 25 participating institutions.

P277

Differences in patients with early and late toxic cardiomyopathy post-chemotherapy: characteristics and prognosis

U Ulises Lopez[1]; J Gonzalez[1]; J Delgado[1]; J Carvajal[1]; S Pernas[1]; C Diez[1]; J Roca[1]; E Garcia[1]; N Manito[1]; A Cequier[1]
[1]*University Hospital of Bellvitge, Barcelona, Spain*

Background Toxic cardiomyopathy (TC) post-chemotherapy is well described. It can be classified as early or late depending on the time of presentation relative to the administration of chemotherapy but there are few studies that have evaluated outcomes according to this classification.
Purpose We aimed to evaluate differences in the characteristics and prognosis of patients according to the timing of appearance of TC.
Methods In this unicentric, observational, retrospective study we evaluated all patients with the diagnosis of TC followed in one heart failure unit since 2004 until 2017. TC was defined as a drop in left ventricle ejection fraction (LVEF) ≥10% with a final LVEF inferior to 50% or as a reduction in LVEF ≥15% with a final LVEF ≥50% after chemotherapy and no other known cause. Early and late TC were defined depending on whether toxicity appeared before or after two years since the beginning of chemotherapy. Improvement in LVEF was analyzed by the Wilcoxon signed Rank test for related samples, and survival free of heart transplant(HT)/death or cardiovascular events (acute myocardial infarction, stroke, hospitalization for heart failure, cardiovascular dead/heart transplant) by Kaplan-Meier curves and multivariate Cox regression analysis .
Results Of 67 patients with TC included, the etiology of cancer was: 46 breast , 17 hematologic and 4 other. Anthracyclines were given in 84% and trastuzumab in 45%. Mean age was 55 years , 25% were in NYHA class III-IV. We found 35 patients with early TC and 32 with late TC. Statistically significant differences between the two groups were: higher LVEF, higher number of patients with trastuzumab, lower values of NT-proBNP and less deegre of mitral and tricuspid regurgitation in patients with early CT compared to late CT. After starting neurohormonal treatment (92% beta blockers, 93% ACEI/ARB, 41% MRA) there was an improvement in the ejection fraction in both groups from a median LVEF of 45% to 58% (p<0.001) in early TC and 40% to 50% (p<0.001) in late TC. After a median of 29 months of follow-up, the group with early TC had better prognosis. In the multivariate analysis, early TC was associated with a better survival free of heart transplant or death: Hazard Ratio: 0.11 (CI 95%:0.02- 0.62), p=0.012.
Conclusions The majority of patients with TC have a significant improvement in LVEF after the beginning of neurohormonal treatment. Prognosis in patients with early TC is better than in patients with late TC.



P278

Left ventricle alterations in anthracycline cardiotoxicity in patients with lymphomas.

E Emelina[1]; GE Gendlin[1]; IG Nikitin[1]
[1]*Pirogov National Research medical univercity , the second hospital therapy cathedra, Moscow, Russian Federation*

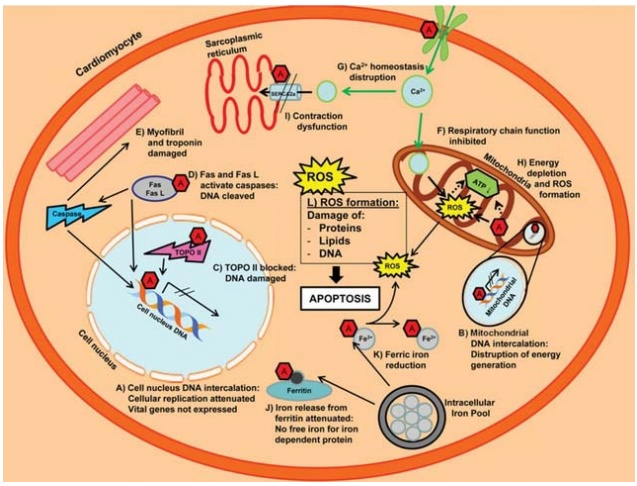
Background: the development of severe chronic heart failure (CHF) is a serious complication of anthracyclines chemotherapy.
Purpose: to identify the specific issues associated with left ventricle remodeling in patients with CHF developed due to anthracycline treatment taken as part of antitumor therapy of lymphoproliferative diseases
Methods: we examined 112 patients with Hodgkin's lymphomas and stages I-IV non-Hodgkin's lymphomas during the anthracyclines treatment and for 6 months thereafter. The total dose of anthracycline (doxorubicin) under the ABVD regimen was 300 mg / m2, BEACOPP regimen 200 mg / m2 and CHOP regimen 300 mg /m2. All patients underwent a standard echocardiographic examination. We used nonparametric statistical methods, and the results are presented as median and interquartile range. Additionally, 92 patients, who have been in remission from 1 to 30 years, were examined.
Results: 13 patients (11.6%), who were examined after a long time following their treatment, had NYHA Functional Class (FC) II and III heart failure symptoms and ejection fraction (EF) from 40% to 55%. Two patients examined 10 and 30 years after chemotherapy had less than 30% EF, and IV FC CHF. In patients, who developed CHF during chemotherapy, the indexed end diastolic volume (iEDV) decreased from 55.8 (42.4 - 72.4) ml / m2 to 51.8 (40.5 - 71.4) ml / m2; the dynamics persisted for the next 6 months – iEDV decreased to 48.2 (38.9 - 61.3) ml / m2 (p = 0.029). In patients who did not have CHF during chemotherapy, iEDV also decreased from 55.6 (37.4 - 79.4) to 47.8 (40.3 - 68.5) ml / m2, but went up to 50.1 (35.8-62.9) ml / m2 during the later period. We also investigated the dynamics of the left ventricle (LV) relaxation fraction of the first third of diastole in the aforesaid patient groups. The patients who developed CHF during our observation period, had a regular decrease of relaxation fraction from 35.5 (25.7 - 54.8)% to 21.2 (19.1 - 53.7)% (p = 0.028), while no such diastolic pattern was revealed in patients with no CHF. We observed 3 types of cardiac remodeling induced by anthracyclines: 1. Cardiomyopathy with a small LV chamber, reduced LV relaxation rate, normal EF and II FC CHF. 2. Patients with a large LV chamber and low EF, and typical course of II-IV FC CHF. 3. The severest cases are patients with a small LV chamber and low EF (<35%), who suffer from the most severe course of CHF often leading to death or cardiac transplantation.
Conclusion: The patients who developed CHF during chemotherapy had a decrease in LV compliance manifesting itself as a decreased relaxation fraction during the first third of the diastole and a decrease in the iEDV. There were 3 types of cardiac remodeling induced by anthracyclines.

P279

Assessing a various biomarker panel for early detection of cardiotoxicity after treatment with anthracyclines

M Trofenciuc[1]; M Puticiu[1]; M Onel[1]; C Hreniuc[1]; H Branea[2]; A Bordejevic[2]; M Tomescu[2]; A Mischie[3]; A Pop-Moldovan[1]
[1]*Vasile Goldis Western University, Arad, Romania*; [2]*University of Medicine Victor Babes, Timisoara, Romania*; [3]*Centre Hospitalier De Montluçon, Montluçon, France*

ntroduction: Breast cancer represents the most frequent form of cancer in women worldwide, comprising 16% off all cancers. A report of the World Health Organization showed that 1 from 6 cancers is determined by breast cancer and this form of neoplasm causes 1.6% of all annual deaths in the world.
Objective: A novel approach, based on the use of biomarkers has recently emerged, resulting in a very effective tool for early, real-time identification, and monitoring of cardiotoxicity. Assessing a diverse biomarker panel (NT-proBNP, TNF-a, galectin-3, IL-6, Troponin I, ST2 and sFlt-1) to detect subclinical cardiotoxicity after treatment with anthracyclines.
Methods: An observational single centre cohort study between 2016-2017. For 35 breast cancer patients, which received treatment with docetaxel, doxorubicin or cyclophosphamide, biomarkers were assessed and one year follow-up echocardiography was performed after treatment with anthracyclines. All female patients with breast cancer, >18 years of age at the time of breast cancer diagnosis who completed (neo) adjuvant treatment were asked to participate in the study. Exclusion criteria were: evidence of breast cancer recurrence or metastatic disease, current heart disease, renal failure at the time of cardiac evaluation, diabetes mellitus, pregnancy or lactation, ionizing radiation within 1 year prior to inclusion, Parkinson's disease. Abnormal levels of biomarkers according to preset standards were used as a measure for subclinical cardiotoxicity. Primary analysis consisted of determination of the prevalence of abnormal biomarkers.Thirty-six millilitres of blood was drawn from every patient for determination of blood and serum markers. Echocardiographic parameters were obtained from all patients (IVSd: interventricular septal thickness in diastole; BSA: body surface area; LVPWd: left ventricular posterior wall dimension in diastole; LVIDd: left ventricular internal dimension in diastole; LVIDs: left ventricular internal dimension In systole; E/A ratio: early to late atrial mitral Doppler peak flow velocity ratio; LV: left ventricle).
Results: Mean age at the time of enrollment was 54,6 ± 2,3 years. 27,9% of patients showed abnormal biomarker levels: NT-proBNP in 16,6%, TNF-a and Galectin-3 in 7,2%. IL-6, troponin I, ST2 and sFlt-1 were normal in all patients. A correlation between left ventricular ejection fraction (LVEF) and NT-proBNP was observed (r=-0,514, p<0.01) and the mean LVEF of the study population was 58,3% (SD 7.6%). Docetaxel was given 75mg/m2, doxorubicin 50mg/m2 and cyclophosphamide 500mg/m2 in each cycle.
Conclusion: The evaluated biomarkers panel do not contribute to early detection or early risk factor assesment. Future research should focus on NT-proBNP and genetic testing and screening. Detection of subclinical cardiotoxicity would be a more desirable approach, since early detection could have clinical implications for individual patients.



Anthracycline mechanism in cardiomyocyte

P280

Activity and outcomes of a cardio-oncology service in a public hospital of Greece; a two-year experience

P Kostakou[1]; V Kostopoulos[1]; E Tryfou[1]; CH Olympios[1]; N Kouris[1]
[1]*Thriassio General Hospital, Cardiology Department, Athens, Greece*

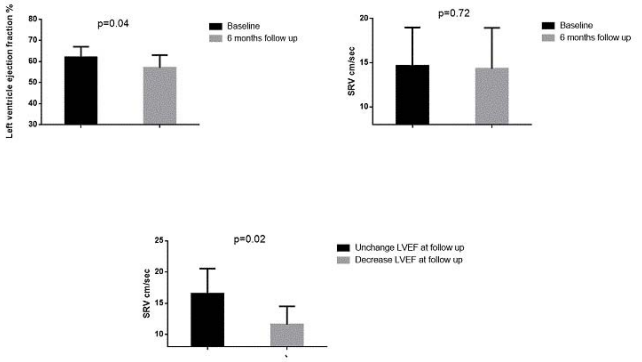
Background: Cardio-oncology focuses on identifying cancer therapy-related cardiovascular side effects and providing optimum multidisciplinary care for cancer patients. However, there are limited descriptive information about case characteristics, activity and outcomes of cardio-oncology departments.
Purpose: The aim of this study is to present the activity and results of a cardio-oncology service focusing on the holistic approach of cancer patient in a public-health hospital without Oncology wards but with outpatient clinic.
Methods: We prospectively followed up 39 patients with cancer referred to our Cardio-oncology service from January 2017 to January 2019. All patients underwent physical and biochemical examination, electrocardiography, two-dimensional (2D), 3D and 2D speckle tracking echocardiography at baseline, during and at the end of cancer therapy. Up-titration of cardiac treatment, continuation of cancer therapy and mortality were used as outcome measures.
Results: Of the 39 patients (77% females) with mean age of 54.3 years old, 74.4% presented with breast cancer, 10% with hematological disease, 5% with lung cancer and 5% with cancer of digestive system. Most of our patients (92.3%) underwent chemotherapy and half of them (56.4%) additionally radiotherapy. Patients with left ventricular systolic dysfunction (LVSD) (n =18) were younger and most of them (n=14) without the usual cardiovascular risk factors (smoking, dyslipidemia, diabetes mellitus, previous exposure to chemotherapy/radiotherapy or history of cardiovascular disease). At a median follow-up of one year, 89% of the patients with LVSD showed improvement in LV ejection fraction (50% pre vs 58% post; p<0.001). One patient (66 years old) presented with complete atrioventricular block during chemotherapy agent infusion and a pacemaker was implanted. All patients with LVSD were able to continue cancer therapy after optimisation of cardiovascular therapy except for one. All patients are alive.
Conclusion: The establishment of a cardio-oncology department in a hospital, especially in the context of preventive cardiology care with full cardiovascular monitoring and therapy, can lead to cancer treatment continuation and better quality of life.

P281

Chemotherapy induced cardiotoxicity. The role of right ventricle.

E Evagelos Oikonomou[1]; M Anastasiou[1]; G Siasos[1]; F Zagouri[2]; A Antonopoulos[1]; S Tsalamandris[1]; G Vogiatzi[1]; A Bamias[2]; MA Dimopoulos[2]; D Tousoulis[1]
[1]*Hippokration Hospital, University of Athens, 1st Department of Cardiology, Athens, Greece*; [2]*Alexandra University Hospital, Department of Clinical Therapeutics, University of Athens Medical School, Athens, Greece*

Background: Cardiac dysfunction, impairment of left ventricle ejection fraction (LVEF) and heart failure symptoms may developed in patients following antineoplastic treatment for breast cancer. Several risk factors have been associated with increased risk of cardio-toxicity. The prognostic role of right ventricle performance has not been tested.
Purpose: To examine the prognostic role of right ventricle performance in the development of left ventricle dysfunction and cardiotoxicity.
Methods: We enrolled 25 female patients (58±12 y) diagnosed with breast cancer and scheduled for anthracycline-based chemotherapy. Patients were treated with epirubicin(75mg/m2) and cyclophosphamide followed by docetaxel and trastuzumab. A transthoracic echocardiogram was performed at baseline, 3 and 6 months after chemotherapy initiation to evaluate LVEF with Simpson's rule and right ventricle systolic performance by measurement of the tissue systolic velocity of the right ventricle free wall (SRV).
Results: At baseline the mean LVEF was (62±5%) and the SRV 14.66±4.33cm/sec. Compared to baseline at the 6 months follow up study there was a significant reduction in LVEF (57±6%, p=0.04) while SRV has not change (14.33±4.61cm/sec, p=0.72). In 7 out of 25 patients there was a clinically significant decrease in LVEF at the 6 months follow up study of more than 5% compared to baseline study. Interestingly, compared to subjects with no change in LVEF, subjects with a decrease in LVEF at the 6 months follow up study had significant lower values of SRV at baseline evaluation (16.5±4.03cm/sec vs. 11.6±2.88cm/sec, p=0.02).
Conclusions: In the present study we found an association between baseline right ventricle systolic performance as it is expressed by SRV and development of chemotherapy induced cardiotoxicity with reduction in left ventricle ejection fraction.



P282

Prevention of heart failure with cardioprotective therapy after early detection of cardiotoxicity during chemotherapy in cancer patients using CMR Fast-SENC intramyocardial LV & RV strain

H Henning Steen[1]; M Montenbruck[1]; P Wuelfing[2]; S Esch[1]; A Schwarz[1]; B Gersak[3]; S Kelle[4]; D Lenihan[5]; G Korosoglou[6]
[1]*Marien Hospital, Hamburg, Germany*; [2]*Jerusalem Hospital, Hamburg, Germany*; [3]*University of Ljubljana, Ljubljana, Slovenia*; [4]*Charite University Hospital, Berlin, Germany*; [5]*Washington University School of Medicine, St. Louis, United States of America*; [6]*GRN-Klinik, Weinheim, Germany*

Background: Heart failure is a growing problem for cancer survivors. Current biomarkers and imaging modalities such as left ventricular ejection fraction (LVEF) are used to detect cardiotoxicity during cancer therapy. Unfortunately, these diagnostics only identify systemic damage in symptomatic patients after the heart is unable to compensate regional dysfunction. Fast-SENC segmental intramyocardial strain (fSENC) is a unique cardiac magnetic resonance imaging (CMR) modality that detects subclinical intramyocardial dysfunction in 1 heartbeat per image plane. This prospective study compares fSENC and conventional biomarkers in patients undergoing cancer therapy.
Methods: This single center, prospective Prefect Study was used to evaluate the cardiotoxicity and the impact of cardioprotective therapy in Breast Cancer and Lymphoma patients (NCT03543228). fSENC was acquired with a 1.5T MRI and processed with the MyoStrain software to quantify intramyocardial strain. Segmental strain was measured in three short axis scans (basal, midventricular, & apical) with 16 longitudinal segments & three long axis scans (2-, 3-, & 4-chamber) with 21 circumferential segments. fSENC CMR was performed before chemotherapy, during and after anthracycline therapy, after taxane therapy, at 1 year follow-up, and as needed. Cardioprotective therapy was offered to patients meeting the definition of cardiotoxicity by EACVI Position paper or those observing a substantial decline in cardiac function.
Results: One hundred eighty seven (187) CMRs were performed in fifty (50) patients (43 female). Patients had an average (± stdev) age of 52 (15) yrs, BMI of 26 (6) kg/m2; 76% had breast cancer, 24% had Lymphoma. fSENC CMRs required 11.6 (2.2) min total exam time. fSENC detected cardiotoxicity in 47% of patients with 27.4% worsening of regional strain (% of normal myocardium), at an average of 79 days of chemotherapy. Upon administrating cardioprotective therapy as well as ensuring compliance based on fSENC testing, regional strain improved to 7.4% reduced function from pre-chemotherapy at 191 days and 3.9% at 368 days. Figure 1 shows

the normalized change in CMR LVEF, the % of normal myocardium (% fSENC < -17%), fSENC GLS, fSENC GCS, echo LVEF, and echo GLS for patients recieving cardioprotective therapy. Patients who did not require cardioprotective therapy only observed 8.0% worsening of regional strain at an average of 78 days and 10.2% at 391 days.

Conclusion: fSENC detects subclinical dysfunction due to cardiotoxic response of chemotherapy and the impact of cardioprotective therapy before other biomarkers and imaging modalities. The ability to detect subclinical effects of diseases and pharmacological cardiotoxicity enables proactive prescription of cardioprotective agents to avoid tissue remodeling that is associated with systemic cardiac dysfunction culminating in damage to myocardial tissue that precedes worsening of global measures such as LVEF.

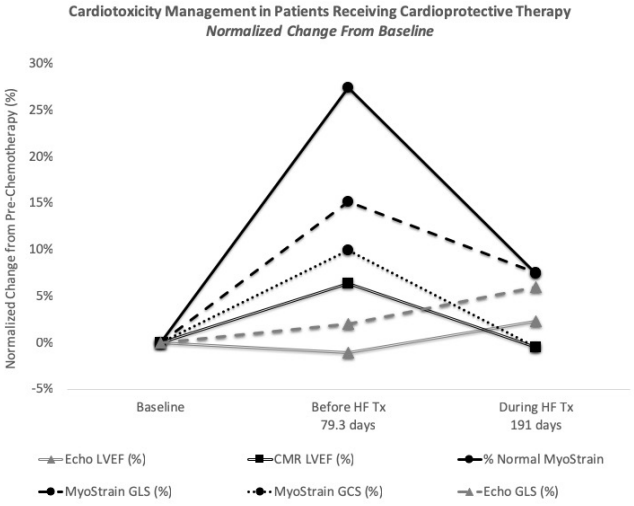


Figure 1

P283

Three-dimensional ECHO in serial monitoring of patients undergoing Trastuzumab therapy

S Savvas Grigoriadis[1]; I Vogiatzis[1]; J Draper[2]; E Gavriilaki[3]; S Kaptenakis[2]
[1]General Hospital of Veria, Veria, Greece; *[2]St Thomas' Hospital, London, United Kingdom of Great Britain & Northern Ireland*; *[3]General Hospital G. Papanikolaou, Thessaloniki, Greece*

Purpose: There is increasing awareness of the effects of chemotherapy on the heart and in particular myocardial function and the need for optimal surveillance and treatment by a specialised cardio-oncology service. Advanced cardiac imaging is key to detecting cardiotoxicity, but there is a large variation in recommended techniques. We examined accuracy of all echocardiographic methods used at our institution.

Methods and results: 116 consecutive patients treated with Trastuzumab were serially evaluated with transthoracic echocardiography according to cardio-oncology protocols. Tissue Doppler, M-Mode, B-mode and 3D ECHO were used to evaluate cardiac function by assessing longitudinal function, volumetric changes and myocardial deformation.

20 patients developed cardiotoxicity requiring heart failure therapy and/or alteration of their chemotherapy regime. The most accurate parameters for diagnosing cardiotoxicity were 3D LVEF (ROC AUC 0.95) and GLS (ROC AUC 0.92). Diagnostic accuracy was not increased by compounding ECHO parameters.

Conclusions: Three-dimensional volumetric analysis is a highly accurate method for detecting chemotherapy-induced cardiac dysfunction, while a full echocardiographic assessment did not confer increased accuracy during serial monitoring. A simplified echo protocol based on 3D ECHO alone for serial monitoring of Trastuzumab cardiotoxicity is feasible and could greatly increase capacity for cardio-oncology units.

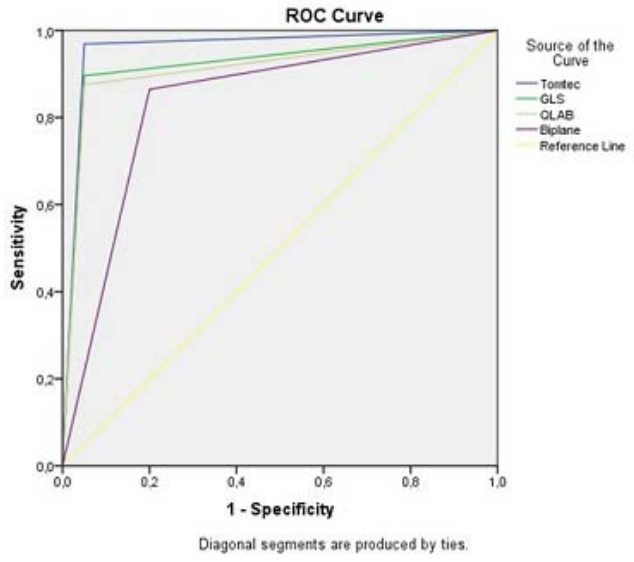
P284

Assessment of three-dimensional echocardiography as a diagnostic tool for detecting chemotherapy-induced cardiotoxicity

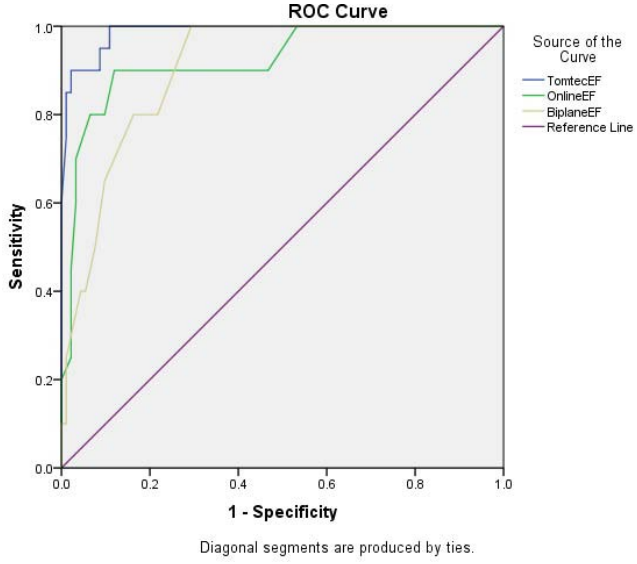
S Savvas Grigoriadis[1]; I Vogiatzis[1]; E Gavriilaki[2]; J Draper[3]; S Kapetanakis[3]
[1]General Hospital of Veria, Veria, Greece; *[2]General Hospital G. Papanikolaou, Thessaloniki, Greece*; *[3]St Thomas' Hospital, London, United Kingdom of Great Britain & Northern Ireland*

Purpose: Cardiotoxicity has become an emerging concern as a side-effect of chemotherapy. We investigated the echocardiographic techniques used for detecting cardiotoxicity, and we evaluated their effectiveness.

Methods and Results: 280 patients treated with chemotherapy, either Anthracyclines or Trastuzumab or combination of the two, were repeatedly evaluated for cardiotoxicity using two- and three-dimensional echocardiography according to our institution's protocols. We constructed Bland – Altman plots, to compare the various echocardiographic techniques with each other. Furthermore, we created ROC curves, so that we could evaluate which method had the highest accuracy in detecting cardiotoxicity. Lastly, we tried to determine the inter- and intraobserver variability of the most successful technique according to our evaluation. The Bland – Altman plots did not show significant differences in the evaluation of Left Ventricular Ejection Fraction (LVEF) among the various techniques. All methods were in good agreement, especially two commercial packages for three- dimensional analyses. Receiver Operating Characteristic (ROC) curves were computed for all methods. Three-dimensional ejection fraction analyzed by a particular commercial program was the most accurate method of all (0.978, 95% confidence interval). The inter- and intra-observer variability of this method was very low. Between the two investigators, the results were in good agreement (0.90, 95% confidence interval), whilst



ROC curve



ROC curve

the intra-observer variability was even lower, with an interclass correlation coefficient of 0.98 (95%, confidence interval) between results.
Conclusion: Three- Dimensional echocardiography was the best method for detecting cardiotoxicity especially the commercial package used in our institution.

P285
Clinical outcomes and predictors of cancer therapy related cardiac dysfunction (CTRCD) in breast cancer patients on Trastuzumab: Real world data from an integrated cardio-oncology service

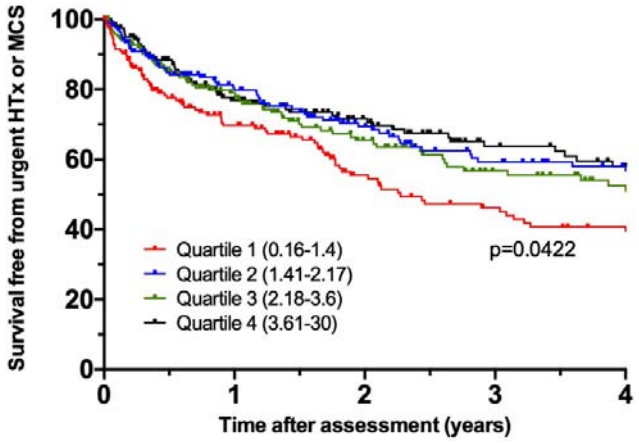
M Maria Mahmood[1]; L Spurgeon[1]; S Naveed[1]; S Apostolakis[1]
[1]*Birmingham City Hospital, Birmingham, United Kingdom of Great Britain & Northern Ireland*

Background: Despite the lack of a standardized approach there is consensus that an integrated cardio-oncology service is vital in early detection and management of cancer treatment related cardiac dysfunction (CTRCD).
Purpose: We reviewed clinical outcomes of women treated with trastuzumab in a newly developed integrated cardio-oncology service at Sandwell and West Birmingham Hospitals (SWBH) NHS Trust. We also assessed the performance of baseline demographic, clinical and echocardiographic parameters in predicting CTRCD.
Methods: This is a retrospective review of 60 women on trastuzumab therapy for breast cancer followed-up between October 2016 and December 2018. CTRCD was defined as more than 10% absolute reduction of LV ejection function (LVEF) to below 55%. Global longitudinal strain (GLS) was utilised as a predictor of CTRCD. Patients with more than 15% relative increase of GLS were considered high risk of developing CTRCD and were managed either by increasing the frequency of echocardiographic surveillance (every 6 weeks) and/or initiation of heart failure treatment. All measurements were performed by dedicated operators using the same equipment. For patients with confirmed CRTCD treatment with an ACE inhibitor or an ARB and a beta-blocker was initiated and increased to the highest tolerated dose unless there was a contraindication. Follow-up was organised in our cardio-oncology clinic service with support by our nurse-led heart failure community service. Interruption or re-initiation of trastuzumab was a joint decision of the oncologists and cardiologists.
Results: Of the 60 patients (mean age 58; range 36-78 years) on trastuzumab followed-up for a median of 346 days (interquartile range 258-629 days), 6 patients (10%) developed CTRCD resulting in temporary (5 patients; 8.3%) or permanent (1 patient; 1.7%) discontinuation of trastuzumab. There was no cardiovascular mortality in our cohort or hospitalization for heart failure. In a binary logistic regression analysis, age (p=0.80), previous treatment with anthracyclines (p=0.27), presence of hypertension (p=1), diabetes (p=1), atrial fibrillation (p=1), coronary artery disease (p=1) or renal failure (p=1) did not correlate with CTRCD. A previously proposed clinical risk score (CRS)1 similarly performed poorly in predicting CTRCD in our cohort (AUC 0.563; 95%CI 0.31-0.82; p=0.61). GLS strongly correlated with CTRCD in our cohort with a value above -17.35 showing 83% sensitivity and 77% specificity for CTRCD. Despite a trend towards lower baseline LVEF in the CTRCD group (64.6 SD 4.7 vs 61.5 SD 2.4) the predictive value of baseline LVEF did not reach statistical significance (AUC 0.70; 95%CI 0.55-0.85; p=0.12).
Conclusions: Monitoring and management of CTRCD in an integrated multidisciplinary cardio-oncology service resulted in low rate of permanent discontinuation of trastuzumab and no adverse cardiovascular outcomes. Baseline clinical characteristics were not predictive of CTRCD.

P286
Low pulmonary artery pulsatility index is associated with adverse outcomes in patients with advanced heart failure

S Cesini[1]; S Bhagra[1]; S Pettit[1]
[1]*Papworth Hospital NHS Trust, Cambridge, United Kingdom of Great Britain & Northern Ireland*

Background. Pulmonary artery pulsatility index (PAPi) is a novel haemodynamic measure of right ventricular function. PAPi is defined as systolic pulmonary artery (PA) pressure minus diastolic PA pressure, divided by right atrial pressure. Low PAPi has been shown to be associated with an increased risk of right ventricular failure after left ventricular assist device (LVAD) implantation and was also associated with an increased risk of mortality in the ESCAPE trial.
Purpose. To determine whether PAPi is associated with adverse outcomes in ambulatory outpatients with advanced heart failure.
Methods. All outpatients who were assessed for heart transplantation at a single centre between January 2010 and January 2019 were included. Each patient underwent right heart catheterisation and PAPi was calculated. Death, urgent heart transplantation and requirement for mechanical circulatory support (MCS) were the co-primary endpoints. Patients were followed up until the first primary endpoint or 1st January 2019. Kaplan-Meier analyses were performed on patients grouped into PAPi quartiles.
Results. A total of 668 patients were included. The median PAPi for the entire study population was 2.18 (interquartile range 1.41-3.60). In total, 272 (41%) patients reached a primary endpoint after a median of 1.49 years follow-up. PAPi was significantly lower in patients who reached a primary endpoint, compared with patients who did not reach a primary endpoint (2.06 vs 2.25, p=0.01552). There was a significant difference in survival free from urgent heart transplantation or mechanical circulatory support when patients were grouped in quartiles (Figure, p=0.0422). Patients with a PAPi of less than 1.4 had the greatest likelihood of death or the need for urgent heart transplantation or mechanical circulatory support.
Conclusions. Low pulmonary artery pulsatility index (PAPi) is associated with adverse outcomes in ambulatory outpatients with advanced heart failure. Clinicians who are undertaking right heart catheterisation for assessment of advanced heart failure should consider calculation of this haemodynamic measure.



P287
Do NT-proBNP levels depend on the diameter of abdominal aorta in patients with chronic HFpEF and AAA?

S-M Spyridon-Michail Papazoglou[1]; U Jaffer[2]; M Aslam[2]; A Trikas[1]; C Pantos[3]; K Toutouzas[4]; P Nihoyannopoulos[5]; CH Stefanadis[5]; D Tousoulis[4]; N Standfield[2]
[1]*Elpis General Hospital, Athens, Greece*; [2]*Imperial College Healthcare NHS Trust, London, United Kingdom of Great Britain & Northern Ireland*; [3]*University of Athens Medical School, Clinical Pharmacology, Cardiology Dept, Athens, Greece*; [4]*Hippokration Hospital, Cardiology Clinic, Athens, Greece*; [5]*University of Athens Medical School, Cardiology Dept, Athens, Greece*

Background/Introduction Abdominal Aortic Aneurysm is a vascular disorder that necessitates regular diagnostic assessment and close evaluation if present among other comorbidities. Endovascular or open surgical repair is the ultimate treatment if patient criteria are fulfilled. HFpEF when associated with AAA might have deteriorating hemodynamic effects that may lead to negative outcomes.
Purpose The purpose of this study was to investigate if a Chronic Heart Failure biomarker as NT-proBNP is related to any changes in diameter of AAA in patients with abdominal aorta aneurysmatic disease and Chronic HFpEF.
Material/Methods 412 (284male,118 female) patients between 58-75 years of age with chronic HFpEF and AAA were recruited on this study. Criteria for diagnosis and evaluation of HFpEF and AAA were according to ESC and ESVS clinical practice guidelines, respectively. All patients underwent U/S Echo assessment and their EF was ≥50 %. Values for HFpEF and AAA were obtained based on a 6-month follow-up period and measurements for this study were considered to be significant for NT-proBNP levels when ≥400pg/ml and for abdominal aortic diameter when ≥4.7cm. Data were analyzed using ANOVA and logistic regression analysis and NT-proBNP levels were analysed as an independent variant. Data are presented as mean ± standard deviation and level of significance was accepted when p<0. 05.
Results Data were analyzed from 412 patients (284 male,118 female) and showed in 106 (25,7%) patients NT-proBNP levels 587± 98 pg/ml and an abdominal aortic diameter of 4.77 ± 0.21 cm. In 96 (23.3%) patients NT-proBNP was 892 ± 96 pg/ml and abdominal aortic diameter of 4.94 ± 0.19 cm. 113 (27.4%) patients with NT-proBNP levels of 1063 ± 103 pg/ml and an abdominal aortic diameter of 5.19 ± 0.23 cm. And 97 (23.6%) had NT-proBNP levels of 1294 ± 99 pg/ml. Increased levels of NT-proBNP p<0.0001 were independently associated with increased abdominal aorta diameter p<0.0001 in patients with AAA.

>1 Marker of congestion - % †	30	28	31	0.74			

Group 1: NTproBNP <125 ng/L or BNP <35 ng/L; Group 2: NTproBNP 125-1000 ng/L or BNP 35-280 ng/L. † - out of 214 patients with complete congestion data. Abbreviations used: N- number; : NTproBNP – N-terminal pro-B-type natriuretic peptide; BNP – B-type natriuretic peptide; LAESV - left atrial end systolic volume; IVCD - inferior vena cava diameter; JVD - jugular vein distensibility.

Conclusion Increased circulating levels of NT-proBNP are independently associated with increased Abdominal Aorta Diameter in patients with chronic HFpEF and abdominal aneurysmal disease.

P288

The prevalence and clinical associations of ultrasound measures of congestion in patients at risk of developing heart failure: insights from the HOMAGE trial.

J Joseph Cuthbert[1]; P Pellicori[2]; R Flockton[1]; A Kallvikbacka-Bennett[1]; J Khan[2]; JG Cleland[2]; AL Clark[1]
[1]University of Hull, Academic Cardiology, Hull, United Kingdom of Great Britain & Northern Ireland; *[2]University of Glasgow, 2. Robertson Institute of Biostatistics and Clinical Trials Unit, Glasgow, United Kingdom of Great Britain & Northern Ireland*

Background: Venous congestion is the hallmark of untreated heart failure (HF), and might be detected by ultrasound before overt clinical signs appear. The prevalence of subclinical congestion by ultrasound in patients at risk of HF is unknown.
Purpose: We investigated the prevalence and clinical associations of congestion by ultrasound in patients with at least one risk factor for HF (diabetes, ischaemic heart disease or hypertension).
Methods: We assessed 238 patients who attended screening for the HOMAGE clinical trial (Heart OMics in AGEing) at 2 centres (Hull and Glasgow) using three ultrasound techniques: 1) inferior vena cava (IVC) diameter; 2) jugular vein distensibility (JVD) ratio (the ratio of the jugular vein diameter during Valsalva to that at rest); 3) the number of lung "comets". Congestion was defined as IVC diameter >2.0 cm, JVD ratio <4.0 and total lung comet count >14.
Results: The prevalence of subclinical congestion was 13% by IVC diameter, 9% by JVD ratio and 13% by lung comets; 30% of patients had at least one marker of congestion but none had all three. Those with congestion had larger left atria than those without. JVD ratio was lower (7.69 vs. 8.80; P=0.05), and the proportion of patients with any lung comets higher (74% vs. 63%; P=0.05) amongst patients with raised natriuretic peptide levels (NTproBNP >125 ng/L or BNP >35 ng/L) but there was no difference in IVC diameter (1.4cm vs. 1.5cm; P=0.07) (table 1).
Conclusions: Approximately 1 in 3 patients at risk of heart failure have at least one marker of congestion by ultrasound. Whether this indicates greater risk of subsequently developing heart failure is unknown.

P289

Pulmonary wedge measurements at the trough of Y-descent provide more reliable and predictive diastolic pressure gradient estimation.

A Manouras[1]; J Johnson[2]; LH Lund[1]; AI Nagy[3]
[1]Karolinska Institute, Institute of Medicine Solna, Stockholm, Sweden; *[2]Karolinska Institute, Centre for Fetal Medicine Department of Obstetrics and Gynecology, Stockholm, Sweden*; *[3]Semmelweis University, Heart and Vascular Center, Budapest, Hungary*

Funding Acknowledgements: János Bolyai Scholarship of the Hungarian Academy of Sciences. Swedish Research Council

Background. The diastolic pulmonary gradient (DPG) has become a cornerstone in the diagnostics of combined pre-capillary (Cpc) pulmonary hypertension (PH)., compared to the traditionally applied pulmonary vascular resistance. However, its diagnostic utility is affected by the high prevalence of physiologically incompatible negative values (DPGNEG). We have shown previously that the presence of large V-waves significantly impacts on DPGNEG occurrence.
Purpose. We hypothesized that left atrial pressure assessment circumventing the oscillatory effect of the V-wave might yield less frequent DPGNEG values. Thus we set out to investigate how PAWP measurement at the trough of Y-descent of the waveform influences DPG calculations, particularly the prevalence of DPGNEG and the prognostic value of resultant index.
Methods. 153 consecutive heart failure patients referred for right heart catheterisation were analysed. Measurements of PVR and DPG, as recommended, were performed.. Additionally, PAWP was also measured at the trough of Y-descent; subsequently, based on this measurement, DPGy was calculated.
Results. DPGy yielded higher values (median 3.7 [1.5 - 5.7]) as compared to DPG (median 0.9 [-1.7 - 3.8] mmHg); p<0.001. Conventional DPG was negative in 45% of the patients whereas DPGy in only15%. During a mean follow-up period of 22 ± 14 months, 58 patients have undergone heart-transplantation or died. The predictive ability of DPGy ≥ 6 for the above defined end-point events was significant [HR 2.1; CI 1.2-3.6, p=0.008] and similar to that of DPG ≥6 mmHg [HR 2.2; CI 1.0-4.6, p=0.043].
Concussion. Measurement of PAWP at the through of Y-descent yields significantly fewer DPGNEG values as compared to conventionally calculated DPG. At the same time, the prognostic value of DPGy is similar to that of conventional DPG.

P290

Right ventricular function using real-time three-dimensional echocardiography according to the acute volume reduction

CS Chan Seok Park[1]; AM Gwon[1]; GH Kim[1]; HS Ahn[1]; JS Cho[1]; HJ Youn[1]
[1]Catholic University Medical College, Seoul, Korea (Republic of)

Background: The evaluation of right ventricular function using 2-dimensional echocardiography is limited due to its complexity in the geometry. In this study, we investigated right ventricular function analysis using 3-dimensional echocardiography is affected by acute changes of preload or not.
Methods: 57 subjects who underwent transthoracic echocardiography including real time 3-dimensional image acquisition of right ventricle before and after hemodialysis were enrolled. End-diastolic and end-systolic volumes were obtained from right ventricular real time 3-dimensional image. Right ventricular stroke volume and ejection fraction were also calculated. Parameters representing right ventricular size and function based on 2-dimensional echocardiography were obtained from real time 3-dimensional image.
Results: The right ventricular functional parameters from real time 3-dimensional echocardiography could be easily obtained from commercially available software with other 2-dimensional functional parameters. And right ventricular ejection fraction obtained from real time 3-dimensional echocardiography was less dependent on acute preload changes.
Conclusion: Conventional structural and functional parameters and strain of right ventricle derived from three-dimensional echocardiographic images are also affected by acute volume reduction. These parameters also should be interpreted with caution considering the body volume status.

Right ventricular function: 3-D Echo			
	Pre-hemodialysis	Post-hemodialysis	P values
End diastolic volume index (mL/m^2)	59.0±14.3	51.8±12.9	<0.001

Best wedge as a predictor of right ventricle

O Yildirimturk[1]; B Gungor[1]; E Bozbeyoglu[2]; D Inan[1]; AI Tekkesin[1]
[1]University of Health Sciences Dr. Siyami Ersek Thoracic and Cardiovascular Surgery Hospital, Cardiology, Istanbul, Turkey; *[2]Siyami Ersek Thoracic and Cardiovascular Surgery Center, Department of Cardiology, Istanbul, Turkey*

Background: Right ventricular failure is an important mortality predictor in heart failure patients especially in continuous flow left ventricular assist devices (LVAD) era. Different indices and risk scores defined as predictors of RVF in these patients. Pulmonary capillary wedge pressure (PCWP) is a crucial parameter in HF. The ratio of PCWP to cardiac index (CI) in shock patients to determine best cardiac filling pressure for given hypertonic solutions. This ratio also could be helpful for HF patients to foresee right ventricular condition.
Purpose: Our aim was to evaluate PCWP/CI ratio in heart failure patients and compare with echocardiographically and invasively calculated parameters.
Methods: One hundred and eighteen patients with a mean age of 48±12 years (85.6% male) included in the study. Right heart catheterization and transthoracic echocardiography performed in the same day. All invasive calculations made using Fick method.
Results: Mean left ventricular ejection fraction was 22±7% and mean cardiac index was 1.9 L/min/m2. Mean PCWP/CI ratio was 13±7. PCWP/CI ratio was positively correlated with systolic, diastolic and mean pulmonary artery pressure (PAP) and negatively correlated with pulmonary artery pressure index (PAPI), tricuspid annular plane systolic excursion (TAPSE) and right ventricular S velocity (Table-1). No correlation has been found between pulmonary vascular resistance and right ventricular stroke work index.
Conclusion: PCWP/CI is well correlated with echocardiographic RV function parameters and PAP and PAPI. This parameter should be evaluated in larger patient series and LVAD patients.

Table-1 Bivariate correlation for PCWP/CI		
Parameters	r	p value
Systolic pulmonary artery pressure	0.545	<0.001
Diastolic pulmonary artery pressure	0.661	<0.001
Mean pulmonary artery pressure	0.641	<0.001
Pulmonary artery pressure index	-0.322	<0.01
TAPSE	-0.302	0.001
Right ventricle S velocity	-0.202	0.041

Correlations between PCWP/CI and echocardiographic and invasive parameters

P292

Changes in the ratio of discocytes and pathological forms of erythrocytes and microcirculation in chronic heart failure

D KH Durbek Rakhmanov[1]; M S Mirmaksudov[1]; I M Baybekov[2]
[1]Tashkent Medical Academy, Tashkent, Uzbekistan; *[2]Republican Specialized Centre of Surgery , Tashkent, Uzbekistan*

Background. Normally, discocytes are the dominant form and make up about - 90% of all red blood cells in the peripheral blood of humans and mammals. There are also so-called pathological forms of red blood cells - stomatocytes, red blood cells with a crest, echinocytes, as well as irreversible forms of red blood cells in the human blood.
It is shown that the ratio of normal erythrocytes - discocytes and their pathological forms, affects the state of microcirculation. The state of microcirculation and the ratio of discocytes and pathological forms of erythrocytes in chronic heart failure has not been studied.
Aim: To study the ratio of discocytes and pathological forms of erythrocytes in peripheral blood and the state of microcirculation in patients with chronic heart failure.
Material and methods. The calculation of normal erythrocytes - discocytes and their pathological forms in the blood obtained from a finger was carried out using the express - methods of "thick drop" in patients with chronic heart failure. Microcirculation of the earlobe skin was evaluated using laser Doppler flowmetry.
Results. In patients with chronic heart failure, shifts in the ratio of discocytes / pathological forms of erythrocytes were revealed. Echinocytes becomes 1.8 times more, stomatocytes 2.5 times, erythrocytes with a comb 3.8 times, and irreversible forms 3 times. The share of discocytes decreases by almost 22%.
Chronic heart failure causes violations of the main indicators reflecting the state of microcirculation. The relative indicator of the arterial component of the microcirculation, the total value of the average velocity of the erythrocytes and the number of functioning capillaries are significantly reduced. The vasomotor activity of microvessels decreases by one third and the speed of erythrocytes almost halves.
Conclusions: In chronic heart failure, changes in the D / PFE ratio determine microcirculation disorders.

P293

Can invasive hemodynamics reflect a poor renal perfusion pressure in end stage heart failure?

S Esmaily[1]; E Bobbio[1]; SE Bartfay[1]; P Dahlberg[2]; E Bollano[2]; G Dellgren[2]; K Karason[1]
[1]Sahlgrenska Academy, Department of molecular and clinical medicine, Gothenburg, Sweden; *[2]Sahlgrenska Academy, Gothenburg, Sweden*

Background: One of the most important comorbidities in heart failure (HF) is renal dysfunction. The so-called cardiorenal syndrome reflects the close interaction between heart performance and kidney function. Several evidences suggest that deteriorating central hemodynamics may contribute to impaired renal function but this relationship is not well defined.
Purpose: To investigate the association between glomerular filtration rate (GFR) and invasive hemodynamic measurements in patients with advanced HF.
Methods: A total of 220 consecutive patients undergoing evaluation for heart transplantation (mean age 48,6 years ± SD 12,9; 73,6 % male) during 1988 and 2018 were included in this study. Patients underwent right sided cardiac catheterization with measurements of central hemodynamics and GFR was measured with chrome-EDTA clearance.
Results: We observed a significant positive correlation between GFR and heart rate (HR), mean arterial pressure (MAP), and mixed venous oxygen saturation (SvO2) but a significant negative correlation was recorded with right atrial pressure (RAP). No correlation was reported with pulmonary artery wedge pressure (PCWP) or cardiac output (CO). In a stepwise multivariate regression analysis adjusted for sex and age, GFR was independently associated with MAP (b-estimate 0.27; p= 0.017), RAP (b-estimate -0.55; p= 0.018), and tended to be related to HR (b-estimate 0.13; p= 0.061).
Conclusion: In patients with end stage HF, impaired GFR is independently related to decreasing MAP and increasing RAP, probably reflecting a poor renal perfusion pressure.

P294
Ventricular function recovery in chronic heart failure patients

V Chaves[1]; V Guiomar[1]; A Monteiro[1]; I Albuquerque[1]; J Pereira[1]; C Gomes[1]; I Ferreira[1]; S Tavares[1]; P Lourenco[1]; P Bettencourt[2]
[1]Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal; [2]Faculty of Medicine University of Porto, ;Internal Medicine Department,Hospital da CUF; Internal Medicine Department,Centro Hospitalar S.João, Porto, Portugal

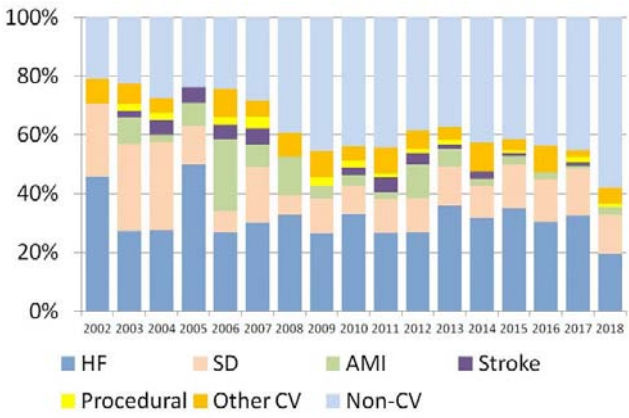
BACKGROUND: Recently, interest in patients with ventricular function recovery has emerged. Data on these patients is scarce, namely concerning the understanding of the phenomenon, its frequency and its natural history. We aimed to characterize the prevalence and characteristics of patients with ejection fraction recovery followed in a Heart Failure (HF) clinic.
METHODS: We analysed patients included and followed in our HF clinic from 2002 to 2015 who had 2 echocardiograms performed during the follow-up period. A total of 334 patients had at least mild left ventricular dysfunction and an echocardiographic re-evaluation. From these, 30 patients were excluded because an intervention (revascularization or surgical valve correction) was performed between image evaluations. Partial recovery was considered when patients presented ejection fraction recovery without attaining ejection fraction of at least 50% and total recovery was considered when patients reached a normal ejection fraction (left ventricle ejection fraction ≥ 50%).
RESULTS: In our population we observe that 150 (49.3%) of the patients showed no ejection fraction recovery or even worsening; 55 (18.1%) had a partial recovery and 99 (32.6%) showed total recovery of left ventricular function. A median time of 34 months was observed between echocardiogram evaluations. Mean patients' age was 66 years and 71.1% were men. Patients had a high comorbidity burden (35.9% were diabetic, 55.9% hypertensive, 55.9% had dyslipidemia and 36.2% were in atrial fibrillation); the aetiology was ischaemic in 35.5%. Patients were on optimally medical therapy: 95.1% were on Angiotensin Converting Enzyme inhibitor or Angiotensin Receptor Blocker, 98% on beta blocker, 53.9% on mineralocorticoid receptor antagonist. Non-recovered patients were mostly men (80.7% against 61.8 in partially and 61.6% in fully recovered patients, p=0.001) with ischemic HF (46.0% against 32.5% in partially and 21.2% in fully recovered patients, p<0.001). Comorbidity burden, New York Heart Association class upon admission and evidence-based therapy were not different between the groups of patients.
CONCLUSIONS: In this chronic HF cohort, half of the patients with HF and reduced ejection fraction showed no systolic function recovery despite optimal medical treatment; one third of the patients presented ejection fraction recovery and around 20% presented partial recovery. Male with ischemic HF is the prototype of the non-recovered patient.

Chronic Heart Failure - Epidemiology, Prognosis, Outcome

P295
Changes in the causes of death in a heart failure unit in Spain along 17 years

P Moliner[1]; J Josep Lupon[1]; M De Antonio[1]; M Domingo[1]; E Santiago-Vacas[1]; E Zamora[1]; J Santesmases[1]; C Diez-Quevedo[1]; MI Troya[1]; M Boldo[1]; S Altimir[1]; N Alonso[1]; B Gonzalez[1]; J Nunez[2]; A Bayes-Genis[2]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain; [2]University Hospital Clinic of Valencia, Valencia, Spain

Background: Advances in heart failure (HF) treatment have achieved a reduction of death in HF patients in the last two decades. Indeed, not only mortality has been reduced but also the mode of death might have been modified through these years.
Purpose: To assess the causes of death in outpatients attended in a HF Unit since the year 2002 up to the year 2018.
Methods: Causes of death were classified as follows: progression of HF (worsening HF or treatment-resistant HF, in the absence of another cause); sudden death (any unexpected death, witnessed or not, of a previously stable patient with no evidence of worsening HF or any other known cause of death); acute myocardial infarction; stroke; procedural (post-diagnostic or post-therapeutic); other cardiovascular causes (e.g., rupture of an aneurysm, peripheral ischemia, or aortic dissection), and non-cardiovascular. Patients who died of unknown cause were excluded from the analysis. Fatal events were identified from the clinical records of patients with HF, hospital wards, the emergency room, general practitioners, or by contacting the patient's relatives. Furthermore, data were verified from the databases of the Catalan and Spanish Health Systems. Trends on every cause of death were assessed by linear regression.
Results: Since August 2001 to May 2018, 2295 HF patients were admitted to the HF clinic (age 66.4 ± 12.8 years, 71% men, 49% from ischemic aetiology, mean LVEF 35.2% ± 14). During the 17 years of the study, 1201 deaths were recorded. Seventy-eight patients (6.5% of deaths) were excluded due to unknown cause of death. The evolution in the mode of death by years is shown in the figure. Two trends were observed: a decrease in sudden death (p=0.05) and a very significant linear increase in non-cardiovascular causes of death (p<0.001). The decrease of sudden death was mainly driven from changes observed in the first 10 years (p=0.014); thereafter the incidence of sudden death remained stable (p=0.18). Remarkably we did not observe significant changes in HF progression as mode of death (p=0.17).
Conclusions: During the 17 years of the study, a very significant trend towards higher percentage of non-cardiovascular deaths was progressively observed. On the other hand, percentage of sudden death showed a gradual decrease, mainly driven from the changes observed in the first 10 years.



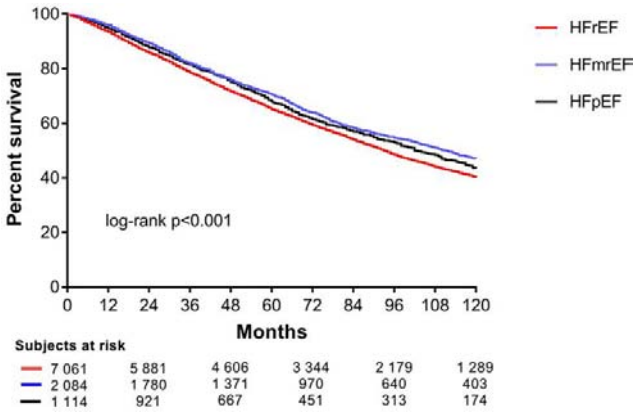
P296

Epidemiology and long-term outcome in outpatients with chronic heart failure in north-western europe

H Hanna Froehlich[1]; N Rosenfeld[1]; T Taeger[1]; K Goode[2]; S Kazmi[2]; T Hole[3]; HA Katus[1]; D Atar[4]; JGF Cleland[5]; S Agewall[4]; AL Clark[2]; L Frankenstein[1]; M Grundtvig[6]

[1]University Hospital of Heidelberg, Heidelberg, Germany; *[2]Castle Hill Hospital, Cottingham, United Kingdom of Great Britain & Northern Ireland*; *[3]Norwegian University of Science and Technology, Trondheim, Norway*; *[4]Oslo University Hospital, Oslo, Norway*; *[5]Imperial College London, London, United Kingdom of Great Britain & Northern Ireland*; *[6]Innlandet Hospital, Lillehammer, Norway*

Objective: To describe the epidemiology, long-term outcomes and temporal trends in mortality in ambulatory patients with chronic heart failure (HF) with reduced (HFrEF), mid-range (HFmrEF) or preserved ejection fraction (HFpEF) from three European countries.
Methods: We identified 10,312 patients from three European HF registries. Patients were classified according to baseline left ventricular ejection fraction (LVEF) and time of enrolment (period 1: 1995-2005 vs. period 2: 2006-2015). Predictors of mortality were analysed by use of univariable and multivariable Cox regression analyses.
Results: Among 10,312 patients with stable HF, 7,080 (68.7%), 2,086 (20.2%), and 1,146 (11.1%) were classified as having HFrEF, HFmrEF, or HFpEF, respectively. A total of 4,617 (44.8%) patients was included in period 1, and 5,695 (55.2%) patients were included in period 2. Baseline characteristics significantly differed with respect to type of HF and time of enrolment. During a median follow-up of 66 (33-105) months, 5,297 patients (51.4%) died. In multivariable analyses, survival was independent of LVEF category (p>0.05), while mortality was lower in period 2 as compared to period 1 (HR 0.81, 95% CI 0.72-0.91, p<0.001). Significant predictors of all-cause mortality regardless of HF category were increasing age, NYHA functional class, NT-proBNP, and use of loop diuretics.
Conclusion: Ambulatory HF patients stratified by LVEF represent different phenotypes. However, after adjusting for a wide range of covariates, long-term survival is independent of LVEF category. Outcome significantly improved during the last two decades irrespective from type of HF.



Survival stratified by HF category

P297

Identification of founder MYBPC3 gene mutations in hungarian patients with hypertrophic cardiomyopathy

A Tringer[1]; L Hategan[1]; B Csanyi[1]; J Borbas[1]; E Palinkas[1]; V Nagy[1]; Z Hegedus[2]; I Nagy[2]; T Forster[1]; R Sepp[1]

[1]University of Szeged, 2nd Department of Internal Medicine and Cardiology Centre, Szeged, Hungary; *[2]Biological Research Centre of Szeged, Szeged, Hungary*

Funding Acknowledgements: Supported by GINOP-2.3.2-15-2016-00039

Background: Hypertrophic cardiomyopathy (HCM) is a primary disease of the myocardium most commonly caused by the mutations in sarcomeric genes. Mutations underlying HCM are mostly unique, "private" mutations. However, the presence of so-called "founder" mutations is also known, where a mutation, occurring in a common ancestor earlier, is present in high frequency in a population, seemingly in non-related patients.
Purpose: We were searching for founder mutations in Hungarian patients with HCM genotyped by next-generation sequencing.
Patient and methods: We examined 133 patients with HCM (81 men, 52 women, average age: 45±15 years). Familial disease was present in 26% of the cases. Maximal left ventricular (LV) wall thickness was 22±6 mm and significant LV outflow tract gradient was observed in 28 patients. Using next-generation sequencing we screened 103 known causative cardiomyopathy genes, the target region consisted of 500.000 base pairs.
Results: Pathogenic or likely pathogenic variants were identified in 66% of the patients. Pathogenic variants most commonly affected the MYBPC3 (35%) and the MYH7 genes (16%). Multiple occurrence of mutations were observed in case of 6 gene mutations among the 133 patients [MYBPC3 p.Ala1056fs: 2 patients (1.5%), p.Arg495Gln: 3 patients (2.3%), p.Gln1233Stop: 9 patients (6.8%), p.Pro955fs: 6 patients (4.5%), p.Ser593fs: 7 patients (5.3%) and MYH7 p.Arg663Cys: 3 patients (2.3%)]. Haplotype analysis of the mutations suggested a founder effect in case of MYBPC3 p.Gln1233Stop, p.Pro955fs and p.Ser593fs mutations.
Conclusion: According to our results founder mutations are present in the Hungarian HCM population. The MYBPC3 gene p.Gln1233Stop, p.Pro955fs and p.Ser593fs founder mutations affect approximately 17% of the Hungarian HCM patients.

P298

Trends in heart failure epidemiology between 2007 and 2016 in Piedmont, Italy: findings from the Epi-HF study

D Castagno[1]; E Pivetta[2]; R Gnavi[3]; R Picariello[3]; G Costa[4]; M Maule[2]; A Maisano[1]; E Strippoli[3]; F Gaita[1]; M Rinaldi[5]

[1]Division of Cardiology, Department of Medical Sciences, University of Turin, Turin, Italy; *[2]Cancer Epidemiology Unit, Department of Medical Sciences, University of Turin, Turin, Italy*; *[3]Epidemiology Unit, ASL TO3, Regione Piemonte, Grugliasco, Turin, Italy*; *[4]Department of Clinical and Biological Science, University of Turin, Turin, Italy*; *[5]Cardiovascular Surgery, Department of Surgical Sciences, University of Turin, Turin, Italy*

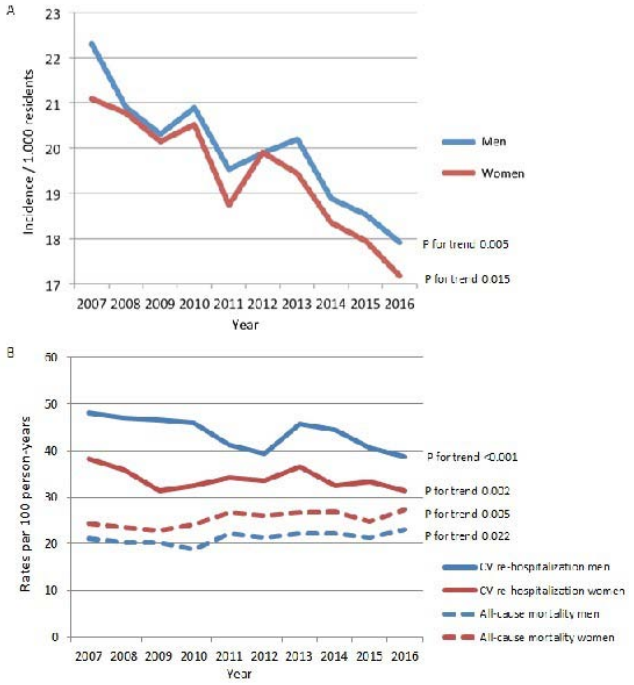
On behalf of: EPi-HF - Heart Failure in Piedmont: Trends in Epidemiology
Funding Acknowledgements: EPi-HF Study was funded by the University of Turin, Turin, Italy and by the Compagnia di San Paolo, Turin, Italy

BackgroundDifferences exist in epidemiology of heart failure (HF) between countries worldwide but recent data on HF temporal trends in Italy are lacking.PurposeTo describe HF epidemiology in Piedmont (about 4.5 million people in Northwest Italy) by analysing trends of first hospitalisation, readmission, survival and variables associated with outcome.
Methods This retrospective cohort study was based on hospital discharge records, tracking all hospitalisations occurred in Piedmont. The study population included residents first discharged between 2007 and 2016 with a principal diagnosis of HF. Endpoints were all-cause mortality and cardiovascular (CV) hospitalisation. Hospitalisation rates were age-standardised by direct standardisation. Crude case-fatality rates were calculated at 30 days, 1 and 3 years from discharge. Kaplan-Meier analyses were used to determine survival. Cox models were used to investigate factors associated with outcome.
Results74292 patients were admitted for the first time with HF (female 48.6%, mean age 77.5 years). The average length of in-hospital stay was 13 days. Since 2007, rates of first HF hospitalisation decreased significantly from 22.3 to 17.9 cases/1000 inhabitants and from 21.1 to 17.2 cases/1000 inhabitants in men and women respectively (Fig.A). In-hospital mortality was 10.7% overall. Mortality was 4.2%, 20.3% and 39% at 30 days, 1 and 3 years respectively. Readmission rates were 13.1%, 48.6%, and 68.9% after 30 days, 1 and 3 years, respectively. Post-discharge one-year mortality increased significantly from 2007 to 2016 in both sexes whereas CV-hospitalisations decreased (Fig.B). At multivariable analysis several factors were associated with outcome (Tab).

Table 1

	1 year all-cause mortality	1 year CV-rehospitalisation		
HR	95%CI	HR	95%CI	
Female (vs. Male)	1.07	1.03-1.12	1.17	1.12-1.21
Age (years) < 6565-74 75-84 >84	1.001.963.52 7.41	-1.74-2.21 3.16-3.93 6.63-8.29	-1.04 0.910.84	-0.99-1.10 0.86-0.96 0.78-0.89
Chronic renal failure	1.43	1.36-1.49	1.21	1.15-1.27
Chronic Obstructive Pulmonary Disease	1.17	1.11-1.23	0.95	0.90-0.99
Cancer	1.70	1.62-1.79	0.96	0.91-1.02
Myocardial infarction	0.98	0.93-1.02	1.26	1.21-1.32
Diabetes	1.02	0.97-1.06	1.11	1.06-1.15
Atrial fibrillation	0.99	0.95-1.03	1.31	1.26-1.35

Conclusions During the last decade, in Piedmont, rates of first HF hospitalisation decreased progressively. However, post-discharge mortality remained high.



P299

Prognostic value of handgrip strength in patients with heart failure

T Furlan[1]; D Kosuta[1]; K Vrbinc Vrtek[1]; V Grilj[1]; S Poznic[1]; K Poposek[1]; B Leskovar[1]
[1]Trbovlje General Hospital, Department of Internal Medicine, Trbovlje, Slovenia

Background. Handgrip strength is used to estimate overall muscle strength. The impact of handgrip strength on prognosis of heart failure is unclear.
Purpose. We evaluated the impact of handgrip strength on hospitalisation rate and survival of patients with heart failure.
Methods. We retrospectively collected data of consequent patients with heart failure from outpatient heart failure clinic. We measured handgrip strength at every visit at the clinic. Study endpoints were all-cause hospitalisation or death and hospitalisation or death because of heart failure. We recorded the first and the last handgrip before endpoint event. We evaluated the impact of handgrip strength on hospitalisation rate and survival wit Cox proportional hazards analysis.
We used the last measured handgrip to define frailty (standardised tables which consider age and body mass index). We divided patients into frail and non-frail groups and compared survival of these groups with Kaplan-Meier analysis.
Results. Out of 215 patients, 73 (34%) were hospitalised or died from any cause and 35 (16%) were hospitalised or died due to heart failure. Patients who reached the endpoint were older, had a higher level of troponin T, a higher percentage of them had arterial hypertension, patients who were hospitalised or died from any cause had higher level of NT-proBNP than non-hospitalised patients. No other significant differences were found between groups in clinical characteristics, comorbidities and laboratory parameters.
Handgrip strength was a statistically important negative prognostic factor of hospitalisation rate and survival in all-cause and heart failure group (Exp(B)=0.958, 95%CI 0.932-0.986, p=0.003 and Exp(B)=0.929, 95%CI 0.889-0.973, p=0.002, respectively). When adding age, type of heart failure and stage of chronic kidney disease as prognostic co-factors, stage of chronic kidney disease showed to be a significant prognostic co-factor besides handgrip in all-cause hospitalisation rate and survival. Patients in the frail group (N=176) had a significantly lower all-cause heart failure survival than the non-frail (N=39) group (14.5±0.8 vs. 18.3±1.3 months, p=0.018 and 17.6±0.9 vs. 20.6±1.0 months, p=0.031, respectively).
Conclusions. Handgrip strength can be used as a prognostic factor in heart failure patients - lower handgrip correlates with more hospitalisation and higher mortality (all-cause and heart failure related).

P300

Trends in incidence and survival in patients with heart failure in sweden: insights from swedish coronary angiography and angioplasty registry

E Elmir Omerovic[1]
[1]Sahlgrenska University Hospital, Gothenburg, Sweden

Background: Aging of the population and prolongation of the lives of cardiac patients by modern therapeutic innovations has led to an increasing prevalence of heart failure (HF). Despite improvements in therapy, the mortality rate in patients with HF has remained high. We aimed to evaluate the incidence and survival in patients who underwent coronary angiography with HF diagnosis in Sweden during the last two decades.
Methods: We used data from the Swedish Coronary Angiography and Angioplasty Registry (SCAAR), which contains information about all coronary angiographies and PCI (percutaneous coronary interventions) performed in Sweden (31 hospitals). We included all coronary angiographies performed in patients with HF diagnosis from 2000 to 2018 in Sweden. We used multivariate Cox proportional-hazards regression to adjust for differences in patient characteristics. Multilevel modeling was used to adjust for clustering of observations in a hierarchical database.
Results: In total, 24,171 patients were included in the study. Of these, 17,677 (73.2%) were men and 6,484 (26.8%) were women. Median follow-up time was 4,510 days (range 0-6648). Mean age was 63.7±11.3, and 32.7% were <60 years old. The number of diagnostic angiographies for HF indication increased by 5.5% per year. Normal coronary angiogram was reported in 63.2% while 36.8% had >50% diameter stenosis in one or more coronary arteries. In patients with significant coronary artery disease (CAD), 37.3% had single vessel disease (SVD), 23.8% had a multivessel disease without the involvement of left main (MVD), and 38.5% had a multivessel disease with involvement of left main (MVD-LM). The majority (53.4%) of HF patients with CAD were treated conservatively while (46.6%) were referred for revascularization with PCI or CABG. In revascularized patients (n=4,589), PCI was performed in 71.1% and 28.9% were referred for CABG. Between 2000 to 2018, age and gender adjusted survival in HF improved by 1.3% per the calendar year both in patients with and without CAD. The number of revascularized patients increased by 7.5% per the calendar year. Compared to HF patients without CAD, adjusted long-term mortality was higher in HF patients with SVD (HR 1.3; 95% CI 1.20-1.41; P<0.001), MVD (HR 1.72; 95% CI 1.58-1.88; P<0.001) and MVD-LM (HR 2.02; 95% CI 1.88-2.18; P<0.001).
Conclusions: The number of patients with HF undergoing coronary angiography and revascularization in Sweden has increased considerably over the last two decades. Long-term survival was substantially improved in HF patients with and without CAD. However, survival is better in HF patients without CAD.

P301

Previous cardiomyopathy in cardiogenic shock

H Santos[1]; J Fernandes[2]; T Vieira[2]; R Pinto[3]; T Filipa[3]; AR Ferreira[2]; M Rios[2]; T Honrado[2]
[1]Hospital N.S. Rosario, Cardiology, Barreiro, Portugal; [2]Sao Joao Hospital, Intensive Care, Porto, Portugal; [3]Sao Joao Hospital, Cardiology, Porto, Portugal

Background: Cardiogenic shock (CS) remains the major cause of death in acute coronary syndrome, and the presence of a previous cardiac dysfunction can influence the outcome.
Purpose: Evaluate the impact of previous cardiomyopathy in CS and the predictors of mortality in CS patients.
Methods: Single-centre retrospective study, engaging patients hospitalized for CS between 1/04/2016-31/10/2018. Multiple linear regression was performed to assess predictors of mortality at admission in CS patients. Then, patients were divided in two groups: A - previous cardiomyopathy in CS, and B - CS without a history of cardiomyopathy. Chi-square, Fisher and T-student tests were used to compare categorical and continuous variables.
Results: 214 patients were included, mean age 62.36±13.92 years, with 78.5% males. Arterial hypertension (AH) (53.3%), dyslipidaemia (DL) (46.7%) and smokers (31.6%) are the most frequent comorbidities. Beta blockers (BB) (31.6%), Angiotensin-Converting-Enzyme inhibitor (ACEI) (40.9%) and platelet antiaggregant (PA) (30.8%) are frequent medications before the CS occurrence. Multiple linear regression revealed age, AH, and ACEI as predictors of CS mortality with an R2a of 0.096 – Table 1. In the group A (50 patients) the most prevalent aetiologies were ischemic (50%), valvular (24%) and alcoholic (12%). The groups were similar regarding gender, AH, DL, diabetes, obesity, values of cardiac troponins, creatinine and platelet count, arterial pressure and arrhythmias at admission and mortality rates. Group A were older (66.34±15.49 vs 61.15±13.22 years, p=0.021), use more cardiovascular medication, BB (81 vs 15.7%, p0.001), ACEI (60 vs 34.8%, p=0.002), spironolactone (24 vs 4.4%, p0.001), furosemide (40 vs 11.9%, p0.001) and PA (53.1 vs 23.9%, p0.001); at admission presented lower values of

haemoglobin (12.39±2.44 vs 13.46±2.24, p=0.008) and leukocytes (13.02±10.27 vs 15.4±7.7, p=0.043). Group B had more angiography performed (84.8 vs 64%, p=0.001), and less time until the angiography (3±3 vs 3.5±2.88 hours, p=0.001) and higher left ventricular ejection fraction (35.64±13.59 vs 28.22±14.07, p=0.02). Linear regression confirmed that previous cardiomyopathy did not influence the mortality rates in CS patients, p=0.612.

Conclusions: Age and AH are the major predictors of mortality in CS and the use of ACEI seems have a protective effect.

Table 1

Independent Variables	β (95% CI)	P value
Age	0.205 (0.002 - 0.013)	0.006
Arterial Hypertension	0.230 (0.067 - 0.390)	0.006
ACEI	-0.252 (-0.409 - -0.100)	0.001

Multiple linear regression models for prediction of mortality in cardiogenic shock.

P302

Revisiting the obesity paradox in heart failure: percent body fat as predictor of biomarkers and outcome

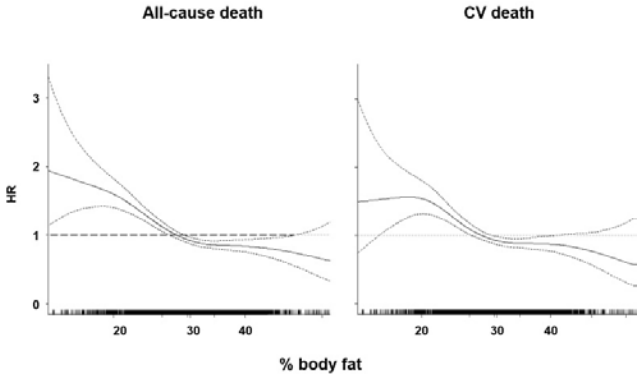
A Aimo[1]; JL Januzzi[2]; G Vergaro[3]; JN Cohn[4]; HP Brunner-La Rocca[5]; A Bayes-Genis[6]; J Lupon[6]; RA De Boer[7]; Y Takeishi[8]; M Egstrup[9]; HK Gaggin[2]; K Eggers[10]; R Latini[11]; K Huber[12]; M Emdin[13]
[1]Azienda Ospedaliero-Universitaria Pisana, Scuola di Specializzazione Malattie dell'Apparato Cardiovascolare, Pisa, Italy; *[2]Massachusetts General Hospital, Boston, United States of America*; *[3]Gabriele Monasterio Foundation, Pisa, Italy*; *[4]University of Minnesota, Minneapolis, United States of America*; *[5]Maastricht University Medical Centre (MUMC), Maastricht, Netherlands (The)*; *[6]Germans Trias i Pujol University Hospital, Badalona, Spain*; *[7]University Medical Center Groningen, Groningen, Netherlands (The)*; *[8]Fukushima Medical University, Fukushima, Japan*; *[9]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*; *[10]Uppsala University, Uppsala, Sweden*; *[11]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy*; *[12]Medical University of Vienna, Vienna, Austria*; *[13]Sant'Anna School of Advanced Studies, Pisa, Italy*

Background: Obesity defined by body mass index (BMI) is characterized by better prognosis and lower plasma N-terminal pro-B-type natriuretic peptide (NT-proBNP) in heart failure (HF). It is unknown whether another anthropometric measure, percent body fat (PBF), reveals different associations with outcome and HF biomarkers (NT-proBNP, high-sensitivity troponin T [hs-TnT], soluble suppression of tumorigenesis-2 [sST2]).

Methods: In an individual patient dataset, BMI was calculated as weight(kg)/height(m)2, and PBF through the Jackson-Pollock and Gallagher equations.

Results: Out of 6468 patients (median 68 years, 78% men, 76% ischemic HF, 90% reduced EF), 24% died over 2.2 years (1.5-2.9), 17% from cardiovascular death. Underweight patients (BMI <18.5 kg/m2) had the shortest survival; prognosis improved from underweight to normal and overweight, being similar from overweight to grade III obesity. Median PBF was 26.9% (22.4-33.0%) with the Jackson-Pollock equation, and 28.0% (23.8-33.5%) with the Gallagher equation, with an extremely strong correlation (r=0.996, p<0.001). Patients in the first PBF tertile had the worst prognosis, while patients in the second and third tertile had similar survival. The risks of all-cause and cardiovascular death decreased by up to 36% and 27%, respectively, per each doubling of PBF (all-cause death: hazard ratio - HR 0.68, 95% confidence interval - CI 0.58-0.80, p<0.001, and HR 0.64, 95% CI 0.53-0.77, p<0.001, with the Jackson-Pollock and Gallagher equations, respectively; cardiovascular death: HR 0.76, 95% CI 0.64-0.91, p=0.003, and HR 0.73, 95% CI 0.60-0.90, p=0.003, respectively). Furthermore, prognosis was better in the second or third PBF tertiles than in the first tertile regardless of model variables. Both BMI and PBF were inverse predictors of NT-proBNP (beta coefficients: BMI -0.206, PBFJackson-Pollock -0.234, PBFGallagher -0.244; all p<0.001) and sST2 (beta coefficients: BMI -0.063, p=0.004; PBFJackson-Pollock -0.083, p=0.001; PBFGallagher -0.084, p=0.001), but not hs-TnT. In obese patients (BMI ≥30 kg/m2, third PBF tertile), hs-TnT and sST2, but not NT-proBNP, independently predicted outcome.

Conclusions: Patient prognosis improves with either BMI or PBF. Obesity, assessed with BMI or PBF, is associated with lower NT-proBNP but not hs-TnT or sST2. hs-TnT or sST2 are stronger prognostic predictors than NT-proBNP among obese patients.



P303

Prognostic significance of obesity after ST-elevation myocardial infarction: the impact on heart failure

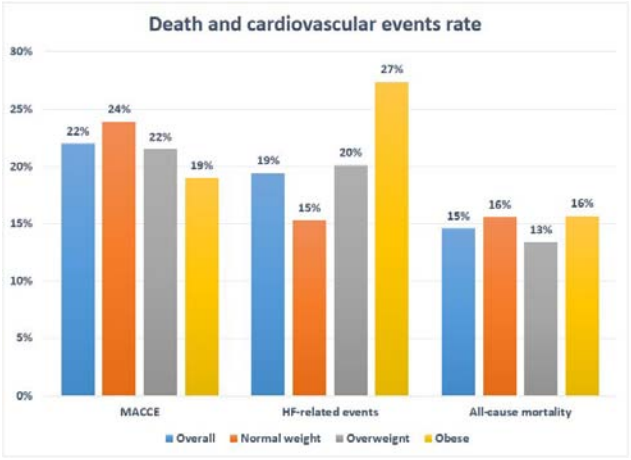
R Costa[1]; R Santos[1]; M Trepa[1]; S Vieira[2]; M Santos[2]; M Oliveira[1]; A Frias[1]; A Luz[1]; M Santos[1]; S Torres[1]
[1]Hospital Center of Porto, Cardiology, Porto, Portugal; *[2]Abel Salazar Institute of Biomedical Sciences, Porto, Portugal*

Introduction: In general population, a normal range body mass index (BMI) is associated with lower mortality. Paradoxically, in several chronic diseases an increased BMI is related to better prognosis, including in post-acute coronary syndrome patients.

Purpose: We aimed to evaluate the relation between BMI and cardiovascular outcomes in a cohort of ST-elevation myocardial infarction (STEMI) patients.

Methods: We retrospectively studied consecutive STEMI patients treated with primary percutaneous coronary intervention at a tertiary hospital between 1st January 2010 and 31st December 2016. Clinical and outcome data were retrieved by chart review. BMI was categorized as low weight (<18.5 kg/m2), normal (18.5-24.9 kg/m2), overweight (25- 29.9 kg/m2) and obese (≥30 kg/m2). Major adverse cardiovascular and cerebrovascular events (MACCE) were defined as occurrence of cardiovascular death, myocardial infarction, stroke or target lesion revascularization. Heart failure (HF)-related events were defined as de novo HF diagnosis, clinical worsening HF (increased dose of diuretics at outpatient clinic) or HF hospitalization.

Results: We included 864 patients (63±13 years, 75% male), 0.6% with low weight, 33.3% with normal weight, 45.1% overweight and 16.1% obese. Obese were younger and exhibited higher prevalence of previous hypertension, diabetes and dyslipidemia. Incidence of MACCE was 20.1%, with a median time to event of 10.1 [1.3-255.1] days and no significant differences between BMI groups. In multivariate analysis, only left ventricular ejection fraction (LVEF; if preserved, HR 0.45, 95 CI 0.23-086) and previous history of hypertension (HR 2.77, 95 CI 1.43-5.39) were independent predictors of MACCE. The overall post-STEMI HF-related events was 18.2% (6.2% de novo HF, 2.7% HF worsening and 9.3% HF hospitalization) with a median time to event of 10.8 [2.4-32.4] months. Independent predictors of



Death and cardiovascular events rate

HF-related events were age (HR 1.05, 95 CI 1.03-1.08), diabetes (HR 1.94, 95 CI 1.17-3.20), Killip-Kimball class (HR 3.02, 95 CI 1.96-5.25), LVEF (if preserved, HR 0.46, 95 CI 0.27-0.79) and obesity (HR 2.43, 95 CI 1.19-4.96).
Conclusion: In a cohort of all-comers STEMI patients, BMI was not associated with MACCE. In contrast, obese patients had an increased risk of developing de novo HF or worsening of preexistent HF. Our data suggests that obesity has a divergent prognostic significance regarding cardiovascular outcomes.

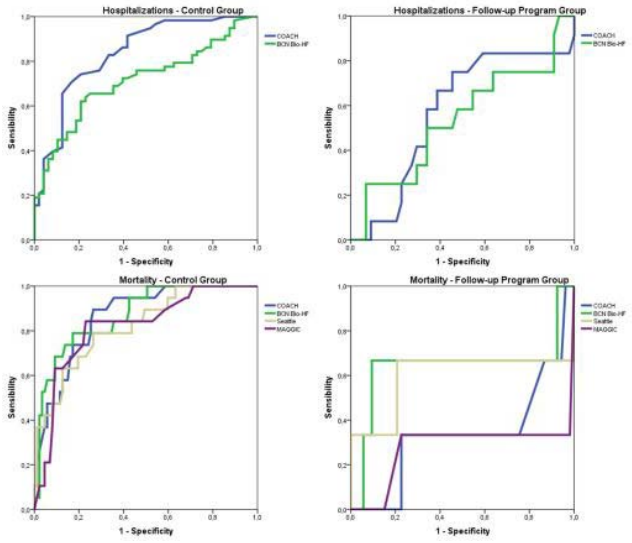
P304

Comparative analysis of multiparametric scores in heart failure: does the type of follow-up matter?

JR Agostinho[1]; T Rodrigues[1]; R Santos[1]; N Cunha[1]; J Rigueira[1]; A Nunes-Ferreira[1]; I Aguiar-Ricardo[1]; I Goncalves[1]; P Antonio[1]; S Pereira[1]; MM Pedro[1]; F Veiga[1]; N Lousada[1]; FJ Pinto[1]; D Brito[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal

On behalf of: RICA-HFTeam

Introduction : Multiple prediction score models have been validated to predict major adverse events in patients with heart failure (HF); however, these scores do not include variables related to the type of follow-up.
Objective : To evaluate the impact of a protocol-based follow-up program (PFP) of pts with chronic HF regarding scores accuracy for predicting 1-year hospitalizations and mortality.
Methods : Data from 2 HF populations were collected: one composed of pts included in a PFP after the index-hospitalization for HF; and a second one – the control population - composed of pts hospitalized prior to the beginning of the PFP. For each pt, the risk of hospitalization and mortality at 1-year was calculated using the COACH Risk Engine, BCN Bio-HF Calculator, MAGGIC Risk Calculator and Seattle Heart Failure Model. The accuracy of each score was established using the area below the ROC curve (AUC), calibration graphs and discordance (disc) calculation. AUC comparison was established by DeLong method.
Results : The PFP group included 56 pts, and the control group, 106 pts, with no significant differences between groups [median age: 67 vs 68.4 years; male sex: 58 vs 55%; median ejection fraction 28.2 vs 30.5%; functional class II: 60.7 vs 56.2%, I: 30.4 vs 31.9; p =NS). Hospitalization and mortality rates were significantly lower in the PFP group (21.4 vs 54.7, P <0.001, 5.4 vs 17.9, p <0.001, respectively).
Hospitalization risk calculated by COACH and BCN Bio-HF was 25.5 and 7.45% (disc: -55 and -79%, respectively) in the PFP group, and 24.5 and 11.5% (disc: 19 and -65%) in the control group. Mortality risk calculated by COACH, Bio-HF BCN, MAGGIC and Seattle was 21.5, 8.35, 11.1 and 13.7% (disc: 298, 55, 106 and 153%) in the PSP group and 20, 13.1, 11.65 and 14.5% (disc: 12, -26, -35 and -19%) in the control group.
When applied to the control group, COACH and BCN Bio-HF had, respectively, good (AUC 0.835) and reasonable (AUC: 0.712) accuracy to predict hospitalization. There was a significant reduction of COACH accuracy (AUC: 0.572; P =0.011) and a non-significant accuracy reduction of BCN Bio-HF (AUC: 0.536; P =0.1) when applied to the PFP group. All scores showed good accuracy to predict 1-year mortality (AUC: 0.863, 0.87, 0.818, 0.82, respectively) when applied to the control group.
However, when applied to the PFP group, a significant predictive accuracy reduction of COACH, BCN Bio-HF and MAGGIC (AUC: 0.366, 0.642 and 0.277, P: <0.001, 0.002 and <0.001, respectively) was observed. Seattle had no significant reduction in its acuity (AUC: 0.597; P: 0.24).
Conclusions : The accuracy of scores to predict major events in pts with HF is, globally, significantly reduced when they are applied to pts under follow-up in PFP. This may be related to the magnitude of reduction in major events rate that these programs entail. In these pts, BCN Bio-HF Calculator maintained reasonable accuracy and should be regarded as the score of choice.



P305

Heart failure in healthy young people with left bundle branch block: long-term follow-u

L Luigi Rivetti[1]; N Sitta[1]; G Allocca[1]; G Turiano[1]; E Lanari[1]; M Centa[1]; P Delise[2]
[1]Conegliano General Hospital, Cardiologia, Conegliano, Italy; *[2]Dr. Pederzoli Clinic, Peschiera del Garda, Italy*

Left bundle branch block (LBBB) is generally associated with a poor prognosis if with known ischemic heart disease and / or left ventricular dysfunction. However, the clinical and prognostic significance of the LBBB in young people (age <50 years old) totally asymptomatic and without any comorbidities is not well recognized.
The aim of our study is to evaluate this condition in a long term follow-up.
From 1996 to 2016, a total of 55 (0.27%) have been enrolled from 20,123 patients. Exclusion criteria were: previous history of cardiac arrest, syncope, any known cardiomyopathies, history of angina or dyspnea, known arterial hypertension. All patients underwent annual clinical cardiac evaluation, ECG recording and complete echocardiogram. Whether clinical appropriate, angiographic evaluation, cardiac magnetic resonance (CMR), and electrophysiological study have been performed. The mean age was 36 ± 11.7 years old and 40 (72 %) were male. More than half practiced any sportive activities and 13 (23%) had positive familial history for cardiac sudden death (SD). Considering the coronary clues, an abnormal origin of circumflex artery had been detected in 3 cases; an intramyocardial bridge of the left main coronary artery in 4 cases; and hypoplasia of right coronary artery in 1 case. About the CMR findings, 10 (18%) showed an area of late gadolinium enhancement (LGE), of whom, 9 in the interventricular septum, and 1 in the apical lateral wall. During a mean follow up of 10 ± 16 years, all patients are still alive, except 1 that died for non-cardiovascular causes. Conversely, 3 (5%) had syncope needing of cardiac pacemaker; 1 (2%) developed heart failure with severe left ventricular heart dysfunction needing of cardiac resynchronization therapy; 1 (2%) had ventricular tachycardia needing of implanted cardiac device.
The LBBB in <50 years old without any overt cardiac disease is a very rare condition, predominantly in males, and could be associated to coronary congenital abnormalities or evidence of fibrosis at the CMR. In a long-term follow-up, LBBB seems not to be associated to mortality neither to development of heart failure; conversely, it could be associated to other advanced atrioventricular block.

Clinical variables	
Number	55

Background. Heart failure (HF) is a leading cause of hospitalization among older adults. Previous studies have suggested that recurrent heart failure hospitalizations are a predictor of cardiovascular (CV) and all-cause mortality. Purpose. This study examined the impact of recurrent HF hospitalizations on CV mortality in real-world UK HF patients. Methods. Adult HF patients identified in the CPRD database with a first (index) hospitalization due to HF recorded in the HES dataset from 01/01/2010 to 31/12/2014 were included. Patients were followed until death or end of study period (31/12/2017). CV death as primary and as any reported cause and all cause death were evaluated. An extended Cox regression model was used for reporting adjusted relative CV mortality rates for time dependent recurrent HF hospitalizations. Adjusted variables were included based on clinical importance or statistical significance at baseline and if missing values were below 30%.
Results. 8603 HF patients with an index hospitalization were included, providing 15975 patient-years follow-up. Patients were relatively old (median [IQR] age of 80 [71-86]); majority were male (54.6%), with main comorbidities being hypertension (65.0%), atrial fibrillation (53.3%) and ischemic heart diseases (48.0%). LVEF values were only available for 1.9% of the sample so were not used in the analysis. Recurrent HF hospitalizations occurred 1, 2, 3 and ≥4 times in 1568 (18.2%), 496 (5.8%), 190 (2.2%) and 144(1.7%) patients, respectively. The median (IQR) time to all cause death was 215 (38-664) for the 50.8% of patients that died during the study period, and 139 (27-531) days for the 31.3% who died due to CV death recorded as primary cause. Compared with those without recurrent HF hospitalizations, the adjusted hazard ratios for CV death were 2.8 (95%CI 2.5-3.1), 3.5 (95% CI 2.9-4.2), 6.2 (95% CI 4.9-7.9) and 6.3 (95% CI 4.7-8.4) for 1, 2, 3 and ≥4 recurrent HF hospitalizations. Conclusion. Recurrent HF hospitalizations are a strong predictor of CV death in the HF population. The risk of CV death and all-cause death increases progressively with each recurrent HF hospitalization. These data highlight the relevance of reducing hospitalizations in the management of HF.

Direct costs of heart failure in a portuguese population.

L Santos[1]; C Fonseca[2]; AP Marques[3]; S Lopes[3]
[1]Hospital Funchal, Internal Medicine, Funchal, Portugal; *[2]Heart Failure Unit, Hospital de Sao Francisco Xavier, Lisbon, Portugal, NOVA Medical School, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*; *[3]NOVA University Lisbon, NOVA National School of Public Health, Lisbon, Portugal*

Funding Acknowledgements: Financial support for data retrieval from Servier.

Introduction: Heart failure (HF) is a global public health issue. Its economic impact in the Autonomous Region of Madeira (ARM) is unknown. Due to the condition's high prevalence and healthcare utilization, profiling its costs is fundamental for improved disease management.
Purpose: To estimate the direct costs related to HF in the ARM. Methods: A prevalence-based cost-of-illness approach was adopted to estimate direct costs of heart failure over a 12 month period from the healthcare system perspective. Prevalence estimates were derived from previous published study. Hospitalization and emergency department (ED) episodes were identified by the International Classification of Diseases 9th edition. Patterns of ambulatory visits and diagnostic tests in the hospital and primary care setting were derived from previous reported research and regional health system data. Medication use was also derived from this study. Costs were based on Diagnosis Related Groups and from the Portuguese official national health system tariffs.

Results: There was a 4.93% prevalence of HF in 2014 in individuals aged above 25 years, equivalent to an estimated 9201 patients. Of these, 4140 were symptomatic (NYHA≥II) and hence considered healthcare consumers. We identified 426 admissions with primary diagnosis of HF, 5.5% of total cardiovascular admissions. There were 16850 primary care ambulatory visits, 857 ED visits and 13414 internal medicine and cardiology ambulatory visits. Total direct costs were €4,089,540. Hospital-related care summed 56% of total costs, of which 49% related to hospitalization. Primary care costs accounted for 22%, medication (20%) and long term care (2%). Average annual cost per patient was €987.81.Conclusion: Total costs amounted to 0.1% of gross domestic product and 1.2% of the healthcare budget of the ARM. This finding is in line with other reports from developed countries. HF is a costly syndrome for ARM, and this research adds information about the disease that was until now unknown. Population ageing is likely to continue to drive increasing costs. These results can help policy making by identifying the financial burden of HF for the healthcare public provider in the ARM. Since it defined several cost components, this study can aid in the implementation of measures to improve disease management in the regional setting and reduce the major driver of costs which is hospitalization.

P308

European Heart Failure Aeareness day: evaluation of self-reported and control of cardiovascular risk factors

S Simone Binno[1]; GQ Villani[1]; GF Misuraca[2]; S Nodari[3]; G Rubino[4]; A Mortara[5]; D Pini[6]; AB Scardovi[7]; M Penco[8]; M Correale[9]; C Cerrai[1]; L Moderato[1]; MF Piepoli[1]
[1]Guglielmo da Saliceto Hospital, Piacenza, Italy; *[2]Ospedale SS Annunziata, Cosenza, Italy*; *[3]University of Brescia, Brescia, Italy*; *[4]Paolo Borsellino Hospital, Marsala, Italy*; *[5]Polyclinic of Monza, Monza, Italy*; *[6]Istituto Clinico Humanitas, Milan, Italy*; *[7]Hospital Santo Spirito, Rome, Italy*; *[8]University of L'Aquila, L'Aquila, Italy*; *[9]University of Foggia, Foggia, Italy*

Introduction In the last decade the Heart Failure Association (HFA) of the European Society of Cardiology promoted the "European Heart Failure Awareness days" initiative, aiming to increase the knowledge and prevention of heart failure (HF). It is known that the knowledge of HF, its causes and risk factors in critically low in general population, despite the high and increasing prevalence of pathology.
Aim During the 2017 initiative, we investigated subjective, and subsequent objective, awareness related to self-control of cardiovascular risk factors as physical inactivity, obesity and healthy diet, hypertension, diabetes mellitus, smoking habits.
Methods A 60-item multiple choice questionnaire has been developed to collect demographic data, presence of overt cardiac disease, adherence to pharmacological treatment, presence and level of physical activity, psychological well-being, diet and smoking habits. The questionnaires were administered to 709 people in 8 different cities.
Results The age of our population was 14-40 years old (yo) in 10%, 51-50 yo in 15%, 51-50 yo in 18%, 61-70 yo in 20%, 71-80 yo in 20% and over 80 yo in 13%. 55% were female and >50% declared high scholarity level. 91 out 709 were active smokers, and 167 out 709 former smoker. In 46% of cases the amount of cigarettes smoked was <10 per day, in 39% between 10 -20 and in 10% >21 cigarettes daily. In the 30% of cases the presence of a known cardiovascular disease was reported. The 68% of people was on pharmacological treatment (40% for hypertension, 11% for diabetes mellitus, 26% for hypercholesterolemia and 32% for cardiac ischemic disease or heart failure). Of these, 81% affirmed to be adherent to a prescribed

treatment but in the subsequent items, we found that 27% often forgot to assume the prescribed drugs. In 21% of cases, deteriorating of clinical status was the cause of voluntary interruption while in 16% due to improvement in symptoms. The self-reported status of physical activity was: satisfactory in 50% of cases (very good only in 5,4%), poor in 25,5%, very poor or absent in 21%. Investigating the amount of time and the intensity of the physical activity, 41% of the population was completely sedentary. Dietary habits were consistent with Mediterranean diet, with a correct assumption of vegetables and fruit in respectively 80% and 71% and a lower amount of fish and legumes (65% and 64%).
Discussion Our study revealed a discrepancy in self-assessed and measured adherence to a prescribed treatment. A better adherence level is pivotal component to maintain a good clinical status in patients with a diagnosis of HF, especially to keep an euvolemic status. Dietary habits were satisfactory while the amount of physical activity was not achieved in half of the cases. These data highlights the importance of increase awareness and to investigate real population adherence to risk factor's management, to obtain a better success in early diagnosis and treatment of HF.

P309

Differences between diabetics and non-diabetics with chronic heart failure and its impact on prognosis

L Lenka Spinarova[1]; J Spinar[2]; J Parenica[2]; M Spinarova[1]; O Ludka[2]; K Labr[1]; F Malek[3]; P Ostadal[3]; J Jarkovsky[4]
[1]Masaryk University,St. Anne's Faculty Hospital,1st Department of Internal Medicine-Cardioangiology, Brno, Czechia; *[2]University Hospital and Masaryk university, Internal Cardiologic Dpt, Brno, Czechia*; *[3]Homolka Hospital, Cardiologic Dpt, Praha, Czechia*; *[4]Masaryk University, Faculty of Medicine, Institute for Biostatistics and Analysis, Brno, Czechia*

The FAR NHL (FARmacology and NeuroHumoraL activation) registry is a database of patients treated in 3 departments with specialized heart failure care in one country. The patients should be treated for systolic heart failure (EF < 50%) and stable for at least one month. It analyses physical status, laboratory tests :blood count, biochemistry, including NT-proBNP, echocardiography and concomitant medication. Continuous variables are described by median, categorical variables are described by absolute and relative frequencies.P-value of Mann-Whitney U test for continuous variables and P-value of the Fisher's exact test for categorical variables are reported for comparison of patients' characteristics according to presence diabetes mellitus. Survival was evaluated after 2 years of follow-up and defined as freedom of death or left ventricle assist device implantation or heart transplantation.
1052 patients were included, and divided to diabetics 409 and non-diabetics 643. Patients with diabetes were older: 67 (60; 73) vs 64 years (54; 72) (p<0.001), had higher BMI 30 (27; 34) vs 28 (25; 31) (p<0.001), higher heart rate 74 (65; 81) vs 71 (64; 80) (p<0.01), higher uric acid 412 (351; 477) vs 388 μmol/l (330; 463) (p<0.003), lower hemoglobin 141 (130; 151) vs 145 (133; 154) g/l (<0.001) and lower glomerular filtration 63 (47; 82) vs 73 (57; 89) (ml/min/1.73 m^2) (<0.001). Diabetics had more often ischemic heart disease 70.9 vs 47.3 % (p<0.001), hypertension 79.7 vs 55.8% (p<0.001), dyslipidemia 89.0 vs 69.2% (p<0.001). The NT-proBNP levels were signifficantly higher in diabetics 681 (225; 1 708) vs 463 (138; 1 462) ng/l in non-diabetics (p<0.003). There were no differences in blood pressure, ejection fraction or presence of atrial fibrillation. Medication for heart failure did not differ in usage of ACEI/ARB, beta blockers and verospiron. Diabetics had more often furosemide 85.8 vs 77.3% (<0.001). Two year survival was 81.2% in diabetics (77.2; 85.3) vs 86.1% in non- diabetics (83.3; 88.9) p<0.057.
Conclusion: Diabetics have more often comorbidities: ischemic heart disease, hypertension, dyslipidemia, decreased renal functions and anemia, which contributes to more severe heart failure evaluated by NT-proBNP and worse prognosis than in non- diabetics with chronic heart failure.

P310

Prognostic nutrition index predicts prognosis in ultra-elderly patients with heart failure

T Kawata[1]; A Ikeda[1]; S Komatsu[1]
[1]Sassa General Hospital, Department of Cardiology, Tokyo, Japan

Background: The prognostic nutritional index (PNI), calculated from the serum albumin concentration and total lymphocyte count, is a simple and objective indicator of postoperative outcomes in patients undergoing cancer surgery. Recent studies have shown that PNI is associated with long-term survival in patients hospitalized for acute heart failure. However, the clinical significance of nutritional risk assessment in ultra-elderly patients with heart failure has not been well established.

Purpose: To test the hypothesis that PNI predicts prognosis in ultra-elderly patients with hospitalized heart failure.
Methods: We enrolled consecutive 48 octogenarian or nonagenarian patients (mean age 86 ± 4 years, 23 male) who were admitted to our hospital for treatment of heart failure. The diagnosis of heart failure was based on the Framingham criteria. Patients with significant (moderate or severe) primary valve disease were not included in this study. Vital status, information about medical treatment, laboratory data and echocardiographic data before discharge were collected from medical records. According to previous reports, PNI > 40 was considered normal value. The date of discharge was considered the entry time-point of observation. Primary outcomes were defined as cardiac death and unplanned hospitalization due to congestive heart failure.
Results: During a median follow-up of 291 days (range, 5 to 1331 days), 23 events (5 deaths, 18 heart failures) occurred. Compared with event free patients, plasma log BNP was significantly higher (2.58 ± 0.36 vs 2.26 ± 0.32, p < 0.01), PNI was significantly lower (35.8 ± 4.9 vs 41.6 ± 4.7, p < 0.01), and hemoglobin was significantly lower (10.5 ± 1.8 g/dl vs 11.8 ± 1.8 g/dl, p < 0.05) in patients with events. Univariate analysis showed that plasma log BNP (hazard ratio [HR] 6.1, 95% confidence interval [CI] 1.7 - 23.4, p < 0.01) and PNI (HR 0.89, 95% CI 0.82 - 0.96, p < 0.01) were predictors of outcome. Although lower hemoglobin level tended to associated with outcome (p = 0.066), none of the echocardiographic parameters were associated with outcome. Multivariate analysis revealed that both plasma log BNP (HR 4.2, 95% CI 1.2 – 16.0, p < 0.05) and PNI (HR 0.91, 95% CI 0.83 - 0.98, p < 0.01) were independent outcome predictors. Kaplan-Meier analysis showed that event rate was markedly higher (log rank, p < 0.01) in patients with PNI ≤ 40 than in those with PNI > 40.
Conclusion: Malnutrition, as evaluated using PNI, was associated with unfavorable outcomes even in ultra-elderly patients with heart failure.

P311

Co-morbid conditions and their relationship with mortality in elderly heart failure patients

VN Larina[1]; DG Karpenko[1]; VG Larin[1]
[1]Pirogov Russian National Research Medical University , Oupatient Medicine, Moscow, Russian Federation

In recent years, there has been growing evidence that multimorbidity is associated with the poor prognosis of chronic heart failure (CHF), but less is known about how these conditions impact outcomes in elderly patients.
Aim. To assess the o-morbid conditions and their relationship with mortality in elderly CHF outpatients. Methods. Eighty outpatients suffering from CHF (44% F/56% M, age 60-89 years) due to coronary heart disease (CHD) or arterial hypertension entered the study. Forty subjects with cardiovascular diseases but without CHF (45% F/55% M, age 60-88 years) were selected as sex- and age-matched controls. All patients provided written informed consent and had clinical, laboratorial evaluation, Echo CG measurements. Frailty was identified according to the score 3 or greater due to questionnaire FRAIL. Validated Charlson comorbidity index (CCI) was calculated. Bone mineral density (BMD) in the femoral neck (FN) were examined using dual-energy X-ray absorptiometry. Statistical analysis was made using software packages SPSS 21.0, Stata 15. Results. Co-morbidity (2 or more chronic conditions) was present in all patients with CHF and in 92,5% of control group. The most common comorbid conditions in CHF were chronic kidney disease (CKD, 66%), osteoporosis (58,6%), falls (48,5%), frailty (42,5%), obesity (35%); in control group - obesity (42%) or CKD (40%). The prevelance of osteoporosis (26,1%, p=0,005), falls (25%, p=0,039), frailty (5%, p<0,001) was less in control group compared to patients with CHF. The most common comorbid conditions ombinations in CHF were osteoporosis and CKD (28%), obesity and CKD (23%), in control group – obesity and CKD (28%), obesity and diabetes (18%). Frailty associated with age of 75 years or higher (p=0,001, OR 6,0, 95% CI 2,1-17,5), CKD (p<0,001, OR 18,9, 95% CI 5,2-20,2), osteoporosis (p=0,019, OR 4,5, 95% CI 1,3-15,8) and past myocardial infarction (p=0,001, OR 6,8, 95% CI 2,2-20,8). During the mediana of follow-up 24,1±13,0 months the mortality rate was the same in the CHF patients with ≥3 diseases or <3 diseases (=0,164). Patients with CHD (p=0,016), history of myocardial infarction (MI, p=0,016), osteoporosis (p=0,018) appear to have aggravated mortality. The relationship of mortality with male gender (=0,001, R 7,9, 95% CI 2,3 - 27,2), CHD (=0,039, R 8,3, 95% CI 1,1-62,4), history of MI (=0,027, OR 3,5, 95% CI 1,2-10,5), low BMD in FN region (=0,016, R 4,3, 95% CI 1,3-17,2), CCI (=0,012, R 1,2, 95% CI 1,04-1,4) was confirmed. Conclusion. Co-morbidities are prevalent in elderly patients with CHF. The presence of CHD, osteoporosis and complex of co-morbidities defined by CCI was indepedently related to increased mortality.

P312

Heart failure whit preserved ejection fraction (HFpEF); a mexican cohort

L Arizmendi[1]; M Rosas-Peralta[2]; D Salinas-Morales[3]; A Chanona[3]; A Contreras[3]; E Ramirez-Arias[3]; G Castro-Martinez[1]; A Cigarroa-Lopez[3]; J Jose Antonio Magana Serrano[4]

[1]Universidad La Salle, Facultad de Medicina, Mexico City, Mexico; *[2]Instituto Mexicano del Seguro Social, Programa "A todo Corazón", mexico city, Mexico*; *[3]cardiology hospital. National Medical Centre "Siglo XXI", IMSS, Division of Heart Failure and Cardiac Transplantation, mexico city, Mexico*; *[4]Hospital of Cardiology at the Siglo XX National Medical Center, Division of Heart Failure and Cardiac Transplantation, Mexico City, Mexico*

Background Several epidemiologic studies indicate that up to 50% of patients with heart failure have a preserved ejection fraction, and this proportion has increased over time. The knowledge of its severity and associated comorbidity is determinant to develop adequate strategies for its treatment and prevention. This study was focus on the creation of a cohort and follow-up of Mexican population and to analyze its severity as well as its interaction with the comorbidity of other cardiovascular risk factors.
Methods We included patients from different sites of Mexico City than were sent to the Cardiology hospital of the National Medical Center in Mexico City for the realization of an Echocardiogram as part of their assessment by the presence of dyspnea, edema, or suspicion of hypertensive heart disease. Complete medical history, physical examination and laboratory studies including Brain Natriuretic Peptide (BNP) serum levels were performed. Diagnosis of diastolic dysfunction was based on symptoms and echocardiographic data including time of deceleration, size of left atrium, e´ septal and e´ lateral, as well as E wave, A wave and its ratio E/A. All patients had left ventricle ejection fraction > 45%.
Results We included 168 patients with HFpEF. The most common risk factor was hypertension (89.2%), followed by overweight and obesity (> 78.5%), dyslipidemia (82.1%) and diabetes (42.8%). Women were dominant, 108 (64.3%); the mean age was 63 years old. When we classify by severity of diastolic dysfunction, we found that 41.1% were grade I, 57.1% were grade II and only 1.8% were grade III. The risk factors most strongly associated with the severity of diastolic dysfunction were hypertension, obesity and dyslipidemia. We found BNP levels highly variables, but the levels were higher detected as the ejection fraction was approaching to 45%. At one year of follow up mortality was not reported.
Conclusion HFpEF is a frequent entity in patients with cardiovascular risk factors in Mexico. The most common risk factor was hypertension. The combination of hypertension, overweight and dyslipidemia predicted the severity of diastolic dysfunction. We recommend that all Mexican patient with hypertension and overweight or obesity should be submitted as a part of its medical evaluation to an echocardiogram study in order to detect diastolic dysfunction even though the signs or symptoms are or not evident.

P313

Structural determinants of therapeutic compliance in chilean heart failure patients

H E Hugo Verdejo Pinochet[1]; F Diaz[2]; PF Castro[1]

[1]Catholic University Clinical Hospital, Santiago, Chile; *[2]Columbia University, New York, United States of America*

Funding Acknowledgements: FONDECYT 1150359 (HV), DI-38-18/"CBC" (FD), FONDAP 15130011 (PC,HV)

Most observational studies have identified a lack of therapeutic adherence as a major cause of heart failure (HF) decompensation. However, the determinants of poor therapeutic adherence behaviors in Chilean population are scarcely known
Aim: To assess determinants of poor therapeutic adherence in subjects admitted to a university hospital due to acute decompensated HF.
Methods: Cross-sectional study. We included patients admitted due to ADHF in a University Hospital between 2015-2017. Therapeutic adherence was assessed using the Morisky-Green Questionnaire; a score of 1 or less was considered as adequate adherence. As determinants of therapeutic adherence, we evaluated sociodemographic characteristics, disease knowledge using a Spanish version of the 15 items Knowledge of CHF Questionnaire. Multidimensional poverty data was assessed from the National Socioeconomic Characterization Questionnaire (CASEN). All analysis was performed on R v. 3.5. Georeferentiation was performed using QGIS.
Results: Ninety-two patients were included, 48.4% female, age 71,2±14,6. Optimal therapeutic adherence (MGQ score 0) was very low (6.5%). Patients with adequate or poor therapeutic adherence did not differ in age (69.4 vs 74.8, p= 0.09), gender (70.4% female vs. 65.9% men with adequate compliance, p= 0,81), employment (66.6% vs. 64.5% economically inactive, p= 0.73), educational level (30.6% vs. 43.3% with only elementary school, p=0.32), or disease knowledge (score 9.35 vs. 8.77, p=0,27). Insurance was a strong predictor of poor adherence (41.8% public insurance vs. 16.2% private insurance in the adequate compliance group, p = 0.027). Since health insurance is a surrogate marker of socioeconomic status, data were georeferenced considering the county where patients live, and data were adjusted using the multidimensional poverty index, which includes wealth, health access and quality of life components. Patients from counties with a higher multidimensional poverty index exhibited lower therapeutic adherence behaviors than those from richer counties (p=0.0023 for trend) (Fig. 1)
Conclusions: Poor therapeutic adherence behaviors in Chilean HF patients are more strongly associated with structural health determinants than with individual socioeconomic variables. Efforts to increase therapeutic adherence should take into consideration the impact of wealth, health access and quality of life in the development of self-care behaviors.

P314

Association between Phase angle and hypoxia in heart failure and chronic obstructive pulmonary disease

A Orea Tejeda[1]; D Gonzalez[1]; R Sanchez Santillan[1]; L Verdeja Vendrell[1]; L Hernandez Urquieta[1]; AA Ibarra Fernandez[1]; Y Pilotzi Montiel[1]; S Hernandez Lopez[1]; A Velazquez Montero[1]; R Hernandez Zenteno[1]; V Pelaez Hernandez[1]; K Balderas Munoz[1]

[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico

Background: Heart Failure (HF) and Chronic Obstructive Pulmonary Disease (COPD) are an important cause of morbidity and mortality around the world.
The decrease of oxygen tissue increases the oxidative distress, peroxides, and free radicals inducing body composition alterations, specifically phase angle (PA) which is an integrity indicator of membrane cellular and a prognosis factor. However, no studies evaluating the relation between hypoxia and PA in HF and COPD patients has been reported.
Objective: To determinate association between hypoxia and PA in HF and COPD patients.
Methods: In a Cross sectional study, 159 subjects older than 40 years with diagnosis of HF and COPD were included. Asthma and cancer subjects were excluded. Body composition and PA were assessed by bioelectrical impedance vectorial analysis (RJL Systems. Quantum IV). Hypoxia was defined by oxygen saturation < 80%
Results: The 58.1 % were woman (mean age was 67.4 ± 12), and 61.83 % had cachexia. Hypoxia subjects had less PA (4.3 ± 0.84 vs 4.94 ± 0.93, p = 0.046), as well higher edema (89.89 % vs 58.8 %, p =0.203) than without hypoxia subjects. No showed statistical significance between the groups in grip strength, impedance index, and skeletal muscle mass.
Conclusion: In HF and COPD subjects, the hypoxia represents an important negative impact in body composition, especially on membrane cellular integrity

P315

Frailty and prognosis in heart failure. A prospective study with a quick and self-administered scale.

J Sanchez Vega[1]; GL Alonso Salinas[1]; S Del Prado Diaz[1]; JM Vieitez Florez[1]; E Gonzalez Ferrer[1]; JL Zamorano[1]

[1]University Hospital Ramon y Cajal de Madrid, Cardiology, Madrid, Spain

Background Heart failure and its associated comorbidities are a delicate health condition that affects both life expectancy and the quality of life of patients. It is necessary to provide questionnaires or scales to stratify the short-term prognosis to address the need of medical attention or to know the death risks. Nowadays, we have scales like the Barcelona Bio-Heart Failure Risk Calculator (BioHF) or the Heart Failure Risk Calculator from MAGGIC investigation group, but its practical utility can be doubtful, due to the difficulties in completing these scales quickly in a consult setting. FRAIL scale has demonstrated a useful tool to detect frail patients at risk of suffering functional impairment, disability or death.
Material and methods
We proceeded to recruit a consecutive sample from the Advanced Heart Failure consults. After all participants signed the informed consent, patients completed FRAIL scale a few minutes before their medical consult. A total of 42 patients were recruited. Following, we analyzed the number of hospital re-entry in relation to acute hearth failure and death, in a period of six months from the first contact, dividing the patients in two groups: frail patients (3 or more points in FRAIL scale) and non frail patients. There were no significant diferences in sex, age and comorbidities between both groups. We compared the results in these groups with the score of the BioHF scale without biomarkers.
Results Compared with non frail patients, the patients with 3 or more points in the scale presented higher rates of hospital ingress due to acute heart failure (33,3% vs 6,9%, p=0,003) and decease (16,7% vs 0%, p=0,024). The prognosis value of FRAIL scale was correlated with the score of the BioHF scale: in the one-year ingress, frail

patients presented a bioHF score of 0,93% (vs 0,69 in non frail patients, p=0,044) and in death a BioHF of 32,5% (vs 17,1%, p=0,019).

Conclusions FRAIL scale has demonstrated in our study to be a useful, simple and fast acquiring tool to assess the risk of hospital re-entry and short-term mortality in patients with heart failure.

Results from study

Results FollowingRisk Stratification After 6 Months

VARIABLES	NON FRAIL(N=29)	FRAIL(N=12)	p
Acute heart failure hospital re-entry	2 (6,9%)	4(33,3%)	0,003
Death	0(0%)	2(16,7%)	0,024
BioHF one year hospital re-entry(%)	0,69; 0,1	0,93; 0,2	0,044
BioHF one year death(%)	17,1;2,9	32,5; 7,1	0,019

The number of hospital re-entry and deaths are presented as absolute values and percentages.Values of BioHF scale are presented as mean and standard deviation.

Snapshot evaluation of heart failure in Turkey: baseline characteristics of SELFIE-TR

A Ahmet Celik[1]; MB Yilmaz[2]

[1]Mersin University, Mersin, Turkey; *[2]Dokuz Eylul University, Izmir, Turkey*

On behalf of: SELFIE-TR Investigators

Objective: The prevalence of heart failure (HF) in our country was found to be 2.9%. However, country-wise profile, frequency and characteristics of different phenotypes,risk factors are not well established. Hence, it is important to identify phenotypes, risk factors and prescription patterns in a sample representative of Turkey.

Method: Twenty threee centers having at least two cardiologists in charge of patients, out of 12 NUTS-1 regions of Turkey were allowed to make consecutive enrolment for heart failure patients, confirmed by principal investigator according to the guidelines and in pre-selected one-day of each week of October or November (2015).

Results: Whole cohort has mean age of 63.3±13.3 years (M/F ratio: 751/353, % 71.3 / %28.7). In the whole cohort, number of acute and chronic HF patients were 712 and 342. Figure 1 shows the ratio of patients with different HF types. Baseline characteristics of patients with HF were summarized in Table 1. In the whole cohort, hypertension was observed in 46%, diabetes mellitus was present in 27.5%, chronic obstructive pulmonary disease was present in 12.8% and previous myocardial infarction was noted in 45.2%. In patients with HFrEF, ACEI/ARB, beta blocker and MRA use was noted in 74.7%, 89.7% and 60.9% respectively.

Conclusion: SELFIE-TR provides important insight since it is the first study to show snapshot of heart failure patients in our country. These information might be beneficial to develop guideline-concordant prevention and treatment strategies.

Epidemiology of heart failure: incidence, prevalence, and risk factors from a systematic review

C Lam[1]; M Stokes[2]; L Qin[3]; J Medina[4]; S Nambiar[5]; G Saraiva[3]

[1]National Heart Centre Singapore & Duke-National University of Singapore, Singapore, Singapore; *[2]Evidera, Saint-Laurent, Quebec, Canada*; *[3]AstraZeneca, Gaithersburg, MD, United States of America*; *[4]AstraZeneca, Madrid, Spain*; *[5]Evidera, Waltham, MA, United States of America*

Funding Acknowledgements: AstraZeneca

INTRODUCTION: Heart failure (HF) is a global public health problem. Recent data on the epidemiology of HF from population-based sources that identify cases using echocardiographic assessments are limited.

PURPOSE: To examine the contemporary worldwide incidence, prevalence, and clinical correlates of HF with reduced (HFrEF) and preserved ejection fraction (HFpEF).

METHODS: Systematic review of peer-reviewed original papers, published in English between January 2013–August 2018, focused on HF prevalence and incidence, and including echocardiographic data.RESULTS: From 11 identified studies (TABLE), prevalence of HFrEF and HFpEF ranged from 3.8¬–4.2% and 3.5–5.5%, respectively (from 3 community-based studies in Germany, China, Brazil); whereas incidence of HFrEF and HFpEF ranged from 0.5–9.3 and 0.6–15.1 per 1,000 person-years respectively (from 8 studies in US, EU, Japan, Australia). Prevalence and incidence of HFpEF was similar to or higher than that of HFrEF in all studies except Brouwers, 2013. Higher HF incidence regardless of EF was reported with older age, physical inactivity, hypertension, myocardial infarction, left ventricular hypertrophy, and increased natriuretic peptides. Female and renal disease were associated with higher HFpEF incidence. One study examining trends in the US between 2000-2010 showed overall decline in HF incidence (more in HFrEF than HFpEF), with increasing proportion of incident HFpEF (vs. HFrEF).CONCLUSIONS: The worldwide prevalence and incidence of HF remain high. Despite advances in identifying individuals at risk, HF, especially HFpEF, remains a global public health problem.

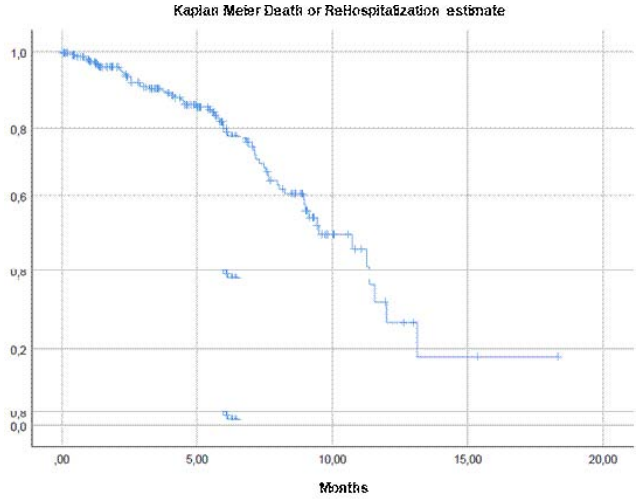
demonstrated an even higher rate of death and re-hospitalizations. The treatment is challenging and requires a multidisciplinary initiative to improve pharmacological and non-pharmacological treatment in this population. This comprehensive multidisciplinary approach is the main goal of the Optimize Program and is focused beyond the pharmacological treatment in educating patients and their families about the disease and providing information for self-monitoring.

Purpose: We aimed at assessing the clinical effect of Optimize-HF Program in a prospective multicenter Brazilian cohort of heart failure patients.

Methods: We prospectively included a total of 288 patients (pts) (180 males, 61.07±12.5 y.o.) with heart failure and reduced left ventricular ejection fraction (LVEF) mainly with non-ischemic etiology (178 pts – 61.8%). Pts were followed in HF clinics of six Brazilian centers and received the orientations of the Optimize program.

Results: The baseline characteristics were: LVEF = 33.7±12.2%, EDLV = 65.7±10.5mm, ESLV = 55.2±10.6mm, systolic arterial pressure = 114.9±22 mmHg, heart rate = 77.9±20.4 bpm, 37.8% of the patients were in NYHA functional class II and 58.7% of the patients were in NYHA functional class III and IV, 31.8% had atrial fibrillation/flutter, 54.9% had hypertension, 31.9% diabetes mellitus, 35.4% smoking, 18.4% obesity, 7.98% had implantable cardioverter defibrillator or cardiac resynchronization therapy. Patients were treated following the recommendations of the guidelines: 93.4% were using betablockers, 78.1% ACE inhibitors or ARBs, 70.8% ARMs, 2.1% ARNI, 18.4% digoxin, 91.7% diuretics, 28.5% warfarin, 23.6% amiodarone, 11.1% nitrate/hydralazine, and 12.9% ivabradine. The follow-up time was 158,7±131,2 days, with 9.7% of mortality and 20.5% of rehospitalization. The low mean LVEF and the worse functional class (NYHA III-IV) suggest that this is a high risk HF population. The outcome rate of death and a combined

outcome of death or rehospitalization were markedly lower in comparison to the Brazilian National Registry of HF, which showed more than 42% of mortality and rehospitalization over 6 months.
Conclusion: The optimization of HF treatment using a multidisciplinary program showed a lower rate of death and death or rehospitalization. These results suggest the potential benefit of this strategy to improve prognosis of patients with heart failure and reduced LVEF.



P319

Prevalence and prognostic association of hyperuricemia in heart failure patients with reduced ejection fraction

I Ines Pereira Oliveira[1]; D Seabra[1]; A Leal Neto[1]; A Andrade[1]; J Azevedo[1]; P Pinto[1]
[1]*Hospital Centre do Tamega e Sousa, Penafiel, Portugal*

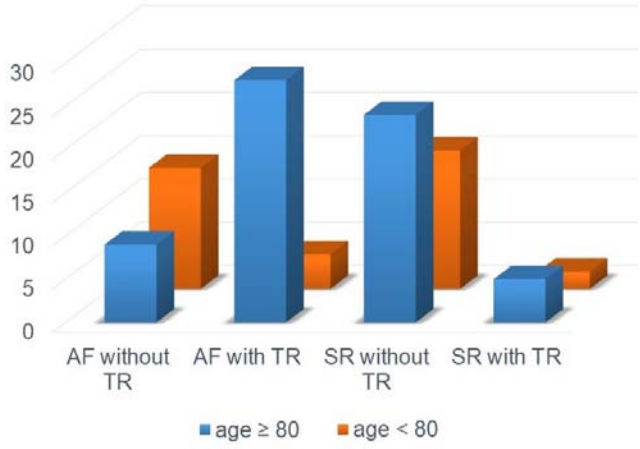
Introduction: Substantial evidence advocates that uric acid (UA) is an independent marker for adverse prognosis in chronic HF of varying severity. Serum UA, produced in the terminal step of purine nucleotide metabolism by xanthine oxidase (XO), seems to be a predictor of mortality in HFrEF, independent of chronic kidney disease (CKD). Whether UA is simply a marker of dismal prognosis or an active contributor in disease pathogenesis is currently unknown.
Purpose: To appraise the association of UA levels with clinical features and prognosis in pts with HF and reduced ejection fraction (HFrEF) in a Heart Failure Clinic (HFC).
Methods: Unicentric, retrospective analysis of pts followed in a HFC since 3/2011. Included pts with reduced ejection fraction (EF) (<50%) and previous diagnosis for at least 6 months. The pts were divided into 2 groups: hyperuricemic (G1) and with normal UA levels (G2). Hyperuricemia was defined has serum UA ≥7.0mg/dL. Clinical, demographic, analytical, electrical, echocardiographic characteristics and major cardiac events – HF hospitalization (HFhosp) and mortality (from cardiovascular cause (CVm) and non-cardiovascular cause (nCVm)) were analysed.
Results: Included 318 pts, mean age 60.4 ± 13.3 years and a mean body mass index (mBMI) of 27.9kg/m2. 74% were male. 41.5% had ischemic etiology. G1 consisting of 153 pts (48%) with mean age of 61.3±13.3 years. There were no differences in age, mBMI and cardiopathy etiology between groups.There were no significant differences in cardiovascular risk factors prevalence, except for smoking (43 vs 32%, p=0.032). The hyperuricemic group correlated positively with the presence of atrial fibrillation (AF) (42 vs 28%, p=0.009) and CKD (41 vs 22%, p<0.001). G1 had more right ventricular dysfunction and lower left ventricular EF (LVEF) at admission (p<0.001). LVEF remained significantly lower in G1 during follow-up (FU) (p=0.045). Although there were no significant differences regarding mortality, G1 pts had more HFhosp (20 vs 12%, p=0.046).
Conclusion: Hyperuricemia was particularly prevalent in this cohort. There were no associations with standard cardiovascular risk factors although hyperuricemic pts had more AF and CKD. Furthermore, higher levels of ventricular dysfunction were observed in this subgroup, with greater presence of biventricular dysfunction and HFhosp.

P320

Echocardiographic features of ultra-elderly heart failure patients in Japan: secondary tricuspid regurgitation due to atrial fibrillation

T Kawata[1]; A Ikeda[1]; S Komatsu[1]
[1]*Sassa General Hospital, Department of Cardiology, Tokyo, Japan*

Background: Japan has the oldest population, with 27.7% of its citizens aged over 65 years in 2017. Moreover, there are over 10 million people over 80 years old in Japan. With the rapidly aging population in Japan and European countries, the prevalence of heart failure (HF) is expected to rise continuously, because the incidence of HF increases with age. Therefore, it seems important to evaluate clinical characteristics of current ultra-elderly HF patients for prevention of future HF.
Purpose: To explore echocardiographic features of ultra-elderly patients with HF.
Methods: We enrolled 102 patients (mean age 78 ± 13 years, 40 male) who were admitted to our hospital for treatment of HF. The diagnosis of HF was based on the Framingham criteria. Patients who have received cardiac surgery or with primary valve disease were not enrolled in this study. We divided our patients into two groups stratified according to age (≥ 80 and < 80 years old). Then, we compared echocardiographic parameters of the patients between both groups.
Results: Most common comorbid disease were atrial fibrillation (n = 55 [54%]), followed by hypertension (n = 50 [49%]), diabetes (n = 20 [20%]). Compared with patients with age < 80 years (n = 36, mean age, 66 ± 11 years), left ventricular ejection fraction was significantly higher (51 ± 14% vs 42 ± 14%, p < 0.01), tricuspid regurgitation (TR) velocity was significantly greater (2.9 ± 0.6m/sec vs 2.4 ± 0.6m/sec, p <0.01) in patients with age ≥ 80 years (n = 66, mean age, 87 ± 4 years). Left ventricular mass index and E/e' were similar in both groups. Although the prevalence of atrial fibrillation and significant (moderate or severe) mitral regurgitation were similar, the prevalence of significant TR was significantly higher in patients with age ≥ 80 years (n = 33 [50%] vs n = 6 [17%], p < 0.01). Interestingly, in patients with atrial fibrillation, the prevalence of significant TR was significantly higher in patients with age ≥ 80 years compared to patients with age < 80 years; in contrast, in patients with sinus rhythm, the prevalence of significant TR was similar and low in both age groups (Figure).
Conclusion: Current ultra-elderly patients with HF had preserved ejection fraction, greater TR velocity. Moreover, the prevalence of significant TR due to atrial fibrillation was very common. Therefore, early aggressive rhythm control strategy may become one of therapeutic option to prevent TR and future HF.



P321

Epidemiology of atrial fibrillation among heart failure patients according to ejection fraction.

A Amina Rakisheva[1]; A Mussagaliyeva[1]; A Klimenko[2]; K Koshumbayeva[1]; A Isabekova[1]; A Tashmanova[3]
[1]*Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*; [2]*RUDN University, Moscow, Russian Federation*; [3]*Kazakh National Medical University, Almaty, Kazakhstan*

Background: Heart failure is a common syndrome in patients with atrial fibrillation (AF), that particular due to similar risk factors and pathogenesis.
Aim of the study:to evaluate the occurrence of the risk factors depending on left ventricular ejection fraction (LVEF) in patients with AF.Material and methods:in

population-based survey 1544 people with cardiovascular diseases were selected; of them 667 were with AF (56,84%). The association of AF and 3 EF groups was assessed. Patients with thyroid disorders and valvular heart diseases were excluded.
Results: When comparing the 3 EF groups, detection of HFrEF was low and amounted to 16,3%, HFmrEF in 21,5% and the highest number of patients were detected in group with preserved EF, in 62,2%. Despite such distribution, the prevalence of cardiovascular risk factors more often detected in group of patients with reduced EF. Thus, 78,9% of men were with HFrEF versus 57,3% with HFpEF (OR: 2,8; CI 1,7-4,6; p < 0.001), twice as often smoking occurred, 26,6% versus 13,98%, respectively, (OR: 2,23; CI: 1.3-3.7; p < 0.001), 41,3% patients with reduced LVEF suffered a myocardial infarction while in group with preserved LVEF only in 17,6% cases (OR: 0,3;CI: 0,19-0,47; p < 0.001). The frequency of diabetes mellitus (DM) in patients with HFrEF was 27,5%, that exceeded in two times the number of patients (16,1%) in HFpEF group (OR: 1,97; CI: 1,2-3,23; p = 0,011). The incidence of hypertension and prior stroke was similar in both group (p = 0,15 and p = 0,13, respectively).
Conclusion: atrial fibrillation was more common in HFpEF versus in HFmrEF versus in HFrEF. Contrariwise, the significant association of cardiovascular risk factors such as gender, prior myocardial infarction, smoking, diabetes mellitus and atrial fibrillation was detected in group of HFrEF. Importantly, hypertension and prior stroke similarly occurred in patients of all 3 EF groups.

P322
Gender differences in heart failure with mid-range ejection fraction patients

J-H Jung-Hyun Choi[1]; JC Choi[1]
[1]*Busan National University Hospital, Busan, Korea (Republic of)*

Background: Little is known on the gender differences in patients with heart failure (HF) with mid-range ejection fraction (EF) (HFmrEF).
Objectives: We aimed to investigate the gender differences in patients with HFmrEF.
Methods: Among 252 consecutive patients with primary diagnosis of HFmrEF (EF 40-49%) and baseline and follow-up echocardiogram in an urban tertiary referral center from October 2013 to March 2017, 131 (52.0%) were in men and 121 (48.0%) were in women. We compared the characteristics and composite event (cardiovascular death and HF readmission).
Results: Compared to women, men had significantly higher rates of prior ischemic heart disease, chronic kidney disease (CKD), and peripheral arterial disease. At baseline, LVEF was not significantly different between men and women. At follow-up, LVEF in women significantly improved from the baseline levels (48.9% vs. 45.3%, p<0.001), whereas no significant changes in LVEF were observed in men. In women, the use of inhibitor of the renin angiotensin system (odds ratio 0.39, 95% confidence interval [CI] 0.18-0.82, p=0.014) was contributed to the improvement of LVEF. Composite event occurred in 80 patients (31.7%). There were no significant differences in the composite event between men and women (32.1% vs. 31.4%, hazard ratio [HR] 1.16, 95% CI 0.74-1.81, p=0.529). Significant contributors for composite event were age (HR 1.04, 95% CI 1.01-1.06, p=0.002), the presence of atrial fibrillation (HR 1.78, 95% CI 1.15-2.76, p=0.010), spironolactone use (HR 0.56, 95% CI 0.36-0.87, p=0.009). Cardiac death occurred in 9 patients (3.6%). Men had a significantly higher rate of cardiac death than women (6.1% vs. 0.8%, HR 1.26, 95% CI 1.01-6.69, p=0.027). In men, age (HR 1.12, 95% CI 1.02-1.22, p=0.015) and CKD (HR 3.14, 95% CI 1.03-6.58, p=0.042) were independently predictive for increased risk of cardiac death.
Conclusions: This study showed that in patients with HFmrEF, women might be associated with improved LVEF and lower risk of cardiac death compared to men.

P323
Capability for self-care of patients with heart failure

A Mlynarska[1]; R Mlynarski[1]; C Marcisz[1]; KS Golba[1]
[1]*Medical University of Silesia, Katowice, Poland*

The lack of compliance with medical and other lifestyle recommendations is a serious problem in elderly patients who suffer from heart failure (HF) and have serious consequences for individual patients and their families as well as for the health care system. The aim of the study was to evaluate the influence of the level of the capability for self-care on the number of rehospitalizations in patients with HF.
METHODS: 180 pts. (aged 72.8±8.0 years; 29.4% W) diagnosed with HF were included in the study. The following inclusion criteria were used: the diagnosed with HF at least 6 months earlier and being more than 60 years of age. The mean follow-up time was 454.6±262.1 days. The treatment for HF was verified and the optimal therapy (pharmacological and/or device-based) was confirmed in all of the participants. Depending on the treatment that was being used, the patients were divided into three groups: Group I: HF being treated conservatively by pharmacological treatment and lifestyle changes (treated conservatively), 51 patients (28.3%); Group II: HF being treated with the implantation of a cardioverter-defibrillator (ICD), 47 patients (26.1%); Group III: HF being treated with the implantation of a cardiac resynchronization system (CRT), 82 patients (45.6%). In all of the patients the Polish version of the nine-item European Heart Failure Self-care Behavior Scale (EHFScBS-9) was used – the more the points one gets, the worse the capability for self-care is. The data were analyzed statistically, and the values were treated as significant when p<0.05. RESULTS: The ROC curves for all groups are presented in the figure below. The EHFScBS-9, which has a cutoff value of >28 points, identified patients that had a significantly higher risk of rehospitalization for HF. The analysis of the impact of the capability for self-care on rehospitalization revealed that in the group of patients that were treated conservatively, the cutoff point was ≤30 points (P=0.1738), in the group of patients that were treated with ICD it was >32 points (P=0.0001) and in the group of patients that were treated with CRT it was >28 points (P=0.0394).
CONCLUSIONS: The level of the capability for self-care in patients with HF has been described as an additional risk factor for rehospitalization. The lower cutoff level for patients with implanted CRT seems to be clinically significant. It concerns the group of the most burdened patients, and despite the fact that it was the group that showed the best capability for self-care, it was the one that was most frequently rehospitalized.

NYHA IV	5.7%	3.9%	0.472
Anemia	38.9%	23.0%	0.000
CKD GFR< 60 ml/min	26.9%	73.4%	0.000
Quality of lifeSPF 36 score	78.4	80.4	0.098
Ace inhibitors	28.8%	37.6%	0.001
ARB blockers	45%	36.5%	0.003
ARNI	10.3%	11.7%	0.49
Betablockers	84.3%	87.4%	0.124
MRA	49.6%	55.5%	0.003

and Chi-square or Fisher test were used to identify differences between groups (Women vs men).
Results: 2099 patients were included from 2016 to 2018,mean age was 67.59 +/- 13.54 years, 43.46% were women. The main differences between men and women are presented in table 1.
CONCLUSIONS: The data from RECOLFACA registry found significant differences according to sex, , women have more HFpEF, more anaemia and less chronic kidney disease. ACE inhibitors, ARB and MRA were used less often in women despite a similar use of beta-blockers and ARNI. There were no differences in the quality of life and NYHA functional class.

P325

Profile comparison of an elderly cohort with HFpEF and HFrEF: a multivariate analysis of mortality risk factors and death causes attested by CID10

E Eduardo Pitthan[1]; VN Hirakata[1]; JN Barbisan[1]
[1]*Institute of Cardiology of Rio Grande do Sul, Porto Alegre, Brazil*

BACKGROUND: The elderly population with Heart Failure with preserved Ejection Fraction (HFpEF) and Heart Failure with reduced Ejection Fraction (HFrEF) display different etiologies, profiles and comorbidity rates, with a consequent variable impact in prognosis.
PURPOSE: To evaluate and to compare an elderly cohort with the gold standard for HFpEF and HFeEF, and the Hazard Ratio (HR) of the risk mortality factors and the cause of mortality registered in death certificates (CID10).
METHODS: We enrolled patients with dyspnea and suspicion of HF in the emergency of a tertiary hospital in our city, in the South of Brazil. The patients were included between March 2006 and September 2012. They were assessed for HF through the Framingham and Boston Score gold standard, Uni + Bidimensional Echocardiogram with Doppler Color and BNP (Biosite, San Diego - CA). The Hazard Ratio (HR) of mortality risk factors in bivariate and multivariate analysis was measured.
There was monitoring for 78 months, average time of 49 months. The primary cause of death and other data were obtained through death certificates (CID10) collected at MIS
RESULTS: A sample with 634 patients included, the majority of patients were white (93%) and women (63%), average age 77,3 sd +- 8,6 years and 40,5% > 80 years. In HFpEF 79,6 sd +- 6,8 years and HFrEF 72 sd +-9,7 years. BMI > 30kg/m2 present in 16% HFrEF and 26% HFpEF, cardiomegaly 72,7%, congestion 70,7%, pleural effusion 52,5% and 18% has showed DCE <30ml/h. Gold standard for HF in 340 patients (53,3%). A total of 216 (63,5%) has showed HFpEF with a median BNP of 380 pg/ml. HFrEF with a median BNP of 800pg/ml. In the multivariate analysis for mortality, BNP > 180pg/ml with HR of 3,4 (CI 95%: 1,2 to 9,6). Age > 80 years, HR: 1.54; [CI: 0.9-2.5]. Cardiomegaly HR: 1.71 [CI: 0.9-3.9], pneumonia HR: 1.63 [CI: 0.0-2.7], DCE < 30ml/h, HR: 2,14 [CI: 1.05-4.4], BMI < 22 in 13%, HR: 1. 821 [CI: 95%; 1. 053-3. 149] p 0.18. Survival analysis throughout the 78 months of the study was carried out by the Kaplan-Meier curve (Fig 1). The HFrEF has displayed a survival average time of 27 months, HFpEF of 52 months and No Heart Failure (NHF) > 50% at the end of the study. The death certificates analysis, total deaths and Hazard ratios follow in Table 1.
CONCLUSIONS Comparing elderly groups with HFrEF, a higher rate of cardiovascular mortality by HF progression, sudden death and IAM, a higher BNP median, and a lower survival average time have been presented. The group with HFpEF has displayed the highest average age, female and BMI. A higher rate of thromboembolic events (stroke and AMI), digestive bleeding and higher rates of comorbidities as well. BNP was the most powerful mortality predictor when adjusted to the other factors in both HFrEF and HFpEF.

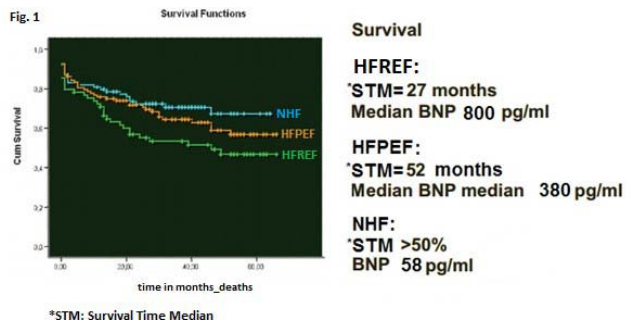

Figure 1

P326

Predictors of combined critical endpoint (all-cause death/heart failure hospitalization) in patients with chronic heart failure and reduced left ventricular ejection fraction.

A Alina Lyashenko[1]; P Babich[1]; N Tkach[1]; L Voronkov[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, department of heart failure, Kiev, Ukraine*

Background. It is known that patients with heart failure (HF) demonstrate high mortality/hospitalization rate. So, the search of clinical and laboratory predictors of combined endpoint (death or HF hospitalization) potentially may improve the estimation of their individual prognosis.
Objective. To establish the predictors of all-cause death/HF hospitalization during 2 – year follow-up in patients with chronic heart failure (CHF) and redused (red) left ventricular ejection fraction (LVEF).
Methods. 134 stable CHF pts (NYHA II-IV, LVEF < 40%) under optimized standard treatment were examined. Statistics programs package SPSS 13,0 was used; cluster analysis and logistic regression were used to calculate the predictors.
Conclusion. Plasma levels of bilirubin, ALT, BUN, NTproBNP, and citrullin as well as LVEF, SBP, BMI, GFR, FMVR and MHFLQ score are the strong predictors of critical event (death or HF hospitalization) in CHF with redLVEF.
Results.

Predictors of mortality/HF hospitalizati

Variable	Cut off level	OR	CI	p
Bilirubin, mkmol/l	> 42,5	5,20	1,94- 13,9	0,001
MHFLQ score	> 40,5	3,91	1,73- 8,82	0,001
BMI,kg/m2	< 28,73	3,53	1,69-7,36	0,001
Citrulline, mmol/l	> 111,5	3,39	1,56-7,33	0,003
NTproBNP, pg/dl	> 818,51	3,26	1,33-8,00	0,014
FMVR, %	< 8,77	3,21	1,41-7,29	0,18
GFR, ml/min/1,73 m2	< 57,5	3,00	1,43-6,25	0,005
SBP, mm Hg	< 130	2,91	1,35-6,28	0,009
BUN, mmol/l	> 2,3	2,62	1,30-5,30	0,011
LVEF, %	< 30	2,50	1,22-5,10	0,018
ALT, mmol/l	> 21	2,46	1,19-5,09	0,023

SBP – systolic blood pressure; MHFLQ – Minnesota HF life questionnaire, BUN – blood urea nitrogen, ALT - alaninaminotransferase, BMI - body mass index, GFR – glomerular filtration rate, FMVR – flow-mediated vasodilatory response.

Prognostic value of depression, anxiety disorders and inflammatory markers in patients with heart failure

E Emine Gazi[1]; E Karaahmet[2]; H Turkon[3]; A Barutcu[1]
[1]*Canakkale Onsekiz Mart University, Faculty of Medicine, Department of Cardiology, Canakkale, Turkey*; [2]*Okmeydani Training and Research Hospital, Psychiatry, Istanbul, Turkey*; [3]*Canakkale 18 March University, Biochemistery, Canakkale, Turkey*

Funding Acknowledgements: This research on NT-proBNP, hs-CRP, IL-6, and TNF-α was supported by the Research Fund of the Çanakkale Onsekiz Mart University (project No TSA-2014-

Background: Heart failure (HF) is a public health problem. Depression and anxiety are more common in HF patients than normal population.
Purpose: We aimed in this study to investigate the relation between depression and inflammatory parameters on survival and hospitalization in HF patients.
Methods: A total of 122 consecutive patients with ejection fraction (EF) ≤45% were included in this prospective study. N-terminal brain natriuretic peptide (NT-proBP), high sensitive C-reactive protein (hs-CRP), tumor necrosis factor alfa (TNF-α), interleukin 6 (IL-6) and neutrophile to lymphocyte ratio (NLR) were evaluated for inflammatory system.
Results: Mean follow-up was 36,4 months. Non-survivors are older (68,6±9,7 vs. 61 ± 8,8 years, p<0,001), have lower EF (32,5 ±6,4% vs. 35,1±6,5%, p=0,037), decreased GFR (51,3 ±19,5 vs. 65,6 ±19,3 ml/min, p<0,001) and serum sodium level (135 ±19 vs. 139 ± 2, p=0,04) (Table 1). Kaplan–Meier survival curves are shown Figure 1.
Conclusions: Depression, anxiety and inflammatory markers were not related to mortality in heart failure patients. Age, EF and GFR was found as independent predictors of mortality.

P328

The difference in association of atrial fibrillation and sinus rhythm with heart failure with reduced, mid-range and preserved ejection fraction.

A Amina Rakisheva[1]; A Mussagaliyeva[1]; K Koshumbayeva[1]; A Isabekova[1]; B Ahyt[1]; F Zeynaliyeva[1]

[1]*Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan*

Background: Atrial fibrillation (AF) is a common disorder in patients with heart failure, mostly with reduced left ventricular ejection fraction (LVEF). The prevalence of AF in HF with preserved EF and HF midrange EF is less well known.

Aim of the study:to evaluate the association of AF with HF with preserved, midrange and reduced EF.

Material and methods:in population-based survey 1544 people with cardiovascular diseases were selected. Authors assessed prevalence of and association of AF and HFrEF versus HFmrEF versus HFpEF.

Results: of 1544 patients with cardiovascular disorders 56,84% with non-valvular AF (1 group) and 43,16% without AF (2 group). The number of men was higher in AF group (63,7%) versus non-AF group (46,4%). The number of patients in both groups decreased with decreasing LVEF, HFrEF 16,3% in 1 group and 6,8% in the 2 group, HFmrEF 21,5% and 7,4% and HFpEF 62,5% and 85,7%, respectively.When compared two groups in association with HFrEF some characteristics had significant relationships with AF. Thus, 78,9% men in AF group versus 33% in sinys rhythm group (OR:7,5; CI:3,68-15,8), more often prior stroke 22% versus 8% (OR:3,1; CI: 1,1-8,6). The association of rest risk factors in patients with HFrEF in both groups was non-significant.The same tendency was in the group with HFpEF. Statistically, the percentage of men with HFpEF was higher in AF group versus sinus rhythm 57,3% and 42,4% (OR:1,8; CI:1,4-2,3), prior stroke- 15% and 8,9 % (OR:1,86; CI:1,29-2,68) respectively. The group with HFpEF different from HFrEF in correlation with hypertension 84% in patients with versus 93% without AF (OR:0,35; CI:0,24-0,53), with age ≥65 years 53,7% in the 1 group and 31% in the 2 group (OR:0,38; CI:0,3-0,4).In both EF group, no association with previous myocardial infarction and AF was observed.

In HFmrEF, beside different in aged patients older than 65 years in AF group 58% versus sinus rhythm 41,5% (OR:0,5; CI:0,28-0,9), the correlation between previous myocardial infarction and AF was observed, 28,7% patients with AF and 60% with sinus rhythm (OR:0,26; CI:0,14-0,49).

Conclusion: AF was associated with clinical characteristics such as male gender and prior stroke in HFrEF and HFpEF, with aged population in HFpEF and HFmrEF. There wasn't association with previous myocardial infarction and HFpEF and HFrEF. In contrast, there was an association with previous myocardial infarction and HFmrEF. The difference in patient characteristics and outcomes in both group depending on LVEF should be explored further.

P329

Correlation of endorgan function and bioimpedance measurement in patients with advanced heart failure

L Roehrich[1]; J Knierim[1]; J Mulzer[1]; M Mueller[1]; V Falk[1]; C Starck[1]; E Potapov[1]; S Suendermann[2]; F Felix Schoenrath[1]

[1]*Deutsches Herzzentrum Berlin, Cardiothoracic and Vascular Surgery, Berlin, Germany*; [2]*Charite - Campus Virchow-Klinikum (CVK), Cardiothoracic Surgery, Berlin, Germany*

Introduction: Bio impedance analysis (BIA) is a non-invasive, low-cost tool to assess frailty. The impact of end-organ dysfunction on the results of BIA is unknown. Impaired renal and cardiac function can cause a fluid shift from the intravascular to the extravascular space and have an impact on the nutritional status of the patient and may cause changes in the phase angle (PA). The PA represents the relationship between resistance and reactance of tissue in the BIA and is mostly influenced by cell mass and water. Laboratory parameters indicative of heart failure, renal and liver function were collected and correlated with the PA.

Methods: In 50 patients (45 female, 5 male) with end-stage heart failure, a BIA measurement was performed prior to LVAD implantation and correlated to NT-proBNP, creatinine, eGFR, albumin, total bilirubin and MELD-XI-Score. Additionally, the correlation between phase angle hemoglobin and hematocrit as a representative of the intravascular fluid status of the patient was assessed. The trial protocol was approved by the local ethics committee (ES2/236/17).

Results: Mean age was 59.9 years (+/-10.4), mean NT-proBNP was 12169pg/ml (+/-11737). 25 (50%) patients were in INTERMACS level I or II, 12 (24%) were stable on inotropic support (IM III) and 13 (26%) patients were in IM level IV. 16 (32%) patients suffered from dilated cardiomyopathy, 31 (62%) patients had ischemic heart disease and 3 (6%) had other reasons for heart failure. 28 (56%) patients had an eGFR under 50 ml/min/1.73 m2. The mean phase angle was 4.0 (+/-1.32). The correlation with laboratory parameters was tested for with the Gaussian distribution ,Kolmogorov-Smirnov-Test and spearman correlation test. The PA correlated strongly with hemoglobin ($rs = .46$, $p < 0.01$), hematocrit ($rs=.42$, $p < 0.01$) and as expected albumin ($rs=0.48$, $p < 0.01$). A weak correlation was found between MELD-XI-Score and PA ($rs=-.28$, $p < 0.05$). There was no correlation between PA and creatinine, eGFR, total bilirubin and NT-proBNP.

Conclusion: The PA had no correlation with routinely used parameters to assess outcome in heart failure patients (NT-proBNP, eGFR, bilirubine). Therefore this parameter might be used to add independent information about frailty in this patient cohort but further investigation and outcome correlation for BIA measurement in heart failure patients is strongly needed.

Chronic Heart Failure - Diagnostic Methods

Functional capacity and body composition in subjects with heart failure and COPD

S Hernandez Lopez[1]; S Galicia Amor[1]; D Gonzalez[1]; A Orea Tejeda[1]; Y Pilotzi Montiel[1]; L Hernandez Urquieta[1]; F Salgado Fernandez[1]; A Jimenez Valentin[1]; AJ Flores Vargas[1]; L Verdeja Vendrell[1]; R Sanchez Santillan[1]; R Hernandez Zenteno[1]; N Garcia Galvez[1]; V Fernandez Badillo[1]

[1]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico*

Background: Heart Failure (HF) and Chronic obstructive pulmonary disease (COPD) are characterized by body composition alterations and low functional

capacity, however is not enough evidence about the body composition alterations and functional capacity in subjects with HF and COPD concomitant.
Objetive: To evaluate the functional capacity and body composition in HF and COPD subjects.
Methods: In a cross sectional study, patients with HF and COPD diagnosis older than 40 years were included, subjects with asthma were excluded. Body composition was determinate by bioelectrical impedance vectorial analysis, functional capacity was performance by 6-minute walk test and muscle strength assess by dynamometer.
Results: 962 subjects were evaluated, subjects were divided into three groups, HF (n = 769),COPD (n = 71), and HF + COPD (n =122). HF + COPD subjects had less skeletal muscle mass index (8.8 ± 1.7 vs 9.0 ± 2.0 vs8.5 ± 1.8, p=0.022), muscle strength (20. 3 ± 8.8 vs22.6 ± 10.3 and25.6 ± 9.5, p =0.007), phase angle (4.6 ± 1.2 vs 4.9 ± 1.6 and 5.2 ± 1.3, p = 0.05) and functional capacity (260.32 ± 146.7 m vs306.2 ± 145.2 m and334.0 ± 123.7 m, p =0.06) than HF or COPD subjects, respectively.
Conclusion: HF and COPD concomitant have less functional capacity and body composition alterations, this induce worse clinical status and quality of life.

Evaluation of body composition and endothelial dysfunction in heart failure and chronic obstructive pulmonary disease subjects

F Salgado Fernandez[1]; D Dulce Gonzalez[2]; A Orea Tejeda[1]; R Sanchez Santillan[1]; AJ Flores Vargas[1]; L Hernandez Urquieta[1]; A Ibarra Fernandez[1]; R Davila Ramos[1]; A Vazquez Montero[1]; K Balderas Munoz[1]; V Pelaez Hernandez[1]; R Hernandez Zenteno[1]
[1]Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico; [2]National Institute of Medical Sciences and Nutrition Salvador Zubiran, Heart Failure Clinic , Mexico City, Mexico

Introduction: Endothelial dysfunction (ED) represents a pathophysiological link between heart failure (HF) and Chronic Obstructive Pulmonary Disease (COPD). In both, there is a high levels of systemic inflammation, body composition alterations, as loss of lean mass, which is associated with a worse prognostic. Nonetheless, there is few evidence on the relationship between ED and body composition alterations.
Objetive: to evaluate the body composition in subjects with ED and HF and COPD
Methods: A cross-sectional study. 233 subjects older than 40 years old with diagnosis of HF and COPD. The subjects with asthma diagnosis were excluded. Body composition was assessment by bioelectrical impedance vectorial analysis (BIVA), ED was assessment by
photoplethysmography.
Results: Mean age was 68.59 ± 12.78 years old, 64.80 % had ED. ED patients were older (70.83 ± 10.57 vs 64.23 ± 15.38, p<0.001) and had resistance/height (356.604 ± 82.27 vs 336.089 ± 70.30, p=0.013), lower prevalence of men (42.6 % vs 54.2 %, p= 0.032), muscular strength (21.79 ± 8.7 vs 24.94 ± 9.1, p <0.001), phase angle (4.95 ± 1.03 vs 5.54 ± 1.06, p<0.001) and skeletal muscle mass index (8.19 ± 1.79 vs 8.84 ± 1.74, p=0.001) compared with subjects without ED. No statically significant differences were observed on ECW, ICW and, arterial hypertension and diabetes.
Conclusion: The subjects with ED present greater alterations in body composition, which gives a poor prognostic.

P332

Performance of an implanted cardiac device heart failure risk predictor, in a real-world tertiary heart failure clinic

B Li[1]; S Langley[1]; L Reid[1]; J Young[1]; J Sibley[1]; P Cliffe[1]; S Harris[1]; P Phen[1]; R Barbagallo[1]; J Dungu[1]; H O Savage[1]
[1]Essex Cardiothoracic Centre, Basildon, United Kingdom of Great Britain & Northern Ireland

Background: The Heart failure risk status (HFRS) is a validated dynamic Heart Failure (HF) risk prediction tool available on Medtronic Cardiac Resynchronization Therapy Device with defibrillation capability (CRT-D) and Implantable Cardioverter Defibrillator (ICD) devices, which integrates diagnostic data to generate a patient-specific assessment of low, medium, or high risk for HF Hospitalization (HFH) in the next 30 days. In this study we aim to determine the accuracy of the HFRS in predicting 30-day heart failure related admissions in patients attending a real-world tertiary heart failure clinic.
Methods: We performed a retrospective analysis of consecutive HFRS transmissions over a 12-month follow up period in patients with a Medtronic ICD/CRT-D implanted. We then correlated this with HFH in the 30 days post transmission. Any relevant admissions up to 1 year after the transmissions were also recorded. We tested two thresholds in our analysis for diagnostic accuracy. Threshold 1 - A positive alert was considered for a Medium or High HFRS and negative alert for a Low HFRS. Threshold 2 - A positive alert was considered for only High HFRS and negative alert for a Low or Medium HFRS. We also obtained drug therapy at the time of these alerts and calculated their adherence score.
Results: Over the 12-month period of analysis, 78 patients sent single HFRS alerts. 95% had a CRT-D implanted, 86% had a primary prevention indication, 58% had an ischaemic substrate for heart failure and 79% were male. The mean age and ejection fraction of all patients was 69±13 years and 27%±10.5 respectively. 36 patients had a low HFRS and 42 had medium/high HRFS. None of the low HFRS resulted in HFH within 30 days of transmission. Of the 42 patients who had medium/high HFRS, 3 were admitted within 30 days for management of heart failure with a mean time to admission from alert, of 15 days. 1 of these patients had a moderate HF adherence score while 2 of them had good scores. Using Threshold 1, sensitivity and specificity of the HFRS was 100% and 48% respectively with a negative predictive value and false positive rate of 100% and 52% respectively. Threshold 2 had a sensitivity of 33% and a specificity of 94.6% with a false positive rate of 5.3%.
Conclusion: This analysis has demonstrated that the HFRS with selected Threshold 1, is reasonably accurate as a point estimator of risk, correctly identifying all HF patients with a risk of decompensation of heart failure in the following 30-day period of the alert, at the expense of a high false positive rate. Improving morbidity and mortality in HF patients involves using tools that identifies at-risk patients in a timely fashion to receive interventions. The drive to develop systems in local health economies to respond to these available device alerts, would likely involve additional clinical information to mitigate false positive signals and improve healthcare resource utilization.

P333

Rate pressure product and severely impaired systolic function in heart failure patients

I Ibtesam Ibrahim El-Dosouky[1]; H, G Abumandour[1]
[1]Zagazig University, Zagazig, Egypt

Funding Acknowledgements: no funding

Background: rate pressure product (RPP) is an independent index of cardiac work. We aimed to assess the significance of the RPP in patients with chronic heart failure (HF)and its relation to their echocardiographic findings.
Methods: thisprospective study included 358 patients with chronic HF[201 (56.1%) HF preserved ejection fraction (HFpEF) & 157 (43.9%)HF reduced EF (HFrEF)],as

3 groups; average resting RPP 7- 10 (n= 229), high resting RPP> 10 (n= 88) and low resting RPP <7 (n= 41). NYHA class, heart rate (HR), blood pressure,RPP were estimated, S3 and rales were evaluated. Echocardiographic parameters; left ventricular end diastolic (LVEDd), LV end systolic dimensions (LVESd),LV-EF and LV- stroke volume index (SVI) were obtained.

Results: Patients with low RRP had significantly higher prevalence of S3, rales, limiting dyspnea and lower EF. Patients with high RPP had significantly higher incidence of left ventricular hypertrophy, the best EF and the lowest SVI. RPP had significant positive correlations with NYHA class, S3, EF, and EPSS. RPP ≤ 7.75 had 79.2% sensitivity and 70% specificity to predictseverely impaired systolic function (EF<30%), (AUC=0.80, P<0.001).

Conclusion: RPP could be a readily available easily measured clinical predictor of low EF, RPP at a cutoff value ≤ 7.75 could be useful to predict severely impaired LV systolic function. With a new emphasis on incorporation of SVI into diagnostic and follow up approach, hand in hand with the EF specifically in those with LVH.

table 1

Improving diagnostic awareness of amyloidosis among cardiologists: effectiveness of online education

J Jelena Spyropoulos[1]; E Van Laar[1]
[1]*Medscape LLC, New York, United States of America*

Funding Acknowledgements: The funding for the advanced outcomes assessment was provided by an independent educational grant from Alnylam

Background: Despite significant advances in treatment of cardiac amyloidosis, many patients remain undiagnosed worldwide, leading to increased mortality and poor outcomes.

Purpose: To determine if an online continuing medical education (CME) intervention could improve knowledge and competence of cardiologists related to assessment and diagnosis of cardiac amyloidosis.

Methods: Cardiologists electively participated in a text-based, CME activity on diagnosing cardiac amyloidosis. The effects of education were assessed using a repeated pairs, pre-assessment/post-assessment study design. For all questions combined, a chi-square test assessed differences from pre- to post-assessment. P values <.05 are statistically significant. Cramer's V was used to assess educational effect. The activity launched on July 25, 2017, and data were collected through October 4, 2017.

Results: Overall significant improvements were seen after education for cardiologists (N=220; P < .001; noticeable educational effect, V=.107), with average correct response rate of 32% pre-assessment, which increased to 51% post-assessment. Improvements were observed in cardiologists' knowledge and competence (Table). Following exposure to education, 36% of cardiologists reported higher confidence related to making a diagnosis of cardiac amyloidosis, compared to pre-education.

Conclusion: The statistically significant improvements observed in this CME intervention demonstrate the benefits of using education to increase knowledge, competence and confidence of cardiologists involved in the diagnosis of patients with amyloidosis, and suggest that this type of intervention has the potential to positively impact patient outcomes.

Improvements in knowledge/competence

Topic	Cardiologists (N=220)Relative % improvement (post-assessment vs pre-assessment; P value)
Knowledge of appropriate tests to confirm diagnosis of hereditary amyloidosis	29% (65% vs 84%; P<.001)
Appropriate referral to cardiology specialist in hereditary amyloidosis	33% (60% vs 80%; P<.001)

P335

Identification of preclinical predictors of systolic dysfunction in the elderly population without a diagnosis of heart failure: Results from the PULSE-HF study

ME Esquerro[1]; R Zamora[2]; D Caruso[3]; ER Perna[4]; C Engel[5]; M Manzotti[6]; S Volman[1]; L Pereyra[1]
[1]*Novartis Argentina S.A., Buenos Aires, Argentina*; [2]*Hospital de Clinicas Jose de San Martin, Department of Internal Medicine, Buenos Aires, Argentina*; [3]*MClin Res, Head of the Clinical Research Department, U.A. Dr. César Milstein, Buenos Aires, Argentina*; [4]*J.F. Cabral Cardiology Institute, Heart Failure and Pulmonary Hypertension Division, Corrientes, Argentina*; [5]*Ministry of Public Health, Supervision of health of the elderly Unit of Non-Communicable Chronic Diseases, Salta, Argentina*; [6]*Hospital Aleman, Geriatric Area, Department of Internal Medicine, Buenos Aires, Argentina*

On behalf of: PULSE-HF study group
Funding Acknowledgements: The PULSE-HF study is sponsored by Novartis Pharmaceuticals

Introduction: Diagnosis of heart failure (HF) in the elderly is challenging due to age-related comorbidities. Development of a simple prediction model for diagnosis of systolic dysfunction may thus help in early diagnosis and effective management of HF.

Purpose: The primary objective of PULSE-HF is to develop a simple predictive score for screening of systolic dysfunction (left ventricular ejection fraction [LVEF] <50%) in elderly population at risk of HF, and evaluate its diagnostic precision against echocardiogram.

Methods: PULSE-HF is a Phase IV cross-sectional study that enrolled 800 elderly (aged ≥70 years) at-risk outpatients without a diagnosis of HF, from 15 centres in Argentina. At Visit 1, patients underwent a physical examination and cognitive (Mini-Cog test), functional (VIDA questionnaire and Edmonton scale), and mood (geriatric depression scale [GDS]) assessments. Patients received prescriptions for any outstanding assessments and the reports were collected at Visit 2 (within 3 months of Visit 1). There were no further assessments at Visit 2. No study drug was administered during the study.

Results: Of the 800 enrolled patients, 762 (95.3%) completed the study. Key demographic data (mean) were: age 76.6 years, body mass index 29.1 kg/m2, male 37.9%, systolic blood pressure 135 mmHg, Charlson Comorbidity Index (CCI) (mild 374 [46.8%], moderate 54 [6.8%], severe 8 [1.0%] and none 361 [45.1%]), hypertension 779 (97.4%), type 2 diabetes mellitus 186 (23.3%), obesity 235 (29.4%), coronary artery disease (CAD) 82 (10.3%), and atrial fibrillation 74 (9.3%). Data from the full analysis set (722 [90.3%]) were used for the development of the predictive model. Univariate linear regression analysis identified the factors significantly associated with LVEF <50% and were subsequently used in multivariate regression analysis. Regression analysis with forward selection method identified the most predictive variables of systolic dysfunction. Independent variables associated with systolic ventricular dysfunction were: N-terminal pro b-type natriuretic peptide (NT-proBNP) (log transformed) (odds ratio [OR] 2.29 [95% confidence interval 1.68–3.12]), gender (0.23 [0.11–0.49]), CAD (2.71 [1.16–6.31]), and cardiomegaly (2.37 [1.16–4.82]) (P<0.05 for all). Adverse events were observed in 147 (18.4%) patients, including cardiac failure in 23 (2.9%) patients.

Conclusions: NT-proBNP, gender, CAD, and cardiomegaly were most predictive of impaired systolic function.

P336
The role of galectin-3 in obese patients with heart failure

A Dadarlat[1]; D Pop[1]; D Zdrenghea[1]; G Bodisz[2]; F Fringu[1]; D Gurzau[1]; S Susca-Hjoda[1]; AD Buzoianu[1]
[1]University of Medicine and Pharmacy, Cluj-Napoca, Romania; [2]Rehabilitation Hospital, Cluj-Napoca, Romania

Background. It is well known that obese patients with heart failure have a more favorable prognosis than normal weight or cachectic patients. In this context, the values of NT-proBNP, an important biomarker of heart failure, are lower, while the clinical diagnosis of heart failure is difficult, and the majority of obese patients have preserved ejection fraction. However, there are data showing the implication of another heart failure-specific biomarker in the development of obesity, galectin-3 (Gal-3), which is a modulator of adipogenesis. The link between galectin-3, obesity and heart failure is still incompletely understood.
Aim. To determine the role that galectin-3 may have in a more accurate diagnosis of heart failure in obese patients.
Material and method. The study included 88 obese patients with a mean age of 69±9 years, 51.13% women, admitted to the Clinical Rehabilitation Hospital, for cardiac decompensation events, NYHA functional class II-IV. All patients were evaluated clinically and echocardiographically. In all patients, NT-proBNP and Gal-3 values were determined. Heart failure was defined according to ESC 2016 criteria.
Results. 73% of the patients were hypertensive, 38% had type 2 diabetes mellitus, 34% were smokers, and 18% had a history of myocardial infarction. The mean ejection fraction value was 45%, 33.7% of the patients having values higher than 50%. The Charlson comorbidity score was 4.65±1.59. The mean NT-proBNP value was 2410±2676 pg/mL, and the mean galectin-3 value was 41±31 ng/mL. Of the patients included in the study, 66 (75%) had increased Gal-3 values (>17.8 ng/mL). There was a significant indirect correlation of NT-proBNP with BMI (r=-0.3, p=0.04) and ejection fraction values (r=-0.37, p=0.001). Regarding Gal-3, these correlations were indirect, but without statistical significance (p=0.5 and 0.6, respectively). Echocardiographically, pseudonormal or restrictive diastolic dysfunction was much more frequently found in patients with increased Gal-3 values compared to those with Gal-3 values <17.8 ng/mL (p=0.05). Patients with Gal-3 concentrations >17.8 ng/mL did not have a significantly larger left atrial area (p=0.8). Of heart failure patients with preserved ejection fraction, 20 (64%) were assigned to a high risk class (Gal-3 values >25.9 ng/mL), 8 (25%) were classified as low risk patients (Gal-3 <17.8 ng/mL) and moderate risk patients, respectively.
In conclusion, in the current study, Gal-3 can be considered a useful biomarker, which can contribute, only in conjunction with NT-proBNP, to the diagnosis of heart failure in obese patients.

P337
Comparative evaluation of the functional state of the lungs in various types of dilated cardiomyopathy

YR Akhmatov[1]; TA Abdullaev[1]; I A Igor Tsoy[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

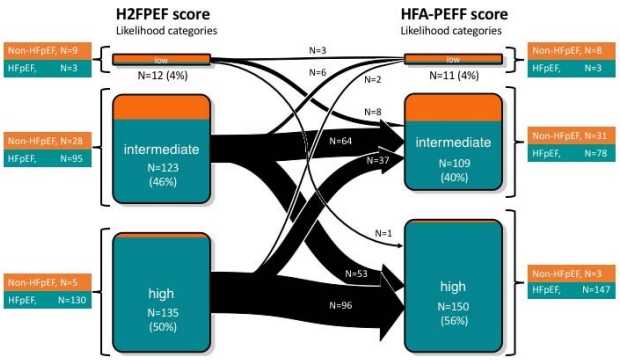
The aim: assessment of the functional state of the respiratory system in patients with dilated cardiomyopathy of the right ventricle (DCMPr) and idiopathic DCMP with biventricular heart failure (DCM-biHF).
Material and methods: The study included 78 patients with various forms of DCM. For a comparative analysis, two groups were formed: 1g. included 21 patients with DCMPr; 2g. - 57 patients with DCMP-biHF. All patients were examined by standard clinical, laboratory and functional examinations. To assess the functional state of the respiratory system, all patients underwent spirometry with the calculation of the Tiffno index.
Results: According to spirometry, it was found that such indicators as respiratory volume of the lungs (RV), reserve volume of exhalation (RVE) and vital capacity of the lungs (VC), when compared with standard values, were reduced in both patients with DCMPr and patients with DCMP-biHF. Namely, RV in 1gr. = 487,14 ± 105,98ml and 2gr. = 450,00 ± 86,77ml; RVE in 1 g. = 878.09 ± 270.36 ml and in 2 g. = 845.43 ± 190.19 ml; VC in 1g. = 2.12 ± 0.56l and in 2g. = 2.02 ± 0.37l (all p> 0.05). All-group reduction of these indicators was regarded by us as a sign of impaired respiratory function. When conducting a comparative intergroup analysis, it was found that all spirometry indicators were lower in patients of group 2, but the difference did not reach the level of confidence, except for the Tiffno index, which in 1g. = 69.14 ± 2.83 e. and in 2g. = 64.11 ± 4.07 u. (p <0.05). The maximum volumetric air velocity (MOAV) at the expiratory level from 25% to 75% of FVC in the compared groups was somewhat controversial (all p> 0.05). There was an inverse correlation between the values of the Tiffno index and the MPAP level (p = 0.000, t = -3.845, r = -0.451), i.e. the normal values of the Tiffno index corresponded to the normal level of MPAP, and the decrease in the indexes of Tiffno index was accompanied by an increase in the level of MPAP and, accordingly, a deterioration in the functions of external respiration.
Conclusion: Pulmonary ventilation rates were equally reduced both in DCMr and in DCM-biHF, but in the latter case the Tiffno index was lower than the standard values, which indicated the prevalence of obstructive respiratory failure, while in DCMPr, the Tiffno index was characterized by inverse correlation with the level of average pressure in the pulmonary artery.

P338
HFA-PEFF versus H2FPEF score for diagnosing heart failure with preserved ejection fraction

S Sandra Van Wijk[1]; A Barandiaran Aizpurua[1]; M Henkens[1]; HP Brunner-La Rocca[1]; VPM Van Empel[1]
[1]Maastricht University Medical Center, Department of Cardiology, Maastricht, Netherlands (The)

Funding Acknowledgements: Health Foundation Limburg, Dutch Heart Foundation

Background: The diagnosis of heart failure with preserved ejection fraction (HFpEF) remains a great challenge, reflected by the recent proposal of 2 diagnostic scores: the H2FPEF-score and the HFA-PEFF-score. Their diagnostic performance has not yet been compared.
Purpose: Investigate the diagnostic performance and reclassification accuracy of 2 new HFpEF-scores.
Methods: Between January 2015 and April 2018, the prospective Maastricht HFpEF cohort included 270 consecutive patients referred to our outpatient clinic with suspected HFpEF. Undergoing a thorough diagnostic work-up, the final diagnosis HFpEF was made in 228 and was rejected in 42 patients. The H2FPEF- and HFA-PEFF-score and their likelihood categories (low, intermediate, high) were calculated as suggested. The diagnostic and discriminative value of the HFA-PEFF-score was compared to the H2FPEF-score, including area under the ROC-curve (AUC), absolute reclassifications, net reclassification index (NRI) and integrated discrimination index (IDI), using the final clinical diagnosis as the gold standard.
Results: Both scores categorized a dominant proportion (i.e. >=50%) of the entire cohort of suspected HFpEF into the high-likelihood category. However, the high-likelihood category was more prevalent using the HFA-PEFF score, leaving a smaller intermediate category (Figure 1, P<0.001). The distribution of the HFA-PEFF score was significantly different between patients with a final HFpEF diagnosis versus non-HFpEF patients (Figure 1, P<0.001), i.e. HFpEF patients scored higher than non-HFpEF patients. This was also true for the H2FPEF-score (Figure 1, P<0.001). The AUC was not significantly higher for the HFA-PEFF-score (0.89, 95% CI 0.82-0.95) versus the H2FPEF-score (0.80, 95% CI 0.72-0.87, P=0.06), although a trend was observed. Reclassification of patients based on the 2 scores is shown in Figure 1. Using the predefined categories, 107/270 (40%) patients were reclassified into a different category (P<0.001). The HFA-PEFF-score reclassified 53 HFpEF patients upward and 36 patients downward, relative to the H2FPEF-score. In non-HFpEF patients, the net reclassification was 0. Together, the net reclassification index of the HFA-PEFF-score was 7.5% (P=0.49). When using likelihood cut-offs (rule-out: 15%, rule-in: 85%), the NRI was 37% (P=0.001). The continuous NRI was 78% (P<0.001) and the IDI was 20% (P<0.001).
Conclusions: The diagnostic accuracy (AUC) of both the HFA-PEFF and the H2FPEF score for diagnosing HFpEF was high. However, the HFA-PEFF and the H2FPEF-score classified patients into likelihood-categories very differently; i.e. 40% of patients were reclassified. Using several measures of discrimination, the HFA-PEFF-score performed at least similar or may be better in classifying patients compared to the H2FPEF-score. This finding needs confirmation in additional, preferably less-selected cohorts.



Reclassification HFA-PEFF vs H2FPEF

P339

Features heart rate variability at patients with ischemic heart disease, arterial hypertension and left ventricle hypertrophy

A Alexey Ibatov[1]
[1]*Sechenov Moscow medical academy , Moscow, Russian Federation*

Purpose: to study heart rate variability (HRV) at patients with ischemic heart disease (IHD) and arterial hypertension (AH) and left ventricle hypertrophy (LVH).
Materials and methods: 34 men with IHD and AH and LVH (average age 56.5±9.9 years) were examined and were included in first grope. Left ventricle hypertrophy was estimated if the left ventricle myocardium mass index was above 134 g/2 for the men. The second group was 37 men with IHD and AH without LVH (average age 58.6±7.7 years; p>0.05). Heart rate variability was examined on 5-min recordings of electrocardiogram at rest, then during the orthostatic test and at rest after orthostatic test.
Results: The groups did not differ on age, duration IHD, AH and therapy. At rest the patients with LVH and the patients without LVH had such parameters of HRV accordingly: heart rate (HR) – 60.3±1.5 and 60.8±1.6 min-1 ($p > 0.05$), SDNN – 38.8±3.5 and 29.7±2.4 msec ($p < 0.05$); rMSSD – 35.4±5.1 and 20.1±2.0 msec ($p < 0.01$); pNN50% - 14.3±3.8 and 4.07±1.6 ($p < 0.05$); TP – 1486.2±266.9 and 859.7±136.3 msec2 ($p < 0.05$); HF – 678.0±187.7 and 176.1±44.6 msec2 ($p < 0.05$); LF – 376.3±55.7 and 270.5±55.9 msec2 ($p > 0.05$); VLF – 431.8±56.1 and 413.1±60.1 msec2 (p> 0.05). At rest the patients with LVH had such parameters of power waves HRV accordingly in percentage: HF% - 45.6%; LF% - 25.3% and VLF% - 29.1% and the patients without LVH: HF% - 20.5% ($p < 0.05$); LF% - 31.5% ($p > 0.05$) and VLF% - 48.0% ($p > 0.05$). Further, the patients with LVH had vegetative balance at rest: 59.4 % predominance of parasympathetic nervous system, 12.5 % balance between parasympathetic and sympathetic nervous system and 28.1 % prevalence sympathetic nervous system. The patients without LVH had vegetative balance at rest accordingly: 43.8 % predominance of parasympathetic nervous system ($p > 0.05$), 12.5 % balance between parasympathetic and sympathetic nervous system ($p > 0.05$) and 43.7 % prevalence sympathetic nervous system ($p > 0.05$). Conclusion: The patients with IHD and AH and LVH, in comparison with the patients without LVH, had higher heart rate variability, especially in high-frequency power waves of spectrum and predominance parasympathetic nervous system in vegetative balance at rest, these data must be considered when prescribing treatment.

P340

Body composition and oxygen saturation recovery after six-minute walk test in heart failure and chronic obstructive pulmonary subjects

Y Pilotzi Montiel[1]; S Galicia Amor[1]; A Orea Tejeda[1]; D Gonzalez[1]; R Sanchez Santillan[1]; S Hernandez Lopez[1]; L Hernandez Urquieta[1]; F Salgado Fernandez[1]; A Jimenez Valentin[1]; L Verdeja Vendrell[1]; K Balderas Munoz[1]; V Pelaez Hernandez[1]; R Hernandez Zenteno[1]; M Teresa Landa[1]
[1]*Instituto Nacional de Enfermedades Respiratorias "Ismael Cosío Villegas", Heart Failure and Respiratory Distress Clinic, Mexico city, Mexico*

Background :Heart Failure (HF) and Chronic Pulmonary Obstructive Disease (COPD) has body composition alterations and decreased infunctional capacity, with important repercussions on clinical status and prognosis. However, there is not enough evidence about the relation between the oxygen saturation (SPo2) recovery and body composition HF and COPD subjects.

TBW.- total body water, ECW.- extracellular water, XC_RJL .- reactance, SpO2 rest .- Saturation rest, SBP .- systolic blood pressure, DBP .- diastolic blood pressure, IND_IMP .- Index impedance,

Objectives: To evaluate the relation between SPo2 recovery after six-minute walk and body composition in HF and COPD subjects.
Materials and Methods: In a cross sectional study, HF and COPD diagnosis, older than 40 years were included, those with asthma diagnosis were excluded. Oxygen saturation recovery capacity was determinate value > 80 of SPo2 difference between recovery period and end of the 6-minute walk test, grip strength was determined by dynamometer, body composition by Bioelectric impedance vectorial analysis.
Results: 120 COPD and HF subjects were included, mean age was 68.5±12.2. Patients with low SPo2 recovery capacity had more total body water (50±8.8 vs 46.3±8.2, p=0.07), extracellular water (23.3±5.6 vs 21.2±2.7, p= 0.07), as well less phase angle (4.7 ± 0.8 vs 5.2 ± 1.1, p=0.02), basal SPo2 (86.4 ± 6.8 vs 91.37 ± 4.5, p= 0.0005) and body weight (73.9 ± 20.9 vs 81.8 ± 22.3, p=0.07) than SPo2 recovery capacity subjects.
Conclusions: Low oxygen saturation recovery capacity had greater body composition alterations, this had an important impact on prognosis in HF and COPD subjects

P341

The relationship of sympathetic regulation with immune inflammation, fibrosis, neurohumoral activation in patients with devices for cardioversion-defibrillation and cardiac resynchronisation therapy

TN Enina[1]; VA Kuznetsov[1]; AM Soldatova[1]; TI Petelina[1]; LA Salamova[1]
[1]*Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Tyumen, Russian Federation*

Introduction: Increased sympathetic activity is known in congestive heart failure (CHF). The role of adrenaline (Adr) and noradrenaline (Nadr) is often identified and not fully studied.
Purpose: To assess the relationship of sympathetic activity with immune inflammation, fibrosis, neurohumoral activation in patients with CHF before implantation of devices for cardioversion-defibrillation (ICD) and cardiac resynchronisation therapy (CRT).
Methods: 209 patients with CHF (79.9% men, mean age 60.6±9.6 years, 74.6% ischemic etiology) were divided into 2 groups before devices implantation: 1gr. (n=125) – ICD; 2 gr. (n=84) – CRT. Electrocardiogram, echocardiographic parameters, plasma levels of Adr, Nadr, interleukins (IL) 1β, 6, 10, tumor necrosis factor alpha (TNF-α), NT-proBNP, matrix metalloproteinase () 9, tissue inhibitors of (TIMP) 1 and 4, ratio Adr/Nadr, MMP-9/TIMP-1, MMP-9/TIMP-4 were evaluated.
Results: Patients of gr.1 were older (61.6±9.4 vs 59.0±9.7 years; =0.049), more often had coronary artery disease (80 vs 66.7%; =0.030), myocardial infarction (60 vs 34.5%; =0.002), percutaneous coronary intervention (42.4 vs 22.6%; =0.003), coronary artery bypass graft (15.2 vs 3.6%; =0.007), lower frequency of the RF-ablation of the AV connection (4.8 vs 23.8%; <0.001), shorter duration of QRS (122.3±26.5 vs 155.8±35.1 msec; <0.001), lower incidence of complete left bundle brunch block (LBBB) (10.4 vs 59.5%; p<0.001). Gr.1 showed the tendency to smaller dimensions of right ventricle (=0.062), significantly smaller left ventricular (LV) end-diastolic and end-systolic dimension (<0.001), LV end-systolic and end-diastolic volume (<0.001), higher LV ejection fraction (p<0.001), lower pulmonary artery systolic pressure (p=0.002); higher plasma levels of Adr (2.0[1.0;3.1] vs 0.8[0.1;2.1] pg/ml; <0.001), Nadr (12.9[7.2;15.6] vs 3.0[0.3;11.5] pg/ml; <0.001), lower ratio Adr/Nadr (0.188[0.120;0.273] vs 0.257[0.128;0.702] units; =0.042); lower levels of IL-1β (2.7[2.3;4.2] vs 3.7[2.8;4.3] pg/ml‘; =0.007), IL-6 (2.4[2.2;3.9] vs 3.1[2.4;4.5] pg/ml; =0.026), NT-proBNP (1050.0[397.8;2925.8] vs 1840.0[1020.5;398.0] pg/ml; =0.001), TIMP-1 (204.8[165.5;300.7] vs 261.0[165.0;421.5] ng/ml; =0.027), higher level of -9 (242.2[177.7;286.2] vs 156.2[126.1;210.6] ng/ml; <0.001), higher ratio MMP-9/TIMP-4 (0.109[0.081;0.140] vs 0.066[0.046;0.099] units; =0.001).
Conclusion: The different plasma Adr and Nadr levels were revealed in patients with ICD and CRT. The lower level of catecholamines in CRT patients associated with a longer QRS duration, higher frequency of LBBB, worse echocardiographic parameters, greater activity of immune inflammation, neurohumoral activation, fibrosis. This may be due to cytokine modulation of the sympathetic function and its depletion. A higher value of ratio Adr/Nadr indicates an increase role of Adr in severity of CHF and can be used to assess the progression of CHF during prospecting observation.

P342

Dynamics of laboratory parameters and left ventricular remodeling in patients with acute myocardial infarction during atorvastatin therapy

L Salyamova[1]; N Burko[1]; T Aryasova[1]; V Valentin Oleinikov[1]
[1]*Penza State University, Penza, Russian Federation*

Purpose: to study the dynamics of several laboratory parameters and the risk of the rapidly progressive left ventricular remodeling in patients with acute myocardial infarction with ST-segment elevation (STEMI) in 24-week atorvastatin therapy different doses.

Methods: 117 STEMI patients were included in the study. The patients were divided into two groups: the main group included 71 patients who took atorvastatin 40-80 mg / day (group 1), the average age was 52 (45; 58) years. The second group (control) consisted of 46 patients who received atorvastatin in low doses, the average age was 52 (43; 58) years. The compared subjects were matched by age, sex, BMI, and office blood pressure. All patients have been receiving treatment for STEMI before study treatment. At baseline and after 24 weeks of follow-up we analyzed lipid profile (TC, LDL-C), brain natriuretic peptide (BNP), C-reactive protein (CRP); an echocardiography was performed using the MyLab apparatus (Esaote, Italy) with determination of the end-diastolic volume index (EDVi) of the left ventricle. The relative risk (RR) of the rapidly progressive remodeling was determined by the dynamics of increased EDVi exceeding> 20% after 24 weeks of follow-up.
Results. In group 1, a more pronounced dynamics of lipid profile was revealed: TC decreased by 43% (from 6.1 ± 1.2 to 3.5 (3.1; 4.0) mmol / l; p <0.001), LDL-C - by 51% (from 4.1 ± 1.1 to 2.0 (1.7; 2.4) mmol / l; p <0.001). In the 2nd group, TC decreased by 25% (from 5.6 (5.1; 6.4) to 4.2 ± 1.0 mmol / l; p <0.001), LDL-C - by 33% (with 3.9 (3.2; 4.5) to 2.6 ± 0.7 mmol / l; p <0.001). In the main group, BNP initially amounted to 71.8 (22.9; 137.5), follow-up - 32.7 (19.2; 69.5) pg / ml (-54.5%, p<0.001); in the control group - 79.7 (45.6; 163.2) and 52.8 (16; 80.1) pg / ml (-33.8%, p <0.001), respectively. Comparative dynamics of CRP in the comparison groups was revealed: in group 1 - from 8.6 (4.5; 18.7) to 1.5 (0.8; 2.4) mg / l (-82.6%, p < 0.001); in group 2 - from 9.4 (4.6; 14.1) to 1.2 (0.7; 3) mg / l (-87%, p <0.001). The EDVi level did not change in group 1: baseline - 60.3 (48.3; 67.7), follow-up - 58.8 (45.9; 74.2) (p = 0.7); in group 2 the EDVi increased from 53.4 ± 17.1 to 64.2 ± 22 (p = 0.001). At the same time, the OR of the rapidly progressive remodeling in the low-dose atorvastatin therapy group was 1.9 [95% CI 1.1; 3.3] (p = 0.02).
Conclusion: In patients with STEMI, in 24-week treatment with high doses atorvastatin, a pronounced favorable dynamics of lipid profile, BNP and a lower risk of rapidly progressive remodeling were diagnosed.

P343

Predictive value of growth differentiation factor-15 levels in chronic heart failure with reduced and mid-range ejection fraction with known diabetes mellitus

AE Alexander E Berezin[1]; AA Kremzer[1]; OV Petyunina[2]; AA Berezin[3]; MP Kopytsya[2]
[1]State Medical University, Zaporozhye, Ukraine; *[2]L.T.Malaya Institute of Therapy, Kharkiv, Ukraine*; *[3]Medical Academy of Postgraduating Education, Internal Medicine, Zaporozhye, Ukraine*

Background: Diabetes mellitus (DM) in patients with established heart failure (HF) influences negatively of clinical state and outcomes. Although there is strong recommendation regarding treatment of HF individuals with DM, biomarker-based risk stratification for diabetics with HF is not completely developed. Growth differentiation factor-15 (GDF-15) belongs to the transforming growth factor-beta/bone morphogenetic protein super family that involves in the pathogenesis of HF and DM.
The objective: to investigate the levels of growth differentiation factor-15 (GDF-15) levels in HF patients with reduced and mid-range ejection fraction with known type 2 DM (T2DM).
Methods: A total of 376 HF patients (left ventricular ejection fraction < 50%) aged 39 to 68 years were prospectively involved in the study. Among all HF patients with reduced ejection fraction (HFrEF; n=125) and mid-range ejection fraction (HFmrEF; n=151) T2DM was diagnosed in 56 (44.8%) individuals and 62 patients (41.1%) respectively. Data collection included demographic and anthropometric information, and hemodynamic performances. The levels of NT- pro brain natriuretic peptide (NT-proBNP) and GDF-15 were determined by ELISA at baseline.
Results: The levels of GDF-15 for HFrEF and HFmrEF patients were 2120 pg/L (confidence interval [CI] 1570 to 3866 pg/L) and 2075 pg/L (CI 1610 to 3796 pg/L) respectively (P=0.22). In HFrEF cohort levels of GDF-15 for both diabetic (2215 pg/mL, CI 1632 to 4012 pg/mL) and non-T2DM patients (2088 pg/mL, CI 1542 to 3878 pg/mL) were similar (P=0.14). In contrast, in HFmrEF cohort levels of GDF-15 in diabetics was significantly (P=0.001) higher (2203 pg/mL, CI 1624 to 3915 pg/mL) to non-T2DM individuals (1998 pg/mL; CI 1366 to 2790 pg/mL). Additionally, the levels of GDF-15 in HFmrEF cohort did not correlate with clinical signs and symptoms of HF including NYHA class, oedema of legs and jugular venous distention, whereas in HFrEF cohort it did. In entire HF cohorts plasma GDF-15 level was positively correlated with plasma NT-proBNP concentration (r=0.810; P=0.012), and negatively correlated with LVEF (r=-0.38, P=0.018). There were not significand changes in plasma NT-proBNP levels for diabetics and non-diabetics in HFrEF and HFmrEF. In multiple variates logistic regression analysis we found that level of GDF-15 ≥ 2215 pg/mL was the best predictor of HFrEF in both non-T2DM and known T2DM HF individuals respectively.
In conclusion, in HFmrEF cohort the levels of GDF-15 were extremely evaluated in T2DM patients to non-T2DM patients, whereas there was not significant difference between levels of GDF-15 in diabetics and non-diabetics with HFrEF. Cut-off point 2215 pg/mL predicted HFrEF for all patients with HF regardless of T2DM presentation.

P344

Markers of heart failure and lipid-lowering effect of atorvastatin in patients with myocardial infarction with ST segment elevation

V Valentin Oleinikov[1]; Y Barmenkova[1]; E Dushina[1]; N Burko[1]; V Galimskaya[1]; A Golubeva[1]
[1]Penza State University, Penza, Russian Federation

Purpose: To study the dynamics of the brain natriuretic peptide (BNP) level, highly sensitive C-reactive protein (hSBR), ejection fraction (EF) in patients who have had a myocardial infarction with ST segment elevation (STEMI), depending on the lipid-lowering effect of atorvastatin.
Methods: 116 patients aged 52 (45.5; 58) years were examined, predominantly men (88%). During the 48 weeks after STEMI, patients have been taking atorvastatin in different doses regularly. At the 7th day, 24th and 48th week after STEMI, serum BNP and hrsRBR were determined using an Olympus AU400 analyzer. EF was determined by the Simpson method on an ultrasound device at the 7th day, and then every 12 weeks thereafter. Depending on the achievement of the target low-density lipoprotein cholesterol (LDL-C) level less than 1.8 mmol / l and / or reduction by 50% from baseline values, two groups of patients were distinguished: effective therapy "E" - 61 people (52.6%)), those who have reached the recommended level of atherogenic lipids; 55 patients (47.4%) who did not reach the target LDL-C level made up the group of low-effective therapy "L". The compared groups were matched by sex, age and anthropometric data.
Results: In the "E" group, by the 48th week, the BNP level decreased by 50% (p = 0.02), in the "L" group this indicator decreased by 41% (p = 0.04) in comparison with the baseline values. By the end of treatment, the level of hsCRP in the effective therapy group decreased by 83% (p = 0.0001), in patients who did not reach the target values of LDL-C, by 73% (p = 0.0001) from baseline values. In the group "E", at the 7th day the EF was 52 (95% CI 49; 55)%, and further increase was observed: by week 12, the EF increased to 55 (95% CI 52; 58)% (p = 0.04), by week 24 - up to 56 (95% CI 53; 59)%, by week 36 - up to 58 (95% CI 54; 61)% (p = 0.004), by week 48 - up to 56 (95% CI 53; 60)% (p = 0.04). In the "L" group, the initial EF was 58 (95% CI 54; 61)%, but by the 48th week of treatment, a negative change was obtained - a decrease to 53 (95% CI 49; 57)% (p = 0, 02).
Conclusion: effective lipid-lowering therapy with atorvastatin contributes to a more pronounced decrease in the progression of heart failure, and is also associated with an increase in myocardial contractility in the post-infarction period.

P345

Serum Levels of sST2, proBNP and cTnI for early risk stratification of acute myocardial infarction after percutaneous coronary intervention

J Jingwei Pan[1]; CJ Gao[1]; ZL Xia[1]; YJ Gao[1]; YJ Tao[1]; MJ Yuan[1]; ZG Lu[1]; YP Wang[1]
[1]Shanghai Sixth People's Hospital of Shanghai Jiaotong University, Shanghai, China

Background: Survivors of acute myocardial infarction (AMI) are at high risk for major adverse cardiovascular events (MACEs). The objective of the study was to investigate the prognostic impact of soluble ST2 (sST2), proBNP, cTnI in AMI patients undergoing percutaneous coronary intervention (PCI).
Materials and Methods: A total of 161 AMI patients were enrolled in the study. The serum levels of sST2, proBNP and cTnI were measured using enzyme-linked immunosorbent assay (ELISA). The prognostic values of sST2, proBNP and cTnI for predicting 3-year and 30-day MACEs, defined as a composite of all-cause death, heart failure (HF), non-fatal MI and ischemia-driven revascularization were evaluated.
Results: All the patients were followed for a median period of 3 years. Compared with the MACEs-free group, the serum levels of sST2, proBNP and cTnI were significantly higher in the 3-year and 30-day MACEs groups. The area under curves (AUC) for 3-year and 30-day MACEs of sST2, proBNP and cTnI at admission were 0.813, 0.808, 0.659 and 0.832, 0.699, 0.673. Cox multiple regression analysis revealed that high serum levels of sST2, proBNP and cTnI at admission were independently associated with 3-year MACEs. Kaplan-Meier curves showed a significant increase in the occurrence of MACEs in high sST2, proBNP and cTnI groups (P<0.001). High serum level of sST2 (>132.2ng/ml) at admission independently predicted 30-day MACEs after adjusting for other risk factors (HR 7.671, 95%CI 1.939-30.347, P=0.004).
Conclusion: The present study demonstrates that sST2 might be a promising biomarker to improve the prediction in AMI patients undergoing PCI.

Cut-off values of sST2, proBNP and cTnI

3-year MACEs	AUC	95%CI	Cut-off values	Sensitivity (%)	Specificity (%)
sST2	0.813	0.743-0.883	62.1	70.0	82.2
proBNP	0.808	0.733-0.883	1022.0	71.7	81.2
cTnI	0.659	0.571-0.746	13.1	61.7	72.3
30-day MACEs	AUC	95%CI	Cut-off values	Sensitivity (%)	Specificity (%)
sST2	0.832	0.733-0.930	132.3	70.6	88.9
proBNP	0.699	0.564-0.834	777.2	76.5	62.5
cTnI	0.673	0.518-0.827	16.1	70.6	67.4

Use of composite laboratory measurements to assess frailty in stable elderly patients with heart failure

A Akihiro Hirashiki[1]; K Kawashima[1]; K Nomoto[1]; M Kokubo[1]; A Shimizu[1]; H Arai[1]
[1]*National Center for Geriatrics and Gerontology, Obu, Japan*

Background: Frailty associated with aging produces subclinical dysfunction across multiple organs and increases the risk of death. There is little information about the relationship between frailty status and laboratory measurements in patients with heart failure (HF). Purpose: To investigate which laboratory measurements indicate frailty in stable elderly patients with HF.
Methods: Ninety-two stable elderly patients with HF were evaluated by laboratory measurements and on the Kihon Checklist (KCL), on which a score of ≥8 indicates frailty. We compared laboratory measurements between the frail (KCL ≥8) and non-frail (KCL <8) groups.
Results: Mean age was 81.6 years, mean left ventricular ejection fraction was 57.9%, mean plasma brain natriuretic peptide content was 184 pg/mL, and mean t-KCL score was 13.1. Patients were allocated to non-frail (n = 29) and frail (n = 63) groups on the basis of their KCL scores. Serum iron concentration was significantly lower in the frail group (frail, 61.2 30.3 μg/dL; non-frail, 89.5 26.1 μg/dL; P 0.001). Blood urea nitrogen (BUN) and C-reactive protein (CRP) levels were significantly higher in the frail group (BUN: frail, 27.3 16.5 mg/dL; non-frail, 19.7 8.2 mg/dL; P = 0.013. CRP: frail, 1.05 1.99 mg/dL; non-frail, 0.15 0.2L mg/dl; P = 0.004). KCL score was significantly correlated with serum hemoglobin, albumin, and iron concentrations, BUN, estimated glomerular filtration rate, CRP, and plasma brain natriuretic peptide level. Multivariate analysis revealed that serum iron concentration, CRP, and BUN were significant independent predictors of frailty (β = −0.069, 0.917, and 0.086, respectively).
Conclusions: Frailty status was significantly associated with serum iron concentration, CRP, and BUN in stable elderly patients with HF. Composite biomarkers (of iron deficiency, inflammation, and renal perfusion) may be useful for assessing the frailty of stable elderly patients with HF.

P347

Predictors of anaemia and iron deficiency in patients with chronic heart failure.

N Ebner[1]; G Dinopoulos[1]; R Evertz[1]; T Garfias Macedo[1]; B Godoy[1]; M Vatic[1]; C Diehl[1]; J Springer[1]; S Von Haehling[1]
[1]*University Medical Center Goettingen, Department of Cardiology and Pneumology, Goettingen, Germany*

Background: Anaemia and iron deficiency (ID) are important factors for muscle function and exercise capacity in patients with chronic heart failure (HF). Their interaction in HF remains to be defined.
Methods: A total of 280 out-patients with stable chronic HF were enrolled with mean age of 67.0±10.7 years, 21%female, mean left ventricular ejection fraction (LVEF) was 38.9±13.4%, mean Body Mass Index (BMI) 29.3±5.5 kg/m^2]. Anaemia was defined according to World Health Organization criteria [Haemoglobin (Hb) <13 g/dL in men and <12 g/dL in women]. ID was defined as ferritin <100 µg/L or ferritin <100 <300 µg/L together with transferrin saturation (TSAT) <20%. Exercise capacity was assessed by spiroergometry (peakVO2), 6 minute walk test (6MWT), short physical performance battery test (SPPB), hang grip strength (HGS) and leg force (LF). All patients were followed up for a mean of 8 month.
Results A total of 89 (32%) chronic HF patients had anaemia and 142 (51%) had iron deficiency at baseline. Patients with anaemia showed significant lower exercise capacity compared to patients without anaemia (peak VO2: 15.3±4.6 vs.18.5±4.8 kg/min p<0.0001, 6MWT: 365.2±135.5 vs. 461.6±127.4 m p<0.0001, SPPB: 9.4±2.3 vs. 11.0±1.6 total points p<0.0001, HGS: 32.5±10.0 vs. 38.8±12.4 kg p<0.0001, LF: 31.4±11.0 vs. 41.3±21.6 kg p<0.0001). The same we found in patients with ID compared to patients without ID (peak VO2: 16.3±5.1vs. 18.6±4.5 kg/min p= 0.001, 6MWT: 400.0±140.8 vs. 458.8±128.4 m p=0.0008, SPPB: 10.0±2.1vs. 10.9±1.7 total points p= 0.0003, HGS: 34.5±11.9 vs. 39.3±11.7 kg p=0.001, LF: 35.7±23.4 vs. 40.5±13.6 kg p=0.04). After a Follow up of mean 8 month 53 patients develop a new onset of either anaemia (n=24) or ID (n=29). Logistic regression analysis showed that gender, 6 minute walk distance, SPPB, HGS and presence of diabetes mellitus at baseline are significantly associated with the development of anaemia or ID (all p<0.05). The strongest predictor was lower SPPB (p= 0.0008). Interestingly known determinates lower peak VO2, higher age, higher NYHA class, Creatinine, and hsCRP were not predictive in our cohort to develop anaemia or ID after 8 month (all p>0.05).
Conclusion: Both anaemia and ID are strongly associated with reduced exercise capacity in patients with HF. The effect of anaemia and iron deficiency together is stronger than that of anemia and ID alone. Reduced SPPB, 6MWT, and HGS are important risk factors for the development of anaemia or ID.

P348

Decrease in Fibrosis-4 index is associated with decrease in NT-proBNP in patients with acute heart failure

T Takashi Yamada[1]; S Sakuragi[1]; M Nakashima[1]
[1]*Iwakuni Clinical Center, cardiology, Iwakuni, Japan*

Objective: In patients with heart failure (HF), liver congestion results in liver stiffness and fibrosis, which might be associated with poor prognosis. Fibrosis-4(FIB4) index, which is calculated with age, aspartate aminotransferase, platelet count, and alanine aminotransferase, emerged as a marker of liver stiffness. In this study, we examined the time course change in FIB4 during hospitalization for acute HF (AHF), and evaluated the factors associated with the change in FIB4.
Method: From January 2015 to October 2017, 183 patients with AHF who had high FIB4 index of 3.01 were enrolled (84 years, 106 male). All subjects were calculated FIB4 index on admission and two weeks later. Blood test including NT-proBNP was also performed at two time points.
Results: During the course, 131 patients had decline in FIB4 (FIB4 decline group), whereas 52 patients did not (FIB4 non-decline group). Baseline characteristics, such as age, gender, coronary risk factors, left ventricular function and ln NT pro-BNP were comparable between the two groups. During the course, total protein and albumin increased in the FIB4 decline group, whereas it remained unchanged in the FIB4 non-decline group. Ln NT-pro BNP decreased in both groups, but delta change in ln NT-proBNP was higher in FIB4 decline group compared with FIB4 non-decline group (-0.53±0.69 vs -0.31±0.45pg/ml, p=0.043). Delta change in ln NT-pro BNP was associated with delta change in FIB4 index in univariate analysis (r=0.224, p=0.0025). This association was still significant after adjustment for confounding factors (beta=1.039, 95%CI 0.460 to 1.619, p=0.0005).
Conclusion: Change in NT-proBNP was associated with change in FIB4 in patients with AHF.

P349

Phoenixin concentration in plasma of heart failure with reduced ejection fraction patients.

T Zemleduch[1]; K Ratajczyk[2]; J Majewska[3]; K Dabrowska[3]; K Marek-Bukowiec[4]; A Ziolkowska[5]
[1]University Hospital in Zielona Gora, Cardiology Department, Zielona Góra, Poland; *[2]Wroclaw Provincial Specialist Hospital, Department of Urology and Oncological Urology, Wroclaw, Poland*; *[3]Polish Academy of Sciences, Immunology and Experimental Therapy Institute, Wroclaw, Poland*; *[4]Wroclaw Provincial Specialist Hospital, Research and Development Center, Wroclaw, Poland*; *[5]University of Zielona Gora, Department of Anatomy and Histology, Zielona Gora, Poland*

Funding Acknowledgements: Project supported by Wroclaw Centre of Biotechnology, The Leading National Research Centre (KNOW) programme for years 2014–2018

Introduction: Cardiovascular disease is the leading cause of death among all noncommunicable disease worldwide. Among those, heart failure is of the outmost importance given its prevalence and overall poor outcome. Heart failure detection and treatment optimization might be improved by biologically active peptides, extensively studied in recent years. Lately, new neuropeptide – phoenixin, produced locally in heart, was found to have cardioprotective features.
Purpose: The aim of this pilot study was to investigate phoenixin presence in plasma of heart failure patients' and its potential usefulness as a biomarker of the disease.
Methods: Study group consisting of 34 patients with heart failure with reduced ejection fraction (HFrEF) and control group of 18 patients without clinical and echocardiographic indications of heart failure were recruited. Study protocol was approved and all patients signed informed consent form. Patients underwent basic laboratory testing, comprehensive physical and echocardiographic examination. Phoenixin plasma concentration was measured. All values were expressed as the mean ± SEM. For comparison of two groups Student's t-test or Mann-Whitney test and for correlation analysis Pearson and Spearman coefficients were used in respect of variables distribution. P value <0,05 was considered statistically significant.
Results: Mean left ventricule ejection fraction in HFrEF group was 30.3±1.3% and in control group 62.6±1.8%, p<0.0001. Heart failure patients had significantly higher LVM index (156.2±5.8 vs 88.6±3.7 g/m2, p<0.0001), left atrium area (LAA) (31.4±1.2 vs 18.7±0.6 cm2, p<0.0001), creatinine, CRP and uric acid concentration. Control patients had markedly higher total, LDL and HDL cholesterol levels. Phoenixin concentration was found to be lower in HFrEF group, however the difference was not statistically significant (0.0934±0.0039 vs 0.1017±0.0044ng/ml, p=0.1914). Phoenixin concentration in control group was found to positively correlate with HDL (r= 0.590, p=0.01) and systolic blood pressure (r=0.467, p=0.05). Importantly, in HFrEF group phoenixin concentration was negatively correlated with LAA (r=-0.488, p=0.0034). Among HFrEF patients atrial fibrillation was associated with markedly lower phoenixin concentration than sinus rhythm (0.0803±0.0057 vs 0.0996±0,0046ng/ml, p=0.0182).
Conclusion: In this pilot study phoenixin plasma concentration did not differ between heart failure patients and controls. Interestingly, its level was found to negatively correlated with left atrium area in HFrEF subjects and was significantly lower in patients with persistent atrial fibrillation compared to patients with sinus rhythm. Further studies are needed to fully elucidate phoenixin involvement in cardiovascular disease, and particularly heart failure, pathophysiology.

P350

Determinant factors of plasma fibroblast growth factor 23 levels in patients with heart failure patients with reduced ejection fraction

D Damien Gruson[1]; AC Pouleur[1]; SA Ahn[1]; M Rousseau[1]
[1]Cliniques Saint-Luc UCL, Brussels, Belgium

Background: Fibroblast growth factor 23 (FGF-23) is an important regulator of the phosphorus homeostasis as well as the bone and mineral metabolism. FGF-23 displays also multiple direct effects on cardiac function and seems to participate to adverse cardiac remodeling. Several recent studies demonstrated that FGF-23 is a strong and independent predictor of adverse events in patients with heart failure (HF). Two types of assays are available to assess FGF-23 levels, those measuring the intact hormone (iFGF-23) and those targeting the C-terminal parts (C-term FGF-23).
Purpose: To examine which factors determine plasma C-term FGF-23 and iFGF-23 in HF patients with reduced ejection fraction (HFrEF).
Methods: Our evaluation included one hundred and seven chronic HF patients (women n=24; men n=83; NYHA II-IV; mean age: 66 years; mean EF: 23 %). A two-site enzyme immunoassay and an automated chemiluminescent immunoassay were used to measure levels of C-term FGF-23 and iFGF-23, respectively. We statistically analyzed the correlation between plasma C-term FGF-23 and iFGF23 levels and several variables including age, EF, estimated glomerular filtration rate (eGFR) and several biomarkers.
Results: Median levels of C-term FGF-23 and iFGF-23 were 169.1 RU/mL and 128.2 pg/mL, respectively. On univariate analysis, plasma C-term FGF-23 levels were significantly correlated with EF, eGFR, calcium, PTH 1-84, 1,25(OH)2 vitamin D, BNP, NT-proBNP, Galectin-3 and sST2. Plasma iFGF-23 levels were significantly correlated with age, EF, eGFR, PTH 1-84, 1,25(OH)2 vitamin D, BNP and Galectin-3. No significant difference was observed between women and men, either of C-term FGF-23 or I FGF-23. On multiple linear regression analysis, sST2 was the strongest independent determinant factor of plasma C-term FGF-23 levels and PTH 1-84 was the strongest independent determinant factor of plasma iFGF-23.
Conclusion: In patients with HFrEF, the strongest determinant factors of plasma C-terminal FGF-23 and intact FGF23 levels are respectively sST2 and PTH 1-84.

P351

Role of exhaled metabolites of biogenic amines in diagnostics of heart failure

N N Nasirdinov[1]; N I Qodirova[1]
[1]Andijan State Medical Institute, Andijan, Uzbekistan

Background. Currently, cardiovascular diseases (CVD) occupy the first place in the structure of morbidity and mortality of the population. As is well known, in the pathogenesis of CVD, metabolic biogenic amines are of particular importance. According to the literature, ischemic heart disease (IHD), complicated by heart failure (HF), a high content of catecholamines in blood plasma and their increased excretion with urine is noted. Cathecholamines standing out in excess, as biochemically active substances, can have a significant impact on the development of the disease, and its outcome. To date, it has been shown to increase the intensity of lipid peroxidation (LPO) in CVD in both acute and chronic forms.
Aim. Purpose of our study was to determine volatile metabolites of biogenic amines - secondary alkylamines (diethylamine) in exhaled air (EA), formed as a result of deamination of catecholamines . To determine diethylamine in explosives, colorimetric and gas analytical methods were used.
Materials and methods: The studied patients (40 people) in the hospital were randomly assigned to 2 groups: the first group (control) consisted of 20 clinically healthy men aged from 30 to 44 years; the second group – 20 men aged (32-50 years) with HF.
The obtained samples of explosives by thermal degassing were evaluated using an amine gas analyzer. Examination of patients with HF was carried out at admission, then at discharge for 10-12 days after treatment.
Results: In the group of clinically healthy men, the indicator of volatile amines in EA was 74 ± 2 10^9 g/l. The maximum level of volatile metabolites of biogenic amines in explosives in the second group was recorded on the first day and amounted to 207 ± 42 10-9 g / l, which is 179.7% higher than the control level. And on the 10-12th day the level of diethylamine dropped to 160 ± 37 10-9 g / l.
Conclusion: The increased content of diethylamine in explosives is apparently due to the impaired function of the sympathetic-adrenal system (SAS) in IHD. Nowadays, it is considered that as a result of deamination of catecholamines , secondary alkylamines are formed, in particular, diethylamine. In the process of lipid peroxidation, Schiff bases are formed. Under cellular hypoxia, under the conditions of the shift of SAS and an increase in the concentration of adrenaline (A), Schiff bases are transformed into secondary alkylamines. As is well known, a stressful situation aggravates hypoxia, which contributes to increasing adrenaline concentration and at the same time stimulates LPO. Therefore, increasing the concentration of Schiff bases and adrenaline leads to the formation of secondary amines. This effect significantly increases the concentration of alkylamines, in particular diethylamine.
The results we obtained, taking into account the literature data, indicate the need to monitor the state of SAS in patients with HF.

P352

Differences in the expression of the novel cardiac biomarkers sST2, GDF-15, suPAR and H-FABP in HFpEF, ICM and DCM patients

P Jirak[1]; M Lichtenauer[1]; B Wernly[1]; V Paar[1]; C Jung[2]; U Hoppe[1]; PC Schulze[3]; R Pistulli[4]; D Kretzschmar[3]; T Bekfani[3]
[1]University Clinics Salzburg, Department of Internal Medicine II , Salzburg, Austria; *[2]University Hospital Dusseldorf, Division of Cardiology, Pulmonology, and Vascular Medicine, Dusseldorf, Germany*; *[3]University Hospital of Jena, Department of Internal Medicine I, Division of Cardiology, Angiology, Pneumology and Intensive Medic, Jena, Germany*; *[4]University Medical Center, Dept. of Cardiology I - Coronary and Peripheral Vascular Disease, Heart Failure, Münster, Germany*

Background: Heart failure represents an ongoing therapeutic and diagnostic challenge to date with a considerable impact on morbidity, hospitalisation rates and health-care costs. Cardiac biomarkers have shown impressive results in risk

stratification and monitoring over the last years and provide great potential as a possible discriminator between different heart failure entities.
Purpose: The aim of this analysis was to analyse four novel cardiovascular biomarkers, namely sST2, GDF15, suPAR, and H-FABP in different heart failure entities (ischaemic cardiomyopathy, ICM; dilated cardiomyopathy, DCM; and heart failure with preserved ejection fraction, HFpEF).
Methods: In total, 252 patients have been included in this study. 77 patients diagnosed with DCM, 62 patients with ICM, and 18 patients diagnosed with HFpEF were enrolled. Additionally, 95 patients without coronary artery disease (excluded by coronary angiography) or signs of acute or chronic heart failure were included as control group. During outpatient visits, serum samples of all patients were obtained and analyzed for sST2, GDF-15 (inflammation, remodelling), suPAR (inflammation, remodelling) and H-FABP (ischemia) by means of ELISA.
Results: Levels of sST2 were significantly elevated in ICM and DCM patients compared to the control group ($p<0.0001$). No significant differences between HFpEF patients and the control group were observed for sST2. Regarding GDF-15, a significant elevation was evident for all heart failure entities compared to controls ($p<0.005$) with no significant differences between the respective groups. For H-FABP, a significant elevation of all heart failure entities was observed compared to the control group ($p<0.0001$). However, H-FABP levels in HFpEF were significantly lower compared to ICM and DCM patients ($p<0.0001$). Similar to sST2, levels of suPAR were significantly elevated in ICM and DCM patients compared to the control group ($p<0.0001$) and HFpEF patients ($p<0.01$) with no significant differences between HFpEF patients and controls.
Conclusion: By means of different expression patterns, novel cardiovascular biomarkers represent a promising tool to further distinguish between different heart failure entities. Multimarker measuring could thereby facilitate diagnosis, risk stratification and therapy monitoring in heart failure patients.

Chronic Heart Failure - Treatment

P353
Ventricular arrhythmias in patients with continuous-flow left ventricular assist devices

A Aggeliki Gkouziouta[1]; M Bonios[1]; D Zarkalis[1]; S Adamopoulos[1]; N Kogerakis[1]
[1]*Onassis Cardiac Surgery Center, Athens, Greece*

Introduction: Ventricular arrhythmias (VAs) pose a significant burden in patients with continuous flow left ventricular assist devices (cfLVADs). However, the incidence, risk factors, and impact on survival are not yet well-described.
Hypothesis: We hypothesized that there were demographic, hemodynamic, and comorbid condition parameters that would predict post-VAD arrhythmias and mortality.
Methods: We performed a retrospective analysis of 37 consecutive patients undergoing placement of cfLVADs between February 2008 and December 2018. Exploring the outcomes of early VA (occurring during the index hospitalization), late VA (occurring after discharge) and death, we compared demographic, comorbid, pharmacologic, and clinical data. Time to event analyses were undertaken to identify predictors of the outcomes.
Results: Most subjects were men (83%) with non-ischemic heart failure (70%) and an ICD (92%) in place.No deaths were obswerved. Pre-LVAD VA , chronic kidney disease and diabetes independently correlated with the incidence of arrhythmias in the time to event analysis. Pre-LVAD VAs occurred in 30 (29%) patients whereas post-LVAD VAs occurred in 33 (31%). The median time to an early VA was 6 days in the 19 patients with an event during the index hospitalization. Patients with an early VA were older
and had a lower pre-operative RVSP (23 vs. 29, p=0.03). Late VAs occurred in 19 (23%) of the 82 patients surviving the index hospitalization. The median time to event was 219 days. Predictors of time to late VA included pre-LVAD appropriate ICD therapy and baseline antiarrhythmic use .
Conclusions: Ventricular arrhythmias following LVAD placement are common and predicted by pre-LVAD arrhythmia and ICD therapy, comorbid conditions and medication use. For the rare patient without an ICD placed pre-LVAD, post-operative implantation should be considered.

P354
Treating advanced heart failure patients with biventricular assist devices in a low organ donation environment

A Aggeliki Gkouziouta[1]; D Zarkalis[1]; S Adamopoulos[1]; N Kogerakis[1]
[1]*Onassis Cardiac Surgery Center, Athens, Greece*

BACKGROUND: Heart transplantation remains the gold standard treatment for patients with end stage heart failure. Low organ donation combined with delayed referral of advanced-stage cardiomyopathy patients necessitates biventricular assist device (BiVAD) support for extended period of time.
METHODS: We retrospectively reviewed the records of the patients treated with this paracorporeal device between June 2004 and December 2018 at our institution. patients (mean age 41.9+-13.3 years, range 11 to 59 years) were supported as a bridge to transplantation. Eighty out of 90 patients were in INTERMACS 1 Level while 15 of them had survived after a successful resusctation (intravenous inotropes, 60; ventilated, 10; mean: CI 1.9 L/min/m2; CVP 19 mmHg; total bilirubin 3.75 mg/dl; NT-proBNP, 35,500 pg/ml). Various short-term devices were used as a bridge to bridge (IABP: 62, Impella:2, Levitronix:2 and ECMO:6). Two patients needed a BiVAD after left ventricular assist device support of 439 and 295 days, respectively.
RESULTS: Thirty day, 180 day, and 1 year survival after implantation (excluding transplanted patients) was 78%, 87% and 80% respectively. Forty nine of them were transplanted and seven are ongoing. Mean time on support was 781 days and 1 out of 90 patients with adult-sized pumps were discharged home with a mobile driver. Thirty patients exceeded 2 years of uncomplicated support before they were transplanted. One of our patients was successfully transplanted after 1460 days of support. One patient with renal failure and dialysis dependence lived at home 3.5 years after implantation. Complications included infection (n=15), bleeding requiring reexploration (n=12), and thromboembolic events (n=20). Thirty four patients died during support due to different reasons. Early mortality was due to multiorgan failure while late mortality regarded mostly cerebrovascular complications.
CONCLUSIONS: Support with BiVAD offers an acceptable rate of survival to heart transplantation. Furthermore, the use of a BiVAD itself does not confer an increased morbidity or mortality, and overall outcomes with this device are comparable to that of implantable LVADs if used strategically in severe congestive heart failure. With the institution of meticulous wound care, morbidity has been significantly reduced, and management as an outpatient is achievable, however readmissions are still frequent.

P355
Coronary flow reserve estimated by 82-rubidium positron emission tomography predicts survival in long-term heart transplant recipients

L Laerke Nelson[1]; TE Christensen[1]; P Hasbak[1]; F Gustafsson[1]
[1]*Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*

Funding Acknowledgements: The Danish Heart Foundation, The Research Fund of Rigshospitalet

Background: Cardiac allograft vasculopathy (CAV) is a leading cause of mortality in heart transplant (HTx) recipients and non-invasive methods to assess and risk stratify patients are highly desirable. Coronary flow reserve (CFR) estimated by 82-rubidium positron emission tomography (82-Rb PET) is affected by both epicardial and microvascular disease and might thus be a reliable tool. This study aimed to investigate the predictive value of CFR after HTx.
Patients and methods: This is a single-centre retrospective study of consecutive HTx recipients receiving 82-Rb PET at our hospital, Denmark, between April 2013 and July 2017. In total 50 patients were eligible for inclusion based on available CFR measurement. 82-Rb PET was performed as part of annual CAV surveillance post HTx in patients not suitable for invasive evaluation. As a CFR value of 2.0 or greater

is widely accepted as normal in clinical practice patients were grouped according to CFR: (i) high-CFR group: CFR > 2 (n=25 (50%)) versus (ii) low-CFR group: CFR ≤ 2 (n=25 (50%)). Presence of CAV at the time of 82-Rb PET was determined by coronary angiography or intravascular ultrasound (IVUS).
Results: Median (IQR) age at time of 82-Rb PET was 57 years (43-68) and 68% were male. There was no significant difference among groups (p=0.31 and p=0.23, respectively). Median time from HTx to 82-Rb PET was 121 months (81-194) with no difference between groups (p=0.15). Median follow-up time from 82-Rb PET was 29 months (20-40) in the high-CFR group and 36 months (25-48) in the low-CFR group (p= 0.26). 12 (24 %) patients died of all-cause mortality during follow-up. In the high-CFR group median CFR was 2.43 (2.26-2.81) and in the low-CFR group median CFR was 1.64 (1.36-1.88). In 28 patients (58%) CAV was present at time of 82-Rb PET with no significant difference among groups (p=0.13). Presence of CAV was determined by IVUS (maximal intimal thickness (MIT) ≥ 0.5 mm) in 11 (39%) patients and by coronary angiography in 17 (61%) patients. In 1 (2%) patient CAV was diagnosed during follow-up and in 1 (2%) patient a percutaneous coronary intervention (PCI) was performed during follow-up. Survival function stratified by CFR group was estimated by Kaplan Meier (figure 1) and there was significant difference between the high-CFR group and the low-CFR group (log-rank test p=0.03).
Conclusion: CFR obtained by 82-Rb PET predicts survival in selected long-term HTx patients and holds promise as a non-invasive method for CAV surveillance and risk-stratification after HTx.

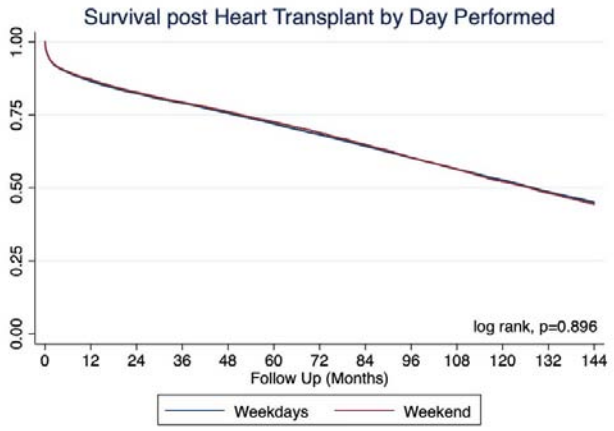
Is there a mortality weekend effect in cardiac transplantation?
R Chand[1]; CJ Lum[1]; A Salimbangon[1]; A Chang[1]; M Deng[1]; A Ardehali[1]; E Depasquale[1]
[1]*University of California Los Angeles, Los Angeles, United States of America*

BACKGROUND: Cardiac transplant surgeries can be complicated, prolonged, resource-heavy procedures that may be affected by the timing of the surgery.
PURPOSE: We analyzed the UNOS database to evaluate for a "weekend effect" on mortality comparing transplant surgeries that occurred on a weekday versus during the weekend.
METHODS: We conducted a retrospective, cohort analysis of the UNOS Organ Registry of all heart-only transplant patients from 1987 to 2018 comparing mortality rates between weekday transplants (WDT) versus weekend transplants (WET). The exclusion criteria included age <10, patients lost to follow-up, multi-organ transplants, and re-do heart transplants. A multivariate Cox proportional hazard regression analysis (adjusted for age, sex, diabetes, race, ischemic time, need for dialysis, on life support, wait time, and HLA mismatch) was performed. Survival was censored at 12 years.
RESULTS: 55,670 patients received heart transplants between 1987-2018 per the UNOS Organ Registry, of which 40,504 patients received a transplant on a weekday and 15,166 patients received a transplant during the weekend. Overall, the mortality for WDT versus WET were 52% and 52% (p=0.98), respectively. The breakdown of cardiovascular and non-cardiovascular mortality were similar for both WDT (15.8%, 36.2%, respectively) and WET (15.8%, 36.2%). Furthermore, there was no significant difference in cause of death between WDT vs WET, looking specifically at graft failure, rejection, infection, cardiovascular, malignancy, multi-organ failure, and other.
CONCLUSIONS: Based on this retrospective, cohort analysis of the UNOS Organ Registry there was no mortality "weekend effect" observed for cardiac transplantation surgeries.



Mortality Post-Transplant

P358
Pregnancy in patients with pre-existing cardiomyopathy and in cardiac transplant patients
L Lenka Vojtickova[1]; M Kubanek[1]; M Podzimkova[1]; M Hegarova[1]; L Hoskova[1]; A Krebsova[1]; V Melenovsky[1]; J Kautzner[1]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Cardiology department, Prague, Czechia*

Introduction: Pregnancy in patients with pre-existing cardiomyopathy or after orthotopic heart transplantation (OHT) represents a high risk both for mother and her child. Therefore, pregnancy is not generally recommended. This case series describes successful outcome of pregnancies in such a cohort of patients.
Methods: We reviewed retrospectively the clinical data of mothers and their children, the course of delivery and complications in the early postpartum period in a high volume transplant center.
Results: In 5 mothers with pre-existing cardiomyopathy, we documented a total of 7 births of 8 healthy children (maternal age 32 ± 7 years, week of delivery 34 ± 4, child birth weight 2220 ± 454 grams). Three patients had dilated cardiomyopathy (DCM) with borderline left ventricular function and 4 pregnancies were carried without any complications. One additional patient with DCM with severe left ventricular dysfunction accomplished two pregnancies despite negative recommendation, the first one complicated with bilateral heart failure and mild pulmonary embolism. Last patient presented clinically with hypertrophic cardiomyopathy, later diagnosed as Danon disease. She became pregnant, developed severe heart failure and required OHT after delivery.
In 4 mothers after OHT (3 patients had DCM as primary disease and 1 left ventricular noncompaction) we recorded 4 deliveries (maternal age 31 ± 3 years, months after the transplantation 67 ± 38, week of delivery 31 ± 4, birth weight 1882 ± 571 grams). During the pregnancy, drug therapy was minimized and immunosuppressives reduced to a combination of tacrolimus and corticoids. One gravidity was complicated with preeclampsia. All the delivered children were hypotrophic, but otherwise in a good health condition. One child developed later incipient cardiomyopathy.
Conclusions: Pregnancy is not recommended in patients with advanced forms of cardiomyopathy and/or after OHT. However, if the future mother accepts the risks, the pregnancy could be carried out relatively safely, employing specific management and close follow up.

Funding Acknowledgements: CIBERCV, Co-financed by FEDER Funds. Unrestricted grant support by Boehringer Ingelheim.

INTRODUCTION AND OBJECTIVES: Anticoagulation in heart transplant (HT) recipients increases the risk of serious hemorrhagic complications during the perioperative period, so the urgent and correct reversal of anticoagulation is of great importance. Dabigatran, a direct thrombin inhibitor, is increasingly being used for anticoagulation in patients with non-valvular atrial fibrillation (NVAF) whose effect can be reversed by idarucizumab in situations where urgent surgery such as a HT may be needed. Aim: To present the preliminary experience of the use of idarucizumab for the urgent reversal of dabigatran in patients receiving a HT in Spain.
METHODS: Observational study, carried out in 12 adult HT Spanish centers to analyze the clinical outcomes of the use of Idarucizumab (5 mg) for urgent reversal of dabigatran effects at the HT surgery.
RESULTS: 53 patients were included, 81.1% male. One patient required a rescue dose. 7.5% required redo surgery in the immediate postoperative period to control bleeding and 66% needed transfusion of blood products. The average length of stay in the intensive care unit was 5 days and the total hospital stay was 23 days. The 30-day survival was 92.4% . There were 4 deaths during hospitalization, three of them in the first five days after HT. In 3 cases, death was not related to bleeding. In one case, a patient transplanted because a congenital heart disease with previous sternotomy, death occurred at 2 days post-HT associated to surgical problems, right ventricular failure, cardiac arrest and bleeding (bleeding ocurred 12 hours after HT surgery)
CONCLUSION: These results may support the use of dabigatran as an alternative to vitamin K antagonists in patients with HT who require anticoagulation for NVAF. More studies are needed to corroborate these observations.

Regenerative therapy in patients with ischemic cardiomyopathy from cardiac transplant waiting list

D Dina Shorikova[1]; A Gabrielyan[2]; E Shorikov[1]
[1]*Bucovinian State Medical University, Chernivtsy, Ukraine*; [2]*National Institute of Surgery and Transplantology n. a. O. O. Shalimov, Kyiv, Ukraine*

Introduction . The possibility of use of mononuclear cord blood stem cells may have a good perspective from the point of view of better safety and efficiency in the restoration of myocardial contractility. However, until now we have very poor clinical data about the delivering of this kind of stem cells in patients with ischemic cardiomyopathy with resistant heart failure.
Materials and methods. We have studied 190 patients with ischemic cardiomyopathy, which are set in a waiting list on the heart transplantation. Instrumental investigation included ECG, cardiac ultrasound techniques, ventriculography. The patients were divided into three groups due to the treatment: coronary artery bypass (66 patients), coronary artery bypass and intravenous transplantation of stem cells (86 patients), conservative therapy (38 patients).
Results. Comparing the efficiency of therapy with umbilical cord blood stem cells in ischemic cardiomyopathy, a reduction in cardiovascular and total mortality was demonstrated by 24,4%, with reliable relative risk 2,61 [1,38 – 4,94] and a odds ratio 1,61 [1,52 – 8,83]. Comparing the efficiency of surgical treatment without cell transplantation and coronary artery bypass with cell transplantation in ischemic cardiomyopathy patients has been shown decrease of cardiovascular and total mortality by 14,0%, RR of 1,90 [1,02-3,57] and OR of 2,27 [1,03 - 5,03]
According to the changes of the data of Strain Rate Imaging after the administration of cord blood stem cells, all patients were divided into groups of "good" and "poor" responders. It has been established that in the cluster of "good responders", after 12 months of stem cells transplantation, certain parameters that characterize the systolic (S, *v*) and diastolic (e, a) functions of the left ventricle improved significally, while in the cluster of "poor responders" the changes were unreliable or even the worsening of the indexes of diastolic blood flow were set ($p<0.05$).
Conclusion: the delivering of umbilical cord blood stem cells can be used as an additional useful procedure for patients with ischemic cardiomyopathy, which are set in the waiting list for heart transplantation.

P361

The impact of extracorporeal photopheresis on peripheral blood leukocyte subclasses in heart transplant recipients

T Timea Teszak[1]; A Assabiny[1]; A Kiraly[1]; Z Tarjanyi[1]; N Parazs[1]; Z Szakal-Toth[1]; I Hartyanszky[1]; Z Szabolcs[1]; A Fodor[2]; Z Farkas[2]; M Reti[2]; B Sax[1]; B Merkely[1]
[1]*Semmelweis University Heart Center, Budapest, Hungary*; [2]*South Pest Central Hospital – National Institute for Hematology and Infectious Diseases, Budapest, Hungary*

Background: The efficacy of extracorporeal photopheresis (ECP) beside standard immunosuppressive therapy in the management of cardiac allograft rejection is proven. However, data regarding its effect on the individual leukocytes still remain elusive. The CD3 cell surface marker is expressed by each mature T cell, CD4 by helper T cells (Th), CD8 by cytotoxic T cells (Tc), while CD19 by B cells. Th and Tc cells can differentiate into either effector cells participating in the maintenance of transplant rejection or into regulatory cells playing a role in the suppression of rejection. Both B cells and natural killer cells (NK) contribute to allograft rejection, while regulatory T cells (Treg) play an important role in its termination.
Purpose: We aimed to evaluate the effect of ECP on peripheral blood leukocyte subclasses in adult Hungarian heart transplant recipients.
Methods: The retrospective study analysed the outcomes of 9 patients between September 2013 and December 2018 who underwent heart transplant for end-stage heart failure. We studied the absolute value and proportion of CD3+, CD4+, CD8+, CD19+ cells, NK cells and Treg cells measured by fluorescence activated cell sorting both before and after the ECP treatment period. The grade of rejection was analysed in transvenous endomyocardial biopsies. Data values were characterized by either mean±standard deviation or median(min-max).
Results: The patients underwent 30(12-39) ECP treatments beside standard immunosuppressive therapy. The absolute value and the proportion of CD3+ and CD4+ T cells increased significantly at completion of the ECP therapy (CD3+ T cells: 0.56 G/l±0.35 G/l vs. 0.81 G/l±0.46 G/l; p=0.027 and 6.04%±3.37% vs. 10.72%±6.17%; p=0.025; CD4+ T cells: 0.33 G/l±0.28 G/l vs. 0.49 G/l±0.41 G/l; p=0.038 and 3.34%±2.37% vs. 6.20%±3.78%; p=0.017, respectively). There was also a significant increase in the proportion of CD8+ T cells (2.45%±1.50% vs. 4.37±3.08%; p=0.036). We observed a fairly significant twofold increase in the proportion of Treg cells after the ECP treatment period (0.19%±0.23% vs. 0.38%±0.21%; p=0.057). The absolute value of B cells and NK cells did not reveal any significant rise. The average grade of cellular rejection improved significantly with approximately one class (gr. 1,22±0,44 vs. gr. 0,50±0,53; p=0,048) and also the humoral rejection moderated after the ECP treatment period.
Conclusion: The ECP therapy may support the predominance of Th and Tc cell subpopulations with anti-inflammatory properties which is confirmed by the improvement of the average grade of both cellular and humoral rejection. Furthermore, the increase of Treg cell count is assumable. Although, the small sample size and the effect of the medical therapy on the leukocytes may present some limitations. Subsequently, for improved understanding of the immunomodulatory effect of ECP, further studies are required focusing both on additional CD cell surface markers and on cytokines.

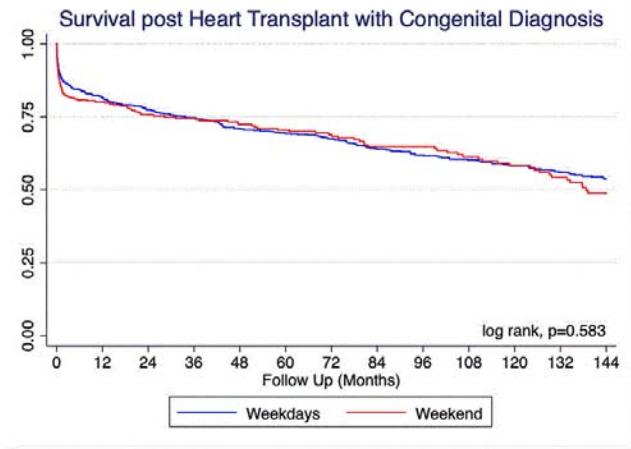
P362

Is there a mortality weekend effect in cardiac transplantation for patients with Adult Congenital Heart Disease?

R Robin Chand[1]; CJ Lum[1]; A Chang[1]; A Salimbangon[1]; M Deng[1]; A Ardehali[1]; E Depasquale[1]
[1]*University of California Los Angeles, Los Angeles, United States of America*

BACKGROUND: Cardiac transplant surgeries can be complicated, prolonged, resource-heavy procedures that may be affected by the timing of the surgery, especially in adult patients with a history of congenital heart disease (ACHD).
PURPOSE: We analyzed the UNOS Organ Registry to evaluate for a "weekend effect" on mortality for transplant surgeries that occurred on a weekday versus the weekend in ACHD patients.
METHODS: We conducted a retrospective, cohort analysis of the UNOS Organ Registry of all heart-only ACHD
transplant patients from 1987 to 2018 comparing mortality rates between weekday transplants (WDT)
versus weekend transplants (WET). The exclusion criteria included age <18, patients lost to follow-up,
multi-organ transplants, and re-do heart transplants. A multivariate Cox proportional hazard regression
analysis (adjusted for age, sex, diabetes, race, ischemic time, need for dialysis, on life support, wait time, and HLA mismatch) was performed. Survival was censored at 12 years.
RESULTS: 1,244 ACHD patients received heart transplants between 1987-2018, of which 923 patients received a transplant on a weekday and 321 patients received a transplant during the weekend. Overall, the mortality for WDT and WET were 41.2% and 41.4% (p=0.63), respectively. The unadjusted and adjusted hazard ratios for WET are 1.00 (p=0.90; 95% CI 0.97-1.03) and 1.00 (p=0.93; 95% CI 0.97-1.03), respectively. The breakdown of cardiovascular and non-cardiovascular mortality were similar between both groups: WDT (16.0%, 25.1%, respectively) and

WET (17.1%, 24.3%, respectively). There was no significant difference in cause of death between WDT vs WET (e.g. graft failure, rejection, infection, cardiovascular, malignancy, multi-organ failure, and other causes).
CONCLUSIONS: Based on this analysis of the UNOS Organ Registry, there was no mortality "weekend effect" observed for ACHD patients undergoing cardiac transplantation surgery, even though ACHD patients can potentially be a more complicated subset of surgical patients.



ACHD Transplant Survival

renal replacement therapy compared to 65% of patients in the nonTT group (p<0.001). Furthermore, the rate of primary graft failure requiring MCS was 53%, nearly 4 times higher in the TT group (14% vs 53%; p<0.001). As expected TT patients experienced longer mechanical ventilation (3.7±4.2 vs 33.2±31.5 days in the TT group; p<0.001) and longer ITU stay (7.1±4.9 vs 34.6±23.3; p<0.001). Despite comparable 30-day mortality between the groups, 90-day mortality was significantly higher in the TT group (29% vs 12%; p=0.009).
Conclusions: In our cohort, one-third of OHT patients required TT. The procedure was safe. Risk factors for TT included previous stroke/TIA, pre-transplant MCS, longer CPB time and higher maximum SOFA score in the first 24 hours post OHT. TT was performed in patients requiring multiple-organ support in addition to prolonged mechanical ventilation.

Tracheostomy after orthotopic heart transplantation

M Zaleska-Kociecka[1]; R Fernandez Garda[1]; M Morosin[2]; J Dutton[1]; D Garcia Saez[3]; A Simon[3]; B Zych[3]; T Aw[4]; N Lees[5]; A Hurtado Doce[1]
[1]Harefield Hospital, Intensive Therapy Unit, London, United Kingdom of Great Britain & Northern Ireland; *[2]Royal Brompton Hospital, Intensive Therapy Unit, London, United Kingdom of Great Britain & Northern Ireland*; *[3]Harefield Hospital, Transplantation and Mechanical Circulatory Support, London, United Kingdom of Great Britain & Northern Ireland*; *[4]Royal Brompton Hospital, Anaesthetics and Intensive Therapy Unit, London, United Kingdom of Great Britain & Northern Ireland*; *[5]Harefield Hospital, Anaesthetics and Intensive Therapy Unit, London, United Kingdom of Great Britain & Northern Ireland*

Background: Tracheostomy (TT) is commonly performed after cardiac-surgery when prolonged mechanical ventilation is required. The main benefits of TT include a reduction in sedation requirement, avoidance of laryngeal injury, airway protection, improvement in patient comfort and allowance of gradual ventilatory weaning. Data regarding TT after orthotopic heart transplantation (OHT) is limited.
Purpose: To describe prevalence, timing and safety of TT in patients after OHT and identify subgroups of patients at highest risk of TT.
Methods: We retrospectively reviewed 153 consecutive OHT patients in our centre between 2013 and 2018.
Results: In total 149 OHT patients were analysed as shown in the flow chart (Fig 1). One-third of them required TT (n=47; 30.2%) during ITU stay. The majority of TT was performed percutaneously (91.1%). Mean time from ITU arrival to TT was 12.3±6.8 days. There were no life-threatening complications related to the procedure (major bleeding, pneumothorax, pneumomediastinum, tube misplacement or cardiac arrest). However, over half of the patients (53.3%) received red blood cell transfusion (on average 313 ml) during the first 24 hours post TT.
Comparison of baseline characteristics showed that patients were of similar age in both groups (44±14 vs 46±16 years in the TT group; p=0.546), however the rate of both previous stroke/TIA (11% vs 27% in the TT group, p=0.013) and pre-transplant mechanical circulatory support (MCS) (35% vs 53% in the TT group; p=0.036) were significantly higher in the TT group. In univariate logistic regression analysis both previous stroke/TIA (OR 3.1; 95% 1.2-7.6; p=0.016) and MCS prior to OHT (OR 2.1; 95% 1.1-4.3; p=0.038) were significantly associated with the risk of TT. Moreover, longer cardiopulmonary bypass (CBP) time was related to the risk of TT (OR 1.1; 95%; 1-1.01; p=0.014) as well as higher maximum SOFA score in the first 24 hours after OHT (OR 1.2; 95% 1.1-1.4; p=0.08).
Postoperative characteristics revealed that the majority of TT patients required additional organ support. Nearly all patients (98%) who received TT experienced

P364
Bicaval vs biatrial anastomosis techniques in orthotopic heart transplantation: an updated analysis of the UNOS database

J Maning[1]; V Blumer[1]; G Hernandez[2]; H Li[3]; S Chaparro[2]
[1]Jackson Memorial Hospital, Department of Internal Medicine, Miami, United States of America; *[2]University of Miami Leonard M. Miller School of Medicine, Department of Cardiovascular Medicine, Miami, United States of America*; *[3]University of Miami Leonard M. Miller School of Medicine, Department of Public Health Sciences, Miami, United States of America*

Background: Despite the significant increase in the number of orthotopic heart transplants (OHT) performed annually using the bicaval anastomosis technique, the impact on long-term outcomes remains a topic of debate. We analyzed the United Network for Organ Sharing (UNOS) database in search of the latest insight.
Methods: We performed an updated analysis using the UNOS database from 2006 to 2016 to identify first-time OHT recipients. Patients were primarily stratified according to anastomosis technique: bicaval vs biatrial. Baseline characteristics and clinical status were recorded. The primary end-point was all-cause mortality. Secondary outcomes included need for postoperative permanent pacemaker (PP), and length of hospital stay (LOS). Kaplan-Meier was used to compare survival between the two groups. Cox proportional hazards regression model was used to conduct multivariable analysis and to obtain adjusted hazard ratio (HR). Statistical significance was established at p <0.01.
Results: A total of 21,597 patients were identified. Of those who met inclusion criteria, 16,573 (77%) underwent bicaval anastomosis. Both groups had similar baseline characteristics. The bicaval anastomosis technique was not associated with increased survival during the study period (HR 0.97, p = 0.3557). The bicaval group required less post-operative PP placement (2.51% vs. 5.79%, p <0.001) and was associated with shorter LOS on multivariable analysis (t associated with the anastomosis technique was -3.45 (p = 0.006), and 95% confidence interval for the unstandardized regression coefficient (b) was 0.94 – 0.98). The adjusted mean LOS for the bicaval group was 16.7 days versus 17.3 days for the biatrial group.
Conclusions: The use of either bicaval or biatrial anastomosis during orthotopic heart transplant offers comparable survival advantage. Nonetheless, bicaval anastomosis is associated with less need for postoperative PP and slightly shorter LOS.

Diastolic function evaluation in heart transplantation

F Ferdinando Loiacono[1]; G Calonaci[1]; A Ibrahim[1]; BM Natali[1]; S Bernazzali[1]; S Mondillo[1]; M Cameli[1]

[1]*University of Siena, Department of Cardiovascular Diseases, Siena, Italy*

Background. Diastolic dysfunction is an early marker of acute rejection and a severity-defining hallmark of cardiac allograft vasculopathy in transplanted hearts. Its non-invasive definition and classification suffer long-standing conflictual evidence. This may be due to morphological and functional specificities of transplanted hearts, such as the post-surgical biatrial enlargement that may reduce left atrial (LA) compensation to progressive end-diastolic left ventricular pressure (EDP) increase, but also denervation, ischemia-reperfusion injury and acute and chronic rejection.
Purpose. To evaluate how current echo guidelines and usual measures stratify heart transplanted (HTx) patients according to their diastolic function; to seek for more reliable non-invasive parameters for diastole evaluation in HTx subjects.
Methods. We conducted a two-phase study. In the first one, we retrospectively enrolled 122 asymptomatic rejection-free HTx and controls subjects in 1:1 ratio. In the second one, we prospectively enrolled 20 asymptomatic HTx patients (mean HTx age 8.7 ± 5.3 years) who were hospitalized for routine follow-up coronary angiography, without systolic dysfunction and irrespectively of rejection history. Invasive EDP measurement during left heart catheterization and transthoracic echocardiogram were performed within one hour.
Results. In the preliminary study, controls and HTx subjects did differ (p<0.005) in A velocity (respectively, 0.8 ± 0.1 vs 0.43 ± 0.12 m/s) and Global peak atrial longitudinal strain (PALS) (31 ± 9.2 % vs 12.2 ± 5.7 %), thus showing LA dysfunction in HTx. According to echo guidelines, there was a proportionate distribution among the four grades of diastolic dysfunction in controls (normal: 51.6%; grade 1: 38.7%; grade 2: 9.7%; grade 3: 0%), whereas a U distribution was observed in HTx group with virtual disappearance of intermediate grades (normal: 51.7%; grade 1: 1.7%; grade 2: 1.7%; grade 3: 45%). In the prospective study, besides finding a similar distribution, no echo parameter did show a significant correlation in univariate and multivariate regression analysis with EDP but two, that were E DecT (R -0.53, p =0.03) and isovolumic relaxation time (IVRT) (R -0.55, p =0.02). We then divided the population according to a strict cutoff of increased EDP, i.e. 13 mmHg. In HTx patients with normal-high EDP (>13 mmHg) compared to those with normal-low EDP (≤13 mmHg), IVRT and E DecT were significantly reduced (respectively, 80.2 vs 95.7 ms, p =0.04; 152.1 vs 178.5 ms, p =0.03). Finally, when ROC curves were calculated, among IVRT, E DecT, E/A, E/e', Global PALS and Global longitudinal strain, IVRT and E DecT were the best predictors of increased EDP (respective AUC 0.82 and 0.77).
Conclusions. Usual non-invasive parameters of diastolic function alone imprecisely stratify HTx patients. Other echo measures, such as E DecT and IVRT, might be more reliable and considered for routine use in these patients.

P367

Mortality risk factors in patients from a heart transplantation waiting list

A Kostomarov[1]; P Fedotov[2]; M Simonenko[3]; YU Sazonova[4]; M Bortsova[5]; M Sitnikova[6]

[1]*Academician I.P. Pavlov First St. Petersburg State Medical University, St-Petersburg, Russian Federation*; [2]*Almazov National Medical Research Centre, Heart Failure SRL, Saint-Petersburg, Russian Federation*; [3]*Almazov National Medical Research Centre, Heart transplantation Department, Saint-Petersburg, Russian Federation*; [4]*Almazov National Medical Research Centre, Thoracic Surgery and Transplantation SRL, Saint-Petersburg, Russian Federation*; [5]*Almazov National Medical Research Centre, Cardiology Department 8, Saint-Petersburg, Russian Federation*; [6]*Almazov National Medical Research Centre, Heart Failure Research Department, Saint-Petersburg, Russian Federation*

Purpose. To study clinical differences of chronic heart failure (CHF) patients who were included in a heart transplantation waiting list (HTx WL) and to estimate their survival.
Methods. We retrospectively analyzed HTx WL data that was collected from 2010 to 2017 and included 151 patients: mean age 47.4±12.8 yrs, male – 113 (75%), BMI – 24.5±4.5 kg/m^2, LVEF (Simpson) 20.8±7.9%, LVEDV - 266±110 ml, TAPSE – 1.3±0.5 cm, pulmonary vascular resistance (PVR) – 3.5±1.5 W.U., mean pulmonary artery pressure (PAP) - 32±13 mm Hg. Causes of CHF were: IHD – 61 (40%), DCM – 66 (44%), non-compacted myocardium – 9 (6%), transferred myocarditis – 4 (3%), RHD – 3 (2%) and others – 8 (5%). Patients were divided into 2 groups: 1st group – survivors in a HTx WL (n=110), 96 of patients underwent heart transplantation (HTx) and 14 of them improved (n=14); 2nd group – patients who died in a HTx WL (n=41). Data were analyzed by using the Statistical Package 'STATISTICA 10.0' (StatSoft Inc., USA).
Results. The duration of stay in a HTx WL was 96 (range 31-192) days and deceased patients spent less time in a HTx WL than survivors (37.0 vs. 115.5 days, =0.004). In 17 (41%) patients death from the moment of inclusion in a HTx WL occurred within 1 month. We found the following differences in deceased patients: lower incidence of IHD (=0.03) and more frequent occurrence of pulmonary embolism (PE), CHF class IV (<0.001) and inotrope-dependent patients (<0.001). In patients who died during their 1st month in a HTx WL a greater degree of mitral regurgitation (MR) was found than in those who died in long-term follow-up (=0.036). In a severe CHF decompensation, survival depended on the urgent implantation of mechanical circulatory support (MCS) or HTx. From 2010 to 2011 the frequency of CHF surgical treatment increased from 20% to 55% and was on the same level from 2012 to 2014 (=0.001) and during the following years. Moreover, in 2015-2017, compared with 2010-2011, patients' mortality significantly decreased (Cox'sF-Test: =0.04). An active optimization of drug therapy made it possible to achieve a significant increase in the survival of patients with status 1B of UNOS compared with patients who did not receive ACE inhibitors / ARA or beta-blockers (p=0.0007 and p=0.009, respectively).
Conclusion. In our Centre HTx WL mortality for the period of 2010-2017 decreased what can be associated with an active use of CHF surgical treatment as a bridge-to-transplantation and optimal drug therapy. HTx WL mortality was significantly higher in patients with CHF class IV, status 1 UNOS and the development of acute decompensation of advanced CHF. The highest mortality is due the first month after inclusion in HTx WL. It is associated with the severity of MR and no opportunity for urgent HTx and MCS implantation.

Incidence of vasoplegic syndrome after cardiac transplant in patients treated with Sacubitril/Valsartan

JM Dominguez[1]; JM Paimes[2]; S Mirabet[2]; E Garcia Romero[3]; J Gonzalez Costello[3]; M Farrero[1]; F Perez Villa[1]

[1]*Hospital Clinic de Barcelona, Advanced Heart Failure and Cardiac Transplant Unit, Barcelona, Spain*; [2]*Hospital de la Santa Creu i Sant Pau, Advanced Heart Failure and Cardiac Transplant Unit, Barcelona, Spain*; [3]*University Hospital of Bellvitge, Advanced Heart Failure and Cardiac Transplant Unit, Barcelona, Spain*

Introduction: Vasoplegic syndrome (VS) is associated with high morbidity and mortality after heart transplant (HT). ACE-inhibitors have shown to increase the risk of VS after heart surgery, but little is known about the effect of Sacubitril/Valsartan (SAC/ VALS), a more potent vasodilator used in heart failure.
Objective: To assess whether SAC/VALS is associated with a higher incidence of VS in patients undergoing a HT.
Patients and Methods: We retrospectively analyzed all consecutive HT performed in 3 in the same city, between January 2017 and August 2018. VS was defined as the need of vasopressors for more than 24 hours to maintain a mean arterial pressure >

70 mm Hg, which included vasopressin or high-dose norepinephrine or epinephrine (> 0,5 mcg/kg/min). Emergent HT and recipients with primary graft failure in the first 48h post HT, defined as ejection fraction <50% or cardiac index <2l/min/m2, were excluded from further analyses.
Results: Among a cohort of 96 HT recipients, 4 were excluded for having previously implanted a IVAD, 16 for primary graft dysfunction and 26 for emergent HT. Our final cohort was 50 HT recipients (66% male, mean age 51±12). 11 patients were on SAC / VALS treatment at the time of HT and were compared to 39 recipients who were not receiving SAC/VALS.
The global incidence of VS was 8%, with no significant differences between the groups: 9.09% in the SAC/VALS group vs 7.69% in the no-SAC/VALS group, p = NS. No significant differences were found either in vasopressor doses 4 h post HT, 24 h post HT and maximal dose, or in post-operative laboratory parameters.
Conclusion: In our study, SAC / VALS was not associated with a higher incidence of VS.

Feasibility of heart transplant in a distant insular population: accessibility and outcomes in patients from the Canary Islands

Z Zorba Blazquez Bermejo[1]; J Hernandez-Afonso[2]; A Garcia-Quintana[3]; JM Medina[4]; JJ Grillo[2]; MD Garcia-Cosio[1]; L Moran-Fernandez[1]; P Caravaca-Perez[1]; I Ponz-De Antonio[1]; P Escribano-Subias[1]; V Sanchez[1]; E Renes[1]; F Arribas-Ynsaurriaga[1]; JM Cortina[1]; JF Delgado[1]
[1]University Hospital 12 de Octubre, Madrid, Spain; *[2]University Hospital Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain*; *[3]University Hospital Dr Negrin, Las Palmas De Gran Canaria, Spain*; *[4]University Hospital Insular of Gran Canaria, Las Palmas De Gran Canaria, Spain*

On behalf of: CIBER de Enfermedades Cardiovasculares

Background: The Canary Islands are located at a distance of more than 1700 km from Madrid. Although the distance between patient and transplant center does not seem to have an effect in the results, whether the inherent difficulty of the insularity has an impact in the heart transplant (HT) accessibility and outcomes is unknown.
Purpose: The aim of the present study was to analyse HT accessibility and outcomes in the population of the Canary Islands.
Methods: All HT performed in our center from 15 January 1991 to 31 December 2017 were analysed. We compared baseline characteristics and follow-up after HT between patients from the Canary Islands and from the Peninsular Spain. In addition, time evolution of the HT rate per million population from 1994 in the Canary Islands and the Community of Madrid were reviewed.
Results: 75.2% of HT in patients from the Canary Islands has been performed in our hospital. Among 562 HT performed in our center, 28.1% were from the Canary Islands. These patients showed better survival compared with the others (log-rank = 0.020) (figure), due presumably to a lower mean age and proportion of ischemic heart disease (table). HT rate per million population in the Canary Islands has been equated to the Community of Madrid rate in the last four years.
Conclusions: Despite distance from the Canary Islands to Peninsular Spain, HT is accessible for its population and with at least comparable results to the rest of the autonomous communities.

Tacrolimus and neoplasia. Do level really be important?

A Antonio Grande Trillo[1]; JM Sobrino-Marquez[1]; MR Caballero-Valderrama[1]; I Sayago-Silva[1]; D Rangel-Sousa[1]
[1]University Hospital of Virgen del Rocio, Seville, Spain

Introduction . Immunosuppressive therapy as Tacrolimus is related with higher incidence of neoplasia in heart transplant (HT) recipients. So, we could hypothesized that a high exposition with higher levels of tacrolimus would increase neoplasia incidence. There are only few studies in other organ solid transplant recipients that assessed it with conflicting results.
Purpose. Our aim is evaluate the relationship between high tacrolimus level and neoplasia in HT recipients.

Methods. We analyzed retrospectively HT recipients treated with tacrolimus in our center from 2005. We evaluate general characteristics, neoplasia history and all measurements of tacrolimus levels. We compare groups with and without neoplasia.
Results. 115 HT recipients (median age 52 years; Q3-Q 42-57 years; 76% male) were analyzed. There were 14 patients with neoplasia (12.2%): 4 cutaneous and 10 solid organ. Mean follow-up was 6 ± 3 years. Univariate and multivariate analysis are in the table 1. Kaplan-Meier analysis in relation with tacrolimus mean level is shown in the figure 1.
Conclusions. In our series higher levels of tacrolimus do not seem to be related with a higher incidence of neoplasia. Age and smoking before transplant are risk factors as other studies. However there are only a few patients with neoplasia and so multicenter studies will be necessary to evaluate this aim.

P371
Donor age in heart transplantation: results and controversies

C Concetta Di Nora[1]; V Ferrara[1]; S Sponga[1]; A Lechiancole[1]; V Tursi[1]; C Nalli[1]; G Guzzi[1]; U Livi[1]
[1]University Hospital Santa Maria della Misericordia, Udine, Italy

Heart transplantation (HTx) is the best therapeutic option for patients suffering from end-stage heart failure, but the shortage of donor hearts still represents a crucial problem, leading to an extension of donor criteria. Since 1985 to December 2017, a total of 611 HTx in 600 patients have been transplanted at our Centre. The aim of the present study is to analyze the short- and long-term results of HTx in patients with older donor age, comparing the < 60 years old (Group A) vs ≥60 – 64 years old (Group B) vs ≥ 65 – 69 years old (Group C). The mean age at HTx was 55±11.1 years. Of these, 561 (91%) received a donor heart <60 years old, while 40 (7%) patients received a donor heart ≥60 – 64 years old (mean donor age 62.7±2.4 years), and 10 patients (2%) received a donor heart ≥ 65 – 69 years old (mean donor age 66.7±2.4 years). Furthermore, recipients from donors of Group A had more previous cardiac surgery (52% vs 31% vs 29%, p < 0.001); but no difference has been reported comparing the Group B vs the Group C (p=0.49). No differences have been reported in the aetiology of the cardiomyopathy or total ischemia time (194.5±58.8 min vs 187.1 ±62.5 min, p=0.4) between the three groups. Considering the donor < 60 years group, 22 HTx patients (4%) died in the first month after HTx; conversely 7 patients (13%) died early from the Group B and 2 HTx patients (20%) from the Group C. In a mean follow up of 216 ± 48 months, a total of 503 patients (81%) was alive after the first year from HTx from the Group A, compared to 38 (76%) from the Group B and 8 (80%) from the Group C. In the older donor groups, the incidence mortality is highest in the first month from HTx; conversely, it appears similar between donor < 60 years old and ≥60 years old, even if when ≥65 years old patients have been considered. It could be reliable to expand the cardiac donor pool by accepting allografts from donors ≥ 60 years of age in selected cases.

Clinical variables among the 3 groups

	Group A<60 years old	Group B≥60 - 64 years old	Group C≥ 65 - 69 years old
N (%)	561 (91)	40 (7)	10 (2)

Is cardiac contractility modulation a new step in heart failure treatment?

O Nikolaeva[1]; O V Sapelnikov[2]; T M Uskach[1]; D F Ardus[3]; D I Cherkashin[2]; I R Grishin[2]; A A Safiullina[1]; V A Amanatova[1]; I V Zhirov[1]; S N Tereshenko[1]; R S Akchurin[2]
[1]Russian Cardiology Research and Production Complex, Heart failure and myocardial disease department, Moscow, Russian Federation; [2]Russian Cardiology Research and Production Complex, Cardio-vascular surgery department, Moscow, Russian Federation; [3]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Heart failure (HF) is one of the most significant cardiac diseases due to its prevalence and frequency of hospitalizations. In many cases treatment with prescribed medications does not improve symptoms enough to significantly reduce risk of cardiac death. Cardiac Contractility Modulation (CCM) is an effective treatment tactics in patients with narrow QRS complexes who are refractory to medical therapy.
Purpose: Current study demonstrates whether CCM leads to symptomatic and functional improvement in patients with heart failure.
Methods: Twenty-seven patients with symptomatic heart failure (II-III NYHA class), persistent/paroxysmal AF and reduced left ventricular ejection fraction (LVEF 30±9%) were included in study. The average age was 50 ±11 years. Mean LA-volume was 117,6±47 ml and average NT-pro-BNP level was 1505 pg/ml.A 6-minute walk distance (6-MWD) was 328 ±48,04 m. Patients were treated with medications optimized for their conditions. All patients were implanted with CCM Optimizer Smart according to the standard implantation protocol.
Results: In two months follow-up CCM stimulation rate 89±7% was observed. A significant improvement in functional and symptomatic parameters was achieved. LVEF increased by 3-10% and reached 36±6% (p-0,141). Mean 6 MWD values were 353± 62 m (p-0,283). NYHA improved by at least one functional class. We observed two deaths: in one case the patient died because of myocardial infarction and in another case the patient died because of thoracic aortic rupture.

Conclusions: CCM is a safe technology for patients with HF and reduced LVEF. It improves functional parameters, including a 6-minute walk distance and NYHA functional class. Apparently CCM prevents HF progression and may influence the outcome, however longer follow-up period would be beneficial to determine the extended prognosis.

P373

Preserved contractile function of the myocardium of the right ventricle as a predictor of the effectiveness of cardiac resynchronization therapy.

DI Lebedev[1]; MV Lebedeva[1]; SV Popov[1]
[1]*Cardiology Research Institute, Tomsk National Research Medical Center of RAS, Tomsk, Russian Federation*

Objective: to identify the effect of the preserved contractile function of the right ventricle (RV) in patients with implanted devices on cardiac resynchronization therapy (CRT). Materials and methods. The study included 110 patients (79 men) with a diagnosis of non-ischemic cardiomyopathy, mean age 54 ± 10.5 years, functional class III heart failure according to NYHA, left ventricular ejection fraction (LV) (EF) 30 ,1 ± 3.8%, six-minute walk (6MWD) 290.5 ± 64.3 m and the final LV diastolic volume (EDV) 220.7 ± 50.9 ml. All patients had a steady sinus rhythm, complete blockade of the left bundle of the His; QRS duration ranged from 146 to 240 ms (183 ± 32 ms). CRT devices were implanted in all patients. All patients, prior to implantation of devices and after 24 months, the contractile functions of the LV and RV myocardium were assessed using equilibrium radionuclide tomoventriculography. Results: follow-up examination was performed after 24 months of CRT, showing favorable clinical changes: HF NYHA decreased in all patients from III to II. 99 patients responded to CRT (86.25%); 11 patients (13.75%) did not respond to CRT. The criterion of the patient's response to CRT was an increase in LV by 15% or more over 24 months. Respondents on CRT showed favorable clinical changes: LV EF increased from 30.1 ± 3.8% to 42.8 ± 4.8% ($p \leq 0.001$); LV EDV decreased from 220.7 ± 50.9 ml to 197.9 ± 47.8 ml ($p \leq 0.005$). In patients who did not respond to treatment, LV EF did not change significantly (30.1 ± 3.8% vs. 33.8 ± 3.8%, $p \leq 0.001$); EAD of LV increased from 220.7 ± 50.9 to 227.8 ± 27.8 ml ($p \leq 0.001$). All patients were retrospectively divided into two groups: group 1 consisted of patients who responded to CRT; group 2 included non-responders. In patients of the 1st group, radionuclide tomoventriculography showed that the frequency of filling of the RV peak (PFR) decreased from 1.8 ± 0.36 to 0.56 ± 0.16 ($p \leq 0.001$); The average rate of diastolic filling (1 / 3FR-m) decreased from 0.6 ± 0.2 to 0.36 ± 0.15 ($p \leq 0.001$). In patients of the 2nd group, these indicators were significantly worse (by 30% and 60%, respectively). It is important to note the fact that the responders prior to the implantation of the devices on all indicators showed a preserved function of the right ventricle, whereas in the patient who did not respond to therapy, it was initially reduced. Conclusion: CRT in patients with severe heart failure was significantly more effective in those individuals who had contractility of the right heart chambers, which was detected before the start of therapy. RV PFR and RV 1 / 3FR-m values can serve as prognostic criteria for a favorable response of patients to CRT.

P374

Predictors of response after cardiac resynchronization therapy implantation in heart failure patients

B Hennawy[1]; H Badran[1]; S Khaled[1]; H Awadallah[1]
[1]*Ain Shams University, Cardiology Department, Cairo, Egypt*

On behalf of: Ain Shams University

BackgroundCurrent inclusion criteria may not be accurate enough to differentiate patients who will or will not respond to CRT. Other pathophysiologic factors such as HF etiology, LV dimensions and function, mitral regurgitation, LV dyssynchrony, position of LV pacing lead, and extent/location of myocardial scar have also shown to influence CRT response.PurposeThis was a retrospective study that aimed at characterization of responders after CRT implantation , determining predictors of good or bad response to CRT.
Methods This study included 50 patients with congestive heart failure refractory to optimum medical treatment who received CRT according to guidelines. All patients were subjected to thorough history taking, physical examination, ECG and echocardiographic study before and after the procedure and a fluoroscopic study to assess LV lead position.
Results Responders to CRT were determined either clinically or according to echocardiographic study, clinical responders were 62% of the patients vs 60% echocardiographic responders. Predictors of good response to CRT were female gender (P=0.009), non-diabetics (P=0.006), non-dyslipidemics (P <0.001), higher NYHA class of the patient (P <0.001), non-ischemic cardiomyopathy (P=0.013), absence of paracardiac conditions (P=0.028), faster heart rate (P=0.017), wider QRS complex (P=0.007), lateral position of LV lead (P <0.001) and larger distance between RV and LV leads (P <0.001)
Conclusion Ten predictors of response to CRT could be identified from this study apart from the current guidelines for CRT insertion.

P375

Dynamics of mechanical dyssynchrony in patients with superresponse to cardiac resynchronisation therapy at a long-term follow-up

N Shirokov[1]; V Kuznetsov[1]; A Soldatova[1]; S Dyachkov[1]; D Krinochkin[1]
[1]*Tyumen Cardiology Center, Tyumen, Russian Federation*

Background: Mechanical dyssynchrony (MD) and superresponse (SR) to cardiac resynchronisation therapy (CRT) relationship is still debated.
Purpose: To study the dynamics of mechanical dyssynchrony in patients with congestive heart failure and SR to CRT as well as to assess clinical features and morpho-functional properties of heart.
Materials and methods: 72 patients were examined (mean age 54.3±8.9 years) at baseline and during follow-up visits: 10.5±3.7 months, 52.0±21.4 months. Patients were divided into 2 groups: I group (n=31) with decrease of left ventricular (LV) end-systolic volume (ESV) ≥30% (superresponders) and II group (n=41) - decrease of LV ESV <30% (nonsuperresponders).
Results: At baseline there was difference in the presence of myocardial infarction (22.5% in the I group vs 46.3% in the II group; p = 0.038), the groups were comparable in severity of electrical and MD. LV pre-ejection period in group I was statistically significantly decreased at both control visits, in group II there was no significant dynamics. Right ventricular pre-ejection period significantly increased only in group I at the second control visit compared to baseline values. The mechanical interventricular delay significantly decreased in group I at both control visits compared to baseline values, in group II only at first control visit. The intraventricular dyssynchrony assessed by tissue Doppler imaging (TDI) significantly decreased in both groups compared to baseline values. The survival rate in group I was 87.1%, in group II was 65.9% (Log-Rank test p=0.038).
Conclusion: SR is associated with decrease of MD and higher survival rate at a long-term follow-up.

P376

Gender differences of patients randomized in the AdaptResponse trial

G S Gerasimos Filippatos[1]; D Birnie[2]; M F El-Chami[3]; M R Gold[4]; A S Hersi[5]; C Kantipudi[6]; K Kusano[7]; C Leclercq[8]; B P Merkely[9]; W Mullens[10]; B Singh[11]; B Gerritse[12]; S Jacobs[12]; B L Wilkoff[13]
[1]*Attikon University Hospital, Athens, Greece*; [2]*University of Ottawa Heart Institute, Ottawa, Canada*; [3]*Emory University Hospital, Atlanta, United States of America*; [4]*Medical University of South Carolina, Charleston, United States of America*; [5]*King Saud University, Riyadh, Saudi Arabia*; [6]*Piedmont Heart Institute, Atlanta, United States of America*; [7]*National Cerebral and Cardiovascular Center, Osaka, Japan*; [8]*University Hospital of Rennes, Rennes, France*; [9]*Semmelweis University, Budapest, Hungary*; [10]*Hospital Oost-Limburg (ZOL), Genk, Belgium*; [11]*Medanta Heart Institute, Gurgaon, India*; [12]*Bakken Research Center, Maastricht, Netherlands (The)*; [13]*Cleveland Clinic Foundation, Cleveland, United States of America*

BackgroundCRT response rates vary significantly with limited clinical improvement in at least 20-30% of device recipients. Women historically do better with CRT but have been under represented in most trials. The AdaptivCRT algorithm provides ambulatory CRT optimization with LV fusion pacing in patients with LBBB and a normal PR interval. The AdaptResponse trial tests the hypothesis that AdaptivCRT is superior to conventional CRT.
PurposeTo describe the baseline characteristics of female versus male patients randomized in the AdaptResponse trial.
Methods AdaptResponse is a global randomized trial, completing enrollments in February 2019. Eligible patients are CRT indicated with NYHA Class II-IV heart failure, LBBB by Strauss criteria (QRS ≥140 ms in men, ≥130 ms in women), and baseline PR interval ≤200ms. The preliminary baseline data are presented here.
ResultsAdaptResponse enrolled 3,540 subjects as of October 26, 2018, of which 3,372 were randomized in 218 centers worldwide, including 43.3% females. Women were older, shorter, had shorter QRS duration, worse baseline CHF, and fewer had ischemic cardiomyopathy. Medication includes more loop diuretics and angiotensin receptor blocker (ARB) and less angiotensin converting enzyme inhibitors (ACEi). Comorbidities such as AF, diabetes and renal dysfunction were less frequent in female patients, whereas more often depression was reported. Final baseline data will be available in 2019.
ConclusionAdaptResponse is the largest randomized CRT trial to date, with a proportion of female patients approaching the actual prevalence of the heart failure population. Importantly, the data from AdaptResponse will provide long term outcome data from the AdaptivCRT algorithm and lead to better understanding of responses to CRT among women.

P377

The efficiency of cardiac resynchronization therapy with atrioventricular correction in patients with chronic heart failure with moderate clinical manifestations

ES Atroshchenko[1]; OV Koshlataja[1]; DV Romanovskiy[1]; YP Ostrovskiy[1]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*

Objective: to assess the efficiency of CRT (cardiac resynchronization therapy) implantation with atrioventricular correction in patients with chronic heart failure NYHA functional lass II at 12 months after surgery

Methods: 30 patients (pts) with ischemic or dilated cardiomyopathy, complicated by CHF NYHA functional lass (FC) II, LV EF below 35%, QRS duration 150 msec nd more and with ECHO confirmed mechanic myocardial dyssynchrony were examined. All patients underwent the LV end-diastolic volume (LVEDV), LV end-systolic volume (LVESV), interventricular delay, dyssynchrony index (TS-DS), all segments max delay were estimated by ECHO. The levels of BNP, the six-minute walk test (6MWT) and life quality (LQ) were measured initially and at 12 months after surgery

Results: At 12 months LVEDV decreased from 343,8±25,3 ml to 213,8±66,6ml (<0,05), LVESV significantly decreased from 270,8±22,47 to 160,8±68,8 (<0,05), LVEF increased evidently from 21,5±1,35% to 38,80±7,4% (<0,05). Intracardiac haemodynamic changes were accompanied by decreased mechanic dyssynchrony event rate - there was trend to the evident decrease of interventricular delay from 71,1±3,97 to 35,2±15,5 msec. (<0,05),improved LQ of patients: LQ evidently decreased from 61,3±2,8 scores to 41,1±4,2 scores (<0,05); distance of 6 MWT increased from 379,6±25,8 m to 428,4±22,3 m; NT-proBNP level decreased from 1476,0±254,54 to 270,2±43,2(<0,05).

Conclusions: At 12 months biventricular heart stimulation with atrioventricular correction evidently enhances heart haemodynamic and the clinical conditions of pts, improving exercise tolerance in pts. with chronic heart failure NYHA functional lass II.

P378

Differences between ischemic and non-ischemic cardiomyopathy and its relationship with long-term outcomes following ventricular assist device placement

A Ada Ip[1]; J Roldan[1]; N Moss[1]
[1]*Mount Sinai School of Medicine, New York, United States of America*

Background: Ventricular assist devices (VAD) are rapidly becoming an option for many end-stage heart failure patients with ischemic (ICM) or non-ischemic cardiomyopathy (NICM). There is limited data regarding disparities in VAD outcomes in patients with these different cardiovascular substrates.

Methods: Retrospective review was performed for all patients who received a VAD between 2010-2016 with 2 years of follow-up and further stratified by ICM or NICM. Endpoints include all-cause mortality, post-VAD stroke, myocardial infarction (MI), infection, and VAD thrombosis. Cumulative mortality was studied with Cox-proportional hazard model. Multivariate logistic regression was performed for endpoints at 2 years. Covariates include age, sex, smoking, hypertension, hyperlipidemia, diabetes, chronic obstructive lung disease, chronic kidney disease, and peripheral artery disease.

Results: Of the 289 patients who received a VAD between 2010-2016, 116 (40.1%) had ICM, and 159 (55.0%) received an orthotopic heart transplant. On average, ICM patients were older, have a higher ejection fraction, and had a prior MI with revascularization. All-cause mortality was higher for patients with ICM over 2 years (p=0.049) (Figure 1). At 2 years, there were no differences in the incidence of post-VAD stroke, MI, major bleeding, infection, or VAD thrombosis.

Conclusion: Survival is worse for patients with ischemic cardiomyopathy compared to those with non-ischemic cardiomyopathy undergoing VAD implantation.

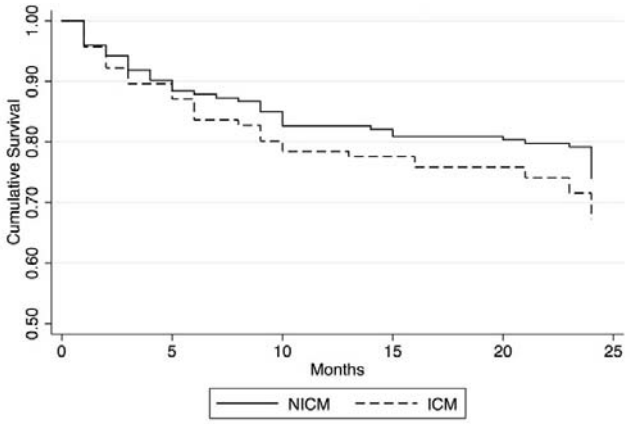

Figure 1: All-cause mortality

P379

Preoperative geriatric nutrition risk index scoring is predictive of survival in LVAD recipients

M Masashi Kawabori[1]; S Lofftus[1]; A Vest[1]; V Pramil[1]; Y Zhan[1]; KG Warner[1]; H Rastagar[1]; MS Kiernan[1]; FY Chen[1]; GS Couper[1]
[1]*Tufts Medical Center, Division of Cardiac Surgery, Boston, United States of America*

Background: Poor nutritional status is associated with poor long term outcomes in patients with chronic heart failure and in those undergoing surgeries, however there is little data in patients on circulatory assist. The Geriatric Nutritional Risk Index (GNRI) is commonly adopted scoring system that evaluates patients' nutritional status and has been reported to have significant prognostic value for adverse events in patients with heart failure as well as those undergoing various surgeries. There is a paucity of GNRI data in left ventricular assisted device (LVAD) recipients and GNRI cut-off value at which patients have significantly worse outcomes has yet to be reported.

Purpose: Our aim of study is to analyze patient outcomes related to preoperative GNRI and develop a GNRI cutoff value for worse overall survival as a prognostic tool to enable better candidate selection for LVAD placement.

Methods: We included 298 end stage heart failure patients who underwent primary LVAD implantation from January 2015 to February 2018 in our single institution retrospective study. GNRI was determined using the formula (14.89 × albumin in g/l) + (41.7 × present/ideal body weight). Receiver operation characteristic (ROC) curve was used to determine a cut off GNRI value for worse overall mortality on LVAD support. This cutoff was used to define two groups as either high or low GNRI. Univariate analysis was used to evaluate GNRI as an independent risk factor for mortality.

Results: ROC curve demonstrated a cut off GNRI value for overall survival as 92.68. High GNRI group (n=178) and low GNRI group (n=120) were defined from this cut off value. Kaplan Meier curve showed significant overall mortality between 2 groups (p=0.04). Univariate analysis showed GNRI p-value of 0.051.

Conclusion: GNRI below a cutoff value of 92.68 is associated with worse outcomes in LVAD recipients including worse overall mortality. For these patients, it is important to consider the surgical indication, timing and nutrition optimization prior to LVAD implantation.

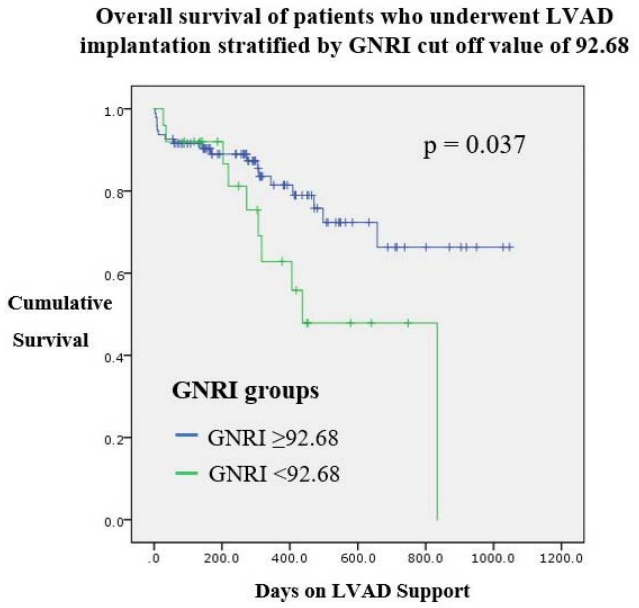

Figure 1.

P380

Monitoring Heart rythm across borders

A Amit Hooda[1]; A Sharma[2]; P Datta[3]; S Attawar[3]
[1]W PRATIKSHA HOSPITAL, Gurgaon, India; *[2]CK Birla Hospital, CTVS, Jaipur, India*; *[3]Global Hospital, CTVS, Chennai, India*

Background: Patients living in remote areas especially the war-torn countries like Iraq may not have access to experienced, high level mechanically circulatory support care. To decrease the incidence of frequent hospitalizations and to prevent complications which may occur as a result of lack of communication between patient and care givers, a remote monitoring system connecting a web based application allows review of LVAD system performance.
Purpose: To assess the feasibility of remote monitoring in patients with advanced heart failure undergoing LVAD implantation
Methods: Four patients with advanced heart failure from warn torn countries(Iraq) which did not have access to advanced mechanical circulatory support care underwent LVAD implantation with scope of remote monitoring. The VADLink Network is a remote monitoring service which connects clinicians to the patients supported by the HA5 LVAD via a secure Internet website to monitor trending. Diagnostic reports can be exported to a hospital network and to a patient file. Alerts regarding the changes in LVAD flow, power or speed can be received by physicians or VAD coordinators in the form of an email or text. Trended data can be displayed from 1 hour to 30 days. A 10 second display of a real time wave form can be requested to add clarity to the trend data.
Results: Normal 10 second waveform showing heart rate of 75 bpm and aortic valve opening (Fig 1)
Through remote monitoring of the LVAD true flow waveform, it was feasible to we have been able to evaluate LVAD function (flow, power and speed) and patient physiologic function such as arrhythmias, trends in cardiac contractility, aortic valve opening and left heart volume status. No pump malfunctions have occurred during the monitoring time. Periodic issues with device communication have been encountered due to the issues with cell tower service.
Sudden change in power trend in a patient indicated probably a thrombus wash through. Patient was immediately contacted and found to have a sub therapeutic PT-INR. Anticoagulant therapy was optimised and further catastrophe was prevented. (Fig 2). Changes in heart rate and waveforms helped in assessing the fluid status of the heart failure patients and their hydration status was immediately optimized.(Fig 3). A low flow with high power alarm showed gradual decrease in LVAD flow from 5 L/min to 3 L/min and further investigation revealed that the patient's systemic blood pressure was>90 mmHg. Antihypertensive dosages were increased and the pump flow returned back to 5 L/min. (Fig 4).Change of normal waveform to erratic one without any change in pump function on further investigation revealed water egression into a connector after the patient has showered (Fig 5)
Conclusion: Remote monitoring has enabled patients living in remote places to receive high level monitoring of their LVAD systems and efficient home care. It helped in preventing complications which could have led to grave consequences.

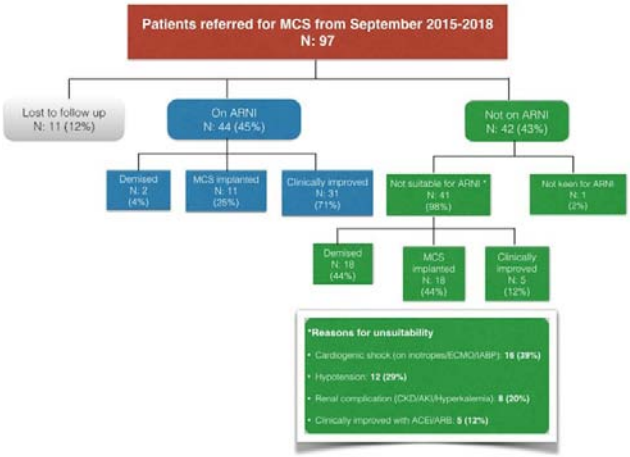
The use of ARNI in the prevention of ventricular assist device implantation among patients with advanced heart failure: a single center experience

RR Cruz[1]; L Teo[1]; J Loh[1]; L Chan[1]; CY Khoo[1]; CT Ng[1]; KL Kerk[1]; D Sim[1]
[1]National Heart Centre Singapore, Cardiology, Singapore, Singapore

Background/Introduction: Ventricular assist devices (VADs) are proven therapy in advanced heart failure for bridge to transplant and destination therapy. The role of Sacubitril/Valsartan (ARNI) is established in guideline directed medical therapy for chronic heart failure, however its role in advanced heart failure is not well defined.
Purpose: To determine the effect of ARNI on patients referred to the National Heart Centre Singapore (NHCS) for mechanical circulatory support (MCS)
Methods: All patients referred to NHCS for MCS from September 2015 to September 2018 were retrospectively reviewed via electronic health records.
Patients were divided into two groups: those who were treated with ARNI and those who were not. Clinical course and outcomes were reviewed.
Results: Among ninety seven patients referred to NHCS for possible MCS implantation, 82% were males and the mean age was 53+/-9 years old. Eleven (12%) were lost to follow up, 44 (45%) were treated with ARNI and 42 (43%) were not. The non ARNI group had a worse hemodynamic profile with Interagency Registry for Mechanically Assisted Circulatory Support (INTERMACS) scale of 1 to 2 in 56% of patients compared to the ARNI group of 11%.
Thirty one patients out of the 44 (71%) treated with ARNI clinically improved leading to deferral of the need for MCS while 11 patients (25%) eventually had MCS implanted. Only two patients (4%) on the ARNI group died.
For non-ARNI group, one patient was not keen on ARNI due to financial constraint. Forty one patients were not suitable due to cardiogenic shock (39%), development of hypotension (29%) or renal side effects (20%) when ARNI was started. Five patients (12%) were able to have significant improvement with Angiotensin Converting Enzyme inhibitors or Angiotensin Receptor Blockers. Majority of the non ARNI patients either died (44%) or had AMCS implanted (44%).



Conclusion(s): Inability to tolerate ARNI portends poor prognosis in patients with advanced heart failure.
Majority of patients who could tolerate initiation of ARNI in advanced heart failure were able to avoid MCS.
Optimisation of guideline directed medical therapy is imperative prior to consideration of mechanical support device therapy in heart failure

P382
Inotropic score on postoperative day 0 and 1 is associated with LVAD patients survival

M Masashi Kawabori[1]; S Lofftus[1]; J Soffer[1]; V Pramil[1]; Y Zhan[1]; M Kiernan[1]; D Denofrio[1]; KG Warner[1]; H Rastagar[1]; FY Chen[1]; GS Couper[1]
[1]Tufts Medical Center, Division of Cardiac Surgery, Boston, United States of America

Background: Immediate postoperative management of left ventricular assist device (LVAD) recipients usually requires support of multiple inotropes and pressors. Poor right ventricular function or vasoplegia may require higher dose support; however, this may complicate the course by causing severe vasoconstriction or lactic acidosis. Currently, there is a paucity of reports regarding postoperative inotrope/pressor use and survival on LVAD support.
Purpose: The aim of this study is to analyze the negative effect of inotrope and pressors for survival on LVAD in our cohort by using Inotropic Score (IS). IS is a previously reported scoring system used to unite the effect of multiple medications in one scale.
Methods: From January 2015 through February 2018, 134 patients with chronic end-stage heart failure underwent primary CF-LVAD implantation in our single center. Pre and intra-operative variables, postoperative IS, and survival of LVAD days were analyzed. IS was defined using the following formula reported in ISHLT consensus 2014. IS = dopamine(x1) + amirinone (x1) + milrinone (x15) + epinephrine (x100) + norepinephrine (x100) with each drug dosed in microgram/kilogram/minutes.
Results: Chi-squared test revealed mortality on LVAD support to be significantly related to the sum of postoperative day 0 to 1 IS (POD 0-1 IS)(p=0.02). Receiver operating characteristic analysis showed an IS of 508.8 as the optimal cutoff value for POD 0-1 IS, with higher IS associated with worse survival. Cox multivariate analysis showed POD 0-1 IS as an independent risk factor for survival (HR 1.00, p=0.05, 95% Confidence Interval 1.00-1.01). Kaplan Meier curve showed a statistically significant survival difference between groups above and below the cut off value (p=0.012)
Conclusion: Our research highlighted that the IS sum from postoperative day 0 to 1 was an independent predictor for mortality with a cutoff value of 508.8. Further research may elucidate the negative effect of high-dose inotropes/pressors for LVAD recipient outcomes.

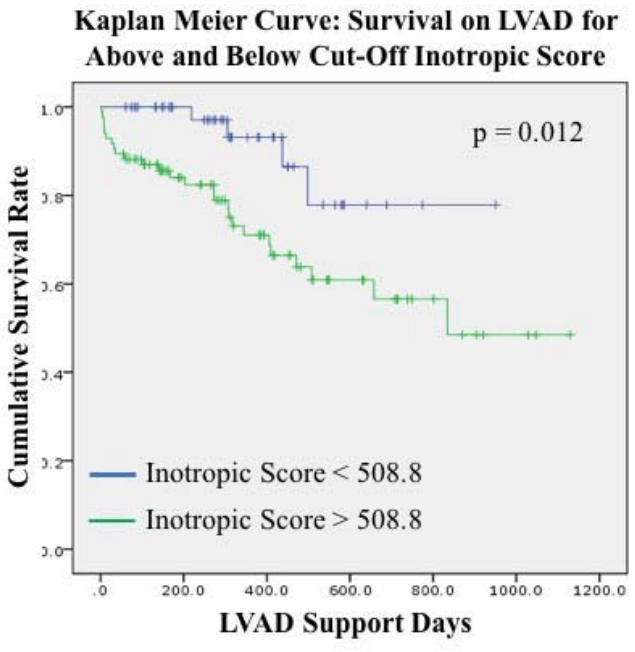


Figure 1

P383
The significance of right ventricular stroke work index for optimizing the selection of suitable candidates for implantation of left heart support

E Eva Ozabalova[1]; J Krejci[1]; P Hude[1]; J Godava[1]; T Honek[1]; H Poloczkova[1]; J Lipoldova[1]; H Bedanova[2]; P Nemec[2]; L Spinarova[1]
[1]St. Anne's University Hospital, Department of Cardiology, Brno, Czechia; *[2]Centre for Cardiovascular Surgery and Transplantation , Brno, Czechia*

Background: Orthotopic heart transplantation is a treatment for selected patients with end stage heart failure. Implantation of left ventricular assist devices (LVAD) can be used to bridge to heart transplant.
Aim of study: To evaluate some hemodynamic parameters obtained by right heart catheterization and echocardiographic parameters in patients before LVAD implantation or HTx. Assess the possible impact of these parameters on the failure of the right ventricle and the further course after the HTx or LVAD implantation.
Methods: Between 1/2016 -12/2017 was performed 59 HTx in Brno transplant center. For 47 of them (40 men and 7 women), average age 56.3 ± 7.6 years, LVEF 18.6 ± 9.9% were available the required parameters. The most common diagnosis leading to the HTx was dilated cardiomyopathy (27 patients), 16 patients underwent HTx for ischemic heart disease, in 2 cases the HTx was performed for restrictive cardiomyopathy, one for valvular defects and next one for cardiac amyloidosis. We evaluated cardiac output and cardiac index (CO, respectively. CI), mean pulmonary artery pressure (MPA), the mean pulmonary capillary wedge pressure (PCWP), the right ventricle stroke work index (RVSWI) obtained by right heart catheterization. Parameters to describe the function of the right ventricle (RV) - the size of RV, tricuspid annular systolic excursion (TAPSE), peak systolic velocity of the tricuspid annulus (s'tri) were mesaured by the echocardiography.
Results: Implantation LVAD underwent 12 patients with prosperous course of 7 patients (58%). In 5 patients (42%) occurred after the implantation RV failure and progression of tricuspid regurgitation witch required tricuspid annulus plastic in 3 patients. Patients with complicated course had significantly lower RVSWI (6.1 ± 1.3 g / m vs 8.5 ± 2.7 g / m) and s'tri (9.0 ± 1.2 cm / s vs. 11.9 ± 3.3 cm / s, both p 0.05). For the other 35 patients after HTx were no previous LVAD implantation. Right heart failure appeared in 17 of them (48%) after the transplant, three of them underwent plastic of tricuspid valve for significant tricuspid regurgitation. The remaining 18 patients (52%) had a favorable early post-transplant course. None of monitored parameters in these groups did not differ significantly.
Patients undergoing LVAD implantation had statistically higher TAPSE (17.3 ± 3.3 mm vs 14.1 ± 3.1 mm s'tri (10.6 ± 3.0 cm/s vs 8.3 ± 2.5 cm/s; all p <0.05) and diastolic dimension of left ventricle (77 ± 9 mm vs 68 ± 10 mm), opposite they have lower LVEF (15.0 ± 3.0% vs 20.0 ± 11.0%; p <0.05) .
Conclusions: Implantation of LVAD has become a part of the transplant program and proper patient selection is crucial to the success of this treatment. Besides the commonly used echocardiographic parameters, the evaluation function of right ventricle using a right ventricle stroke work index might be another parameter of risk prediction RV failure in the postoperative period.

P384
Prolonged mechanical ventilation after left ventricular assist-device implantation: risk factors and clinical implications

M Maria Papathanasiou[1]; RI Mincu[1]; L Johannsen[1]; L Tsourelis[2]; N Pizanis[2]; C Ilias[2]; M Kamler[2]; T Rassaf[1]; P Luedike[1]
[1]University of Duisburg-Essen, West German Heart Center, Cardiology, Essen, Germany; *[2]University Hospital Essen, Department of Thoracic and Cardiovascular Surgery, West German Heart and Vascular Center, Essen, Germany*

Background: Unsuccessful weaning from ventilator after major cardiovascular procedures has been shown to be associated with increased postoperative morbidity and mortality. Purpose: Our study aimed to identify predictors and clinical implications of prolonged mechanical ventilation (PMV) after left ventricular assist device (LVAD) implantation. Methods: We analyzed the data of patients receiving a continuous-flow LVAD in our center from 12/2010 to 09/2017. PMV was defined by a duration of invasive ventilation of > 7 days after LVAD implantation. Multivariable logistic regression analysis was performed for predictors of PMV. Survival was estimated by the Kaplan-Meier method. Results: During the study period 156 patients received a continuous-flow LVAD in our center. Seventeen patients were excluded due to early death (<7 days) and 139 patients were enrolled in the study. PMV was observed in 43% of patients. Overall, patients on PMV were characterized by a more severe disease state at baseline, compared to the group of early extubation, as reflected by their INTERMACS level (level 1-3: 72 vs. 49%, p =0.008). Patients with PMV exhibited higher pulmonary wedge pressures (25 vs. 21 mmHg, p=0.04), lower estimated glomerular filtration rate (eGFR) (53 vs. 60 ml/min/1.73m2, p=0.02), lower hemoglobin (10.6 vs. 11.6 g/dl, p= 0.02) and lower platelet counts

(189 vs. 240/nl, p=0.02). The percentage of patients with a history of previous sternotomy was increased (32 vs. 13 %, p=0.006) and at least three-fold higher rates of preoperative circulatory support (p=0.006), invasive ventilation (p<0.001) and dialysis (p=0.001) were reported for the group of patients with PMV. Logistic regression analysis revealed that eGFR, platelet count and previous sternotomy were independent predictors of PMV in this patient cohort. PMV was accompanied by significantly longer ICU- and hospital stay (p<0.001 and p= 0.003, respectively). Survival analysis revealed a profound increase in the reported mortality rates at 180 days post-implantation in the PMV group (62 vs 10%, Log-rank test: p < 0.001). Conclusions: PMV is common after LVAD implantation. Certain biomarkers and previous sternotomy are associated with increased risk for PMV postoperatively, which is accompanied by decreased survival at 180-days post-implantation and longer hospitalizations.

P385

Clinical profiles, outcome and prognostic factors of patients treated with percutaneous left ventricular assist devices for protected PCI and cardiogenic shock

M Noutsias[1]; M Ali[1]; M Matiakis[1]; M Mammadov[1]; A Rigopoulos[1]
[1]University Clinic Halle (Saale), Mid-German Heart Center, Department of Internal Medicine III (KIM-III), Division of Cardiology, Halle, Germany

Introduction: Percutaneous left ventricular assist devices (Impella) are used both for protected PCI (pPCI) and for patients with cardiogenic shock (CS).
Aims: We investigated the clinical profiles, outcome and prognostic factors of patients under Impella support for pPCI and CS in our monocentric registry.
Results: We evaluated n=25 consecutive patients (males: 72%; age: 67.4+11.2 years; range: 43-86 years), treated with Impella devices from 11/2016 to 01/2018 at our tertiary center. Impella 3.5 / CP was used in 48%, and Impella 2.5 in 52% of the patients. 88% of the patients had ischemic heart disease, and additional 3 cases had CS due to non-ischemic cardiomyopathy (dilated cardiomyopathy: n=2; non-compaction cardiomyopathy: n=1). The indications for the implantation of Impella were pPCI in 48%, and CS in 52% of the patients, respectively. All cases with pPCI were treated with an Impella 2.5, while all but one CS cases were treated with an Impella 3.5 / CP (p<0.0001). The mean duration on Impella-support was 53.8+157 hours. The rate of non-fatal complications was 9.8% (i.e. bleeding, hematoma), however, no fatal complications due to the use of the Impella occurred. Intra-hospital mortality occurred in 52% of the total patients, and was significantly higher in CS patients (84.6%) as compared with patients with pPCI (16.7%; p=0.0007). Furthermore, intra-hospital mortality was significantly associated with CPR (p=0.0017), with peak creatine kinase (CK; p=0.0020), with peak high-sensitive Troponin T (hsTnT; p=0.0011), and with peak lactate (p=0.0002).
Conclusions: Our data confirm the safety of Impella for pPCI and CS. Intra-hospital mortality in severe CS patients is still high despite Impella support. In contrast, mortality in patients with severe coronary artery disease subjected to pPCI is low. In addition to myocardial ischemia markers (CK, hsTnT), peak lactate might prove a relevant prognostic marker for adverse outcome in this setting.

P386

Organisation programme for left ventricular assist device in end stage heart failure patients - Single centre experience

D Kosevic[1]; MP Milojevic[2]; MP Peric[1]; PV Vukovic[1]; PM Milacic[1]; S Micovic[1]; LJ Djokovic[1]; I Petrovic[1]; P Dabic[1]; D Radoicic[1]; M Bojic[1]
[1]Cardiovascular Institute Dedinje, Belgrade, Serbia; *[2]Zan Mitrev Clinic, Cardiac surgery, Skopje, North Macedonia*

Background: End stage heart failure patients are challenging for treatment and burden to the society, especially in the developing countries. In our coutry of 8 million residents, 5 cardiac surgery centers, we still do not have data of number of end stage heart failure patients. .In lack of donors and incrising numbers of heart failure patients, we started LVAD programe.Our primary goal was to organize our outpatient clinic in terms to register and evaluate all patients with end stage heart failure, to decide who is candidate for HT and/or LVAD. Secundary goal was to determine risk factors that may influence survival in patients on medical therapy and in LVAD patients.
Methods: We established patient selection programe with essencial support of Advanced heart failure department from an hospital in Houston, Texas. We analyzed data of prospectively admitted 65 patients with end stage heart failure , from June 2017 . Nine patients undervent LVAD implantation from December 2017 until December 2018. We evaluated and compared one year survival, functional capacity, right ventricle function, liver and renal function in patient on medical therapy alone, waiting for HT, compared with 9 LVAD patients.
Results: One year survival rate for patients with end stage heart failure that are indicated for medical therapy and heart transplant programe was 83 % and in group that undervent LVAD implantation, survival is 100%. Significant improvement in survival, functional capacity in LVAD patients , MVO2, renal function (P<0.05 for all) were detected after 3, 6 and 12 months. In multivariate Cox regression analysis renal failure and right ventricle function was found to be independent risk factor for the overall survival (P<0.001).
Conclusion: In our data, LVAD is successful treatment option for patients with end stage heart failure and significantly improves survival, functional capacity and renal function. Our goal, supported by Hermmann Hospital from Houston, is to provide safety and quality to all patients with end stage heart failure by establishing HT/LVAD programme.

Safety of sacubitril-valsartan vs. ramipril in left ventricular assist device carriers and comparison of NTproBNP levels - a pilot study

N Jakus[1]; R Ister[2]; I Planinc[1]; B Skoric[1]; H Jurin[1]; J Samardzic[1]; D Lovric[1]; J Ljubas Macek[1]; D Fabijanovic[1]; D Milicic[1]; M Cikes[1]
[1]University Hospital Centre Zagreb, Dept. of cardiovascular diseases, Zagreb, Croatia; *[2]University Hospital Centre Zagreb, Zagreb, Croatia*

Background: Currently, there is no consensus on the optimal medical therapy for patients after left ventricular assist device (LVAD) implantation, but usually the HFrEF therapy is continued beyond implant. We compared NT-proBNP values in LVAD patients treated with ramipril or sacubitril/valsartan (sac/val).Patients and Methods: A single centre, retrospective study included data from 26 patients (88% male, mean age 59±11 years). 54% were continuously treated with ramipril, and 46% were switched to sac/val. The median follow-up was 13.3 months (IQR 8.5-15.4).
Results: Baseline patient data are presented in Table 1. Throughout the follow up, the mean arterial blood pressure, creatinine and glomerular filtration rate (GFR) values did not change significantly (Figure 1a). A decrease in NT-proBNP values was noted in both groups, although without significant difference between them. However, a difference in trends expressed as negative logarithms of ratios of NT-proBNP at 3 months follow up and at baseline is seen in the sac/val group compared to those on ramipril, achieving significance (p=0.009) for the low medication doses (Figure 1b). During follow-up, 3 patients died in the ramipril subgroup and none in the sac/val group, but the sample size precluded survival analyses.Conclusion: Our data suggest a good safety profile of sac/val in LVAD recipients. A decrease in NT-proBNP values is seen in patients in both treatment groups, with results suggestive of a decrease in the biomarker with sac/val. However, a larger prospective randomized study is required to to establish the consistency of this finding and its translation to treatment benefit.

Baseline data of the patient population

	Sac/Val (n=12)	Ramipril (n=14)	p-value
Age at implant	53±13	63±5	0.016
LVAD type - HM2, n (%)	1 (8.3%)	7 (50%)	0.07
LVAD type - HW, n (%)	3 (25%)	2 (14.3%)	
LVAD type - HM3, n (%)	8 (66.7%)	5 (35.7%)	
Female gender, n (%)	1 (8.3%)	2 (14.3%)	0.64
Etiology of HF - Ischaemic, n (%)	5 (41.7%)	10 (71.4%)	0.13
- Dilated, n (%)	7 (58.3%)	3 (21.4%)	
- Other, n (%)	0 (0.0.%)	1 (7.1%)	
NT-proBNP at baseline, [ng/L]	1863 [1381, 2129]	1774 [983, 3631]	0.96
GFR at baseline, [mL/min/1.73m^2]	68.3±24.0	77.7±24.5	0.33
MAP at baseline, [mmHg]	86.2±11.3	85.6±12.6	0.91

Implementation of the 2016 ESC guidelines for treatment of heart failure in patients after continuous flow LVAD implantation

F Felix Schoenrath[1]; L Roehrich[1]; J Mulzer[1]; M Mueller[1]; C Starck[1]; E Potapov[1]; V Falk[1]; J Knierim[1]; P Pergantis[1]
[1]*Deutsches Herzzentrum Berlin, Cardiothoracic and Vascular Surgery, Berlin, Germany*

Funding Acknowledgements: The study is financially supported by Novartis

Introduction /Background2016 European heart failure guidelines recommend the neprilysin inhibitor Sacubitril, for the treatment of heart failure. When medical therapy and device therapy fail, patients with HFrEF might be candidates for LVAD therapy.
Purpose Despite studies showing reverse remodeling under aggressive heart failure medication, data about the efficacy and the safety of guideline directed medical treatment in patients with LVAD therapy is lacking.
Methods From October 2017 onwards the pharmacological management of heart failure in patients with continuous flow LVAD therapy was updated in accordance with the ESC Guidelines of heart failure management, including the application of Sacubitril/ Valsartan. The trial protocol was approved by the local ethics committee (ES2/236/17).
Results Since October 2017, 54 newly implanted continuous flow LVAD (HeartWare and HM III) patients were treated according to the current guidelines. The mean duration of postoperative hospital stay was 33 days (+/- 36.64). Mean follow-up after hospital discharge is currently 117 days (+/- 105.87), medication is displayed in table 1.
Conclusion Adherence to guideline recommended therapy at hospital discharge and at first follow-up visit was excellent. 72% of patients received beta-blockers at discharge; approx. 85% were under dual RAAS blockade (including 61% combined therapy with Sacubitril/Valsartan) at discharge and nearly 92% had a beta-blocker at follow-up. No patient under treatment with Sartan plus neprilysin inhibition died during follow-up or was rehospitalized for worsening of renal failure or hyperkalemia. The current heart failure therapy algorithm appears to be safe in patients under continuous flow LVAD therapy after a short term follow up.

Medication at discharge and at follow up	
Medication at discharge	Number of patients (n=54)

Temporal changes in N-Terminal prohormone brain natriuretic peptide do not predict pump thrombosis and cardiovascular death in patients with a continuous flow left ventricular assist device

F Eismark[1]; SS Knudsen[1]; F Gustafsson[1]; E Wolsk[1]
[1]*Rigshospitalet - Copenhagen University Hospital, Department of Cardiology, Copenhagen, Denmark*

Background: Natriuretic peptide concentrations reflect intracardiac pressure in patients with heart failure. Continuous flow left ventricular assist device (cfLVAD) recipients are at risk of pump thrombosis and cardiovascular (CV) death, which could be preceded by changes in natriuretic peptide levels.
Purpose: This study aimed to evaluate whether serial changes in the N-terminal prohormone of brain natriuretic peptide (NT-proBNP) precede pump thrombosis or CV death in patients with cfLVAD, making this a candidate biomarker for outpatient monitoring.
Methods: This was a single center observational study. Pre-scheduled sampling of NT-proBNP was measured pre-implant, at discharge, every 3 months within the first year, and annually afterwards in patients implanted with a cfLVAD. Pump thrombosis or CV death was used as a combined endpoint. Time-to-event analyses, using both time-updated cox modeling and restricted cubic splines, were used to identify any differences in the temporal changes of NT-proBNP concentrations in patients with and without an event.
Results: In our cohort of 53 patients, a total of 176 NT-proBNP samples were analyzed. Patients has a mean±SD age of 56±13 years, eGFR of 57±25 ml/min/1.73m2, and BMI of 27±3 kg/m2. Thirty-one (58%) patients were implanted with the HeartMate 2, and 22(42%) with the HeartMate 3. Median NT-proBNP (post-implant) was 175 [IQR 107-358] pmol/l (equal to 1488 [IQR 910-3043] pg/ml). During a median follow-up time of 447 days [IQR 229-739], 10 patients experienced a pump thrombosis and 3 patients died of CV causes. Temporal changes in NT-proBNP were not associated with subsequent events, neither for the composite endpoint (HR: 1.0 [0.49-2.0], p=0.99), nor for each component; pump thrombosis (HR: 0.85 [0.37-1.9], p=0.69), CV death (HR: 1.6 [0.42-6.0], p=0.50).
Conclusion: Our analysis did not show that changes over time in NT-proBNP concentrations were associated with the outcome of pump thrombosis or CV death.

Gastrointestinal bleeding after left ventricular assist device implantation: serious problem, multi factorial cause, no proved treatment?

T Popov[1]; J Dejanovic[1]; A Redzek[1]; M Golubovic[1]; N Gocic Peric[2]; M Petrovic[1]
[1]*University of Novi Sad, Medical Faculty, Novi Sad, Serbia*; [2]*Institute of Cardiovascular Diseases of Vojvodina, Clinic for Cardiology, Novi Sad, Serbia*

Introduction: Gastrointestinal bleeding (GIB) is a serious problem after left ventricular assist device (LVAD) implantation. Its incidence has been estimated between 15% and 61%. LVAD associated gastrointestinal bleeding is associated with significant morbidity, hospital readmission and cost.
Case presentation: A male, 63 years old, with ischaemic cardiomyopathy, low systolic function of left ventricle, recurrent hospital treatment because of heart failure, underwent LVAD implantation. Patient was under treatment for sideropenic anemia, has diabetes mellitus non insulin dependent and no other significant co-morbidity. In postoperative period there was persistent anemia with repeated blood transfusion. High inflammatory markers were registered and no causative agent isolated. There was postoperative pericardial and pleural effusion, regularly checked by echo and RTG. Drainage of pericardial effusion, which was hemorrhagic, was on 5th postoperative day done, and left pleural, which was serohemorrhagic, on 9th and 22nd day. The drop in hemoglobin value was further present with repeated blood transfusion, and no clear signs of blood loss or hemolysis. On 24th postoperative day melena was registered. Patient underwent gastroduodenoscopy, erosive gastritis was found, but there was no active bleeding lesions. As melena persisted, colonoscopy was performed and small intestine scintigraphy, with no bleeding lesions detected. Colon was filled with hematized content. As there was further significant drop in red

blood count exploratory laparotomy with colonoscopy, ileoscopy and gastroduodenoscopy was performed, no bleeding lesion was detected, but intestinal walls were coated by parietal coagulums. Somatostatin 0,1 mg s.c. TID was introduced. GIB was most likely multifactorial, caused by anticoagulation, acquired Von Willebrand syndrome, platelet dysfunction and increased incidence of arteriovenous malformations due to chronic low pulse pressure. Treatment with somatostatin lasted twenty days and then mesalazin 2 gr in one dose for 2 weeks was continued. Anticoagulant therapy included acenocumarol with strict control of prothrombic time. No further drop in red blood count and GIB were registered.
Conclusion: Gastrointestinal bleeding is multifactorial and related to lowered pulse pressure with relative hypoperfusion of the gut, a systemic decrease in high molecular weight Von Willebrand factor multimers, and impaired platelet aggregation, with angiodysplasia and gastro-duodenal erosive disease as predominant etiologies. Somatostatin is an option for advanced medical management but has not yet been proven in a large cohort of patients.

P391
Clinical outcome and issues of implantable left ventricular assist device (LVAD) treatment at a non-transplant institution located in central Tokyo

Y Yumi Yasui[1]; T Sasaoka[1]; T Fujiwara[1]; T Yonetsu[1]; Y Maejima[1]; T Mizuno[1]; M Goya[1]; H Arai[1]; K Hirao[1]
[1]Tokyo Medical And Dental University, Tokyo, Japan

Background: Organ donation is quite limited due to the traditional value of life, death and religious outlook in Japan; however, the numbers of patients who benefit from LVAD therapy is increasing after approval of implantable LVAD in 2011. Even though the majority of patients with advanced heart failure were treated in heart transplant institutions in central Tokyo, but some patients were forced to be treated in non-transplant LVAD institutions for some reasons, i.e. borderline heart transplant candidacy.
Purpose: We sought to analyze the clinical outcome and issues of LVAD therapy in a non-transplant institution.Method and Results: We retrospectively reviewed 18 consecutive patients who were treated with implantable LVAD between 2011 and 2018. Underlying disease of the patients were dilated cardiomyopathy (n=9, 50%), ischemic cardiomyopathy (n=3, 17%), myocarditis (n=2, 11%), and the others. Overall survival rate is satisfactory good; 94% (17/18 patients) with average support duration of 1023±310 days. Among them, 10 patients (56%) were cardiogenic shock at the time of admission, and all of them but one were supported by temporary circulatory assist devices (IABP only n=1, IABP+V-A ECMO n=8). All those patients underwent paracorporeal LVAD as a bridge to candidacy before converted to implantable device. Median duration between admission and registration of heart transplant list was 64 days in bridge to candidacy patients, which leads to significantly longer hospital stay in those than de-novo implantable LVAD patients (median 222 vs 157 days, $p<0.05$). 9 patients (50%) experienced at least one event of re-admission, mostly for the treatment of driveline infection.
Conclusion: In the locational and institutional circumstances, majority of the patients treated in our institution were bridge to candidacy patients; however, our data showed LVAD therapy provides considerable survival benefits even for those patients. High prevalence of re-admission and long hospital stay are the common issues to be addressed.

P392
The role of LVAD coordinator in programe for mechanical circulatory support. One year single centre experience.

Z Vasic[1]; V Maricic[1]; S Josifovic[1]; N Simic[1]; J Vukasinovic[1]; S Boric[1]
[1]Cardiovascular Institute Dedinje, Belgrade, Serbia

Background: Heart failure is a life-threatening condition in which the heart is not strong enough to pump enough blood to meet the body's needs. The new artificial heart technology - left ventricular assist device (LVAD) has in recent years provided new life and hope for patients.To establish successful VAD programe for mechanical circulatory support (MCS) , a serious planning and organization of educated personnel is required. The VAD coordinator is an important part of the VAD team and involves serious inpatient and especially, outpatient care and helps to bridge the technical and medical aspects of the field.
Methods: Our LVAD core team has cardiologists, cardiac surgeons, intensive care spacialists, anestesiologists,perfusionists, physical therapists, LVAD coordinator/nurse and a team of educated nurses from intensive care unit and cardiac surgery department. The role of LVAD coordinator is to integrate all team, starting from patient selection.
Results: Our LVAD team has one year experience in selecting patients for LVAD implantation, starting from the initial evaluation and following the continuum of care including pre procedure, post procedure, and continued follow-up post VAD implantation. We have 8 implanted CF-LVAD (6 bridge to transplantation and 2 patients for destination therapy). Caring for the hospitalized patient with an LVAD begins with a thorough assessment of both the patient and LVAD. Monitor blood pressure and mean arterial pressure (MAP); the goal is 60 mm Hg to 80 mm Hg. Elevated MAP decreases flow and perfusion. The LVAD requires regular care and system checks, including power-source changes, daily self-tests, and driveline dressing changes. Performing these tasks by LVAD coordinator team in the hospital provides teaching opportunities for patients and caregivers. LVAD coordinator is available for counceling 24/7. Most frequent questions are regarding INR level, blood pressure measurment and drive line dressing. Every follow up visit is scheduled and assisted by LVAD coordinator.
Conclusion: The kee role of LVAD coordinator is very clear, since he /she is liaison among physicians, staff, patients, families, and payers to ensure effective utilization of resources, education and coordination of care. LVAD coordinator ensures maintenance of electronic database, and submits patient demographic, medical and progress report information. LVAD coordinator participates in the department quality improvement program and strives to optimize patient outcomes through patient education and clinical expertise.

P393
Prevalence, predictors & outcomes of vitamin D deficiency in heart failure patients in an ambulatory care setting in Ireland.

L Laura O'connor[1]; T Mannion[1]; BF Mcadam[1]; S Fitzgerald[1]
[1]Beaumont Hospital, Heart Support unit, Dublin, Ireland

Background: The TILDA study determined 1 in 8 older Irish adults are deficient in vitamin D, however limited data exists on vitamin D levels in the heart failure population in Ireland. Various studies have investigated the role of Vitamin D in improving outcomes in heart failure. Vitamin D deficiency was reported as an independent predictor of mortality in patients with heart failure. Supplementation of patients with HFrEF in the Vindicate study showed a modest improvement in left ventricular function. Purpose: To examine the prevalence, predictors and outcomes of low 25-hydroxyvitamin D (25(OH)D) levels in heart failure patients attending an ambulatory setting.
Methods: Retrospectively 85 (53 males: 31 females) patients in the period February to December 2018 were included. Serum vitamin D levels were obtained, with patients categorized to Vitamin D deficient or non-deficient. Demographic descriptors including; age, gender, heart failure type, etiology, NYHA classification, biochemical measures including NTproBNP, CRP, GFR, creatinine, phosphate, calcium, magnesium & albumin were extracted. Number of admissions (all cause & cardiovascular) & mortality data was also collected over the intervening months. Chi Square analysis was completed to assess for associations. A subgroup analyses was conducted to assess response to vitamin D supplementation in patients with vitamin D deficiency (20 treated/17 non treated) in the above outcomes.
Results: 44% of patients had clinically significant Vitamin D deficiency (vitamin D level <50) with mean vitamin D levels 29.2±10.4. A statistically significant relationship was found between gender & vitamin D levels with males having a greater levels of deficiency compared to females (33.3% vs 10.7% p0.04). No other statistically significant relationships were revealed between demographic variables, biochemcial measures & vitamin D levels ; however there was a trend towards vitamin D deficiency in patients with ischemic etiology (p0.08). There was no significant relationship with vitamin D level on admissions & mortality; however there was a trend toward increased admissions for cardiovascular causes in patients who were vitamin D deficient (25% vs 13.1%, p0.07).
Vitamin D supplementation was initiated in 20 patients. Interestingly, pre post test analysis revealed vitamin D levels improved in both treated & non treated vitamin deficient patients (p value0.02 versus p0.05). Moreover, there was no association between vitamin D supplementation & outcome measures; GFR, NYHA class, admissions & mortality.
Conclusions: 44% of our sample had vitamin D deficiency with males more likely to be deficient. Vitamin D deficiency did not significantly affect patient's outcomes in this small study with relative shorter term follow up. The study showed an improvement in vitamin D levels whether patients were taking vitamin D which may have confounded an ability to see any impact on outcomes with active supplementation.

P394
Effect of therapy with ARNI on cardiac remodelling, functional and biomarker responses in selected cohort of patients with HFrEF and influence of aetiology, gender and medication dose.

T Mannion[1]; L O'connor[1]; J Kelly O Haire[1]; G O'gara[1]; BF Mcadam[1]
[1]Beaumont Hospital, Supportive Heart Service, Dublin, Ireland

Background: The PARADIGM HF trial demonstrated the therapeutic effect of ARNI in reducing morbidity and mortality in HFrEF. However, studies demonstrating ARNI's effect in modifying the remodelling process are scant. Additionally, the influence of HF aetiology on the degree of reverse remodelling following treatment with

ARNI is lacking. Purpose: To explore the therapeutic effect of ARNI in reverse remodelling of HF patients and determine the role of underlying HF aetiology, gender & medication dose on these outcomes. Method: Data from 90 HFrEF patients were collected (74 male: 16 female) with patients categorised based on HF aetiology (55 ischemic: 35 non-ischemic), prior to initiating ARNI & 12 months post achieving maximum tolerated dose. Indices of cardiac function were recorded including LVEF & LVIDd with neurohormonal cardiac biomarkers (NTproBNP). Functional capacity was determined based on NYHA Class. Paired sample t-test was completed to assess for statistically significant changes. Results: Median maximal tolerated dose for all patients was 49/51mg BD, 97/103mg BD for non ischemic patients and 49/51mg BD for ischemic patients. A statistically significant mean increase of 7.9% in LVEF was revealed among all patients (p0.00). This remained significant among groups categorised based on HF etiology however there was a greater increase in LVEF in non-ischemic as compared to ischemic (10.2% vs 5.4%, p0.01). Chi Square analysis revealed no statistically significant dose dependent relationship with LVEF (p0.29). LVIDd also reduced by mean of 0.4 cm (p0.04) which remained significant for non-ischemic patients (p0.02) but not for ischemic patients (p0.47). NTproBNP levels reduced from 2252 pg/mL to 1560 pg/mL (0.01) which remained clinically significant for ischemic (p0.02) and non-ischemic patients (p 0.02), though a greater reduction was found in ischemic patients (-916 pg/mL vs -338 pg/mL). A statistically significant reduction in NYHA Class (p0.00) was revealed among all patients which remained significant ischemic and non-ischemic patients (p0.001 vs 0.000). Gender did not influence degree of cardiac remodelling based on LVEF (0.55), LVIDd (0.27) or NTproBNP (0.87), however males appeared to have greater functional improvement following treatment than females (p0.00 vs p0.68). Conclusion: This small study assessed the effect of ARNI therapy on cardiac structure & function in HFrEF patients. These findings indicate that treatment with ARNI results in favourable effects on reverse remodelling, neurohormonal indices and functional improvement. The response was similar in ischemic and non-ischemic patients, but increases in LVEF and LVIDd were significantly greater in non-ischemic patients. Functional improvement was greater in males than females although this did not correlate with clinically significant improvements in other measures of cardiac remodelling based on gender. No dose dependent relationship was revealed in this small-scale study.

P395

Aerobic exercise, designed with individualized method based on lactate threshold definition, initiate reverse myocardial remodeling in heart failure patients

T Tatiana Lelyavina[1]; MYU Sitnikova[1]; VL Galenko[1]; MA Bortzova[1]; PS Kozlov[1]
[1]Almazov Federal Center of Heart Blood & Endocrinology, Saint Petersburg, Russian Federation

Funding Acknowledgements: RSF 16-15-10178; 2016-2018:

Background. Finding ways to non-pharmacological effects on myocardium is very relevant. Objective. To evaluate the effects of long-term aerobic training, designed with individualized method based on lactate threshold definition, on myocardial remodeling inversion in heart failure patients and to find its predictors. Methods. We evaluated 143 HF patients, mean age 51±3.8, 98 men, with NYHA class III, LVEF 31,6±2,1%. CPET performed on a treadmill ("Oxycon Pro") at baseline, in every 8 weeks and after 9 months. All patients were randomized into following groups: 83 patients of study group (SG) mean age 53±4.3, 61 men, BMI 23±3,6 kg/m2, with NYHA class III, LVEF 29,3±4,0%, atrial fibrillation 13%, anemia 5%, chronic obstructive pulmonary disease 35%, CRT 23%, who underwent physical rehabilitation program (PRP), calculated due to lactate threshold; and 60 HF patients control group (CG) mean age 52±5.1, 45 men, BMI 25±4,1 kg/m2, with NYHA class III, LVEF 31,5±5,8%, atrial fibrillation 10%, anemia 8%, chronic obstructive pulmonary disease 41%, CRT 15%, who underwent physical training, calculated based on VO2 percentage. Results. At baseline CPET results in both groups did not significantly differ. V2 at lactate threshold and V2peak were 8.8±0,5; 13,5±0,9 ml/min/kg and 9.0±0.9; 13,6±1,2 ml/min/kg in study group and control group, respectively (p1=0,08, p2=0,07, respectively). After 9 months of training V2LT and V2peak were better in the study group than in control group: the increase of V2LT and V2peak was 15% and 20% in the main group, and 4% and 7% in the control group, respectively (p1<0,01, p2<0,01). After 9 months of aerobic training it was significant improvement of myocardial contractile function in SG patients: LA, at baseline and after training were 5,52±0,09 and 5,35±0,05sm; LVEDD 6,37±0,08 and 6,10±0,09sm; LVESD 5,91±0,12 and 5,68±0,08sm, LVEF 30±1,31 and 39,29±2,07%, p<0,05. In CG patients the improvement of myocardial contractile function was not observed: LA, at baseline and after training were 5,46±0,38 and 5,41±0,35sm; LVEDD 6,32±0,57 and 6,27±0,45sm; LVESD 5,91±0,50 and 5,87±0,29sm, LVEF 36±5,3 and 39,2±4,7%, p>0,05. We found correlation between LVEDD changes and duration of training (r=0,9, p<0,05), LVEDD changes and BMI (r= 0,7, p<0,05), LVEDD changes and b-blockers dose (r=0,4, p,0,05), LVSED changes and blood creatinine (r=-0,4, p<0,05). Conclusions. Aerobic exercise, designed with individualized method based on lactate threshold definition, increase exercise tolerance, improves myocardial contractile function more than aerobic training, calculated based on VO2peak percentage. Predictors of myocardial remodeling inversion in heart failure patients were: aerobic training duration (r=0,9, p<0,05), BMI (r= 7, p<0,05), b-blockers dose (r=4, p,0,05), blood creatinine (r=-4, p<0,05).

P396

High-intensity interval training alleviates consumptive coagulopathy in patients with heart failure

JS Jong-Shyan Wang[1]
[1]Chang Gung University, Graduate Institute of Rehabilitation Science, Tao-Yuan, Taiwan, Province of China

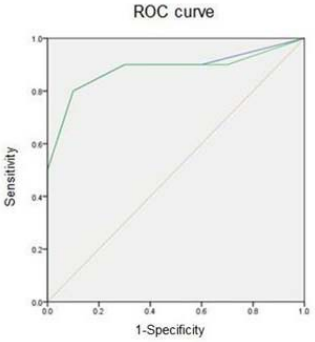
Background: Consumptive coagulopathy is associated with increased mortality in patients with heart failure (HF). Exercise may impact the risk of major vascular thrombotic events.
Purpose: This study investigates how high-intensity interval training (HIIT) influences the capacity of endogenous thrombin generation (TG) by modulating circulatory procoagulant microparticles (MPs) in HF patients.
Methods: Thirty-eight HF patients and 38 normal counterparts (N-C) were recruited into this study. The HF patients performed HIIT (3-min intervals at 40% and 80%VO2peak) on a bicycle ergometer for 30 min/day, 3 days/week for 12 weeks. Plasma TG kinetics, procoagulant MPs, coagulation-related factors, and oxidative stress/proinflammatory status were analyzed.
Results: Compared to N-C, HF patients exhibited (i) less endogenous thrombin potential (ETP) and TG rate, (ii) fewer levels of total and tissue factor (TF)-rich MPs derived from erythrocytes/leukocytes/platelets, (iii) lower TF and tissue factor pathway inhibitor (TFPI) concentrations and TF activity, and (iv) higher vascular endothelial shedding, myeloperoxidase, and interleukin-6 levels. After adding TF to plasma, HF patients revealed higher changes of ETP and TG rate than N-C did. However, HIIT diminished the extents of HF-declined ETP and TG rate and procoagulant MPs, which were associated with increased TF/TFPI concentrations and TF activity. Moreover, HIIT decreased vascular endothelial shedding and plasma myeloperoxidase/interleukin-6 levels in HF patients.
Conclusions: The HF progression reduces the capacity of endogenous TG, which is associated with decreased (or consumed) circulatory procoagulant MP levels. However, HIIT alleviates HF-induced endogenous TG reduction and vascular endothelial damage through recuperating TF-related coagulation activity and suppressing oxidative stress/proinflammatory status.

P397

Contributing factors to exercise induced desaturation during a six-minute walk test in pulmonary arterial hypertension

J-H Jung-Hyun Choi[1]; BJ Lee[1]; JY Shin[1]
[1]Busan National University Hospital, Busan, Korea (Republic of)

Objective: To evaluate the prevalence of exercise induced desaturation (EID) and elucidating the contributing factors in pulmonary arterial hypertension (PAH) patients.
Methods Analyze 20 pulmonary arterial hypertension patients' data (EID group = 10) from April 2016 to May 2018. Comparisons of background characteristics, comorbidity, trans-thoracic echocardiography (TTE), cardiac catheterization, pulmonary function test (PFT), 6MWT with gas analysis, body composition test and muscle power test between EID and non-EID patients were conducted.



Score	Sensitivity	1-Specificity
0	1.000	1.000
1.5	.900	.600
2.5	.900	.300
3.5	.800	.100
4.5	.500	.000
5.5	.400	.000
6.5	.200	.000
8	.000	.000

Results Epidemiological characteristics, TTE data and cardiac catheterization data did not differ between 2 groups. Forced expiratory volume in the first second (FEV1), 6MWD and peak oxygen consumption (VO2peak) were significantly low in EID group. We suggest a "predictive scale for exercise induced desaturation in pulmonary arterial hypertension (PSEID)". EID might be considered as PSEID is 4 and more, by 80% of sensitivity and 90% of specificity (figure 1).
Conclusion The EID was found in the half of PAH patients and FEV1, 6MWD and VO2peak were most relevant factors. Result of TTE and cardiac catheterization was not correlated with EID

P398

Effects of cardiovascular rehabilitation in heart failure patients with mid-range ejection fraction: is there age difference?

D Marinkovic[1]; M Deljanin Ilic[2]; V Stoickov[2]; B Ilic[1]; I Krstic[1]; D Petrovic[1]
[1]Institute for Treatment and Rehabilitation Niska Banja, Nis, Serbia; *[2]University of Nis, Medical Faculty, Institute of Cardiology Niska Banja, Nis, Serbia*

Background: The positive effects of exercise training in patients with chronic heart failure (CHF) are reflected in improving exercise tolerance, reduce symptoms and less hospitalization, increasing survival and improving quality of life (QOL). Elderly patients have more advanced CHF than younger because they tend to be more sedentary and thus do not note symptoms or do not receive a diagnosis of CHF until their cardiac limitation is advanced. Heart failure with mid-range ejection fraction (HFmrEF), the "middle child", as a new entity, in heart failure family, has limited data regarding exercise tolerance and training, functional capacity and QOL.
Objective: To evaluate the effects of short-term exercise training on physical exercise, tolerance and level of markers of inflammation, neuro-humoral activation, endothelial function and QOL in patients with HFmrEF, in relation to age.

Patients and Methods: The study involved 36 HF patients (21 male; mean age 60.5 ± 4.7 years, with established ischemic heart disease, which fulfill criteria for HFmrEF. All patients were included in three-week rehabilitation program in the residential center, based on strictly controlled and individually prescribed exercise training. Before and after rehabilitation, all patients were underwent exercise stress test, and from the veins blood samples, biochemical markers of inflammation, atrial natriuretic peptide (ANP), brain natriuretic peptide (BNP) an endothelin (ET) were determined. In relation to age, patients were divided into three groups: A (n=14, <60 yrs), B (n=10, 60-69 yrs) and C (n=8, ≥70 yrs).
Results: After rehabilitation, in group C, significantly lower serum ANP (p = 0.048), BNP (p=0,034) and ET (p=0,047) were registered, compared to the values before rehabilitation. In groups A and B, there was decreasing trend of these neurohormons after rehabilitation but without significance. After rehabilitation, value of BNP was lower in group C than in group B (p=0,067), and significantly lower than in group A (p=0,04), while ANP and ET did not show significant changes in all three groups. Inflammatory markers: erythrocyte sedimentation rate (ESR), hs-CRP, fibrinogen, and white blood cell count (WBC) after cardiovascular rehabilitation showed a decreasing trend but not significant, in all groups. Exercise tolerance improved in all groups (p <0.001 for all). After the rehabilitation in group C, heart rate at rest, was substantially lower than in the group A (p = 0.03) and B (p=0,038). The quality of life assessed by Minnesota Living With Heart Failure Questionnaire was improved in all groups (p=0,001).
Conclusion: Residential short-term rehabilitation decreased the level of neurohormons (ANP,BNP,ET) in patients with mid-range CHF, especially in patients older than 70 year. Those positive effects on neurohumoral status were associated with significant increase of exercise tolerance, improvement of QOL and decreasing trend of inflammatory markers.

P399

Does religious denomination influence coping in chronic heart failure?

AD Farcas[1]; MA Stoia[1]; CM Goidescu[2]; DL Mocan-Hognogi[1]; RM Chiorescu[2]; M Mocan[2]; FP Anton[1]
[1]University of Medicine and Pharmacy of Cluj Napoca, Department of Cardiology County Emergency Clinical Hospital Cluj, Cluj Napoca, Romania; *[2]University of Medicine and Pharmacy of Cluj Napoca, Faculty of Medicine, Department of Internal Medicine, Cluj Napoca, Romania*

Purpose. Chronic heart failure (HF) causes a marked physical and psychological discomfort, thus requiring an significant coping effort from patients. Achieving problem-centered or emotion-centered coping is influenced by a number of factors. Some studies support the adaptive - even active - character of religion as a coping mechanism in chronic HF, therefore, the aim of our study was to investigate how the denomination influences coping in chronic HF patients.
Methods. 96 patients with chronic HF (34.4% males and 65.6% females, mean age 68.4 ± 12.6) were included in the study after having signed informed consent, divided into two groups according to their denomination: Orthodox (55) and Reformed (44). The patients completed the MHLF (quality of life) and Brief-COPE (mechanisms of coping) questionnaires and undergone a semi-structured interview. The study methodology was approved by the Ethics Committee of the University of Medicine and Pharmacy "Iuliu Hatieganu" Cluj-Napoca; statistical analysis was done using SPSS 20.
Results. All patients reported a reduction in the quality of life with an important impact on all its three aspects: physical, emotional and social. In order to cope with it, Orthodox patients have turned to religion more than Reformed patients (69.1% vs 65.9%, p <0.05). The term "religion" was defined by 44.8% of patients as attending religious service at least once weekly, by 74% as reading or saying of daily prayer and by over 85.4% as having intrinsic religious beliefs and attitudes. Using this coping mechanism was more frequent in patients with more severe impairment of emotional and social aspects of quality of life and was associated with the use of emotional support (p <0.05). Reformed patients used more frequently "active coping" (84.09% vs 80%, p <0.05), "use of instrumental support" (79.5% vs. 76.4%, p <0.05) and "planning" (75% vs 72.7%, p <0.05) than Orthodox patients. Orthodox patients used more frequently "use of emotional support" (87.3 % vs. 81.8%, p <0.05), "positive reframing" (81.8% vs. 77.3%, p <0.05) and "self-blame" (78.2% vs 72.7%, p <0.05). The most common mechanisms (used in relatively equal proportions by both patient groups) (Fisher test, p > 0.05) were: "accepting", "venting", "denial", and "self-distraction". "Substance use" and "humor" were the least used coping mechanisms in both Orthodox and Reformed patients. Conclusion. Recourse to religion is an important and often used coping mechanism for patients with chronic HF, regardless of their denomination. However, denomination seems to influence the type of coping, in our study the Reformed patients using "problem-centered coping" more frequently, while Orthodox patients used "emotion-centered coping".

Lomonosov Moscow State University, Medical Research and Education Center , Moscow, Russian Federation; *[2]Altay State Medical University, Barnaul, Russian Federation*; *[3]Altay Regional Cardiology Centre, Barnaul, Russian Federation*; *[4]Ryazan State Medical University, Ryazan, Russian Federation*; *[5]Samara Regional Cardiology Dispensary, Samara, Russian Federation*; *[6]Northern State Medical University, Arkhangelsk, Russian Federation*; *[7]The postgraduate doctors' training institute, Cheboxary, Russian Federation*; *[8]Kuban State Medical University, Krasnodar, Russian Federation*; *[9]National Medical Research Centre named after V. A. Almazov, Saint-Petersburg, Russian Federation*

Funding Acknowledgements: Russian Heart Failure Society

Background Exercise training (ET) is highly recommended by ESC and Russian heart failure society guidelines, but it is still severely underutilized in heart failure (HF) patients all over the Russia.
Purpose
To explore current level of HF patients involvement in ET and describe potential barriers and motivations to ET as well as patients' personal characteristics which leading to positive attitudes to ET.
Methods
The study had a cross-sectional survey design. HF patients visiting Open clinics in 7 cities during 2018 Heart Failure Awareness Days were given the self-administered questionnaire containing questions about social and educational status, attitudes and believes about ET and motivation and barriers for ET performance. Questions describing HF features were filled out by medical practitioners. Code number were used to further de-identify the participants and ensure their confidentiality. Exact confidence limits (CLs) for proportions (as the parameters of multi-nominal distribution) were calculated using StatXcat-8 software (Cytel Inc., USA). CLs for the proportion difference and/or proportion ration were estimated applying the MOVER method.ResultsA total of 560 HF patients (52% women) of mean age (95% CI: 63 to 65 yr) were included. In average women were 3 years older than man (95% CI; for the age difference 1,3 to 4,9 yr). II-III NYHA FC- 90%. HFrEF- 49% (n=265). 62% (n=350) had non-cv comorbidities; 41% Diabetes; 25% - arthritis. In total 17% of patients (N=91) reported involvement in ET. Patients younger than their median age (62 yr for males and 65 yr for females) reported involvement in ET and desire to start exercise significantly more often than older patients. OR =2.3 (95% CI: 1,6 to 3,3, mid-p=0,00002). Patients with higher level of education were more likely to take part in ET or to express a desire to start OR = 2.7 (95% CI from 1.6 to 4.7, midp= 0,00015). Ability to influence the course of the disease was most important motivator for ET for the both genders. Proportion of this answer was 65% (95% CI; 26 to 81%) in males and 54% (95% CI: 36 to 72%) in women. Poor health condition was noted by 62% of patients as a main barrier for participation in ET. Only 55% of patients were aware that ET could be a treatment method for the HF, and only 50% of those patients got this information from the medical practitioner.

Discussion
Currently the level of HF patient's participation in ET is extremely low. Younger patients and patients with higher levels of education are more likely to participate in ET. Our study demonstrates that medical practitioners very unlikely prescribe ET as a treatment for HF.

Comparison of characteristics and benefits in patients with heart failure with reduced ejection fraction referred to a cardiac rehabilitation unit

J G Jesus Gabriel Sanchez Ramos[1]; P Toledo Frias[1]; S Martinez Huertas[1]; F Burillo Gomez[1]; T Gil Jimenez[1]; M Lopez Perez[1]; J Caballero Borrego[1]; P Martin De La Fuente[1]; A Baustista Paves[1]; E Moreno Escobar[1]
[1]*San Cecilio University Hospital, Granada, Spain*

INTRODUCTION: Cardiac rehabilitation (Rc) in patients with heart failure with reduce eyection fraction (HF-EFr) is still underused. Objective: to compare the characteristics and benefits of Rc in this patients.
METHOD: Prospective cohort study of patients referred to Rc in our center during 2016. Group 1 included patients with EF <40% and group 2 patients with EF≥ 50%. We analyzed clinical differences between groups, and then results in effort capacity and risk factors control.
RESULTS: Of 334 patients referred to Rc, 44 were group 1 (13.2% of all Rc patients) and 253 were group 2. 37 patients with intermediate EF were excluded. The baseline clinical characteristics of both groups were very similar (view table), except for a lower origin after an ACS and a tendency to higher baseline blood glucose in group 1. Only one third of the patients had a functional grade ≥ II
219 patients completed the Rc program with a dropout rate of 26%. 87.4% of group 2 performed only 12 to 16 sessions, compared to 63.9% of group 1 which required 24 sessions. In both groups, the exercise capacity improved before and after the Rc, measured by ergometry in METs (8.1 + -2.3 vs 9.7 + -1.9, increase of 1.58 METS, 95% CI 1.35 -1,80, p 0,0001), percentage of maximum heart rate reached (72 + -21 vs 58 + -33, decrease 14%, IC95% 10.7-17.7, p 0.0001) and final heart rate training (100.7 + -15 vs114.5 + -17, increase 13.7 bpm, 95% CI 12.6-14.8, p 0.0019), although there wasn´t difference in these benefits between the two groups at the end of the program (figure). Significant benefits were obtained in weight control, abdominal perimeter, LDL cholesterol and basal glycemia, but without differences between the two groups after the program.
CONCLUSIONS: Patients with HF-FEr that are referred to Rc represent a minority, have clinical characteristics and obtained benefits similar to the rest.

Baseline clinical characteristics

	Group1(n=44)	Group2(n=253)	P

Wearable defibrillator for the prevention of sudden cardiac death: our preliminary experience.

ML Fais[1]; A Scalone[1]; D Daniele Pasqualucci[1]; GF Tola[1]; B Schintu[1]; A Setzu[1]; N Sanna[1]; PP Orru[1]; M Corda[1]; G Befacchia[1]; G Binaghi[1]; A Giardina[1]; M Porcu[1]
[1]*G. Brotzu Hospital, Cardiology, Cagliari, Italy*

Introduction. The implantation of an ICD for primary prevention of sudden cardiac death (SD) is indicated in patients at high risk according to current European Society of Cardiology (ESC) Guidelines. However, in some patients it is not possible to quantify immediately the arrhythmic risk and the indication to an ICD should be re-evaluated after a period of observation and pharmacological therapy optimization. Wearable defibrillators (WD) can protect against fatal arrhythmic events during this period. Purpose. We report our preliminary experience with the use of WD as a bridge to decision. Methods. Forty-seven patients (40 M; mean age 51,9 years; range 11-76) underwent WD placement between Aug. 2016 and Aug. 2018. Indication for WD was ischemic LV dysfunction in 18 patients (recent myocardial infarction and/or left ventricular dysfunction treated with revascularization), dilated cardiomyopathy in 12, ICD explant in 2, other causes in 15 patients (tachycardiomiopathy, myocarditis, congenital diseases, etc.). All patients wearing WD have been followed by remote monitoring (LV Network, Zoll). Until the final decision, pharmacological therapy the diagnostic process was completed and pharmacological therapy was individually optimized. Results. Patients wore WD for an average of 71.6 days (range 3-27). The average daily use was high (22.4 hours). An effective electrical therapy was delivered in only one patient for a ventricular fibrillation and normal heart rhythm was restored after 4 shocks. In one case, the device recorded a sustained, self-terminating ventricular tachycardia. An inappropriate shock on supraventricular tachycardia was delivered in one patient. After the observation period, 26 patients (55.3%) underwent ICD implantation. For 16 patients (34%) the ICD implantation was not longer indicated. Among them, 15 showed a recovery of the systolic function and 1 underwent cardiac transplantation. Of the remaining 5 patients, 2 still have active WD, 2 refused the ICD implantation, and 1 died from non-cardiac causes. A patient presented a transient allergy, which did not excluded the use of WD. Conclusions. In our experience WD allowed to critically re-evaluate the ICD indication in over 1/3 of the potential candidates. The device adequately protected 1 patient against a potentially lethal arrhythmia. The device was well tolerated, with a satisfactory wearing time.

P403
Subacute ICD-lead perforation in patients with noncompaction cardiomyopathy

B Schneider[1]; U Desch[1]; H Keller[2]; S Klotz[3]; P Jirak[2]; C Stoellberger[2]
[1]*Sana Kliniken, Lübeck, Germany*; [2]*Rudolfstiftung, Vienna, Austria*;
[3]*Universitätsklinikum Schleswig-Holstein, Luebeck, Germany*

Introduction: Noncompaction cardiomyopathy (NCCM) is a rare abnormality characterized by a hypertrabeculated left ventricular wall with a sponge-like appearance and a two-layered structure with a subepicardially located compacted zone and a subendocardially located noncompacted zone. The right ventricle may also be affected. Cardiac manifestations comprise heart failure, thromboembolism and malignant arrhythmias. There is evidence that guidelines for primary prevention of sudden cardiac death (SCD), developed for dilative or ischemic cardiomyopathy, may also apply to patients with NCCM.
Subacute perforation of the right ventricular (RV) free wall by an ICD lead is a rare complication and with use of newer devices has been reported in less than 1%. However, little is known about this complication in patients with NCCM.
Methods: Over a 5-year period (2009-2013), ICD leads had been implanted in 248 patients by 2 experienced physicians. In all cases active fixation leads (Medtronic Inc.) were used. The rate of subacute RV wall perforation was compared in patients with NCCM (diagnosed by echocardiography and/ or cardiac magnetic resonance imaging) and those with other cardiac abnormalities.
Results: ICD leads were implanted for primary prevention of SCD in 121 patients (49%) and for secondary prevention in 127 patients (51%). Overall, 55/248 patients (22%) with left bundle branch block and heart failure received a CRT-D system.
Implantation of an ICD lead was performed in 8 patients with NCCM (2 female, 6 male, mean age 59±12 years). The indication was primary prevention of SCD in all patients. A CRT-D was implanted in 5 of the 8 NCCM patients (62%). Complications occurred in 2/8 patients: 1 pocket infection and 1 subacute lead perforation of the RV free wall 10 days after implantation requiring emergency cardiac surgery. During a follow-up period of 1.5 to 5 years no additional lead perforation was observed.
Subacute RV perforation of an ICD lead occurred in 1/8 patients with NCCM (12.5%) versus 0/240 patients with various other cardiac abnormalities (p=0.03). No patient with NCCM had obvious RV involvement by cardiac MRI and/ or echocardiography. This observation raises the question that despite its normal appearance there may be subtle structural RV abnormalities in NCCM favouring ICD lead perforation.
Conclusion: Subacute RV perforation after ICD implantation is more frequent in patients with NCCM. A septal insertion site of the lead tip may be preferable since the interventricular septum is rarely involved in the noncompaction process.

P404
Impact of sacubitril-valsartan compared to angiotensin inhibition on ventricular tachycardia burden in heart failure patients with reduced ejection fraction and implantable defibrillator

K Polymeropoulos[1]; A Stavrati[1]; J Zarifis[1]
[1]*General Hospital G. Papanikolaou, Cardiology Department, Thessaloniki, Greece*

Purpose: To determine the effect of Angiotensin receptor - neprilysin inhibition (ARNI; sacubitril-valsartan) compared to angiotensin receptor inhibition on ventricular tachycardia burden in recipients of Implantable Cardioverter Defibrillator (ICD) and Heart Failure with reduced ejection fraction (HFrEF).

Methods: We included 42 patients (31 men), mean age 67±9 years with HFrEF, left ventricular ejection fraction ≤35% and New York Heart Association class ≥II. Most of the patients (68%) had ischemic cardiomyopathy and secondary prevention of Sudden Cardiac Death (SCD) was the main indication (57%) for ICD implantation. All patients were treated with Angiotensin Converting Enzyme Inhibitors (ACE-I) or Angiotensin Receptor Blockers (ARB) plus beta-blockers and Mineralocorticoid Receptor Antagonist (MRA) for 12 months (group A) and subsequently they switched to ARNI for the next 12 months (group B). All detected sustained ventricular tachycardia (VT) episodes and appropriate interventions (antitachycardia pacing-ATP and shocks) were thoroughly reviewed and analyzed.
Results: All patients received the highest tolerated doses of their medications for HFrEF. There was no difference between groups concerning the dose of b-blocker or MRA. No statistically significant difference was observed on recorded VT episodes (9 VT episodes in 8 patients in group A versus 7 VT episodes in 7 patients in group B, p=0.776); delivered shocks (5 shocks in 4 patients and 3 shocks in 3 patients respectively, p=0.693), and ATP interventions (14 ATP in 8 patients and 9 ATP in 6 patients respectively, p=0.558).
Conclusions: Angiotensin receptor - neprilysin inhibition compared to angiotensin receptor inhibition did not reduce VT burden and appropriate ICD interventions (shocks or ATP) in our cohort of HFrEF patients with an ICD.

P405

Effect of loading dose of sacubitril-valsartan on the incidence of ventricular tachycardia as assessed by ICD interrogation -single center experience

L Dujka[1]; J Vranova[2]; J Simon[1]; J Petru[1]; J Sediva[1]; M Chovanec[1]; M Janotka[1]; P Hala[1]; P Neuzil[1]; F Filip Malek[1]

Funding Acknowledgements: Supported by MH CZ - DRO (Nemocnice Na Homolce – NNH, 00023884), IG170501

Background: Sacubitril-valsartan (SV) has been shown to reduce risk of sudden cardiac death compared to enalapril in patients with HFrEF in the PARADIGM-HF trial. In one recent study, SV reduced significantly episodes of non-sustained-VT, sustained VT and need for ICD shocks after 9 months follow-up. In another observational single center study, starting with SV was associated in 6 of 108 patients with arrhythmogenic storm.
Study objective: to evaluate the effect of SV treatment on incidence of VT as assessed by ICD in our center.
Patients and methods: we analyzed data from 52 patients with HFrEF frome a tertiary HF clinic, and who started treatment with SV from October 2017. Total number of 46 patients had ICD implanted in our centre, one patient stopped SV for intolerance, one patient died and one patient received LVAD during follow-up. Complete data from ICD interrogation before and after SV were finaly available in 24 patients. We analyzed any NSVT, VT or ICD therapy before and after SV therapy at the last and follow-up ICD interrogation at pacemaker clinic. All patients were on optimal therapy including maximal tolerated doses of BBs, MRAs (and diuretics) and therapy did not change during follow-up of a mean 12 months.
Results: Mean age of the patients cohort (22 men and 2 women) was 64 years, 11 patients had ischemic and 13 pts on-ischemic cardiomyopathy. Median NYHA before SV was 3 and mean LV EF 27%. Mean SV loading daily dose was 137 mg (median 100 mg). Any VT was revealed in 15 patients before SV therapy, from that group in 7 patients before, but not after SV therapy, and in 8 before and after SV therapy. In 4 patients, VT was not present before SV therapy but after SV therapy, in 5 patients none VT before and after therapy. Difference was not significant.
Conclusion: Loading dose of sacubitril-valsartan had no effect on the incidence of VTs in our HFrEF patients cohort. Our observation is limited by a small number of subjects. We need more evidence on the effect of SV on the incidence of VTs as the current available data are contradictory.

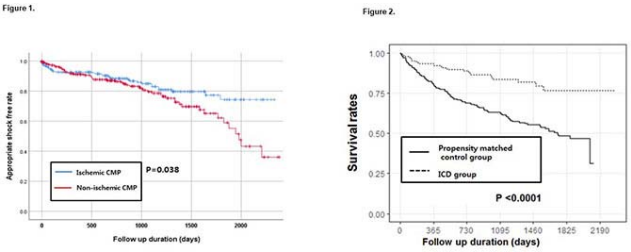
Primary prevention of implantable cardioverter-defibrillator in systolic heart failure: result of Korean multicenter study

D Kim[1]; SE Lee[2]; JO Choi[1]; ES Jeon[1]
[1]Samsung Medical Center, Internal medicine, Seoul, Korea (Republic of); *[2]Asan Medical Center, Seoul, Korea (Republic of)*

Background The benefit of implantable cardioverter-defibrillator (ICD) has been well documented in systolic heart failure from randomized trials, however, real world data of efficacy of ICD in Asian heart failure patients is very limited.
Purpose We investigated efficacy of primary prevention ICD using a large multicenter Korean registry cohort.
Methods Retrospective multicenter study was performed in 15 Korean hospitals. A total of 568 patients with systolic heart failure (LVEF ≤ 35%) who referred for ICD for primary prevention during Jan 2012- Dec 2016 were enrolled. Efficacy of ICD was compared to propensity matched control group from Korean Acute Heart Failure (KorAHF) registry (n=1406). All-cause mortality were compared between 216 patients from ICD group and corresponding propensity matched control group (n=216). All-cause mortality and incidence of appropirate shock and inappropriate shock were compared between ischemic vs. non- ischemic cardiomyopathy patients in ICD group.
Results During follow up durations of 35.1 ± 19.6 months, 39 patients died in ICD group. Mean age of ICD group was 65 year old and 67% were men. In ICD group, 195 (34%) were ischemic cardiomyopathy. In ICD group, all-cause mortality did not differ between ischemic and non-ischemic cardiomyopathy, however, incidence of appropriate shock was significantly higher in non-ischemic cardiomyopathy (HR: 1.58, 95% CI: 1.022-2.436, p=0.038) (Figure 1). Appropriate shock-free survival started to show difference after 40 months of follow up. All-cause mortality was significantly lower in ICD group compared to propensity matched control group (HR:0.357, 95% CI: 0.233-0.547, p<0.001) (Figure 2).
Conclusion From our multi-center real-world data, ICD for primary prevention in Korean systolic heart failure patients showed significant benefit over mortality. Although overall survival did not differ between ischemic and non-ischemic patients were similar, appropriate therapy was significantly higher in non-ischemic cardiomyopathy, reflecting delayed benefit of ICD in non-ischemic cardiomyopathy patients.



Figure

P407

Etiology of dilated cardiomyopathy as the leading predictor of efficiency of implantable cardioverter-defibrillators in prevention of sudden cardiac death

E A Elena Solovyova[1]; OV Blagova[1]; VP Sedov[1]; EA Kogan[1]; EV Zaklyazminskaya[1]; AV Nedostup[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Purpose: to study the predictors of efficiency of ICD/CRTD in prevention of sudden cardiac death (SCD) in patients with dilated cardiomyopathy (DCM).
Methods: 275 patients with DCM syndrome were included (185 males; 46.8±12.5 years). Inclusion criteria were left ventricular end-diastolic diameter (LV EDD) more than 5.5 cm and LV ejection fraction (EF) less than 50%.The average EF 37.8±11.6% and EDD 6.5±0.8 cm. Patients with coronary artery stenoses more than 50% were excluded. Cardioverter-defibrillators were implanted in 78 (28. 4%) of patients (54 males, 48.8±12.8 years): 43 ICD, 35 CRTD. The follow-up was 14 [6; 120] months.
Results: defibrillators were implanted in patients with more severe dysfunction: EDD (6.7±0.8 vs 6.4±0.8 cm in patients without devices, <0.005), EF (32.5±9.5 vs 40.1±11.8%, <0.001), RV (3.4±0.8 cm vs 3.1±0.8 cm, <0.05), pulmonary artery systolic pressure (45.4±16.6 vs 49.6±15.0 mmHg, =0.02), mitral regurgitation (2.0 vs 1.5, <0.005). The following causes of DCM syndrome have been identified: the isolated myocarditis (n=137, 49.8%), the primary (genetic) DCM (n=54, 19.6%), the genetic basis with myocarditis (n=68, 24.7%) and anthracycline-induced cardiomyopathy (n=4, 1.5%). Genetic forms of DCM were represented by non-compact myocardium (n=64), ARVC (n=12), TTR-amyloidosis (n=1), myopathy (n=6). The pathogenic mutations in the genes LMNA (n=1), DES (n=2), DSP (n=2), EMD (n=2), PKP2 (n=1), MUH7+MyBPC3 (n=2), MyBPC3 (n=4) were detected. The appropriate shocks rate (ASR) was 21. 8%. The only reliable predictor of ASR was identified the genetic nature of DCM syndrome (in combination with myocarditis in 67% or isolated in 30% in comparison with 35/20% in patients without ASR, p<0.005, AUC 0.733, RR 1.66, 95% CI 0.711-3.885). In patients with shocks were detected the higher frequencies of stable/unstable VT (22 / 67%) in comparison with patients without shocks (1.7 / 73%, =0.06), a low QRS voltage (39 vs 13%, <0.05), absence of LV hypertrophy signs on the ECG (83% vs 53%, =0.07). The average LVEF was higher in patients with ASR (34.4±9.4%) in comparison with patients without ASR (25.9±9.0%), <0.003. There were no differences of NYHA class, the sizes of cardiac chambers. The mortality in patients with DCM was 18.9% (n=52), death + transplantation 22.5% (n=62), SCD 2.9% (n=8); in patients with defibrillators – 23.0%, 31.0%, 2.6%; in patients without devices – 17.3%, 19.3%, SCD 3.1%. There were no differences between the groups.

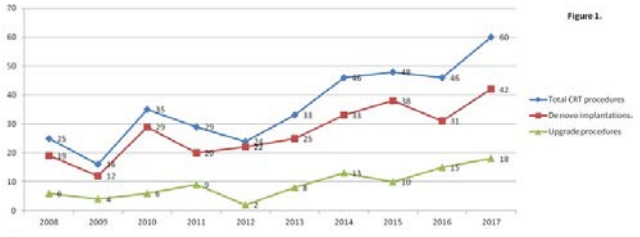
onclusion. Due to effective ICD therapy, death rate did not exceed those of less severe patients without devices. As criteria for ICD implantation, it is necessary to use the genetic nature of DCM, sustained / unsustained VT, the low QRS voltage, and the absence of LV hypertrophy (ECG). The genetic nature of DCM syndrome (alone or in association with myocarditis) is the more important predictor of appropriate shocks than EF.

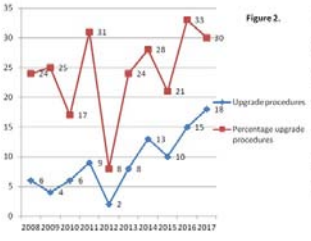
P408

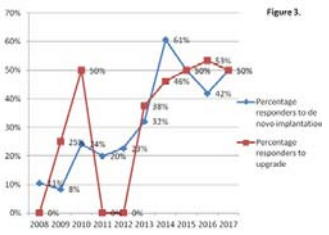
Temporal trend and outcome of de novo and upgrade CRT procedures; a ten year single centre retrospective analysis

M Matthew Schroyens[1]; D Dilling-Boer[1]; P Koopman[1]; J Schurmans[1]; J Vijgen[1]; J Verwerft[1]; R Geukens[1]; P JR Timmermans[1]
[1]*Heart Centre Hasselt, Hasselt, Belgium*

Introduction In appropriately selected patients with heart failure and reduced ejection fraction (HFrEF), cardiac resynchronisation therapy (CRT) reduces morbidity and mortality and improves symptoms and quality of life. As right ventricular pacing may induce heart failure, patients with a permanent pacemaker or implantable cardioverter-defibrillator (ICD) and high degree of right ventricular (RV) pacing can benefit from upgrade to CRT.
In 2016, the Heart Failure Association (HFA) published modified indications for CRT implantation. A class IA recommendation was given for patients with HFrEF, an indication for ventricular pacing and high degree AV block, regardless of New York Heart Association (NYHA) class. This might imply a similar recommendation for CRT upgrade in symptomatic patients with HFrEF and a high degree of RV pacing. However, due to lack of clinical trial evidence, a class IIbB recommendation was provided. The 2013 European Heart Rhythm Association (EHRA) guidelines provide a class IB recommendation for CRT upgrade, but only for NYHA class III and ambulatory IV.
Methods
A single centre retrospective analysis was performed. Data on every CRT implantation from January 2008 to December 2017 was collected. The CRT procedures were divided into de novo implantations and upgrades. The left ventricular ejection fraction (LVEF), as measured by the referring cardiologist, was used to assess response to treatment. We defined CRT-response as an improvement of LVEF to ≥45% after six months. Line plots were constructed, showing the number of procedures, the percentage of upgrades and the percentage of responders over the ten year period.
Results
From January 2008 to December 2017, 362 CRT devices were implanted. 25% of all procedures were upgrades (figure 1). The number of procedures increased yearly, up to 60 in 2017. The number of upgrades increased as well, from 6 in 2008 to 18 in 2017. There was no upward trend in percentage of upgrades, remaining 30% in 2017 (figure 2). Response to treatment was high, remarkably so in the last 4 years. Response rates were similar between de novo implantations and upgrades (figure 3).
Conclusion There is an increase in both de novo and upgrade CRT implantations. There is no upward trend in the percentage of upgrades, but the overall percentage is higher than would be suggested by the current HFA and EHRA guidelines. Previous surveys demonstrated an equally high number of upgrade procedures, reflecting the schism between guidelines and clinical practice.
Importantly, we report a similarly high rate of echocardiographic response to treatment in upgrades as in de novo implantations.







The current rate of upgrade procedures across Europe and the high rates of response in our single centre experience suggest that the current HFA and EHRA guidelines can be reinforced. Prospective randomised trials are needed to confirm the high response rates in CRT upgrade procedures to broaden current recommendations.

P409

The dynamics of quality of life in patients with congestive heart failure according to cardiac resynchronisation therapy response

GS Pushkarev[1]; VA Kuznetsov[1]; AD Sapozhnikova[1]; YA Fisher[1]; AM Soldatova[1]; TN Enina[1]
[1]*Tyumen Cardiology Research Center, Tomsk National Research Medical Center, Russian Academy of Scienc, Tomsk, Russian Federation*

Background: Research studies showed that cardiac resynchronisation therapy (CRT) improve the prognosis and quality of life (QoL) in patients with congestive heart failure (CHF) both in short- and long-term follow-up periods. However, the studies about QoL related to CRT response in patients are insufficient.
Purpose: To assess the QoL changes in patients with CHF during one year after CRT according to the response.
Methods: The study included 82 patients (68 males and 14 females) aged from 30 to 74 years (mean age 55.8±9.2) who underwent implantation of a biventricular cardiac pacemaker for CRT. Based on left ventricular end systolic volume (LVESV) all patients after CRT were divided into two groups: group 1 included 56 patients with reduction of LVESV by 15% and more (responders), and group 2 comprised 26 patients with reduction of LVESV by less than 15% (non-responders). The SF-36 questionnaire was used to measure QoL. The results of the questionnaire were represented as scores over the eight subscales: physical functioning (PF), role-physical functioning (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role-emotional (RE), and mental health perceptions (MH). Each item is scored on 0 to 100 range with 100 considered as absolute health. A higher score indicated a higher level of QOL. QoL assessment was performed before and one year after CRT. A total of 82 pair comparisons were performed (56 in responders group and 26 in non-responders group). Student's paired t-test was applied in statistical analysis for comparing normally distributed values, while the Wilcoxon nonparametric test was used when the sample data were not normally distributed.
Results. Group of responders one year after CRT had significantly higher rates of improvement of QoL in PF (45.2±26.0 before CRT vs 57.1±26.4 after CRT, p=0.001); in VT (46.5±20.8 vs 54.4±19.7, p=0.01) and in SF (60.9±26.4 vs 70.8±20.8, p=0.01). The statistical tendency towards QoL improvement was revealed in BP (57.5±25.1 before CRT vs 64.8±23.8 after CRT, p=0.08), in GH (45.3±16.4 vs 49.1±18.0, p=0.08) and in MH (57.7±18.9 vs 62.5±17.7, p=0.08). In the group of non-responders the statistical tendency towards decrease in QoL was detected during one year after CRT in RE (46.2±45.3 before CRT vs 26.9±41.1 after CRT, p=0.07). No significant differences were found in paired comparisons of other QoL indicators.
Conclusion: The study showed that QoL was generally improving one year following CRT in responders while a tendency towards decrease in RE was detected in non-responders.

P410

The impact of CRT therapy on valvular regurgitation differ between men and women

M Mance[1]; I Bitunjac[2]; R Matasic[1]; P Lepetic[3]; M Lovric-Bencic[1]
[1]*University Hospital Centre Zagreb, Cardiovascular diseases, Zagreb, Croatia*; [2]*General Hospital Slavonski Brod, Cardiology, Slavonski Brod, Croatia*; [3]*University Hospital Sestre Milosrdnice, Oncology, Zagreb, Croatia*

Funding Acknowledgements: No financial support

Introduction: This study was conducted on patients with symptomatic chronic heart failure (CHF) and implanted cardiac resynchronization therapy device (CRTD) according to guidelines in order to evaluate possible differences in mitral (MR) and tricuspid (TR) valvular regurgitation grades and left ventricle ejection fraction (LVEF) between male and female CRTD patients during follow up of 6 months after CRTD implantation.
Methods: We analyzed 135 patients (89 M, 46 F) with CHF due to any cause, implanted CRTD, optimal medical therapy with atrial fibrillation or in sinus rhythm. Clinical (NYHA class) and echocardiographic data (valve pathology, LVEF) were assessed before and 6 months after CRTD implantation. Using color and continuous flow Doppler, PISA, regurgitation volume and vena contracta measurements, MR and TR were stratified in 3 grades.
Results: Mean age of patients was 60 (±10) years.The results showed improvement in LVEF from 28% up to 37% (p<0.001) in all patients regardless of sex and age, as well as worsening of TR (p<0.001) and no difference in MR (p=0.195). In male patients (N=89), significant worsening in MR and TR was present (p<0.05) while there was no significant worsening in MR (p=0.42) nor TR (p=0.06) in female patients (N=46). In patients older than 60 years (N=82, female 27 (33%), male 55 (67%)), as

well as younger than 60 years (N=53, female 19 (36%), male 34 (64%)) significant worsening of TR grade was observed (p<0.05) while the grade of MR remained the same (p=0.255 and p=0.534).
Conclusion: Six months after CRTD implantation the grade of MR and TR remained the same in female patients while significant worsening in MR and TR grade was found in male patients. TR worsening was probably due to implanted electrodes. The changes in LVEF, TR and MR did not differ in patients younger and older than 60 years of age. Despite improvement in NYHA class and LVEF, the changes of MR did not meet our expectations.

P411
Efficacy, safety and cost of comprehensive versus standard remote monitoring of patients with cardiac resynchronisation therapy: design and rationale of the ECOST-CRT Study

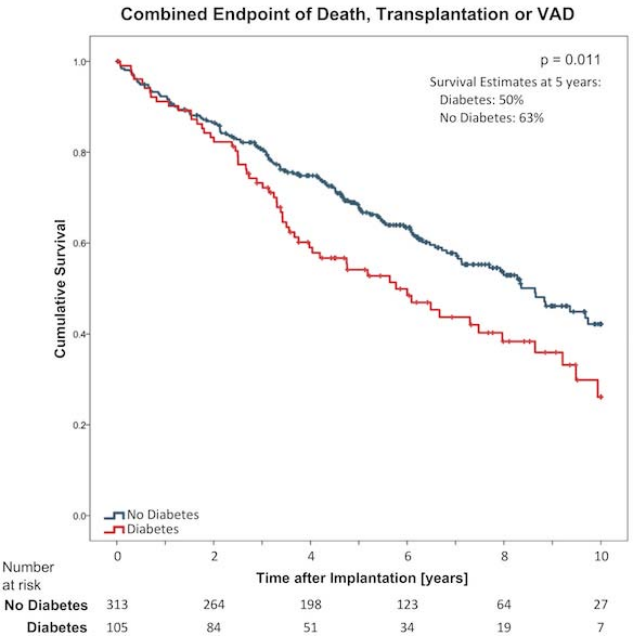
L Guedon-Moreau[1]; C Leclercq[2]; A Lazarus[3]; P De Groote[1]
[1]CHU Lille, Lille, France; *[2]Hospital Pontchaillou of Rennes, Rennes, France*; *[3]Clinique Medico-Chirurgicale Ambroise Pare, Neuilly sur Seine, France*

Background/Introduction: Heart Failure (HF) patients implanted with a cardiac resynchronisation (CRT) pacemaker or defibrillator warrant a close follow-up. Their hospitalisation rate for heart failure has a significant impact on their quality of life and health costs, and their risk of death remains high. Previous studies have demonstrated the clinical and economical benefit of remote monitoring considering rhythmic and technical parameters transmitted by conventional defibrillators. These results have yet to be confirmed in HF patients with CRT devices. In addition, remote monitoring of heart failure related parameters, combined with assessment of patients' symptoms, could improve their management.
Purpose: The primary objective of the ECOST-CRT study is to determine whether comprehensive remote follow-up in HF patients with CRT devices will reduce the combined endpoint of all-cause mortality or worsening heart failure hospitalisations, whichever comes first, when compared to basic remote monitoring, over a 27-month follow-up.
Methods: The ECOST-CRT study is a prospective, interventional, randomized, parallel group, national multicentre, open and blinded endpoint study. Approximately 652 HF patients just implanted with a CRT device will be randomized 1:1 to the standard (control) or the comprehensive remote monitoring (active) group before hospital discharge. Scheduled in-office visits will be mandatory 1-3 months after implantation, and after 9, 15, 21 and 27 months of follow-up. Remote monitoring will only address ventricular arrhythmias and technical parameters of the CRT device in the control group, while it will also include supraventricular arrhythmias, HF parameters, and patients' symptoms and clinical signs in the active group. Active patients will have to answer to automatically sent symptoms and signs questionnaires, monthly or triggered by worsening of remotely monitored parameters. Data will be available on line and will trigger notifications. The management of notifications will be performed according to decisional trees. Additional ambulatory visits will be scheduled if appropriate.
Results: The study should complete recruitment in 2019.

P412
Differential effect of CRT in diabetes mellitus: a retrospective cohort study

P C Kahr[1]; J Kuster[1]; P Kaufmann[1]; J Tonko[1]; D Hofer[1]; A Breitenstein[1]; AM Saguner[1]; F Ruschitzka[1]; J Steffel[1]; SH Winnik[1]
[1]University Heart Center, Cardiology, Zurich, Switzerland

Background: Cardiac resynchronization therapy (CRT) has become an important therapy in selected patients with heart failure with reduced left ventricular ejection fraction (LVEF), reducing morbidity and mortality. The effect of diabetes mellitus (DM) on long-term outcome in these patients is controversial.
Purpose: This study sought to assess the effect of DM on long-term outcome in patients undergoing CRT implantation, and to elucidate the role of DM in the subgroups of ischemic and non-ischemic cardiomyopathy.
Methods: All patients undergoing CRT implantation at our institution between November 2000 and January 2015 were consecutively enrolled. The study endpoint was a composite of all-cause mortality, heart transplantation or implantation of a ventricular assist device (VAD).
Results: 418 patients (average age 64.6 years, 22.5% female, 105 (25.1%) with DM) were followed over a median of 4.8 years. In the overall population, diabetic patients had an increased risk to reach the composite endpoint (HR 1.50, 95%CI 1.10-2.04, p=0.011, see Figure). Reverse remodeling (improvement of LVEF ≥10%) did not differ between diabetic and non-diabetic patients. In ischemic cardiomyopathy, survival rates were not significantly different in diabetic vs. non-diabetic patients, whereas diabetic patients had a higher risk of reaching the composite endpoint (HR 1.65, 95%CI 1.06-2.58, p=0.027) in non-ischemic cardiomyopathy. However, the latter effect was not independent of other risk factors.
Conclusions: Among patients undergoing CRT, long-term follow-up revealed an increased risk for all-cause mortality, heart transplantation or VAD in diabetic compared with non-diabetic patients. The detrimental effect of DM appeared to weigh heavier in patients with non-ischemic compared to ischemic cardiomyopathy.



P413
New hemodynamic index to identify different profiles in patients implanted with HM3

A Andrea Montalto[1]; V Piazza[1]; M Comisso[1]; F Nicolo[1]; C Contento[1]; A Cammardella[1]; F Musumeci[1]
[1]San Camillo Hospital, Cardiac Surgery and Heart Transplantation, Rome, Italy

Introduction LVAD (Left Ventricle Assist Device) represents a valid alternative to heart transplantation in patients who suffer from end-stage heart failure. The ventricular devices show a different performance related to preload, afterload and the fixed set revolutions per minute (RPM). Our main intention was to introduce a new hemodynamic index that accounting for the RPM setted, can easily identify different hemodynamic profile occurring during LVAD support.
Methods
From November 2015 to March 2018, 19 patients implanted with HM 3 underwent ramp tests during right heart catheterization. Basal data were collected and Hemodynamic Index (HI) was calculated according to the following formula:
Results
Three main profile could be identified. Profile 1 HI less than 60 and a higher risk of right failure. Profile 2: HI between 65-90, requiring speed optimization, Profile 3 HI > 90 requiring afterload optimization. A ROC curve analysis identified an HI value of 60 as highly predictive of late right ventricular failure.
Conclusion
RPM should be set balancing optimal unloading with adequate afterload and preload and accounting for the right ventricular function. We proposed a new hemodynamic index that integrating different variables can stratify patients into three main profile according to which the best treatment can be provided.

P414
Pulse oximeter usefulness for blood pressure monitoring in patients implanted with latest generation L-VAD (left ventricle assist device).

A Palermo[1]; A Andrea Montalto[1]; E Vitalini[1]
[1]San Camillo Hospital, Cardiac Surgery and Heart Transplantation, Rome, Italy

INTRODUCTION The measurement of blood pressure (BP) in patients with CF-VADs can present unique challenges because traditional BP measurement by auscultation or automated cuff is less reliable. We tested the efficacy of blood pressure estimation by using the sphygmomanometry combined with finger pulse oximetry.

METHODS 4 implanted with HVAD, 25 implanted with HM3 were prospectively studied during follow up period and mean arterial pressure was estimated by using 3 different methodologies; ultrasound Doppler, pulse oximeter and automated blood pressure cuff. For each method, 3 consecutive evaluations were conducted in 3 follow-up visits.
RESULTS For each patient 9 different evaluations were obtained, 3 for each method. The overall success rate was 100% for blood pressure assessment conducted with doppler and pulse oximeter, 80% - 87% the rate for automated monitor evaluations. 100 was the percentage of three successful consecutive measurements for the first two methodologies and 60 the percentage for the last one. Pearson's correlation analysis showed a good correlation when measurements of Doppler and pulse oximeter were compared. High variability emerged between estimations obtained by using an automated monitor and poor correlation was found when this method was compared with Doppler and pulse oximeter.
CONCLUSION According to our results pulse oximeter method showed d high success rate and a good correlation level with the standard proedure. Our data encourage the use of oximeter for domiciliary blood pressure assessment in patients implanted with h centrifuge flow device.

Development of a co-designed written resource for carers of patients with heart failure.

L Lorna Cassidy[1]; L Hill[1]; D Fitzsimons[1]
[1]Queen's University of Belfast, School of Nursing and Midwifery , Belfast, United Kingdom of Great Britain & Northern Ireland

On behalf of: Queen's University Belfast
Funding Acknowledgements: Northern Ireland Chest Heart and Stroke

Background: There is growing evidence that carers of patients with heart failure (HF) have unique unmet needs that impair their own quality of life and potentially that of their loved one. Studies found carers requested better communication with healthcare professionals, more information on symptoms and current and future management . A recent systematic review found that a written material was a common and useful resource that could significantly improve a range of carer outcomes including quality of life, depression and HF knowledge. Indeed, there is an urgent clinical need for tailored information and support that would suitably equip carers in their daily caregiving role.
Purpose: To co-design a written resource for carers of patients with heart failure.
Methods: All written resources available for carers and published in English were retrieved. Booklets from organisations including Northern Ireland Chest Heart and Stroke, British Heart Foundation and Irish Heart Foundation were analysed, along with online information available from HeartFailureMatters.org. Key topics were combined with those that were considered important from studies included within a recently completed systematic review.
Results: No information booklets were found that were designed exclusively for carers of patients with HF. The resources that were found were primarily targeted towards patients, with brief information sections for carers consisting of 2-3 pages at the back. They provided general information on areas such as the financial implications of becoming a carer, symptoms of HF, managing medications and dealing with emotions that may be experienced such as depression and stress. Topics that were considered important from written resources used within studies included in a systematic review included: communicating with the patient in a positive and motivating way, practical skills to assist with self-management at home, palliative care and problem-solving skills. Following feedback and discussions with key stakeholders made up of carers of patients with HF and health care professionals, a written booklet was developed. The booklet comprises of five chapters: 1. What is heart failure? 2. Your role as a carer, 3. Looking after yourself, 4. Communication and 5. Planning for the future.
Conclusion: There are currently no written resources specifically designed for carers of patients with HF. This innovative and co-designed resource is unique for carers and will be piloted among carers across Northern Ireland. It provides useful information with key contact numbers to signpost carers to further support and adds to the information currently available online for carers. It has the potential to influence clinical practice and could be a useful information tool that health care professionals managing HF can disseminate.

Chronic Heart Failure - Prevention

P416

Differences in the quality of life related to health among informal primary caregivers of right heart failurepatients according to the level of perceived burden

LA Martinez-Bautista[1]; V Pelaez-Hernandez[1]; LV Pachicano-Romero[1]; C Pineda-Sanchez[1]; A Orea-Tejeda[1]; GL Luna-Rodriguez[1]; KL Rosales-Castillo[1]; K Balderas-Munoz[1]; D Gonzalez-Islas[1]; NR Sanchez-Santillan[1]; CR Zepeda-Dominguez[1]; AA Ibarra-Fernandez[1]; AJ Flores-Vargas[1]; R Davila-Ramos[1]; A Jimenez-Valentin[1]
[1]National Institution of Respiratory Diseases "Ismael Cosío Villegas", Departament of Cardiology, Mexico City, Mexico

Introduction: The attention and the daily care of patients with heart failure is on charge of non-professional persons called caregivers, whose responsibility is based in to the treatment and the well-being of the patient. Caregivers present affectations in different aspects of their life from the physical to the psychological, which together deteriorates their quality of life and the care provided, making them a silent patient.
Purpose: To evaluate the differences in the quality of life related to health in the caregivers of right heart failure patients, according to the level of perceived burden.
Methods: In a cross-sectional participated 57 caregivers of patients diagnosed with right heart failure.Was evaluated the quality of life through the SF-12 health questionnaire and the perceived burdenwith the Zaritburden interview.In agreement to this latter, they were classified into 3 groups: without burden(G1, n=23), mild burden (G2, n=18) and intense burden (G3, n=16). For a statistical analysis it was used ANOVA to compare the quality of life means according to the burden groups in SPSS v.25.
Results: In relation to sociodemographic data, the groups by age and sex were G1: 55±15 years, 69.6% men; G2: 55±13 years, 61.1% men; G3: 56±9 years, 87.5% men. There were statistically significant differences ($p<0.05$) between groups (G1, G2, G3) in quality of life (76.35±16.01, 66.74±24.31, 59.03±18.07); mainly in the dimensions: physical function (81.52±26.34, 72.22±34.18, 67.19±36.19), physical role (79.35±31.67, 68.06±40.95, 67.19±37.32), bodily pain (75±35.35, 68.06±40.95, 67.19±37.32), general health (64.13±33.56, 43.06±37.18, 45.31±33.19), vitality (75.22±31.89, 60.56±35.88, 46.88±43.62), social function (82.06±27.13, 87.5±24.25, 58.59±31.53), emotional role (83.15±18.14, 68.33±40.86, 62.03±29.21) and mental health (74.34±15.9, 62.59±23.88, 57.91±24.21).
Conclusions: The caregivers develop had higher perceived burden and a lower quality of life, in comparison with caregivers with burden mild or null. The responsibilities involved in caring for patients and monitoring treatment can lead to burden in the caregivers and reduce their quality of life, so it is important to implement preventive interventions in this population to avoid the development of chronic diseases.

P418

Hand strength measured by dynamometry related to cognitive function in patients with right heart failure associated with COPD

L Lilian Victoria Pachicano-Romero[1]; V Pelaez-Hernandez[1]; A Orea-Tejeda[1]; C Pineda-Sanchez[1]; GL Luna-Rodriguez[1]; LA Martinez-Bautista[1]; CR Zepeda-Dominguez[1]; L Garcia-Flores[1]; KL Rosales-Castillo[1]; AA Ibarra-Fernandez[1]; L Hernandez-Urquieta[1]; A Flores-Vargas[1]; A Jimenez-Valentin[1]; D Gonzalez-Islas[1]; AS Hernandez-Lopez[1]
[1]National Institute of Respiratory Disease, Department of Cardiology, Mexico City, Mexico

Introduction: As age increases, hand strength decreases, while the presence of cognitive impairment increases. In right heart failure patients, even more in comorbility with COPD, whose state of health compromises cerebral perfusion. Notwithstanding, a relationship between these variables has not been established, being important indicators of the health status of these patients.
Purpose: To investigate the relation between hand strength and cognitive impairment in patients with right heart failure related with COPD.
Methods: In a cross-sectional study, 80 patients with right heart failure patients related with COPD was participated. Hand strength was evaluated with a YAMAR brand hand dynamometer, model GRIP-A, establishing the mean strength for men in 38 kg and 22 kg for women, standardized in mexican population from 60 to 70 years. The Montreal Cognitive Assessment (MOCA) was applied for determines the presence of cognitive impairment with a score of ≤26. Pearson correlation was performed in the SSPS v25 software.
Results: The average of age of the patients was 65.5±16.2 in men (n=34, 70.6% with cognitive impairment) and 68.6±12.9 for women (n=46, 89.1% with cognitive impairment).
The hand strength mean in men was 26.4±8.6 kg, with relation statistically significant differences ($p<0.05$) with cognitive function (rP=.411), particularly with the components: conceptual alternation (rP=.447), viso-spatial (rP=.501), visuoconstructive (rP=.327) y attention (rP=.352).
In women, the hand strength mean was 16.6±7.1 kg, relating cognitive performance (rP = .524) especially with the skills of identification (rP = .377), visuoconstructive (rP = .385), attention (rP = .566), repetition of sentences (rP = .326), verbal fluency (rP = .392) and orientation (rP = .459), presenting higher correlations and with more components, compared to men.
Conclusions: The hand strength, according to established standards, as well as a significant presence of cognitive impairment were present. In both aspects, women

are more affected, mainly in executive functions. The relationship between both variables could predispose the patient to a worse state of health and prognosis.

P419

Predictive factors of depression in patients with cardiorespiratory failure

GL Luna-Rodriguez[1]; LV Pachicano-Romero[1]; C Pineda-Sanchez[1]; V Pelaez-Hernandez[1]; A Orea-Tejeda[1]; A Jimenez-Valentin[1]; MF Salgado-Fernandez[1]; LA Martinez-Bautista[1]; CR Zepeda-Dominguez[1]; KL Rosales-Castillo[1]; AA Ibarra-Fernandez[1]; L Hernandez-Urquieta[1]; AJ Flores-Vargas[1]; K Balderas-Munoz[1]; RA Davila-Ramos[1]
[1]National Institute of Respiratory Diseases, Mexico City, Mexico

Introduction: One of the most common comorbidities within the Chronic Obstructive Pulmonary Disease (COPD) is the Heart Failure (HF), leading to Cardiorespiratory distress syndrome. In patients with this condition, the presence of depression is common, and this can lead to complications in the treatment such in the patient's quality life, even increasing the mortality rate. Nevertheless, there are few information about the factors that predict this complication.
Purpose: To research the predictive factors of depression in patients with cardiorespiratory distress syndrome.
Methods: A descriptive cross-sectional study was conducted, involving 83 patients with COPD and HF. The following test was used: SF-12 Questionnaire for evaluating the quality life, the Hospital Anxiety and Depression Scale (HADS), the Montreal Cognitive Assessment (MoCA) for evaluated the cognitive impairment, the Psychological Well-being Scale. A multiple regression model analysis was performed by means of the SPSS software version 25.
The Results: The average age was 67±14 years old, 55.42% were men, the regression model (F (3, 51) = 51.20, p < .001, R2 = .62) that includes: psychological well-being (t= -6.3, p= .000, β= -.441), Cognitive impairment (t= -3.7, p= .000, β = -2.45), and anxiety (t= 5.8, p= .000, β = .414), they explain 62% of the total variance of the model, over the others variables clinic and psychological adjusted for age and sex.
Conclusions: The present research shows that the psychological well-being, the cognitive impairment and the anxiety influence in the depression prevalence in these patients, hence is important a multidisciplinary treatment focused on the management of these factors.
Conclusions: The present research shows that the psychological well-being, the cognitive impairment and the anxiety influence in the depression prevalence in these patients, hence is important a multidisciplinary treatment focused on the management of these factors.

P420

Cognitive impairment in hospitalized patients with right heart failure according to the length of hospital stay

C Pineda-Sanchez[1]; V Pelaez-Hernandez[1]; A Orea-Tejeda[1]; L V Pachicano-Romero[1]; G L Luna-Rodriguez[1]; L A Martinez-Bautista[1]; C R Zepeda-Dominguez[1]; K L Rosales-Castillo[1]; A A Ibarra-Fernandez[1]; L Hernandez-Urquieta[1]; A Flores-Vargas[1]; A Jimenez-Valentin[1]; R Davila-Ramos[1]; M F Salgado-Fernandez[1]
[1]National Institute of Respiratory Diseases, Department of Cardiology, Mexico City, Mexico

Background: Heart failure has become a public health problem. One of the main comorbidities occurs at the respiratory level, with COPD, leading to right heart failure, which presents a particular pathophysiology, nonetheless, the cognitive impairments in these patients have not been studied. It is known that when a patient with left heart failure is decompensated and hospitalized, it has higher rates of mortality, dependence, functional deterioration and cognitive impairment. Successively, the latter is associated with a higher risk of functional deterioration and death after hospital discharge in patients with this syndrome.
Purpose: To research the cognitive affectations in patients with right heart failure according to the length of hospital stay.
Method: A cross-sectional comparative study was recorded. Forty patients with right heart failure participated. The patients were classified into within two groups according to the length of hospital stay: G1 (≤5 days, n = 26, 61.58 ± 14.32 years, 53.8% were women) and G2 (> 5 days, n = 14, 65.00 ± 12.21 years, 64.3% were men). Cognitive dysfunction was measured through the Montreal Cognitive Assessment (MOCA), which establishes a cut-off point in the total score where ≤26 is considered mild cognitive impairment. This test evaluates cognitive processes such as visual-spatial ability, attention, language, abstraction, memory and orientation. A student T test for independent samples by means of was realized the SPSS software version 25.
Results: Statically significant differences (p <.05) were found between both groups (G1 vs G2) for the cognitive impairment (15.42 ± 7.19 vs 10.50 ± 4.53), specifically in the visuospatial processes (0.35 ± 0.48 vs 0.00 ± 0.00), attention (2.88 ± 2.00 vs 1.79 ± 1.36) and orientation (4.50 ± 1.72 vs 3.29 ± 1.43). No significant differences were found in processes as identification (2.46 ± 0.811 vs 2.71 ± 00.469), language (00.81 ± 00.849 vs 00.36 ± 0.633), abstraction (1.19 ± 00.849 vs 00.64 ± 842) and memory (1.27 ± 1.61 vs 00.43 ± 1.08), although its performance was clinically better.
Conclusion: There are differences in the cognitive status of patients according length of hospitalization, presenting a higher level of cognitive dysfunction in relation to a longer hospitalization time. Which is related to a worse prognosis and a higher mortality in the literature. Therefore, it is suggested to evaluate the cognitive function in this population and to study its usefulness as a forecast indicator, as well as to train caregivers and health personnel about this condition.

P421

Differences in quality of life and burden between caregivers of right heart failure and COPD patients with different levels of family functionality

C Pineda-Sanchez[1]; V Pelaez-Hernandez[1]; A Orea-Tejeda[1]; LV Pachicano-Romero[1]; L Luna-Rodriguez[1]; LA Martinez-Bautista[1]; C R Zepeda-Dominguez[1]; K L Rosales-Castillo[1]; D Gonzalez-Islas[1]; A A Ibarra-Fernandez[1]; L Hernadez-Urquieta[1]; A J Flores-Vargas[1]; M F Salgado-Fernandez[1]; A Jimenez-Valentin[1]; R Davila-Ramos[1]
[1]National Institute of Respiratory Diseases, Department of Cardiology, Mexico City, Mexico

Background: The patients with right heart failure (RHF) present limitations in their daily life due to their health condition. Therefore, they require constant care, which generally provided by a family member (caregiver). Caring a chronic patient generates difficulties and problems for the caregiver, which, combined with poor family functioning, generates burden and affects their quality of life.
Purpose: To research the differences in quality of life and burden between caregivers of right heart failure and COPD patients with different levels of family functionality.
Method: A cross-sectional comparative study was recorded, 57 caregivers of patients with RHF participated. The subjects were classified within three groups according to the degree of family functionality, which was measured through Family Apgar: G1 (normo functional, N = 3, average age 60.00 ± 12.16 years, 100% of the subject were women), G2 (mild dysfunction, N = 11, average age 53.09 ± 9.82 years, 54.5% women) and G3 (severe dysfunction, N = 43, average age 55.84 ± 13.35 years, 74.4% women). The Quality of life was measured using the SF-12 inventory, where to higher score, greater presence of the variable. The burden was measured through the Zarit caregiver's burden scale, which yields results in a total score of the burden and their impact in dimensions of care, interpersonal relationship and expectation of self-efficacy. An ANOVA analysis was realized by means of the SPSS software version 25.
Results: Statically significant differences were found between groups (p <.05) for the quality of life (G1= 41.11 ± 5.74, G2= 65.65 ± 26.27 and G3= 71.08 ± 18.19). Care Impact (G1=32 ± 13.45, G2=16.09 ± 8.84 and G3=12.79 ± 7.24), interpersonal relationship (G1= 9.67 ± 8.14, G2= 4.27 ± 3.58 and G3= 2.56 ± 2.80), expectation of self-efficacy categories (G1= 10.67 ± 2.30, G2= 7.45 ± 2.84 and G3=4.53± 3.34), burden (G1= 52.33 ± 22.36, G2= 27.82 ± 13.71 and G3= 19.88 ± 10.39) and mental health (G1= 33.33 ± 25.16, G2= 59.09 ± 25.78 and G3= 70.07 ± 18.66) the differences were significant at the p <.01 level.
Conclusion: The obtained results demonstrates that the caregivers with a normal family functionality have a lower level of burden and a higher perception of quality of life, highlighting the importance of social support for caregivers. Those caregivers whom have few family support and a serious family dysfunction, present a greater level of burden, which can lead to a risk of claudication and abandonment of the patient; furthermore the development of chronic diseases.

P422

Association of Isolated cardiometabolic syndrome and the incidence of heart failure

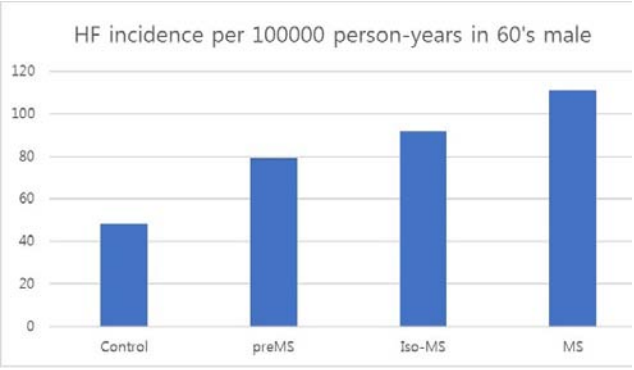
S Sung Hea Kim[1]; HJ Kim[1]; HS Kim[1]; SW Han[2]; KH Ryu[2]
[1]Konkuk University Hospital, Seoul, Korea (Republic of); [2]Hallym University, Cardiology, Dongtan, Korea (Republic of)

Background: Studies on association with HF (HF) and the cardiac metabolic syndrome (MS) have been conducted in a few because of the need of long term follow up. Moreever there are few data on the association between HF and Isolated MS (Iso-MS), furthermore in Asian.
METHODS: In this study, 7,077,015 study subjects who were aged between 30 and 70 years and had received national health checkups in 2009 were retrospectively included and followed up for 7 years. Participants excluded were those with cardiovascular disease and cancer. Iso-MS is defined by MS without the prescription of any medications on Hypertension, DM and lipid. Based on revised National Cholesterol Education Program-Adult Treatment Panel III criteria, subjects were

divided into three groups according to their number of MS factors: the control group (0), Pre-Iso MS Group (1-2), and Iso-MS group (3-5). The occurrence of HF was defined by the ICD-10 coding system after considering medication history and admission to a tertiary hospital. The incidence of HF was presented as the rate per 100,000 person-years, and the risk of HF with respect to MS was analyzed through Cox proportional hazard regression analysis. Confounding variables were gender, age, health behavior (e.g., smoking and exercise), family history (e.g., stroke, hypertension, heart disease, and diabetes), body mass index, and blood creatinine and hemoglobin values. The results are presented as hazard ratio (HR) and 95% confidence interval (95% CI).

RESULTS: A total of 895,774 (12.7%) of the 7,077,015 subjects were assessed as having MS. The incidence rate per 100,000 person-years was 21.2 for HF. The incidence of HF in the Pre-Iso MS and Iso-MS groups was 24.44 and 41.62, higher than that in the control group (12.45, $p<0.05$). The incidence of HF in Iso-MS groups was located between the pre MS and MS (Fig1). The risk of HF in Iso-MS was 1.4 times higher than that in the control group, even after adjustment for all confounding variables.

Conclusion: Isolated MS, which is far away from medical service, was associated with a higher risk of HF in Korea.



P423

Heart failure awareness status in Korea -Rationale and design of the KNOW-HF Study

JH Jae Hyuk Choi[1]; JO Na[2]; MH Jung[3]; HL Kim[4]; S Lee[5]; YH Cho[6]; KI Cho[7]; EJ Kim[2]

Background Heart failure has become one of the most important diseases worldwide in terms of prevalence, morbidity, life expectancy, and in health care management and costs. Despite significant improvements in prevention and treatment, heart failure remains increasing incidence and a high hospitalization and death rate.

As major health care problem it deserves full attention of health care authorities. Unfortunately, the seriousness of heart failure and the therapeutic possibilities are often not recognized by patients, doctors and health care authorities.

Objectives

Several activities were challenged to improve HF awareness in recent years. The KNOW-HF study aims improving HF care by increasing awareness and perception of the disease in Korea. This manuscript describes the rationale and design of the study.

Methods and Results

Total of 1000 participants selected based on sex, age groups and urban vs. rural location will be surveyed using a 23 question telephone interview. Questions for the general public focus on recognition, incidence and prevalence, severity, prognosis of the disease and therapeutic possibilities in comparison to other disease areas.

A minimum of 100 primary care physicians, 100 hospital internists and 100 cardiologists will be surveyed using an e-mail. The specialist's questionnaire contains 20 questions focusing on current status of knowledge on HF. Questions are concerning diagnostic procedures and various treatments carried out in their own office and their knowledge of newly developed concept, diagnostic tools and therapeutic options.

Conclusion The KNOW-HF study will provide important information about the level of knowledge and understanding of HF of the general public, as well as appropriate diagnostic and therapeutic approaches by primary care physician, hospital internists and cardiologists in Korea. This knowledge will be valuable when it comes to defining optimal educational programmes in the different target groups.

Cardiovascular risk in caregivers of right heart failure patients

V Pelaez-Hernandez[1]; LV Pachicano-Romero[1]; A Orea-Tejeda[1]; C Pineda-Sanchez[1]; L Luna-Rodriguez[1]; A Martinez-Bautista[1]; C Zepeda-Dominguez[1]; K Rosales-Castillo[1]; D Gonzalez-Islas[1]; AA Ibarra-Fernandez[1]; L Hernandez-Urquieta[1]; AJ Flores-Vargas[1]; K Balderas-Munoz[1]; MF Salgado-Fernandez[1]; RN Sanchez-Santillan[1]

[1]*National Institute of Respiratory Diseases, Mexico City, Mexico*

Background: Caregiver is the responsible person for patient care. Generally, the caregivers share the patient's habits and they are submitted to high levels of stress, putting their physical and mental health at risk.

Purpose: To research the presence of cardiovascular risk factors in caregivers of right heart failure patients and their level of cardiovascular risk.

Methods: A descriptive cross-sectional study was performed, this included 29 caregivers of right heart failure patients, who were evaluated through blood chemistry, resting blood pressure and tobacco consumption. The SCORE modified of the European Society of Cardiology was utilized to determine the cardiovascular risk for at 10 years; higher (> 10%), high (5-10%), moderate (1-5%) or low (<1%). The Zarit Burden Interview, the Beck Depression Inventory and the Beck Anxiety Inventory were applied. The data was analysed of the SPSS software version 25.

The results: The subjects had an average age of 58±12.3 years, 65% were women. Regarding with the blood test, a high percentage of the subjects had abnormal levels of triglycerides (72.4%, ≥150 mg/dL), total cholesterol (34.5%, ≥200 mg/dL), Cholesterol LDL (35.5%, ≥100mg/dL), Cholesterol HDL (41.4%, ≤60mg/dL), and glucose (20.7%, ≥100mg/dL). The mean of systolic blood pressure was 133.7±23.3 mmHg and the mean of diastolic blood pressure was 80.0±10.7 mmHg. The 20.7% of the subject currently smoke, 58.6% are sedentary and 65% don't have a healthy diet. According to the SCORE, the 89.7% of the IPC's presents cardiovascular risk (44.8% moderate, 17.2% high 27.6% higher). Furthermore, reported 27.6% had depressive symptoms, 41.3% anxiety and 62% chronic stress (burden).

Discussion: The caregivers have a high level of cardiovascular risk at 10 years, due to the their several risk factors. In general present physical and psychological effects, which can be aggravated due to unhealthy lifestyles. Is necessary to focus on this population at risk and perform interdisciplinary preventive interventions.

Background: Accurate prediction of the development of heart failure and identification of underlying biological processes that drive disease progression, which may also be therapeutic targets, could inform strategies to improve the prevention of heart failure. Myocardial fibrosis may be one relevant pathway for which spironolactone might be an appropriate intervention.
Purpose: To describe the baseline characteristics of patients with cardiovascular disease and an elevated plasma concentration of natriuretic peptides (who are thought to be at increased risk of developing heart failure) enrolled in a randomised trial investigating the effects of spironolactone on clinical, biochemical, biomarker (including collagen fragments) and echocardiographic variables.
Methods: A randomised, open-label trial comparing spironolactone (up to 50mg/day) or control, given for up to nine months, to patients with, or at high risk of, coronary artery disease who had a plasma NT-proBNP between 125-1,000ng/L or BNP 35-280ng/L but excluding those with atrial fibrillation, heart failure, those treated with loop diuretics or with an eGFR <30ml/min/1.73m2. Results are described as proportions and median [interquartile range].
Results: Of 877 patients screened, 527 were randomised (median age 73 [69-79] years), of whom 135 (26%) were women, 412 (78%) had hypertension, 377 (72%) had coronary artery disease, 212 (40%) had diabetes and 121 (23%) had an eGFR ≤60ml/min/1.73m2. Body mass index was 28 [25-32], heart rate was 61 [55-67]bpm, systolic blood pressure was 140 [128-154]mmHg and (site measurements) NT-proBNP was 214 [137-356]ng/L and BNP was 68 [48-111]ng/L. By echocardiography (not indexed to body surface area and for the control group only), left ventricular (LV) ejection fraction was 63 [56-67]%, LV end-diastolic volume was 83 [68-96]mL, LV mass was 184 [149-225]g, e/e' was 9.4 [7.5-11.8] and left atrial volume was 61 [48-71]mL. The most frequently prescribed treatments were lipid-lowering agents (82%), aspirin (71%), beta-blockers (70%), ACE inhibitors (52%), ARB (28%), calcium channel blockers (21%) and thiazide diuretics (16%).
Conclusions: Patients with, or at high risk of, coronary artery disease often have modestly elevated plasma concentrations of natriuretic peptides which are often associated with left atrial dilation and LV hypertrophy but normal LV volumes and ejection fraction. Such patients thus appear to have a high prevalence of 'diastolic' LV dysfunction. This may indicate a greater propensity to develop heart failure which might be prevented by interventions such as spironolactone.

P426

To evaluate the efficacy of heart failure reversal therapy using NT-proBNP levels in patients with chronic heart failure

ROHIT Sane[1]; RAHUL Mandole[1]
[1]*Madhavbaug Multidisciplinary Cardiac Care Clinics and Hospitals, Mumbai, India*

Funding Acknowledgements: Vaidya Sane Ayurvedic Education and Agricultural Trust

Background: Heart failure is considered as a life-threatening epidemic disorder affecting about 26 million world's population and associated with considerable morbidity, mortality and healthcare expenses. Despite the availability of a range of advanced treatments and sophisticated therapies the prevalence of heart failure represents a herculean challenge.Purpose: To address the challenge, the current investigation was conducted by evaluating the efficacy of Heart Failure Reversal Therapy (HFRT) in reducing left ventricular distress by assessing N-terminal pro-brain natriuretic peptide (NT-proBNP) levels in congestive heart failure (CHF) patients.
Methods: Total 76 CHF patients with NYHA Class II and III were screened from March to May 2017 and 15 CHF patients with NT-proBNP = 300-1500pg/ml were selected for the study. NT-proBNP is measured as a marker, the value of which increases with an increase in severity of CHF. The study therapy, HFRT comprises of traditional procedure of panchkarma that includes snehana (external oleation), swedana (passive heat therapy), hrudaydhara (concoction dripping treatment) and basti (medicated enema) was administered twice daily for 7 days. Post HFRT, ARJ kadha was administered for next 12 weeks follow-up. NT-proBNP levels were measured after a follow-up period of 90 days along with some other parameters like BMI, VO2peak (evaluated by cardiac stress test with modified Bruce protocol) and weight.
Results: The findings of the investigation revealed significant reduction in NT-proBNP levels (42.46%, p = 0.009), weight (4.82%, p = 0.0007) and BMI (3.67%, p = 0.034) at the end of the follow-up period. The study also yielded significant improvements in VO2peak (50.96%, p = 0.004).
Conclusions: The overall results suggest that HFRT can possibly be explored as add-on therapy or a feasible alternative for the effective management of CHF.

Change in the levels of study parameters

TimeParameter	Baseline	90 days Post HFRT
Metabolic Equivalent	4.88±2.12	7.37±1.71 (p=0.001)
VO_{2peak}	17.09±7.41	25.80±5.99 (p=0.001)

Self-efficacy, burden, anxiety and depression in caregivers of heart failure and chronic obstructive pulmonary disease patients

C Zepeda Dominguez[1]; LV Pachicano-Romero[1]; V Pelaez-Hernandez[1]; C Pineda-Sanchez[1]; A Martinez-Bautista[1]; A Orea-Tejeda[1]; L Luna-Rodriguez[1]; AA Ibarra-Fernandez[1]; D Gonzalez-Islas[1]; K Rosales-Castillo[1]; L Hernandez-Urquieta[1]; MF Salgado-Fernandez[1]; NR Sanchez-Santillan[1]; R Davila-Ramos[1]; AJ Flores-Vargas[1]
[1]*National Institute for Respiratory Diseases, Mexico City, Mexico*

Introduction: Heart failure (HF) is a frequent chronic affection associated with Chronic Obstructive Pulmonary Disease (COPD) in approximately 20.9% of the cases. The patients with both conditions have multiple symptoms and limitations, so they need a caregiver. Generally, caregivers do not receive preparation or support, so their perception of self-efficacy is affected and they frequently present psychological effects, affecting both caregiver and patient. Nevertheless, the relationship between self-efficacy, caregiver burden, anxiety, and depression has been rarely explored, even when they're frequent conditions. Purpose: To explore if there is a relationship between self-efficacy, caregiver burden, anxiety and depression in caregivers of patients with HF and COPD. Method: Transversal study in 57 caregivers of patients with COPD and HF. The assessment was made with Beck Depression Inventory, Beck Anxiety Inventory, Zarit Burden Interview, and the Perceived Self-efficacy Scale for Informal Caregivers of Chronically Ill; in all the scales higher score equals to higher presence of the variable. According to the level of self-efficacy, participants were classified into three groups: low (G1, n=19, 55.21 ± 11.11 years, 68.4% women), moderate (G2, n=21, 56.33 ± 12.19 years, 85.7 % women), and high (G3, n=17, 54.88 ± 15.12 years, 58.8% women). ANOVA analyze was utilized to determine the differences between groups, and Pearson correlation analyze was utilized for the association between quantitative variables, on SPSS V25 software. Results: The caregivers presented multiple psychological affectations: 35.1% depression, 63.4% anxiety and 39.6% caregiver burden. There was significant differences between groups (G1/G2/G3) for depression scores (10.88±9.93 / 8.86±6.45 / 4.35±4.01) [F(2,54)=3.55, p<0.05], caregiver burden (32.74±15.96 / 18.24±9.93 / 18.41±10.38) [F(2,54)=8.85, p<0.01] and anxiety (15.26±11.74 / 8.67±5.54 / 3.24±3.56) [F (2, 54) = 10.70, p<0.01]. Significant correlations were found between self-efficacy

with caregiver burden (r=-.39; p<0.01), and anxiety (r=-.39; p<0.01). Conclusion: Caregivers with mayor perception of self-efficacy show low levels of anxiety, depression, and caregiver burden, in comparison with informal caregivers with reduced self-efficacy. Thus, it's important to give the necessary tools to caregivers to fulfill their role, increase their self-efficacy, prevent the onset of own diseases and promote a better quality of care.

P428

Gender differences in anxiety, depression, and functional capacity in heart failure patients

C Zepeda Dominguez[1]; LV Pachicano-Romero[1]; V Pelaez-Hernandez[1]; C Pineda-Sanchez[1]; A Martinez-Bautista[1]; A Orea-Tejeda[1]; L Luna-Rodriguez[1]; AA Ibarra-Fernandez[1]; D Gonzalez-Islas[1]; K Rosales-Castillo[1]; L Hernandez-Urquieta[1]; RN Sanchez-Santillan[1]; K Balderas-Munoz[1]; R Davila-Ramos[1]; AJ Flores-Vargas[1]
[1]*National Institute for Respiratory Diseases, Mexico City, Mexico*

Introduction: There is a large body of evidence that indicates that anxiety and depression symptoms are common outcomes in patients with heart failure, impacting on patient's quality of life and, therefore, functional capacity. Nevertheless, there is either not enough or non-consistent evidence that indicates the differences between genders in symptoms of anxiety and depression and functional capacity in heart failure patients.
Purpose: To explore the differences between genders in anxiety, depression and functional capacity in patients heart failure patients.
Method: Transversal study was conducted. A total of 97 patients were included in this study. The assessment of anxiety and depression was made with the Hospital Anxiety and Depression Scale (HADS). Functional capacity was assessed with the 6 Minute Walk Test (6MWT). To determinate the differences between gender groups, t test was utilized, on SPSS V25 software.
Results: Fifty-six percent of the sample was female, the average age for females was 68±12 years, and for males was 65±16 years. There were significant differences (p<0.05) for males and females in anxiety (4.07±3.90 vs 5.93±4.40), depression (4.86±3.78 vs 6.67±4.02) and 6MWT distance (313.20±137.39 vs 213.12±135.80).
Conclusion: Female heart failure patients tend to present higher levels of anxiety and depression and walk lower distances in contrast with male patients. Thus, it's important to approach functional and psychological symptoms in heart failure patients, considering gender differences.

Chronic Heart Failure - Clinical

P429

Comorbidity of recurrent angina pectoris and depression

SA Matskevich[1]; MI Belskaya[1]
[1]*Scientific and Practical Center "Cardiology" , Minsk, Belarus*

Objective. To assess the presence and severity of depression in patients with recurrent (post-operation) angina pectoris in long-term period after CABG.
Materials and methods. A total of 150 individuals with NYHA class II and III recurrent angina pectoris complicated by NYHA class II and III chronic heart failure (CHF) (CHF class II – 56.7%, CHF class III - 43.3%), mean-age 58.6±4.72 y.o. Time after CABG was 19.6±2.79 months. Signs of angina pectoris had appeared in patients following 8.6±1.13 months after surgery. All patients underwent clinical examinations. Heart US imaging was performed using Vivid−7 (GE, USA - Belgium), left ventricular ejection fraction (LVEF) in class II CHF was 54.6±5.13%, in class III CHF – 45.7±4.76%. Medical treatment included standard antianginal therapy combined with aspirin and statins. The CES-D (Center of Epidemiological studies of USA-Depression) questionnaire was used as a screening instrument to identify depression. The assessment of clinical depression was performed using the Beck Depression Inventory-BDI and HADS (the Hospital Anxiety and Depression Scale). All the individuals were queried about the quality of life (QOL) estimated in scores using the Seattle Angina Questionnaire. Results. The psychological testing (CES-D score) has shown that 25.3% patients had signs of depression: 17.3% of individuals showed signs of mild depression, while 8% showed signs of moderate depression. For a stricter verification, we opted for an identification of the presence and severity of depression using two more tests. Data obtained from the Beck Depression Inventory have shown that 26% of individuals had signs of mild to moderate depression, whereas 9% had a clinically severe condition. Correlation analysis has shown positive correlations between QOL and the severity of depression (r=0.51, <0.001). Based on the HADS, sings of depression were established in 24.6% of cases. Moreover, signs of clinically severe depression were identified in 8% individuals, while subclinically severe depression was present in 16.6% of individuals. The QOL in the individuals with depression is 1.3 times worse compared to those with normal psychoemotional status. Correlations between the QOL and the severity of depression were identified (r=0.55, <0.01). Additionally, the QOL index in the individuals with concurrent depression was 1.5 times worse than in those without a comorbidity. The group of individuals with class III CHF were more frequently prone to show signs of clinically severe depression compared to those with class II CHF (<0.01).
Conclusion. Irrespective of the test used, the results of the investigation suggest that even in the long-term after CABG, a quarter of all the individuals maintain signs of depression, with the quality of life deteriorating significantly in the presence of depression. Individuals with recurrent angina pectoris aggravated by class III CHF, more frequently demonstrate a clinically severe depressive disorder.

P430

Co-morbid pathology in long-time prognosis in patients with chronic heart failure decompensation

SU Volkova[1]; KA Tomashevich[2]; EV Panteeva[1]; AY Efanov[3]
[1]*Tyumen State Medical University, Tyumen, Russian Federation*; [2]*"Neftyanic" hospital, Tyumen, Russian Federation*; [3]*Tyumen Department of the South-Ural Scientific center RAMS, Tyumen, Russian Federation*

Relevance. We estimated long-term lethality in patients with chronic heart failure decompensation, hospitalized in "Neftyanic" hospital, depending on comorbidity, pharmacotherapy prescribed, and left ventricular ejection fraction.

Materials and methods. 177 patients have been investigated (88 males, 89 females, average age 73.2 +11.1 years old). We estimated lethality end point probability during 4 years of follow up in this group of patients.
Results. Factors, affecting lethality in long-time period were: low left ventricular ejection fraction (<0,001); Charlson comorbidity index > 4 at admittance (χ^2=5.1; =0.024); chronic kidney disease with low glomerular filtration rate <60ml/min/1.73 m2 (χ^2=5.4, =0.02); diabetes mellitus (χ^2=4.7, =0.03); hemodynamic disorders (hypotension, hypertension) (χ^2=10.8, =0.001); valvular heart diseases (χ^2=9.8, =0.0018); class 3 obesity (<0,1). Some factors showed association with negative prognosis at a certain period of follow up: mild and moderate anemia affected prognosis during 750 days of follow up (χ^2=9.6, =0.002); pneumonia at admittance increased lethality during 100 days of follow up (χ^2=11.03, =0.0009); NT-proBNP plasma level more 1200 fmol/ml increased lethality during 500 days of follow up (χ^2=5.4, =0,045). Left ventricular ejection fraction at admittance showed no relation with long-term prognosis.
Conclusion. Prospective survey showed that lethality long-term prognosis in patients with CHF decompensation mostly depend on comorbidity rather than onleft ventricular ejection fraction at admittance.

P431

Relation between reduce ejection fraction and severity of ischemic stroke

NC Zareba[1]; CE Sandoval[1]; S Garcia Zamora[1]; M Urdapilleta[1]; CL Gonzalez[1]; JJ Herrera Paz[1]
[1]*FLENI Institute, Cardiology, Buenos Aires, Argentina*

Background: Altough we know that the presence of reduced ejection fraction (rEF) with ischemic myocardipathy means a worse prognosis, it still not clear the relationship between ischemic stroke and rEF.
Objectives: To evaluate if patients with rEF have more severe ischemic strokes or if there are different etiologys in comparison to preserved ejection fraction (pEF). We seek to measure the relationship between rEF and atrial fibrillation in our population.
Materials and methods
We retrospectively evaluated patients admitted in the stroke unit in one center of our city, between October 2016 and October 2018. The hospitalizations were consecutive and for the first time.
Ejection fraction (EF) was measured with echocardiography during hospitalization. The population was divided in three groups, pEF (≥53%), mild to moderate ejection fraction (mmEF) (>30 and <53%) and severe ejection fraction (sEF) (≤30%) In all patients a sample of high sensitive troponin was taken at 24 hs of admission and NIHSS scale calculated.
Results: 711 patients were included with a mean age of 70 years (interquartile range 58 – 79 [IQR]; 57.6% were men. 31.5% had a transient ischemic attack (TIA) and 68.6% were ischemic strokes. The mean hospitalization stay in days was 2. Mortality during hospitalization was 1.4%.
In terms of EF, 90% was preseverd EF; 6.5% mild to moderate EF and 2.8 severe EF
We found a trend to higher mortality in groups with reduced EF. (rEF 1.1%, FEy mmEF 4.4% y sEF 5%, p=0,075).
Conclusions
Patiens with reduce EF were older, had a higher NIHSS score at admission, positive troponin and a longer hospitalization stay. They also presented a higher percentage

of cardioembolic stroke, atrial fibrillation history and new onset of atrial fibrilation. There was also a trend in terms of mortality and lower EF values.
We didn't find any significant differences between mmEF and sEF, probably due to the low number of the sample.

Table 1

Characteristics	Preserved EF	Mild/Moderate EF	Severe EF	p
Age	70 (58-78)	76 (65-84)	76.5 (70-81)	0.0008

Hypothyroidism versus hyperthyroidism in patients with heart failure. Which is worse?

B Bogdan Caloian[1]; M Suceveanu[1]; I Garboan[1]; H Comsa[1]; D Gurzau[1]; F Fringu[1]; D Zdrenghea[1]; D Pop[1]
[1] *"Iuliu Hatieganu" University of Medicine and Pharmacy, Cardiology-Rehabilitation, Cluj-Napoca, Romania*

Introduction . The relationship between thyroid hormones and cardiovascular disease is well-known, being the subject of research in numerous clinical trials. However, the results of these studies have not always been consistent, some demonstrating a benefit of correcting thyroid dysfunction in patients with heart failure, while others have been prematurely discontinued due to a trend towards increased mortality in patients with heart failure undergoing thyroid hormone replacement therapy. The purpose of this study was to evaluate the causal relationship between serum TSH levels and the severity of heart failure and to evaluate which type of thyroid dysfunction is associated with a worse prognosis.
Methods. The study population consisted of 68 patients with a history of thyroid dysfunction and heart failure diagnosed according to the European Cardiology Society's Cardiovascular Society Cardiovascular Review published in 2016, who were clinically evaluated, echocardiographically and by determining NT-proBNP (N-terminal-pro-Brain natriuretic peptide) and to which the serum level of TSH and FT4 have been dosed.
Results. The study included 31 men with average age 70.3 ± 9.1 years and 37 women with mean age 72.2 ± 9.6 years. Of the total patients, 16 (23.5%) had TSH values within normal range, 31 (45.58%) had elevated TSH, with an average of 14.64 ± 12.56 U / mL and 21 (30.88%) had low TSH levels, with a mean value of 0.13 ± 0.09 U/mL. 16 (76.19%) of patients with hyperthyroidism and 14 (45.16%) of those with hypothyroidism were under specific endocrinological treatment at the time of evaluation. The mean FT4 in the group of patients with elevated TSH was 1.23 ± 0.27 ng/dL, whereas in those with low TSH it was 1.83 ± 0.34 ng/dL. In the euthyroid group, the average values of NT-proBNP were 1213.8 ± 1012.5 pg/mL, with an ejection fraction (FE) of 47.37 ± 10.8%, in the hypothyroidism group, the mean value of NT-proBNP was 6214.2 ± 4325.8 pg/mL (p = 0.008), with FE = 41.23 ± 11.78%, and in those with hyperthyroidism, NT-proBNP = 3450.9 ± 3125.6 pg/mL (p = 0.006), FE = 50.21 ± 4.58%.
Conclusion. Abnormal TSH values are associated with significantly higher NT-proBNP levels in patients who associate heart failure and thyroid dysfunction than in those with euthyroidism. Although patients with hyperthyroidism had a better ejection fraction, their NT-proBNP levels were higher compared to those with hypothyroidism, presumably by heart failure with preserved ejection fraction.

P433

Analysis of the level of anxiety and depression, and personality type in outpatients with chronic heart failure and the influence of these factors on quality of life and commitment to therapy

SU Volkova[1]; EV Panteeva[1]
[1] *Tyumen State Medical University, Tyumen, Russian Federation*

Aim: to identify the level of anxiety and depression, the prevalence of personality type D (distressing) in ambulatory patients with chronic heart failure (CHF), as well as their impact on patient adherence to prescribed therapy

Material and methods. The study included 98 people, observed on the basis of MMAU "city polyclinic 5" with CVD and concomitant CHF, of which 24.6% men and 75.4% women , mean age 71 ± 2.1 years. All patients initial screening, including hospital scale of anxiety and depression (HADS), the test Moriscos green to determine adherence to treatment, a test for detecting psycho (DS-14) questionnaire for measuring quality of life (SF-36). Statistical processing of research results, preparation of registers for long-term dynamic observation was carried out using the software package Microsoft Office Excel 2007.
Results: Basically, the group was represented by patients with 1-stage CHF – 78%, CHF 2A stage in 22% of subjects. The main reason for the development of CHF was a combination of CHD and hypertension - 71%, only hypertension was found in 29%. According to the questionnaire HADS subclinical anxiety was diagnosed in 25% of the observed, clinical anxiety is diagnosed in 16.5% and mainly among women (82,4% of the subgroup). Subclinical depression was diagnosed in 23.5% of patients; the clinical depression was 14.1%, also mainly women (75% of the subgroup). Psycho D was found in 17 patients (22,07%), of which 76.5% of women. Assessing adherence to therapy may be noted that in our patients is mainly observed with high - 88,2% and the average at 11.7%. Moreover, among patients with identified psycho D – high commitment to treatment and medical appointments indicated 70% of patients, 30%- medium. Among patients with an average adherence to treatment 60% had abnormalities in the HADS test, while among patients with high adherence to therapy was 55%, while the level of anxiety and depression in these groups differed.
Conclusions: Based on the results obtained, it is advisable to study the influence of the level of anxiety and depression, as well as behavioral type of the individual (psycho) on the course of CHF, and to determine the individual approach to the treatment and correction of psychological features to enhance compliance in patients with CHF, depending on individual psychological characteristics

P434

Changes in respiratory pulmonary function in patients with advanced heart failure listed for heart transplantation.

B Keller[1]; JM Dominguez[1]; S Vazquez[1]; G Spitaleri[1]; M Farrero[1]; F Perez-Villa[1]; M A Castel Lavilla[1]
[1] *Hospital Clinic de Barcelona, Cardiology Department, Barcelona, Spain*

Introduction and Objectives: Respiratory function is commonly affected in advanced heart failure (HF) patients waiting for Heart Transplantation (HT). They frequently have a resting restrictive ventilatory defect caused by their cardiomyopathy with a reduction of total pulmonary volumes and diffusion capacity for carbon monoxide (DLco). Moreover, an obstructive pattern may also be present in many patients and its relation to mortality is not well defined. The aim of this study was to evaluate the prevalence and type of respiratory functional patterns in advanced HF patients and how it affects their outcomes after HT.
Methods: We evaluated retrospectively all consecutive patients listed for HT in one single centre from 2014 to 2018. Patients were classified in three groups depending on their functional pulmonary test: a) Normal pattern if force vital capacity (FVC) ≥ 80% and forced expiratory volume in 1 second (FEV1)/FCV ≥ 70%; b) Restrictive pattern if FEV1/FCV ≥ 70% and FCV < 80%; and c) Obstructive pattern if FEV1/FVC < 70%. We also evaluated if DLco were diminished (DLco < 80%) and the presence of an altered FEV1 (<70%) . Patients listed for urgent HT or from other centres without a complete pulmonary function test were excluded from analysis.
Results: From a total of 77 patients, 48 patients were included in the study. They were 73% male, mean age 57± 10 y (18-70), IMC 25 ± 4 kg/m2, 6.3% active smokers, 25% former smokers. 47.9% showed an obstructive pattern, 41.7% a restrictive pattern and 10.4% a normal pattern. 77.8% of them had an altered DLco and 54.2% an altered FEV1. Kaplan Meier analysis showed a higher mortality after HT for patients with FEV1<70% compared to other groups (p=0.01)
Conclusions: Patients with advanced heart failure show a high prevalence of altered respiratory functional patterns. Patients with a low FEV1 had a higher mortality after HT.

P435

Iron status and correlates of its deficiency in chronic heart failure patients in a west african cardiology practice

U Amaechi[1]; AC Mbakwem[1]; MO Kehinde[1]
[1] *Lagos University Teaching Hospital, Lagos, Nigeria*

Background: Iron deficiency (ID) is the commonest nutritional deficiency in chronic heart failure (HF) and might suggest severe HF. Iron deficiency and its correlates in HF appears to have received inadequate research attention in Sub Saharan Africa.
Purpose: This study therefore tried to establish the iron status and correlates of ID in a cohort of HF patients in a cardiology practice in West Africa.

Methods: Eighty-eight (88) chronic stable HF patients with eGFR >60% and no demonstrable cause of blood loss or iron deficiency were recruited and their demographic and clinical parameters obtained. They underwent laboratory (full blood count, iron studies and eGFR) and echocardiography assessments. Full blood count parameters, serum ferritin and transferrin saturation were used to assess the iron status and its relationship with age, NYHA (New York Heart Association) functional class, pulse rates, LVEF (Left Ventricular Ejection Fraction) among other parameters in chronic HF.
Results: There were 47 (53%) females and 41 (47%) males with a mean age of 53.93+12.52; BMI 27.61+6.42; pulse rate of 78.45+10.19; SBP 120.91+19.21mmHg and DBP 76.22+12.28mmHg. The mean eGFR was 91.06+30.90 mL/min. The median NYHA class was 2(2-3) with 60 (68.2)%) in NYHA II, 15 (17%) in NYHA III and 13 (14.8%) in IV. The mean haemoglobin concentration (Hb) was 12.54+1.62g/dl for males and 12.28+1.65g/dl females; mean cell volume was 86.08+6.73fl; mean cell haemoglobin 28.5+2.26pg, mean cell haemoglobin concentration 32.94+1.25g/dl. The median serum ferritin was 145.76mcg/L and mean transferrin saturation (Tsat) was 18.91+8.69%. Iron deficiency was found in 30 (34%) of chronic HF patients; !5 (17%) had absolute while 15 (17%) had functional ID. ID was worse with higher NYHA functional class but did not change remarkably with LVEF. Only 16 (53%) of the ID participants had anaemia. NYHA functional class was the strongest independent predictor of ID, followed by advancing age.
Conclusion: Iron deficiency occurs in about one-third of chronic HF patients, is more common and worse in advanced functional classes, and anaemia is present in only about half of the ID patients.

P436

Etiology of community-acquired pneumonia in patients with chronic heart failure

AA Bobylev[1]; SA Rachina[2]; SN Avdeev[3]; MV Sukhorukova[1]; SB Yatsyshina[4]; S Omar[2]; OT Zorya[2]; AE Solovjeva[2]
[1]Smolensk State Medical University, Smolensk, Russian Federation; *[2]RUDN University, Moscow, Russian Federation*; *[3]Sechenov University, Pulmonology Research Institute, Moscow, Russian Federation*; *[4]Central Research Institute of Epidemiology, Moscow, Russian Federation*

Background: Comorbidity may influence the etiology of community-acquired pneumonia (CAP). Chronic heart failure (CHF) is one of the most common concomitant diseases in elderly patients with CAP. The knowledge of predominant microbial patterns of CAP in this subpopulation represents the basis for empirical antibiotic therapy (ABT).
Purpose: To assess the etiology of CAP in patients with concomitant CHF.
Methods: Prospective observational study recruited adult patients hospitalized with radiographically confirmed non-severe CAP and concomitant CHF. CHF had to be present for at least 3 months before hospitalization and supported by previous medical documentation. Sputum or oropharyngeal swabs (OPS) and urine samples were collected in all eligible patients prior to the first dose of systemic ABT. Sputum culture was performed for typical bacterial pathogens (Streptococcus (S.) pneumoniae, Staphylococcus (S.) aureus, Enterobacterales, etc.) in accordance with standard methods and procedures. Detection of Mycoplasma (M.) pneumoniae, Chlamydophila (C.) pneumoniae and respiratory viruses (influenza, parainfluenza viruses, coronavirus, human metapneumovirus, respiratory syncytial virus, etc.) in sputum or OPS was performed by real-time polymerase chain reaction. Urine samples were used to determine the soluble antigens of Legionella (L.) pneumophila serogroup 1 and S.pneumoniae using immunochromatographic test kits directly at the bedside.
Results: Altogether 50 patients, mean age 72.2±9.5 years old, 27/50 (54%) females, were enrolled. The etiology of CAP was confirmed in 52% (26/50) cases. S. pneumoniae was the most commonly identified pathogen – 16/26 (61.6%) cases, followed by respiratory viruses – 6/26 (23.2%), namely rhinovirus, parainfluenza virus, coronavirus, human metapneumovirus (3/6, 1/6, 1/6 and 1/6, respectively), Haemophilus influenzae – 1/26 (3.8%), S. aureus – 1/26 (3.8%) and Klebsiella pneumoniae – 1/26 (3.8%). Co-infection of S.pneumoniae and parainfluenza virus was revealed in 1/26 (3.8%) of patients.
Conclusions: S.pneumoniae and respiratory viruses were predominant causative agents of non-severe CAP in hospitalized adults with concomitant CHF. It is worth mentioning that atypical bacterial pathogens (M.pneumoniae, C.pneumoniae, L.pneumophila) were not identified; gram negative bacteria as well as S.aureus were rarely seen.

P437

Depleted iron stores are associated with decreased exercise capacity in patients with non-ischaemic cardiomyopathy

M Drozd[1]; M Tkaczyszyn[1]; A Zapolska[1]; T Walczak[1]; J Tobiszewski[1]; P Franczuk[1]; A Kosiorek[1]; I Flinta[2]; J Jaroch[3]; A Soltowska[3]; K Kulej-Lyko[4]; W Banasiak[4]; P Ponikowski[5]; EA Jankowska[1]
[1]Wroclaw Medical University, Laboratory for Applied Research on Cardiovascular System, Department of Heart Diseases, Wroclaw, Poland; *[2]Wroclaw Medical University, Department of Physiology, Wroclaw, Poland*; *[3]Cardiology Dept., T. Marciniak Hospital and Faculty of Health Sciences, Wroclaw Medical University, Wroclaw, Poland*; *[4]Military Hospital, Cardiology Department, Centre for Heart Diseases, Wroclaw, Poland*; *[5]Wroclaw Medical University, Department of Heart Diseases, Wroclaw, Poland*

Funding Acknowledgements: This research was financially supported by the National Science Centre (Poland) grant number 2014/13/B/NZ5/03146

BackgroundIn patients with chronic systolic heart failure (HF) concomitant iron deficiency (ID) was demonstrated as independent predictor worse functional capacity. However, available data regarding negative consequences of ID for the exercise tolerance in HF are based mainly on heterogenous (regardine aetiology) groups of patients diagnosed with either ischaemic or non-ischaemic HF.PurposeWe prospectively investigated whether ID independently predicts decreased exercise capacity in patients with symptomatic non-ischaemic cardiomyopathy (NICM).
Methods We analyzed clinical data and examined 50 patients with stable NICM (36 men; age: 53±13 years; left ventricular ejection fraction [LVEF] 31±10 % [min-max: 13-49]; median N-terminal pro-B-type natriuretic peptide (NT-proBNP): 730 pg/mL [lower and upper quartile: 277-1894]; NYHA class I/II/III: 24/74/2 %). Iron deficiency was defined as ferritin <100 μg/L (absolute ID - depleted iron stores) or ferritin 100-299 μg/L with transferin saturation <20% (functional ID). Exercise capacity was objectively evaluated using comprehensive cardiopulmonary exercise testing (CPET) on a treadmill.ResultsAmong studied patients with NICM 27 (54%) met the criteria of predefined ID, out of which 23 had absolute ID and the remaining 4 had functional ID. Patients with ID (compared to those without this condition) had lower haemoglobin concentration (Hb, 13.8±1.6 vs. 15.3±1.0 g/dL, p<0.001), and there was a trend towards younger age (50±14 vs. 56±11 years, p=0.09) in this subgroup. 13 female patients were iron-deficient (93%) as compared with 14 male subjects (39%, p<0.001). There were no differences regarding NYHA class distribution, high-sensitive C-reactive protein, NT-proBNP, LVEF, and serum creatinine in patients with vs. without ID (all p>0.1). In univariable linear regression models peak oxygen consumption per kg body mass (peakVO2/kg) correlated with body mass index (BMI, r=-0.54, p<0.001), NYHA class (r=-0.40, p=0.006), serum creatinine (r=-0.36, p=0.01), uric acid (r=-0.39, p=0.006), C-reactive protein (r=-0.32, p=0.03), and serum ferritin (r=0.31, p=0.03). PeakVO2/kg was not related to sex, age, LVEF, haemoglobin concentration, plasma NT-proBNP, and TSAT. Finally, in multivariable linear regression model serum ferritin and BMI remained independently related to peakVO2/kg (β=0.37, p=0.002; and β=-0.54, p<0.001; respectively; p for model <0.001, corrected R2=51%) when adjusted for aforementioned significant predictors from univariable analyses.
ConclusionsIn patients with stable HF due to NICM depleted iron stores are independently associated with objective measures of exercise intolerance. Beneficial effects of intravenous iron therapy in this population of patients are anticipated.

P438

Relationship between domains of Kihon Checklist with frailty status and exercise capacity in stable elderly patients with heart failure

A Hirashiki[1]; K Kawashima[1]; K Nomoto[1]; M Kokubo[1]; A Shimizu[1]; H Arai[1]
[1]National Center for Geriatrics and Gerontology, Obu, Japan

Background: The Kihon Checklist (KCL) is used extensively in Japan to identify elderly persons who are at risk of requiring support or care. The KCL has 25 yes/no questions that are categorized into the following domains: instrumental activities of daily living (IADL), physical, nutrition, eating, socialization, memory, and mood. There is little information about the relationship between these KCL domains with frailty status and exercise capacity in patients with heart failure (HF).
Aim: To determine whether or not the scores in each domain of the KCL could be used to estimate exercise capacity in HF by the use of cardiopulmonary exercise testing (CPX) and to support a diagnosis of frailty.
Methods: In a cross-sectional study, 120 elderly patients (>65 years) with stable HF were evaluated by the KCL and CPX. Patients with total KCL scores of ≥8 were classified as frail.
Results: Mean age was 81.6 years, mean left ventricular ejection fraction was 57.9%, mean plasma brain natriuretic peptide (BNP) content was 184 pg/mL, and mean total KCL score was 13.1. Peak VO2 was closely, and BNP moderately, correlated with total KCL score (r = −0.52 and r = 0.26, respectively). The IADL domain score was significantly correlated with peak VO2 and BNP (r = −0.50 and r = 0.21, respectively); the physical domain score was significantly correlated with peak VO2 (r = −0.47), but not with BNP. The nutrition and eating domain scores were not correlated with either peak VO2 or BNP. The socialization domain score was significantly correlated with peak VO2 (r = −0.34), but not with BNP. The memory domain score was weakly correlated with peak VO2 and BNP (r = −0.19 and r = 0.21, respectively). The mood domain score was significantly correlated with peak VO2 and BNP (r = −0.41 and r = 0.25, respectively).

Conclusions: Not only the total KCL score but also the scores in its domains may be useful for assessing the frailty and exercise capacity of stable elderly patients with HF. For interventions in frail patients with HF we should check the domains of KCL.

P439

Comorbidities in patients with coronary artery disease: gender differences

A Alexey Sumin[1]; EV Korok[1]; AV Shcheglova[1]; OL Barbarash[1]
[1]*Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation*

Background: Comorbidities in patients with coronary artery disease have received significant attention due to increasing social significance of cardiovascular diseases. However, problem solution involves studying cardiac pathology along with concomitant diseases, such as diabetes mellitus, pulmonary pathology, kidneys, etc.), but not a comprehensive approach, which takes into account all available comorbidities. An important issue that should be considered in the shift to the personalized medicine is the presence of gender differences, which varies greatly and depends on different correlations with specific comorbidities.
Purpose: To study gender differences in comorbidies in patients with coronary artery disease (CAD).
Material and Methods: 742 patients with stable coronary artery disease, examined in the Research Institute for Complex Issues of Cardiovascular Diseases in 2011 before elective surgical treatment were included in the study. All the patients were enrolled into 2 groups depending on the gender: Group 1 - females (n = 147), Group 2- males (n = 595).
Results: The obtained results reported that women were commonly older than men and more often had excess body weight (p <0.001). The majority of current smokers were males (p <0.001). 12.9% of women and 7.4% of men suffered from myocardial infarction (MI) in the preoperative management (p = 0.031). However, positive history of MI was more often found in male patients (p = 0.004). The evaluation of the severity of clinical signs and symptoms of angina pectoris and chronic heart failure (CHF) reported that men had predominant angina functional classes 1-2 (p = 0.057 vs. p = 0.007) and stage I CHF (p <0.001), whereas women had angina functional classes 3-4 (p = 0.005 vs. p = 0.050) and stage IIa CHF (p <0.001). Women more often than men suffered from hypertension (p = 0.01) and atrial fibrillation (p = 0.024). But, significant peripheral artery disease prevailed among men (p = 0.022).
The analysis of comorbidities in the study groups showed that disorders of carbohydrate metabolism, thyroid disease, bronchial asthma and varicose veins were more common in female patients (p <0.05), whereas chronic hepatitis (p = 0.079) and urolithiasis - in males (p = 0.028). The comorbidity score did not differ significantly between the study groups (p>0.05). However, the mean score was 66.0% in women and 70.4% in men. Conclusion: Detection of comorbidities in CAD patients based on gender differences is advisable to improve both the immediate results of surgical management and further preventive measures.

P440

Prevalence of post-stroke erectile dysfunction and associated cardiovascular risk factors and co-morbidities

M Trofenciuc[1]; A Pop-Moldovan[1]; M Onel[1]; N Dugacicu[1]; M Puticiu[1]; M Tomescu[2]; H Branea[2]; A Bordejevic[2]; D Gaita[2]; A Mischie[3]; C Hreniuc[1]
[1]*Vasile Goldis Western University, Arad, Romania*; [2]*University of Medicine Victor Babes, Timisoara, Romania*; [3]*Centre Hospitalier De Montluçon, Montluçon, France*

Objectives: The aim of this study was to establish a correlation between prevalence and severity of erectile dysfunction (ED) and cardiovascular (CV) co-morbidities and ongoing medication and other risk factors associated with post-stroke ED.Materials and MethodsFor 153 patients (57.04 ± 6.54 years) with ischemic stroke, we

evaluated the pre- and post-stroke prevalence of ED using the five-item International Index of Erectile Function questionnaire (IIEF5).
Erectile Function questionnaire (IIEF5). Within 5 days of admission we determined the stroke site location and severity using the National Institute of Health Stroke Scale (NIHSS). The pre- and post-stroke data obtained were compared with those of 30 control non-stroke patients (52.27 ± 8.35). Additional cardiovascular co-morbidities, medication and risk factors were asset and analyzed.
Results The IIEF5 scores were much lower [median 17 interquartile range (IQR) 10-20] post stroke than pre-stroke (median 22 IQR 12-23) and lower than in control group (median 22.5 IQR 21-24).
From the analysis of comorbidities and risk factors for stroke of post- stroke group and the control group, we infer that diabetes (p = 0.003), hypercholesterolemia (p <0.001), and hypertension (p <0.001) were more common in patients with stroke than those in the control group. (Table 1).
From the statistical analysis of data on medication use by patients, results that more patients have used ACE inhibitors, calcium antagonists, beta blocking agents, diuretics, statins, oral agents, antiplatelet and oral anticoagulants after the stoke than before, and in terms of consumption of drugs before stroke compared with the control group, differences were not significant.
Conclusions The prevalence and severity of ED increase after stroke due to disruption of autonomous central structures. The depression, functional impairment, CV co-morbidities and medication used after stroke may contribute to ED.

Funding Acknowledgements: ResMed

Introduction: Sleep disordered breathing (SDB) is a common comorbidity in patients with several cardiovascular diseases. In particular, SDB is highly prevalent in either atrial fibrillation (AF) or heart failure (HF). It was reported that SDB plays important roles in the pathogenesis and/or progression of both AF and HF. In patients with HF, coexisting AF was associated with the presence of Cheyne-Stokes respiration (CSR) which is one form of SDB, possibly through the high left ventricular (LV) filling pressure. Thus, there might be an interaction across AF, HF and SDB. However, limited data is available regarding the presence of SDB in patients with AF, and regarding the relationship between SDB and LV filling in those with AF.
Methods: AF patients followed in Juntendo University Hospital were studied. Apnea-hypopnea index (AHI) and Cheyne Stokes respiration (CSR) pattern were determined by cardiorespiratory polygraphy. In addition, patients' profiles and echocardiographic parameters were prospectively collected. Multiple regression analyses were performed treating AHI or CSR as dependent variables.
Results: Overall, cardiorespiratory polygraphy was done in 135 patients with AF. Among them, 121 patients were included in the final analysis and SDB (defined as AHI≥15/hour) was detected in 52 (43%) of these patients, in which the average of AHI and 3% oxygen desaturation index (ODI) were 22.8/hour and 26.2/hour, respectively. Male gender, body mass index (BMI), and left atrium diameter were significantly high in patients with SDB. Multiple linear regression analysis showed that male gender, BMI, history of HF, and beta blocker were independent correlates of the AHI (p=0.035, 0.015, 0.024, and 0.005, respectively). On the other hand, chronic AF, age, use of diuretics, and E wave in LV inflow by echocardiography were significantly associated with the percentage of Cheyne-Stokes Respiration (CSR) (p=0.008, 0.008, 0.018, and 0.029, respectively).
Conclusion: SDB is prevalent in patients with AF. CSR was associated with LV high filling pressure and the chronic AF.

P442
"Obesity Paradox" in patients with chronic heart failure and comorbidity

EV Elena Efremova[1]; AM Shutov[1]; MI Tolstyga[2]; SA Suvorova[2]; IV Kozlova[1]; VN Sporova[1]; VA Novgorodskij[1]
[1]Ulyanovsk State University, Ulyanovsk, Russian Federation; *[2]ULYANOVSK REGIONAL CLINICAL CENTER OF SPECIALIZED TYPES OF MEDICAL AID, Ulyanovsk, Russian Federation*

The improved survival in obese patients compared with patients with normal body weight (obesity paradox) has not been insufficiently studied in patients with chronic heart failure (CHF). The aim of this study was to investigate nutritional status of patients with CHF, depending on comorbidity.

Methods. 200 patients with CHF (130 males and 70 females, mean age was 61.5±9.6 years) were studied. CHF was defined according to ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure, 2016. Age-adjusted Charlson Comorbidity Index (ACCI) was estimated. The studied patients were divided into 3 groups: I group (low comorbidity) with an index ≤ 3 scores; II group (moderate comorbidity) with an index 4–5 scores and III group (high comorbidity) with an index ≥ 6 scores. Follow-up period was 12 months.
Results. Age-adjusted Charlson Comorbidity Index was 5.0±2.1 scores. Metabolic syndrome was observed in 89 (43.8%) patients, obesity with a BMI ≥ 30 kg/m2 - 97 (48.5%), overweight - 62 (31.0%) patients with CHF. Metabolic syndrome was diagnosed more often in patients with CHF with low comorbidity compared patients with high comorbidity: 38 (71.6%) vs 24 (31.2%), resp., $\chi 2$ =19.05; PI-III=0.009. Waist circumference in CHF patients with high comorbidity was less than in patients with low comorbidity: 100.4±15.6 vs 106.8±14.5 cm, resp., PIII-I=0.01. Patients with CHF and low comorbidity had higher body mass index compared with patients with high comorbidity: 32.1±6.1 vs 28.9 ± 5.5 kg/m2, resp., PI-III=0.04. Relative risk of death within 12 months in patients with CHF and high comorbidity was 1.68 (95% CI 1.35 - 2.09) in comparison with patients with low comorbidity. According to the results of our study, patients with CHF and higher body mass have lower comorbidity, i.e. more favorable long-term prognosis.
Conclusions. Patients with chronic heart failure and high comorbidity have lower body mass index, higher waist circumference and a poor prognosis compared with patients with chronic heart failure and low comorbidity . This fact may be one explanation for the 'obesity paradox' in patients with chronic heart failure.

Plant Gain, Chemoreflex Gain, Circulation Time and Cheyne-Stokes Respiration in Heart Failure

A Alberto Giannoni[1]; F Gentile[1]; A Navari[1]; C Borrelli[1]; G Vergaro[1]; G Mirizzi[1]; G Catapano[1]; F Grotti[1]; DP Francis[2]; C Passino[1]; M Emdin[1]
[1]G. Monasterio Foundation, Pisa, Italy; *[2]St. Mary's Hospital and Imperial College, International Centre for Circulatory Health, London, United Kingdom of Great Britain & Northern Ireland*

RATIONALE. The contribution of the plant gain (PG) to Cheyne-Stokes respiration (CSR) in heart failure (HF) has never been directly evaluated, but only hypothesized by mathematical models.
OBJECTIVES. To evaluate the PG together with the chemoreflex gain (CG), and the circulation time (Ct) in patients with systolic HF (LVEF<50%) with or without CSR and to identify predictors of CSR severity and cycle length.
METHODS. A group of 20 HF patients (age 72.4±6.4 years, LVEF 31.5±5.8%), 10 with relevant CSR (24-hour apnea-hypopnea index, AHI≥10 events/hour) and 10 without (AHI<10 events/hour) underwent 24-hour cardiorespiratory monitoring to assess CSR severity and cycle length, as well as the lung-to-finger Ct (LFCt), CG to hypoxia (CGO2) and hypercapnia (CGCO2) by rebreathing technique, and PG assessment through a visual system, also performed in 10 healthy subjects.
MEASUREMENTS AND RESULTS. PG test was feasible and showed high repeatability (ICC 0.98, 95% CI 0.91-0.99); the best-fitting curve to express the PG was a hyperbola (R2≥0.98). Patients with HF and CSR showed increased PG, CGCO2 (but not CGO2), and LFCt compared with patients without CSR. PG was the only predictor of the daytime AHI (R=0.56, p=0.01) and together with the CGCO2 also predicted the nighttime AHI (R=0.81, p=0.0003) and the 24-hour AHI (R=0.71, p=0.001). LFCt was the only predictor of CSR cycle length (R=0.82, p=0.00006).
CONCLUSION. Plant gain appears to be a powerful contributor to CSR in HF, beyond chemoreflex gain and circulation time.

Ensuring the "safety" of cancer octogenarian patients with comorbid chronic heart failure during non-cardiac operations in a multidisciplinary surgical clinic.

YF Yulia Frolova[1]
[1]Petrovsky National Russian Research Center of Surgery, Cardio Surgery of Heart Failure, Moscow, Russian Federation

Background. Heart failure (HF) is very common in the elderly and there are numerous challenges in diagnosis, prognostication, and treatment. HF octogenarian patients have a higher risk of postoperative cardiac problems . Oncocardiology is an actual medical discipline focusing on the detection, prevention and treatment of chronic heart failure (CHF) associated with the treatment of cancer.
Aim. To evaluate the risks of progression of concomitant CHF in octogenarian cancer patients after radical surgery for colorectal cancer.
Material and methods. From 2015 to 2018 a 26 elderly patients (pts) with verified cancer and history of CHF (42% female, 89% with LVEF ≤45%) were analyzed after radical surgery for colorectal cancer. The mean age was 85±2,7 years. 17(65%) pts

had II FC NYHA (functional class, New York Heart Association), 27% - III FC and 8% - IV FC NYHA due to 6-min walk test. 12(46%) pts had diabetes Mellitus, 21(81%) pts – hypertension, 12 (47%) pts – atrial fibrillation, 20(78%) pts - atherosclerosis of the aorta and its branches, 5(19%) - obesity. The level of NT-proBNP- 1269±44pg\ml, cTnI – 2,52±0,23ng/mL , CKD 41,2 ± 3,7 ml\min\1.73m2. Aldosterone antagonists received 10(%)pts, ACE-inhibitor/angiotensin or BRA receptor blockers – 21(81%)pts, beta-blockers-13(50%)pts, diuretics 11 (42%)pts, statins 17(65%)pts. According to ECHO, there was registered diastolic dysfunction also, /' 17,1±3,2.
Results. Postoperative death was observed in one case due to septic shock. 25 pts were discharge from hospital within 17±3,5days after operation with no clinical changes in FC NYHA.
Conclusion. We conclude that standard HF therapies is beneficial in the elderly patients, who have a higher risk of postoperative cardiac problems.Only in close cooperation with all members of the multidisciplinary team in surgical clinic and careful weighing of risks, according to stratification scales, can noticeable success be achieved in treating oncological octogenarius patients with comorbid CHF.

Needs for psychological support in heart failure patients

C Silva-Ruz[1]; J Sanchez-Sosa[2]; M Martinez-Rios[3]; D Garcia-Romero[1]; M Balbuena-Madera[1]; O Fiscal-Lopez[1]; E Tapia-Lopez[3]; EJJ Eduardo Julian Jose Chuquiure[3]
[1]Instituto Nacional de Cardiologia Ignacio Chavez, Centro en Insuficiencia Cardiaca, Mexico City, Mexico; *[2]Universidad Nacional Autonoma de Mexico, Facultad de Psicologia, Mexico City, Mexico*; *[3]Instituto Nacional de Cardiologia "Ignacio chavez", Mexico City, Mexico*

Heart failure (HF) is a serious health problem that affects a large population worldwide, with great impact on hospitalizations, mortality, costs and quality of life. Our purpose was to identify prevalence of: psychological stress, anxious or depressive symptomatology, asssociated with HF deterioration.
Material and Method
Patients over 18 years old with a HF diagnosis according to ESC guidelines criteria were included. In addition, with clinical stability six months prior to inlusion, without any HF treatment modification or hospitalizations in abscense of psychological disorder diagnosis or treatment. We evaluated demographic, clinical and therapy parameters. Psychological distress level was tested through the Distress Thermometer (DT), adapted for HF patients, Anxiety/Depressive symptomatology, with Hospital Anxiety and Depression Scale (HADS). Comparative bivariate statistics were performed. We declare p value <0.05.
Results
A total of 45 outpatients participated, age 59.3 + 13.3 years, (60% men). History of: diabetes 31.1%, Hypertension 35.5%, ischemic etiology: 33.3%. 84% NYHA class I-II with optimal therapeutic levels. The psychological evaluation indicated that 59.3% of patients tend to have dysfunctional thoughts about their illness, 48.1% have experienced nervousness, 44.4% distress, 66.7% have gradually lost interest in their personal appearance, 35.7% reported perceiving a high level of psychological distress that requires assistance, and only 10.7% have high levels of depressive symptomatology.
Conclusions
Psychological evaluation on HF patients is relevant to assess and identify the main emotional, cognitive and instrumental needs that gives information about the psychological impact, as well as tools for integral management.
This type of studies in HF patients allows to identify psychological support needs, in order to design psychological-intervention programs with specific and personalized topics. These patients have high risk of anxious, depressive symptomatology and psychological distress, we recommend psychological evaluation and effective intervention.

P447

High risk of ischemic stroke but not of cerebral bleeding in patients with heart failure without atrial fibrillation: a longitudinal 2-year follow-up study based on the Swedish Heart Failure Registry

C Hjalmarsson[1]; M Fu[2]; T Zverkova-Sandstrom[2]; M Schaufelberger[2]; C Ljungman[1]; E Bollano[1]; U Dahlstrom[3]; A Rosengren[2]
[1]Sahlgrenska University Hospital, Department of Cardiology, Gothenburg, Sweden; *[2]Sahlgrenska Academy, Medicine, Cardiology Unit, Östra, Gothenburg, Sweden*; *[3]Linkoping University, Department of Cardiology and Department of Medical and Health Sciences, Linkoping, Sweden*

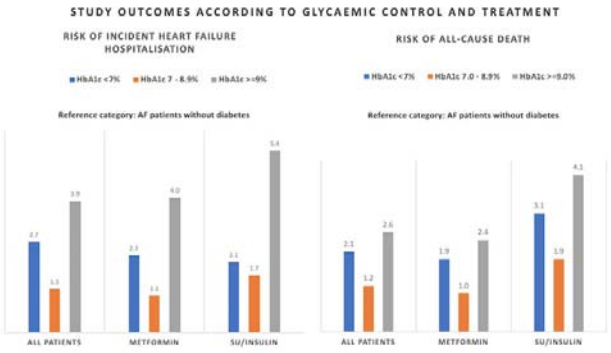
Background. Few studies have compared the risk of incident stroke among heart failure (HF) patients in a population-based and nationwide setting; moreover, the risk rates for ischemic- and haemorrhagic stroke were not examined separately, and patients with concomitant atrial fibrillation and/or anticoagulant treatment were not excluded.
Purpose. To compare the risk of TIA/ischemic stroke (IS), haemorrhagic stroke (HS), and death in incident HF patients without atrial fibrillation (AF) with that of a control population.
Methods. Data from incident HF patients without AF and /or anticoagulants, reported in the Swedish Heart Failure Register (SwedeHF) from January 2003 until December 2013, were analysed. For each case, maximum two age- and gender-matched controls without HF, AF and/or anticoagulants at inclusion were randomly selected from the Swedish Population Register. Information regarding use of medication was extracted from the Swedish National Drug Register and data on medical diagnoses were collected from the National Patient Register for both cases and controls, during a two-year follow-up period after the diagnosis.
The study population was categorized in three groups according to left ventricular ejection fraction: HFrEF (EF<40%); HFmrEF (EF 40-49); and HFpEF (EF ≥ 50%). Proportions were compared by Chi-square test. Hazard ratios (HR) with 95% confidence intervals (CI), for IS, HS, and death were estimated by Cox proportional hazard regression model, with adjustment for age, gender, and comorbidities (hypertension, diabetes mellitus, previous TIA/ischemic stroke, COPD, and kidney dysfunction).
Results. We identified 16,865 patients with incident HF (38.9% women) and 31,347 control individuals (39.2% women); 19.4% - HFpEF; 20.9% - HFmrEF; and 59.7% - HFrEF. Two years after diagnosis, the rate of events in the HF compared with the control group were; IS, 3.3% vs 1.5%, (p<0.001); HS, 0.3% vs 0.3% (p=0.838); mortality, 26% vs 4.9% (p<0.001). No significant difference in IS (p=0.970) and HS (p=0.076) incidence was found across EF groups; In a sex-, age, and comorbidity-adjusted Cox regression analysis, the HR for IS in HF patients vs controls was 2.09 [1.83-2.38; p<0.001], while the HR for HS was 0.95 [0.65-1.40; n s].
Conclusions. In this nationwide, population-based study, patients with HF without atrial fibrillation have a markedly increased risk of ischemic stroke but a similar risk of haemorrhagic stroke regardless of left ventricular ejection fraction.

P448

Diabetes increases long-term risk of new-onset heart failure and mortality in atrial fibrillation: impact of glycaemic control and diabetes treatment

M Polovina[1]; I Milinkovic[1]; I Veljic[2]; D Djikic[2]; I Petrovic-Djordjevic[2]; V Kovacevic[2]; L Vajagic[3]; J Simic[1]; A Pavlovic[2]; G Krljanac[1]; M Asanin[1]; PM Seferovic[1]
[1]University Clinical Center of Serbia, Cardiology Clinic, Faculty of Medicine, Belgrade University, Belgrade, Serbia; *[2]University Clinical Center of Serbia, Cardiology Clinic, Belgrade, Serbia*; *[3]University Belgrade Medical School, Belgrade, Serbia*

BACKGROUND: In patients with atrial fibrillation (AF), type-2 diabetes (T2D) portends a worse prognosis, but how glycaemic control and drug treatment modify outcomes is unclear. In a cohort of AF patients without prior HF, we aimed to assess whether the associations between T2D and risk of new-onset HF and mortality are influenced by glycaemic control and antidiabetic treatment.



METHODS: We included diabetic and nondiabetic AF patients, without prior HF. In diabetic patients, mean glycosylated haemoglobin (HbA1c) was calculated from all HbA1c measurements taken from inclusion to the end of the prospective follow-up. Study outcomes were: first hospitalisation for new-onset HF (HFH) and all-cause mortality. Cox analysis, adjusted for relevant confounders, was used to assess the association between T2D, stratified by categories of the mean HbA1c (<7.0%, 7.0-8.9%, ≥9.0%), and outcomes. The association between drug treatment (metformin; sulfonylurea[SU]/insulin) and outcomes was also analysed.
RESULTS: Among 1,288 AF patients (mean-age: 68±11 years; 61% male) without prior HF, 17% had T2D. During a median 5.4-year follow-up, HFH occurred in 298 (rate, 3.9; 95% confidence interval [CI] 3.5-4.4) and 424 died (rate, 5.5; 95%CI,

P448: Risk of HFH and all-cause death

	HR (95% CI)					
	All patients, n=1288		Metformin, n=122		SU/insulin, n=90	
	HFH	All-cause death	HFH	All-cause death	HFH	All-cause death
AF without T2D	1.0 (ref.)	1.0 (ref.)	1.0 (ref.)	1.0 (ref.)	1.0 (ref.)	1.0 (ref.)
AF with T2D	1.9 (1.3-2.8)	1.6 (1.1-2.1)	1.8 (1.4-3.0)	1.3 (1.1-2.8)	2.5 (2.1-3.4)	2.3 (1.9-3.1)
HbA1c						
<7.0%	2.7 (1.9 3.4)	2.1 (1.7-3.2)	2.3 (1.7 - 3.3)	1.9 (1.5 3.8)	2.1 (1.7-3.2)	3.1 (1.9-5.2)
7.0-8.9%	1.3 (1.2-2.0)	1.2 (1.1-2.1)	1.1 (1.0-2.2)	1.0 (0.9-2.2)	1.7 (1.1-2.1)	1.9 (1.4-2.5)
≥9%	3.9 (3.1-4.8)	2.6 (2.0-3.1)	4.0 (3.2-4.9)	2.4 (2.0-3.9)	5.4 (2.0-5.1)	4.1 (2.7-5.1)

5.0-6.1). Compared with nondiabetic patients, there was a U-shaped relationship between HbA1c categories and the risk of HFH and all-cause mortality in patients with T2D, irrespective of treatment (Table & Figure). Patients on metformin had lower risk of both outcomes compared to patients on SU/insulin, across all HbA1c categories (Figure).

CONCLUSIONS: In AF patients without prior HF, T2D confers greater long-term risk of HFH and all-cause mortality. There is a U-shaped relationship between HbA1c and outcomes, with the lowest risk in patients with moderate glycaemic control and those treated with metformin. This suggests that lenient glycaemic control may be an optimal strategy to improve outcomes in patients with AF and T2D.

P449

Prognostic role of diabetes and of medium-term glycemic control in heart failure

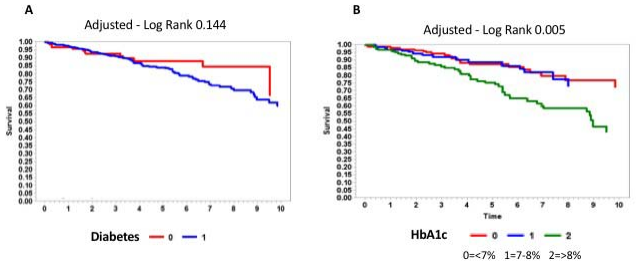
On behalf of: MECKI score

Background: Diabetes mellitus (DM) is common in heart failure (HF) patients and seems to adversely influence long-term morbidity and mortality. However, many variables affect HF prognosis and the exact role of DM and of glycemic control in presence of other well-known prognostic indicators is not clear. Aim of the present analysis was to assess in a large HF population the prognostic role of DM, the prognostic effect of insulin treatment, and the relationship among glycated hemoglobin (HbA1c) and prognosis over time and in presence of other prognostic predictors.

Methods: Data from HF patients with reduced ejection (HFrEF) fraction enrolled in the MECKI score database were retrospectively analyzed. In a first step analysis we compared the 10-year prognosis of diabetic and non-diabetic patients; then we compared the prognosis at 10 years of diabetic insulin and non-insulin dependent patients; last we compared the 10-year prognosis of diabetics according to HbA1c values (<7%, 7-8%, >8%). All the survival analyses were made at baseline and after correction for the variables included in the MECKI score (EF, Hb, Na, peakVO2, VE/VCO2 slope, MDRD). The primary endpoint was a composite of cardiovascular death, urgent heart transplantation and ventricular assist device implantation.

Results: Data from 3927 HFrEF patients (79% M, 61.7±13.2 years) were included in the present analysis; 897 patients (23%) presented a definite diagnosis of DM at baseline. Not-adjusted Kaplan-Meier analysis showed a worst prognosis in diabetic compared to non-diabetics as regards the primary study endpoint (Log Rank p=0.04), however after correction for the MECKI score variables no further prognostic differences were observed (Log Rank p=ns) (Figure 1A). The comparison between insulin (n=304) and non-insulin (n=567) diabetics showed an increased occurrence of the primary endpoint in patients on insulin (Log Rank p=0.05), however this difference disappeared after correction for the MECKI score variables (Log Rank p=ns). Last, the three groups of HbA1c showed significant survival differences (Log Rang p<0.001), having patients with HbA1c >8% (n=149) a worst prognosis, with comparable survival in patients with HbA1c <7% (n=266) and between 7-8% (n=133). These differences persisted even after correction for the MECKI score variables (Log Rank p=0.005) (Figure 1B). Conclusion: DM is a prognostic predictor in HFrEF patients, however its role may be mitigated by the presence of other important prognostic indicators. Differently, impaired medium-term glycemic control, expressed by elevated HbA1c, maintains over time its prognostic role independently from the presence of other well-known prognostic indicators. Thus, our efforts in diabetic patients needs to be concentrated on glycemic homeostasis stability over time.



P450

A multicenter, randomized, parallel-group pilot study of patiromer in optimizing mineralocorticoid receptor antagonist therapy in hyperkalemic heart failure patients (CONTINUE-HF): study design

M Boehm[1]; L Bernard[2]; C Mori[3]; B Mueller[4]; D Fliser[1]

[1]Saarland University Hospital, Homburg, Germany; *[2]OM Pharma, Meyrin, Switzerland*; *[3]Vifor Pharma, Glattbrugg, Switzerland*; *[4]Fresenius Medical Care Nephrologica Deutschland, Bad Homburg, Germany*

Funding Acknowledgements: Fresenius Medical Care Nephrologica Deutschland GmbH, a Vifor Pharma Group Company

Background/Aims:
Mineralocorticoid receptor antagonists (MRAs), e.g. eplerenone and spironolactone, are recommended in heart failure (HF) guidelines for reduction of morbidity and mortality in HF patients with reduced ejection fraction (HFrEF). However, as inhibitors of the renin–angiotensin–aldosterone system (RAAS), MRAs can induce hyperkalemia (HK), especially in patients with renal dysfunction, and are frequently discontinued or underdosed due to hyperkalemia concerns.
Patiromer is a new potassium-binder using calcium as a counterion exchange. The CONTINUE-HF study (EudraCT number 2017-003555-35) will evaluate, if patiromer added to standard treatment (including MRA) in hyperkalemic HFrEF patients will enable more patients to continue or achieve the guideline recommended target MRA dose compared to standard of care (SoC).

Methods: This is a multicenter, randomized, prospective, open-label, controlled, parallel group pilot study of patiromer in HFrEF patients with intended dose reduction or discontinuation of MRA therapy due to hyperkalemia.
The study consists of a screening period (up to 14 days), a 42-day treatment phase and a safety follow-up. Inclusion criteria include HFrEF (EF <40%), NYHA Class II/III, eplerenone or spironolactone therapy, and HK (serum potassium ≥5.1 mmol/l) that limits ability to maintain or increase MRA dose. Eligible patients are randomized 1:1 to receive patiromer or SoC (potassium dietary restriction, enhanced renal potassium elimination, reduction of potassium-sparing drugs) in addition to the MRA. Patients in both treatment groups receive dietary counselling.
The primary endpoint is the proportion of subjects maintaining or achieving the guideline recommended target MRA dose of 50 mg/day in the patiromer versus the SoC group at D42. Secondary endpoints are Patient Global Assessment (PGA), change in EQ-5D-5L, NYHA class, functional capacity, and eplerenone/spironolactone dosage from baseline over time. Additionally, the proportion of subjects on same or higher MRA dose compared to baseline, the change in HF and kidney related parameters such as NT-proBNP, troponin, and urine albumin/creatinine ratio will be analyzed.

CONTINUE-HF is an ongoing study being conducted across 25 sites in Germany and will randomize approximately 100 subjects stratified based on current MRA therapy (eplerenone or spironolactone) and serum potassium level (≥5.1 mmol/l to <5.5 mmol/l or ≥5.5 mmol/l).
Conclusions: We anticipate that in CONTINUE-HF the proportion of subjects maintaining or achieving optimal (guideline recommended, maximal tolerated dose) eplerenone/spironolactone dosage in the patiromer group will be larger than in the SoC group. The results of this pilot study could be used to design future studies assessing the beneficial effects of enabling eplerenone/spironolactone in this population.

P451
Improving management of iron deficiency in patients with CHF: an online educational intervention

S Sarah Mendly[1]; J Spyropoulos[1]
[1]*Medscape Global, London, United Kingdom of Great Britain & Northern Ireland*

Background: Iron deficiency (ID), independent of anemia is a common co-morbidity present in patients with chronic heart failure (CHF). However, routine screening of ID, independent of anemia in patients with CHF is lacking in clinical practice worldwide, and, as a consequence, many patients who develop ID are not optimally managed.
Purpose: To determine if an online continuing professional development (CPD) intervention could improve knowledge/competence and confidence of cardiologists and primary care physicians related to diagnosis and management of iron deficiency in the setting of CHF.
Methods: Cardiologists and primary care physicians electively participated in a video-based, 4-faculty educational discussion on diagnosing and treating iron deficiency. The effects of education were assessed using a repeated pair, pre-assessment/post-assessment study design. For all questions combined, a chi-square test assessed differences from pre- to post-assessment. P values <.05 are statistically significant. Cramer's V was used to assess level of educational effect. The activity launched on June 29, 2018 and data were collected through August 13, 2018.
Results: Overall significant improvements were seen after education for both cardiologists (N=438; P <.001; considerable educational effect, V=.270) and primary care physicians (N=619; P <.001; considerable educational effect, V=.287). Pre-assessment, the average correct response rate was 38% for cardiologists and 35% for primary care physicians, while post-assessment average correct response rates were 68% and 60%, respectively. Significant improvements were observed in cardiologists' and primary care physicians' knowledge and competence related to the guideline-recommended treatment of ID in the setting of CHF (Table).
As a result of the education, 26% of cardiologists and 28% of primary care physicians reported greater confidence in ability to treat ID in patients with CHF.
Conclusion: The statistically significant improvements observed in this intervention demonstrate the benefits of using education to increase knowledge, competence and confidence of cardiologists and primary care physicians and suggest that this type of intervention has the potential to positively impact recognition and treatment of ID in patients with CHF.

Knowledge and competence improvements

Topic	Cardiologists (N=438)Relative % improvement (post-assessment vs pre-assessment; P value)	Primary care physicians (N=619)Relative % improvement(post-assessment vs pre-assessment; P value)
Assessing ID treatment response	146% (25% vs 62%; P<.001)	101% (26% vs 53%; P<.001)
Knowledge of safety and efficacy of IV therapies for ID in the setting of CHF	60% (45% vs 71%; P<.001)	79% (36% vs 65%; P<.001)

Contributing factors to anemia in acute decompensated heart failure patients with or without preserved ejection fraction

R Ryoto Horai[1]; K Sakane[1]; S Nakayama[1]; D Maeda[1]; K Akamatsu[1]; K Tsuda[1]; M Ozeki[1]; T Fujisaka[1]; Y Kanzaki[1]; T Ito[1]; K Sohmiya[1]; M Hoshiga[1]
[1]*Osaka Medical College, Cardiology, Osaka, Japan*

Background: Anemia is known as one of the most important comorbidity and associated with poor prognosis in heart failure (HF) patients. Anemia in HF is complex and multifactorial. The major factors contributing to HF related anemia involve chronic kidney disease (CKD) and iron deficiency (ID). CKD and ID were also common in HF patients. However, the relationship between anemia and CKD or ID in HF patients is not fully understood.
Purpose: We hypothesized that contributing factors to anemia might be different between HF with reduced vs. preserved ejection fraction (HFrEF vs. HFpEF). This study aimed to investigate contributing factors of anemia in HF patients and its prevalence.
Methods and Results: We analyzed 255 patients hospitalized for acute decompensated HF between January 2015 and December 2017. Patients were categorized into two groups based on left ventricular ejection fraction assessed by echocardiography, HFrEF (EF < 40%, n = 85) and HFpEF (EF ≥ 50%, n = 111). HF with mid-range EF (EF 40 – 49%) patients were excluded. Anemia was defined as the hemoglobin level < 13 g/dL in male and < 12 g/dL in female. ID was defined as serum ferritin < 100 ng/mL or 100 – 200 ng/mL if transferrin saturation <20%. CKD was defined as eGFR < 60 ml/min/1.73m2. Anemia (54.1% vs. 73.9%) and ID (54.1% vs. 74.5%) were more frequent in HFpEF patients than HFrEF patients. In HFrEF patients, the prevalence of anemia was significantly higher in patients with CKD than those without CKD (62.3% vs. 18.8%, p = 0.002), whereas in HFpEF patients it was higher in patients with ID than those without ID (80.8% vs. 62.1%, p = 0.04). Multiple logistic regression analysis revealed that in HFrEF patients CKD and use of anti-platelet agents were independently associated with anemia (OR 0.97, 95% CI 0.94 - 0.99, p = 0.04, and OR 3.16, 95% CI 1.10 - 9.07, p = 0.03, respectively), whereas in HFpEF patients only ID was independently associated with anemia (OR 3.40, 95% CI 1.31 - 8.82, p = 0.01).
Conclusion: Our study suggests that CKD in HFrEF and ID in HFpEF are the major contributing factors to anemia. Further study is required for fully understanding of pathophysiological mechanisms of anemia in HF patients.

The prevalence of anemia in HF patients

	Iron deficiency (ID)	Chronic kidney disease (CKD)				
without ID	with ID	p value	without CKD	with CKD	p value	
HFrEF	Hemoglobin (g/dL)	13.1 ± 2.6	12.1 ± 2.2	0.05	13.7 ± 2.3	12.3 ± 2.4	0.03
Anemia (%)	48.7 (19/39)	58.7 (27/46)	0.39	18.8 (3/16)	62.3 (43/69)	0.002	
HFpEF	Hemoglobin (g/dL)	11.3 ± 2.4	10.4 ± 2.1	0.04	11.6 ± 2.1	10.4 ± 2.2	0.02
Anemia (%)	62.1 (23/37)	60.8 (59/73)	0.04	66.5 (19/29)	76.8 (63/82)	0.22	

Acute Heart Failure

P454
The significance of plasma osmolarity for in-hospital course and long-term outcome in patients with acute heart failure.

M Sokolski[1]; JM Sokolska[1]; R Zymlinski[1]; J Biegus[1]; K Swoboda[2]; P Siwolowski[1]; P Gajewski[1]; S Nawrocka-Millward[2]; W Banasiak[2]; P Ponikowski[1]

Funding Acknowledgements: The research was financed from the statutory grant for Department of Heart Diseases, Wroclaw Medical University, Poland (ST-905).

Background. Plasma osmolarity reflects an electrolyte-water balance and is related to the pathophysiological pathways as neurohormonal activation, cardiorenal interaction and treatment used in patients with acute heart failure (AHF). The clinical relevance of plasma osmolarity in AHF has not been well established.
Purpose. The aim of the study was to interlink the plasma osmolarity with clinical characteristic and outcome in patients hospitalized with AHF.
Methods: Baseline plasma osmolarity was calculated using concentrations of plasma sodium, plasma glucose, and blood urea nitrogen (osmolarity = 1.86×sodium mmol/L + (glucose mg/dL/18) + (BUN mg/dL/2.8) + 9). The primary endpoints were: in-hospital heart failure worsening (WHF) and 1-year all-cause mortality.
Results. We investigated 340 patients with mean age: 68±13 years, 76 % were men. The median with interquartile range [IQR] of serum osmolarity was 294 [287;304] mmol/l. Patients were divided according to the quartiles baseline plasma osmolarity into four groups (A: < 287, B: 287-294, C: 294-304, D: >304 mmol/L, n=85 in all subgroups). Patients from group A and D had more frequent decompensated

chronic heart failure (76 vs 60 vs 62 vs 73 %). There was increasing age gradient in the subsequent groups (63±14 vs 66±13 vs 69±12 vs 74±11 years) and patients differ in occurrence of arterial hypertension (60 vs 74 vs 80 vs 80 %) and diabetes (30 vs 30 vs 39 vs 56 %). At admission there were identified differences in mean systolic blood pressure (122±27 vs 135±29 vs 140±35 vs 133±31 mmHg), mean haemoglobin level (13±2 vs 13±2 vs 13±2 vs 12±2 g/dL), mean creatinine level (1.0±0.3 vs 1.1±0.3 vs 1.3±0.4 vs 1.9±0.8 mg/dL), median NTproBNP level (6124 [3189;11958] vs 4191 [2608;7550] vs 5363 [2671;9930] vs 7611 [5255;8654] pg/mL). Regarding to the treatment before hospitalization and at admission there were no significant differences between the groups, except catecholamine use (14 vs 4 vs 8 vs 17 %). Additionally, there was a difference in incidence of in-hospital WHF (20 vs 9 vs 10 vs 22 %) and one year all-cause mortality (31 vs 18 vs 22 vs 37 %). In all above mentioned comparisons A vs B vs C vs D group P<0.05. Figure 1 presents Kaplan-Meier curves demonstrating 12-month survival rate of patients with AHF divided according to the baseline plasma osmolarity quartiles.

Conclusions. Among AHF patients, baseline plasma osmolarity is associated with clinical presentation and carries an important prognostic information. The U-shaped distribution for short and long-term prognosis according to baseline plasma osmolarity is seen in AHF.

Introduction . To the date we have accumulated a large amount of knowledge related to the role of macrophages in development of the cardiovascular pathology. However, there is no significant advancement in clinical studies.

Purpose. The purpose was to assess prospects for implementation of cardiac macrophage phenotyping in patients with MI in clinical practice.

Methods. The study included 41 patients with fatal MI type 1. Group 1 (n=24) comprised patients who died within 72 hours of MI (the inflammatory phase of MI) and group 2 (n=17) comprised patients who died 4-28 days after MI (the regenerative phase of MI). Macrophage infiltration in the heart was assessed by double immunofluorescence. We used CD163, CD206 and stabilin-1 as markers of M2-like macrophages, while α-smooth muscle actin (α-SMA) was considered as a marker of macrophage transdifferentiation. Cells were counted in the infarct and non-infarct area. Each area was evaluated in 20 random fields.

Results. We identified CD163+/CD206-, CD163-/CD206+, CD163+/CD206+, stabilin-1+/α-SMA-, stabilin-1+/α-SMA+ macrophages. In the infarct area, the number of CD163+/CD206-, CD163+/CD206+, stabilin-1+/α-SMA- macrophage was lower during the inflammatory phase of MI than during the regenerative phase. Group 1 vs group 2 (number of cells in 20 random fields, median): 22 vs 83 (CD163+/CD206-, p=0.03), 12 vs 94 (CD163+/CD206+, p<0.0001), 30 vs 103 (stabilin-1+/α-SMA-, p=0.03). The number of CD163+/CD206+ macrophages in the infarct area (IA) correlated with the incidence of recurrent MI (R=0.46, p=0.006). The number of CD206+/CD163- cells in the IA correlated with in-hospital mortality according to the GRACE risk score: R=-0.43, p=0.01. The number of stabilin-1+/α-SMA+ macrophages in the IA correlated with the incidence of type 2 diabetes (R=-0.4, p=0.04), hypertension (R=-0.6, p=0.003), ventricular aneurysm (R=0.4, p=0.03), and the relative number of peripheral blood monocytes prior to the onset of death (R=-0.6, p=0.04). In the non-infarct area, the quantity of CD163+/206- cells correlated with the history of prior MI (R=0.4, p=0.02) and the incidence of recurrent MI (R=0.4, p=0.02), while the quantity of CD206+/163- macrophages correlated with the absolute number of peripheral blood monocytes at admission (R=0.4, p=0.04).

Conclusions. We revealed subpopulation of stabilin-1+/α-SMA+ macrophages, that indicated the possibility of cellular transdifferentiation and macrophage plasticity. CD206+/CD163- macrophages were proposed as a subpopulation that correlated with adverse scenario of MI. CD206+/CD163- and stabilin-1+/α-SMA- macrophages were proposed as subpopulations that correlated with the development of chronic inflammation in the heart. Our study supports prospects for implementation of macrophage phenotyping in clinical practice that might become a step to precision medicine, a breakthrough in the development of new methods for management of MI and following complications.

P456

T-lymphocytes and natural killers cells in patients with acute myocardial infarction complicated by acute heart failure

OK Lebedeva[1]; GA Kukharchik[2]
[1]*North-Western State Medical University named after I.I.Mechnikov, Saint-Petersburg, Russian Federation*; [2]*Federal State National Medical Research Center named after VA Almazov, Saint-Petersburg, Russian Federation*

The level of lymphocytes and natural killers (NK) cells in myocardial infarction (MI) is relatively reduces, while the neutrophil-to-lymphocyte ratio (NLR) increases. CD16+ T-lymphocytes and NK cells have a cytotoxic effects. Their significance in the development of acute heart failure (AHF) has been little studied.

The aim was to assess changes in the count and ratio of lymphocytes and neutrophils in patients with MI and AHF.Materials and methods: 142 patients with MI were included in the prospective cohort study. Group 1 included 37 patients (26%) who developed AHF Killip II-IV, group 2 – 105 patients with AHF Killip I. The total number of leukocytes, neutrophils, CD16+ and CD16-T-lymphocytes and NK-cells were evaluated using flow cytometry with Cytodiff panel in 1, 3 and 14 days of MI. The NLR is the ratio of neutrophils to lymphocytes counts. Statistical analysis was performed using the STATISTICA 10.0 package. Non-parametric methods of statistical analysis were used.

Results: Patients in 1 group were older than patients in the 2 group: 73.5(63; 80) vs 64.5 (58; 73) years. On the 1 day, leukocytes and neutrophils counts were equal high in both groups and normalized up to the 14th day. The total number of leukocytes did not differ in both groups during the observation period. On 3 day, the number of neutrophils was higher in group 1 then in the group 2: 5821(4921;8936)/μl vs 4935(4100;6843)/μl, p=0.03. On the 14th day, the number of neutrophils is equal in both groups. The total number of lymphocytes in groups 1 and 2 was: on 1st day, 1334(906;1855)/μl vs 2007(1368;2308)/μl, p=0.03; on 3rd day, 1374(1015; 1920)/μl vs 2150(1721;2578)/μl, p=0.0041; on the 14th day, 1917(1528;2264)/μl vs 2322(1983;2659)µl, p=0.011, respectively.The counts of CD16- T-lymphocytes and NK cells in 1 and 2 groups were: on 1st day, 1061(659;1196)/μl vs 1396(913;1683)/μl, p=0.02; on 3rd day, 1094(781;1467)/μl vs 1587(1166;1854)/μl, p=0.008; on the 14th day, 1351(1965;1886)/μl vs 1728(1298;2028)/μl, p=0.08, respectively.The number of CD16+ T-lymphocytes and NK cells in groups 1 and 2 was: on 1st day, 116(97;190)/μl vs 222(186;272)/μl, p=0.004; on 3rd day, 205(61;295)/μl vs 345(202;453)/μl, p=0.0005; on the 14th day, 289.8(124;335)/μl vs 342(236;518)/μl, p=0.05, respectively. The number of B-lymphocytes in both groups were the same.NLR on the 1st day was high and comparable in all patients. On days 3 and 14, NLR decreased in both groups, but was higher in 1 group: 5.38(2.43;8.98) vs 2.21(1.76;3.75), p=0.0014 and 2.73(1.8;4.32) vs 1.81(1.51;2.54), p=0.02.

Conclusions: in patients with MI, the development of severe AHF is associated with higher and prolonged absolute and relative neutrophilia, as well as lower level of T-lymphocytes and NK cells, both regulatory (CD16-) and cytotoxic (CD16+). AHF develops in patients with more significant inflammatory response. And NK cells seems to play a protective role during MI.

Frequency and predictors of mortality in arrhythmia-induced cardiomyopathy: a diagnosis not to be missed

S Sofia Alegria[1]; A Marques[1]; AR Pereira[1]; A Briosa[1]; D Sebaiti[1]; AR Almeida[1]; R Miranda[1]; S Almeida[1]; L Brandao[1]; O Simoes[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

Background: Arrhythmia-induced cardiomyopathy (AIC) is characterized by left ventricular (LV) systolic dysfunction caused by arrhythmia which is reversible once

the arrhythmia is properly controlled. There is scarce scientific evidence regarding the clinical features and therapeutic implications of this condition.
Purpose: To characterize the population of patients with suspected AIC and to determine predictors of recovery of LV systolic function and of all-cause mortality.
Methods: Retrospective analysis of patients admitted in a Cardiology department with a probable diagnosis of AIC between 2012 and June 2018. Logistic and Cox regression analyses were used to determine predictors of recovery of LV systolic function (improvement of LV ejection fraction – EF of ≥10%) and of mortality, respectively.
Results: Fifty-eight patients were included, with a mean age of 62±10 years, and male predominance (66%). The most common associated arrhythmia was AF (50%), followed by atrial flutter (AFL – 26%), both AF and AFL (19%) and other tachyarrhythmias (5%). The mean body mass index was 29±5kg/m2, the prevalence of arterial hypertension was 57%, cerebrovascular disease 13% and hypothyroidism 9%. On admission most patients were on functional class III or IV (61 and 23%, respectively), the median NT-proBNP was 2511 pg/ml, the mean LV EF was 28±10%, 54% had a dilated LV, 87% a dilated left atrium and 68% right ventricular systolic dysfunction.
During follow-up (median 637 days), 84% of patients converted to sinus rhythm (SR); 50% were submitted to electric cardioversion, 17% to pharmacological conversion and 41% to catheter ablation (success rate of 88%). Among patients who converted to SR, 52% had recurrence of AF or AFL during follow-up.
On reassessment (median 257 days after admission) 60% of the patients were in SR, and the heart rate (HR) was controlled in 93% (median HR 70 bpm). There was an improvement in functional class (4% in class III and none in class IV), NT-proBNP (median 639 pg/ml), and LV systolic function (88% had recovery and 60% normalization of systolic function – mean LV EF 51±10%).
Recovery of LV function was associated with both SR and controlled HR in reassessment. On multivariate logistic regression analysis, the predictors of recovery of LV function were the presence of hypothyroidism and the mean HR on reassessment, with an increase in HR by 1 bpm associated with a reduction of 9% in the likelihood of recovery.
During follow-up 17% of patients died and the independent predictors of all-cause mortality were an history of cerebrovascular disease and absence of recovery of LV function.
Conclusions: In our population AIC was more commonly associated with AF, and patients usually presented with severe symptoms and LV systolic dysfunction. Both maintaining SR and controlling the HR are important for the recovery of LV systolic function, which was a predictor of survival in this population.

P458
Initial blood pressure variability in patients with acute heart failure is associated with increased rehospitalization

J Y Jae Yeong Cho[1]; KH Kim[1]; HY Kim[1]; H Park[1]; HJ Yoon[1]; YJ Hong[1]; HW Park[1]; JH Kim[1]; Y Ahn[1]; MH Jeong[1]; JG Cho[1]; JC Park[1]
[1]Chonnam National University Hospital, Cardiology, Gwangju, Korea (Republic of)

Background: Blood pressure variability (BPV) is associated with adverse clinical outcomes in patients with hypertension. However, there are few established data about the impact of BPV on prognosis in patients with acute heart failure (AHF). The aim of this study was to investigate the impact of BPV on long-term clinical outcomes in patients with AHF.
Methods: A total of 123 patients (69.6±13.6 years, 63 males) with acute heart failure consecutively admitted to a tertiary hospital between 2012 and 2013. All patients were diagnosed with acute heart failure according to symptoms, signs, biomarkers, and echocardiography. The initial 24hr of blood pressures in intensive care unit (ICU) were recorded for all patients and the standard deviation (SD) and coefficient of variation (CV) reflecting BPV were calculated in the patients. Patients were divided into two groups according to BPV during the first 24hr in ICU; the high BPV group (SD ≥11 mmHg) (n=70, 72.4±11.5 years, 33 males) vs. the low BPV group (SD <11 mmHg) (n=53, 65.9±15.4 years, 30 males). Receiver operating characteristics-curve analysis identified the SD of 11 mmHg as a cut-off value for long-term adverse outcomes. Baseline characteristics, echocardiographic findings, laboratory findings, and clinical outcomes were compared between the two groups.
Results: The mean value of 24hr mean SBP was 124.0±20.9 mmHg and DBP was 68.9±10.2 mmHg. Patients in the High BPV group were older than those in the low BPV group (72.4±11.5 vs. 65.9±15.4 years, p=0.011). There was no gender difference between the two groups (males: 47.1% vs. 56.6%, p=0.299). There was no significant difference in SD (11.1±3.3 vs. 12.0±4.3 mmHg, p=0.281) and CV (8.9±2.0% vs. 9.7±3.0%, p=0.114) between the patients who died and those who survived at 1-year follow-up. However, SD (13.1±4.0 vs. 11.3±4.0 mmHg, p=0.031) and CV (10.4±2.8 vs. 9.2±2.7, p=0.034) in patients with any rehospitalization during 1-year follow-up was higher than in those without rehospitalization. Rehospitalization rate was higher in patients with high BPV group than in those with low BPV group (37.1% vs. 13.2%, p=0.003). Multivariate analysis using binary logistic regression showed that high BPV was an independent predictor of rehospitalization in AHF patients (OR 3.37, 95%CI 1.30-8.71, p=0.012).
Conclusion: There was no difference in 1-year mortality among AHF patients with high BPV and low BPV. However, rehospitalization was more frequent in AHF patients with high BPV than in low BPV.

Funding Acknowledgements: No funding to declare.

Background/Introduction: Renal congestion due to acute decompensated heart failure is associated with worse outcomes in hospitalized patients. Furthermore, literature date (ESCAPE trial) showed that persistent hyponatremia was an independent factor for mortality and rehospitalization for patients with heart failure.
Purpose The aim of our study was to evaluate what kind of impact diuretic therapy administered to patients with heart failure had on serum electrolytes (sodium, potassium) and renal functions (assessed through serum creatinine and urea).
Methods We performed a retrospective study on 100 heart failure patients admitted to our clinic during a 12 month period. Data regarding patient demographics, medical history, comorbidities, laboratory results, echocardiography and in-hospital treatment were collected for all patients. Those with unavailable laboratory assay results, echocardiographic assessment or in-hospital treatment were not included. Data analysis was performed using SPSS, version 20 in order to obtain descriptive and inferential statistics using parametric and non-parametric tests.
Results Of the 100 patients enrolled, 50 had heart failure with preserved ejection fraction (HFpEF) and 50 had heart failure with reduced ejection fraction (HFrEF). The mean age was 71,10 ± 10,93 with patients in the HFpEF slightly older (74,66 ± 9,44 vs. 67,54 ± 11,24). More women had HFpEF (82% vs. 36%).
Patients has urea, creatinine, sodium and potassium levels assessed throughout their hospital stay and both minimum and maximum values noted for all. It is apparent that the maximum urea level has a different distribution across the two patient subgroups (mean value in HFpEF 55.99 ± 33.41 vs. 71.87 ± 43.06, p=0.031), as had the minimum level of sodium (mean value in HFpEF 140.66 ± 5.79 vs. 137.64 ± 9.40, p=0.013), but not maximum creatinine (mean value in HFpEF 1.04 ± 0.53 vs. 1.31 ± 0.46, p=0.180) as suggested through the use of non-parametric tests such as the Mann-Whitney U Test. Minimum sodium levels correlated with the total dose of spironolactone used during the entire hospital stay (r=0.211, p=0.047) and maximum urea correlated with the total dose of oral furosemide (r=0.297, p=0.005) but not with intravenous furosemide (r=0.123, p=0.252).
Conclusion(s) Patients with a reduced ejection fraction, rather than those with HFpEF, more often present to hospital with decompensated heart failure, exhibiting signs and symptoms of pulmonary and systemic congestion and thus require higher doses of diuretics. It is quite expected that they would have higher maximum urea and lower minimum sodium values as compared to HFpEF patients. However, unexpectedly, creatinine does not seem to follow the same trend.

P461
Both admission hypo- and hyper-glycemia are associated with increased 1-year mortality in patients with acute heart failure

E Eiichi Akiyama[1]; R Cinotti[2]; A Cohen-Solal[3]; J Lassus[4]; O Miro[5]; AP Maggioni[6]; C Mueller[7]; J Parenica[8]; JJ Park[9]; J Spinar[8]; N Sato[10]; K Tamura[11]; K Kimura[12]; E Gayat[3]; A Mebazaa[3]

On behalf of: the GREAT (Global Research on Acute Conditions Team) Network
Funding Acknowledgements: This work was supported by a research fellowship from Japan Heart Foundation (E.A.)

Background: Hyperglycemia is common, regardless of diabetes mellitus (DM), and is associated with increased short-term mortality in patients with acute heart failure (AHF). However, relationships between abnormal blood glucose levels, especially hypoglycemia, and long-term mortality in AHF remain undetermined.

Purpose: This study sought to investigate the effect of hypo- or hyper-glycemia at admission on 1-year all-cause mortality in AHF patients.
Methods: From the GREAT (Global Research on Acute Conditions Team) registry, 13840 patients presenting with AHF whose admission glucose levels were available were included and followed up for 1-year all-cause mortality. Hyperglycemia was defined as a glucose levels of ≥7 mmol/L for patients without history of DM and ≥10 mmol/L for those with history of DM and hypoglycemia was defined as a glucose levels of ≤4 mmol/L.
Results: There were 193 (1.4%) patients with hypoglycemia, 6418 (46.4%) patients with hyperglycemia, and 7229 (52.2%) patients with normoglycemia. One-year mortality was higher in patients with hypo- and hyper-glycemia than those with normoglycemia (81 [42%], 1911 [30%], and 1821 [25%], respectively). Even after adjustment, the risk for 1-year mortality was significantly higher in hypo- (hazard ratio [HR] 1.69, 95%-confidence interval [CI] 1.18-2.44, P=0.004) and hyper-glycemia (HR 1.14, 95%-CI 1.04-1.26, P=0.008) compared with normoglycemia. Detrimental effects of dysglycemia on 1-year mortality were similar in DM and non-DM patients (p for interaction 0.05 for hypoglycemia and 0.75 for hyperglycemia), while more severe in de novo AHF patients than in patients with history of HF (p for interaction 0.05 for hypoglycemia and 0.004 for hyperglycemia).
Conclusions: In patients with AHF, both hypo- and hyper-glycemia at admission are associated with increased risk for 1-year mortality, especially in de novo HF patients.

P462

Relationship between early drop 13.5% in systolic blood pressure, worsening renal function and long-term outcome in patients with acute heart failure

T Takehiko Kido[1]; T Okabe[1]; J Saitou[1]; S Shimazu[1]; T Kimura[1]; Y Oyama[1]; W Igawa[1]; M Ono[1]; S Ebara[1]; K Yamashita[1]; M Yamamoto[1]; K Amemiya[1]; T Yakushiji[1]; N Isomura[1]; M Ochiai[1]
[1]*Showa University Northern Yokohama Hospital, Division of Cardiology and Cardiac Catheterization Laboratories, Yokohama, Japan*

Background: Worsening renal function (WRF) is associated with poor prognosis in patients with heart failure (HF). Previous studies suggested that early drop in systolic blood pressure (SBP) was associated with increase in the risk of WRF.
Purpose: Our purpose was to identify the optimal cut-off value of early drop in SBP for WRF and to evaluate the association between early drop in SBP and long-term composite outcome of HF re-admission and cardiovascular mortality in HF patients.
Methods: We retrospectively enrolled acute decompensated HF patients who admitted our hospital from March 2010 to July 2016. WRF was defined as a relative increase in serum creatinine of at least 25% or an absolute increase in serum creatinine 0.3 mg/dL from the baseline. SBP was measured on admission and each 4 hours within first 24 hours. The early drop was defined as drop in SBP within first 24 hours. We investigated that the relationship between early drop in SBP, WRF, and long-term composite outcome using multivariate analyses.
Results: A total of 413 patients with acute HF were enrolled. The mean age was 77.0±14.8 years and 60.7% were male. During the median 897 days (interquartile range, 186 to 1568 days) follow up period, 138 patients (34.4%) had HF re-admission or cardiovascular death. WRF occurred in 143 patients (34.6%). Mean SBP on admission was significantly higher in patients with WRF than in patients without WRF. However, mean SBP after 24 hour from admission was significantly lower in patients with WRF than in patients without WRF. The receiver operating characteristic curve analysis identified that the optimal cut-off value for WRF was 13.5% drop in SBP. Multivariate Cox regression analysis showed that early drop in SBP ≥13.5% (Odds ratio, 9.05; 95% confidence intervals, 4.36-20.02; P <0.001), inotropic agents, creatinine level, female gender, and tolvaptan were associated with WRF. Regarding to composite endpoint of HF re-admission and cardiovascular mortality, Cox proportional hazard models showed that age, previous history of HF admission, WRF, and creatinine level were associated with increase in composite endpoint risk. The early drop in SBP was not associated with increase in composite endpoint risk.
Conclusion: Early drop in SBP ≥13.5% was a strong predictor of WRF in patients with HF. However, early drop in SBP ≥13.5% was not the independent predictor of HF re-admission or cardiovascular mortality.

Validation of radiofrequency determined lung water using thoracic CT: findings in acute decompensated heart failure Patients

C Wheatley[1]; P Sajgalik[1]; BS Cierzan[1]; RJ Wentz[1]; BL Ziegler[1]; BD Johnson[1]
[1]*Mayo Clinic, Cardiovascular Diseases, Rochester, United States of America*

Funding Acknowledgements: ZOLL

Introduction: To date, noninvasive outpatient monitoring for heart failure (HF) to track disease status has been met with limited success. We validated radiofrequency (RF) determined lung water's ability to identify volume overload compared to thoracic CT's ability to do the same.
Methods: Two different groups were studied: 27 acute HF (AHF) inpatients (pts) and 26 subjects without AHF (Control – 16 healthy and 10 stable HF). All underwent supine thoracic CT scans (age= 78±8 vs. 56±16 yrs.; female= 37 vs. 27%; BMI=31.6±7.4 vs. 26.8±4.5, AHF vs. Control respectively; p < 0.05 for all). This was followed with supine RF readings from a wearable patch device (ZOLL LifeVest, Pittsburgh, PA) placed on the left mid-axillary line. RF based lung fluid model was built using reflected RF signals and anthropometric data. Lung fluid was reported as percentage of lung volume. Classification analyses were used to compare RF and CT performance.
Results: AHF pts presented with higher lung water levels measured by both CT and RF model (CT: 20.2±3.8 % vs. 14.8 ± 2.5 %; RF: 18.7±2.5 % vs. 16.4±1.5 %, AHF vs. Control respectively; p < 0.05 for all). The RF model performed as well as CT to identify AHF pts from Control subjects (Table).
Conclusions: Noninvasive nonionizing RF determined lung water provides a potential alternative to other measures for diagnosing and monitoring pulmonary fluid overload and the presence of pulmonary congestion. Further studies will guide the clinical utility of RF determined lung water in HF patient management.

RF and CT Classification Analyses

AHF vs. Control	Sensitivity [%]	Specificity [%]	Positive Predictive Value [%]	Negative Predictive Value [%]	Positive Likelihood Ratio	Negative Likelihood Ratio
RF Model	78	85	84	79	5.1	0.3
CT	74	85	83	76	4.8	0.3

Decongestion by bioimpedance analysis in patients hospitalized with decompensated heart failure depending on ejection fraction

O Lukina[1]; A Soloveva[1]; M Bayarsaikhan[1]; K Gudieva[1]; N Soseliya[1]; A Metelkin[1]; E Troitskaya[1]; S Villevalde[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Department of Internal Medicine, Moscow, Russian Federation*

Objective: Similar congestion and decongestion by clinical data had been reported in patients with acute heart failure (HF) depending on ejection fraction (EF) phenotypes. The aim of the study was to evaluate decongestion by bioimpedance analysis (BIA) in patients with decompensated HF (DHF) based on EF.
Methods: Congestion was assessed on admission and at the day of discharge by tetrapolar BIA. Resistance (R) and reactance (Xc) values on single 50kHz frequency were standardized by height (h). Congestion status was defined by graphical results of R/h and Xc/h depending on deviation from validated BIA data in the normal population. Decrease of R/h and Xc/h means increase of severity of congestion. Patients were divided into 3 groups based on EF: HF with reduced EF<40% (HFrEF), HF with mid-range EF 40-49% (HFmrEF) and HF with preserved EF≥50% (HFpEF). Mann-Whitney and Wilcoxon tests were performed. P<0.05 was considered significant.
Results: Study included 149 patients with DHF (104 male, 69 (60;78) years, arterial hypertension 93%, history of MI 48%, diabetes 41%, NT-proBNP 4046 (1956;5456) pg/ml, EF 39 (29;50)%. 50, 21 and 29% of patients had HFrEF, HFmrEF and HFpEF, respectively. On admission mild, moderate and severe congestion was revealed in 13, 26% and 40% of patients. Incidence of corresponding baseline congestion was 8, 31 and 41% in HFrEF group, 13, 19 and 36% in HFmrEF and 23, 23 and 40% in HFpEF (p=0,15).
Patients with HFrEF vs HFmrEF and HFpEF tended to have more pronounced baseline congestion according to lower values of R/h (229 [188;289] vs 257 [223;285], p=0.062 and 252 [212;306] Om/m, p=0.022) and Xc/h (18.9 [14.1;25] vs 23.3 [15;30], p=0.049 and 20.8 [15.7;24], p=0.31 Om/m) and tented to receive longer (p=0.052) and higher total dose of iv furosemide (560 [300;860] vs 420 [180;600] and 320 [200;640] mg, p=0.033), more commonly were treated with spironolactone (89.3 vs 71 and 42%, p<0.001). Patients with HFpEF vs HFmrEF and HFrEF were more often additionally treated with thiazides (23 vs 16.1 and 5.3%, p=0.014).
Significant changes of weight, R/h and X/c were revealed (p<0.001) without differences between groups based on EF.
Mild, moderate and severe congestion at discharge was identified in 15, 31 and 7% patients with HFrEF, 10, 13 and 10% in HFmrEF, 28, 28 and 5% in HFpEF. Patients with HFpEF had higher rate of congestion at discharge comparing to HFmrEF (61 vs 33%, p=0.02).
HFrEF group vs HFmrEF and HFpEF was characterised by tendency to a lower R/h (269 [231;301] vs 301 [280; 335], p=0.011 and 296 [260;335], p=0.005 Om/m) and Xc/h at discharge (24.4 [19.9;28.9] vs 30.4 [23.5;34.2], p=0.007 and 25.3 [21.8;29.3], p=0.45 Om/m).
Conclusion: There were no significant differences in the decongestion by BIA between different EF phenotypes of DHF. Patients with HFrEF tended to be more

congested both on admission and at discharge and to receive more intensive diuretic therapy.

P465

Serum sodium and chloride levels in relation to congestion and outcomes in decompensated heart failure

A Soloveva[1]; M Bayarsaikhan[1]; Y Kurilyuk[2]; S Bondari[1]; V Nosova[1]; V Aleshin[1]; S Villevalde[1]; Z Kobalava[1]

[1]Peoples' Friendship University of Russia (RUDN University), Department of Internal Medicine with the subspecialty of cardiology and functional diagnostics, Moscow, Russian Federation; *[2]The Federal State-Funded Educational Institution of Higher Education, Department of the legal regulation of economic activity, Moscow, Russian Federation*

Objective: Recently similar or even higher prognostic significance was attributed to hypochloremia (HypoCl) as compared with hyponatremia (HypoNa) in stable chronic heart failure (HF). HypoCl associations and impact on outcomes in decompensated HF (DHF) are less well understood. We examined the incidence of HypoNa and HypoCl and their associations with congestion and outcomes in patients with DHF.
Methods: Incidence of HypoNa≤135 mmol/l and HypoCl<96 mmol/l was assessed on admission and discharge (median at 9 [8;10] day) in 167 DHF patients with signs of congestion (120 males, 68±12 years [M±SD], hypertension 93%, myocardial infarction 46%, atrial fibrillation 61%, diabetes mellitus 39%, chronic kidney disease 27.5%, ejection fraction [EF] 39±14%, EF<40% 51.5%, NT-proBNP 4218 [1943;5726] pg/ml). Congestion was assessed and graded by bedside clinical assessment scale (ESC Scientific Statement 2010) and by bioimpedance analysis (BIA). Outcomes data were available for 163 patients. p<0.05 was considered significant.
Results: Baseline HypoNa and HypoCl were revealed in 5.9 and 7.2% cases (both were presented in 6 patients). Only HypoCl was associated with higher clinical congestion (5.5 [4;7.5] vs 4 [2;6] points, p=0.031), both were not associated with BIA congestion and outpatient diuretic therapy. During hospitalization incidence of HypoNa and HypoCl increased to 15.6% and 18.6%, respectively (only HypoNa, only HypoCl and both were presented in 11, 16 and 15 cases). Na and Cl moderately correlated (r=0.45 and 0.49 on admission and discharge, p<0.001). HypoCl at discharge was associated with more pronounced baseline clinical congestion (6 [4;6] vs 4 [2;6] points, p=0.035), higher haematocrit changes (6 [2;15] vs -2[-10;6.7]%, p=0.010) and decongestion by BIA (R/h 28 [19;41] vs 15 [5.4;29]%, p<0.001, X/c 51[28;88] vs 27[4.4;53]%, p<0.001), lower potassium (4.1±0.6 vs 4.4±0.6 mmol/l, p=0.008) and Na (135±4 vs 139±3, p<0.001) at discharge, more intensive iv loop diuretic (start dose 120 [80;160] vs 80 [60;120] mg, p=0.016, total iv dose 720 [490;1040] vs 480 [280;820] mg, p=0.024) and thiazide therapy (35.5 vs 7.4%, p<0.001), but characterised by similar incidence of outcomes comparing to patients without HypoCl. Patients with vs without HypoNa at discharge did not differ by decongestion, also received longer and higher doses of loop diuretics, but characterised by negative prognosis (higher 1 and 3-month death (15.4 and 19.2 vs 2.2 and 6.6%, p=0.002 and 0.035) and HF readmissions (15.4 and 26.9 vs 3.6 and 12.4, p=0.016 and 0.056). Electrolytes disturbances had no impact on 6- and 12-month outcomes.
Conclusions: HypoCl at discharge diagnosed in 18.6% patients was not associated with outcomes showing significant associations with decongestion and higher doses of loop diuretics, while HypoNa at discharge, revealed in 15.6% of cases and also related with more intensive diuretic therapy, was associated with higher short-term negative outcomes.

Diagnostic value of remote dielectric sensing (ReDS) technology to predict pulmonary congestion on computed tomography in consecutive patients with acute dyspnea

A Anne Sophie Olesen[1]; K Miger[1]; A Fabricius-Bjerre[1]; J Wamberg[2]; C Mascmann[2]; MM Wille[3]; AG Abild-Nielsen[3]; J Nybing[3]; L Pedersen[4]; HH Schultz[4]; OW Nielsen[1]

[1]Bispebjerg University Hospital, Department of Cardiology, Copenhagen, Denmark; *[2]Bispebjerg University Hospital, Department of Emergency Medicine, Copenhagen, Denmark*; *[3]Bispebjerg University Hospital, Department of Radiology, Copenhagen, Denmark*; *[4]Bispebjerg University Hospital, Department of Respiratory Medicine, Copenhagen, Denmark*

Funding Acknowledgements: Funding was provided by Sensible Medical and the Department of Cardiology, Bispebjerg University Hospital, Copenhagen, Denmark.

Background Remote Dielectric Sensing (ReDS) is a non-invasive electromagnetic energy-based technology that quantifies lung fluid content in less than 2 minutes without radiation. However, it is not known if ReDS can diagnose congestion on a chest computed tomography (CT) in unselected consecutive patients with dyspnea and possible comorbidities in the emergency department (ED).
Purpose
The primary aim is to examine if increased lung fluid content on ReDS can predict or exclude congestion on a low dose CT in consecutive dyspneic patients in the ED.
Methods
Patients >50 years of age with acute dyspnea in max 14 days admitted to the ED were included. All patients had a physical examination, chest X-ray, lung ultrasound (LUS), low-dose CT, ReDS-examination and echocardiography within 12 hours.
We defined ReDS as positive for congestion, if the average of right and left lung exceeded 35%. A normal ReDS estimated lung fluid content has previously been shown to be in the range of 20 to 35%. Congestion on CT was defined according to the Fleischner society, and CT scans were reviewed by two radiologists blinded for clinical data. Congestion on LUS (14-zone protocol) was defined as at least one zone bilateral with a minimum of 3 B-lines or bilateral pleural fluid.
Results
37 consecutive patients were examined on January 2019, 13 females and 24 males, with a mean age of 74 years, 23% had chronic heart failure, 81% active/past smokers, 23% had diabetes, 60% had copd, 30% had AFLI and 25% IHD. Out of 37 patients 6 (16%) had congestion on CT of whom 5 also had a positive ReDS-examination. Thus, 31 of 37 patients did not have congestion on CT: 7 of these patients had a positive ReDS while 24 had a negative ReDS. Therefore, a positive ReDS-examination was significantly (p=0.005) associated with congestion on CT with a specificity of 81% and a sensitivity of 83%.
Patients with versus without congestion on CT differed according to ReDS, mean (SD), 38.2 % (4.6) vs 29.4% (5.9), p=0.002; Total number of B-lines 19 (9) vs 6 (5), p=0.014; NT-proBNP 845 pmol/L (902) vs 175 pmol/L (265) p=0.13. Comparison of ROC analyses showed no statistically significant difference between ReDS, B-lines on LUS or NT-proBNP to predict congestion on CT (AUC 0.84; 0.89; 0.88, respectively: p=0.62 and p=0.76 for comparison with ReDS).
Conclusion These preliminary results show that increased lung fluid content on ReDS is significantly associated with pulmonary congestion on a chest CT in consecutive breathless patients in the ED. ReDS seem to predict congestion on CT as effectively as LUS and NT-proBNP. A normal ReDS-examination may exclude congestion on CT in patients with acute dyspnoea, but thresholds for abnormality should be further explored. Firm conclusions must await more patients, and during the congress we will present updated data on anticipated 90 patients.

P467

The reliability of Lung ultrasound and conventional X-ray in the stage differentiation of pulmonary congestion

T Tatyana Valova[1]; ID Ivailo Daskalov[1]; LD Lilya Demirevska[1]; KR Konstantin Ramshev[1]

[1]Military Medical Academy of Sofia, Cardiology and intensive therapy, Sofia, Bulgaria

Introduction: Pulmonary congestion is one of the most frequent complications of acute decompensated heart failure usually presenting with acute dyspnea. In emergency units the differentiation of the origin of dyspnea is sometimes a big challenge especially when time is of great importance for the administration of decongestive therapy.
Purpose: To evaluate the reliability of lung ultrasound and conventional X-ray in the diagnosis of different stages of pulmonary congestion in patients with dyspnea and acute decompensated heart failure.
Methods: Positive LUS B-lines score (>15) detection was tested against conventional X-ray in 100 dyspneic patients (n=44 NYHA III; n=56 NYHA IV) with pulmonary congestion and 58 healthy controls. Focus echocardiography (E/e>15) and NT-proBNP (>1000pg/ml) were used as referred methods.
Results: X-ray pulmonary blood flow redistribution was detected in all NYHA III patients and in no NYHA IV patients. Pulmonary alveolar edema was found in all NYHA IV patients and in no NYHA III patients. Interstitial pulmonary edema was found both in NYHA III and NYHA IV patients with a little prevalence for NYHA III patients. Positive LUS B-lines score >15 was detected in all NYHA IV patients (n=56; 100%). Bilateral LUS B-lines between 11-14 were detected in 35 NYHA III (79,5%) patients: 29 (66%) NYHA III patients with X-ray detected pulmonary blood flow redistribution and in 15 NYHA III patients (34%) with X-ray detected interstitial pulmonary edema. Positive LUS B-lines score was not detected in 9 NYHA III patients (20%) with X-ray estimated pulmonary blood flow redistribution. The difference in results between NYHA III and IV subgroups demonstrated excellent possibilities for LUS in differentiation of interstitial and alveolar edema in NYHA IV patients and moderate possibilities in differentiating of pulmonary blood flow circulation in NYHA III patients. X-ray staging of pulmonary congestion demonstrated an advantage in NYHA III patients. Focus echocardiography detected elevated left ventricle filling pressure (E/e>15) in all NYHA IV patients and corresponded with NT proBNP > 1000pg/ml and alveolar pulmonary edema detected with X-ray. E/e between 8 and 15 (grey

zone) was detected in most of the NYHA III patients which moderately correlated with NT-proBNP and strongly with pulmonary blood flow redistribution and interstitial pulmonary edema from X-ray.
Conclusions: X-ray differentiation of the stages of pulmonary congestion is preferable in NYHA III patients where LUS shows moderate reliability because of no positive B-lines score detection in most of the patients. LUS B-lines positive score is detected in all NYHA IV patients with interstitial and alveolar edema and demonstrates excellent reliability in these patients with acute dyspnea when time saving is of great importance for the choice of therapy.

Funding Acknowledgements: BIOSTAT-CHF was funded by the European Commission and an unrestricted research grant by Corvidia therapeutics

Background/Introduction: Inflammation is a central process in the pathophysiology of heart failure (HF), but trials targeting tumor necrosis factor-α (TNF-α) were largely unsuccessful. Interleukin-6 (IL-6) is an important inflammatory mediator and a potential pharmacologic target in HF. Little is known regarding the association between IL-6 and clinical characteristics, outcomes and other inflammatory biomarkers in HF.
Purpose: We aimed to characterize the association between IL-6 and clinical characteristics, other inflammatory biomarkers and outcomes in HF.
Methods: IL-6 was measured in 2329 patients [89.4% with a left ventricular ejection fraction (LVEF)≤40%] of the BIOSTAT-CHF cohort. The primary outcome was all-cause mortality and HF hospitalization during 2 years, with all-cause, cardiovascular [CV], and non-CV death as secondary outcomes.
Results: Elevated brain-type natriuretic peptide, procalcitonin, hepcidin and having iron deficiency, atrial fibrillation (AF) and LVEF>40% independently predicted elevated IL-6 levels. In a dendrogram-based correlation analysis IL-6 clustered with leukocyte counts, C-reactive protein, procalcitonin, transferrin saturation and hepcidin and was distinct from other inflammatory biomarkers, including TNF-α-related markers. IL-6 independently predicted the primary outcome (HR [95%CI] per doubling: 1.16 [1.11-1.21], p<0.001), all-cause mortality (1.22 [1.16-1.29], p<0.001) and CV as well as non-CV mortality (1.16 [1.09-1.24], p<0.001; 1.31 [1.18-1.45], p<0.001), but did not improve discrimination in previously published risk models.
Conclusions: In a large, heterogeneous cohort of HF patients, elevated IL-6 levels were observed in iron deficiency, LVEF>40%, AF and poorer clinical outcomes. IL-6 was distinct from other inflammatory biomarkers, including TNF-α-related biomarkers. These findings support further exploration of IL-6 as a therapeutic target in HF.

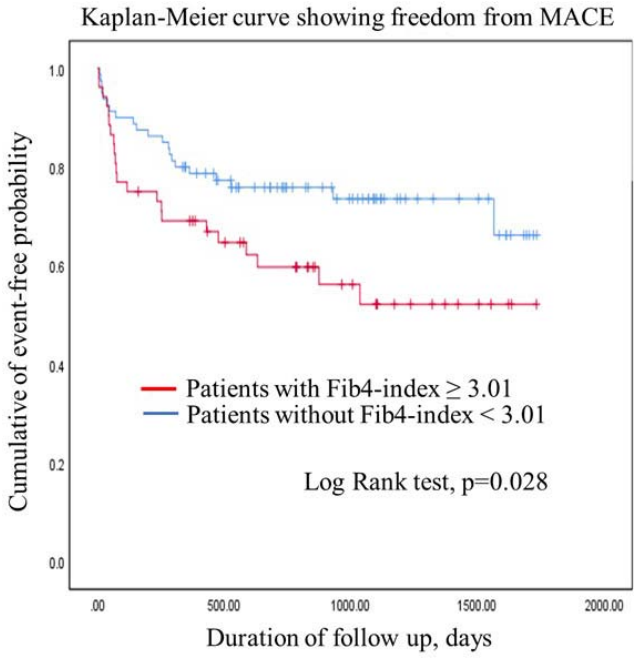
Liver stiffness assessed by fibrosis-4 index; noninvasive marker using serum biomarkers is associated with right ventricular function and cardiovascular prognosis in HFpEF

M Mitsutaka Nakashima[1]; S Sakuragi[1]; N Kodera[1]; T Ida[1]; T Yamada[1]; A Mori[1]; Y Koide[1]; T Wada[1]; K Kawamoto[1]; M Tanakaya[1]; Y Katayama[1]
[1]Iwakuni Clinical Center, Cardiology, Iwakuni, Japan

Background: Liver stiffness is reported to be associated with right atrial pressure and worse prognosis of heart failure. Fibrosis-4 (FIB4) index (age (years) × aspartate aminotransferase (IU/L) / platelet count (109/L) × square root of alanine aminotransferase (IU/L)) is known as a useful and simple marker for evaluating liver stiffness. However, the association between FIB4 index and prognosis in heart failure with preserved ejection fraction (HFpEF) was not elucidated.
Purpose: This study aimed to clarity the association between FIB4 index and right ventricular (RV) function and major adverse cardiac events (MACE) of HFpEF.
Method: From February 2012 to December 2015, 132 subjects diagnosed as HFpEF after hospitalization of acute decompensation were enrolled (79 years, 59 male). Subjects performed thoracic surgery or percutaneous coronary intervention within half a year and died before discharge were excluded. All subjects were measured FIB4 index and tricuspid annular plane systolic excursion (TAPSE) to assess RV function before discharge. In addition, patients were classified into two groups: high-(≥3.01, n=52) and low-FIB4 index groups(<3.01, n=80). MACE incidence during the follow-up period were compared between these groups.
Results: Patient with high-FIB4 index were older and higher level of blood pressure. There was no difference in prevalence rates of history of liver disease. In multivariate Linear regression analysis, FIB4 index was significantly association with TAPSE independently confounding factors. Kaplan-Meier analysis showed that patients with high-FIB4 index experienced more CV events during the 1734 days of follow-up (42.3% vs 26.2%, p=0.028) (figure).
Conclusions: FIB4 index is associated with RV dysfunction and a high risk of future CV event of HFpEF.



Kaplan-Meier curve freedom from MACE

P471
The trajectory of biomarkers in patients with acute heart failure and atrial fibrillation

O Barnett[1]; Y Horiuchi[2]; N Wettersten[2]; P Murray[3]; A Maisel[2]
[1]Danylo Halytsky Lviv National Medical University, Lviv, Ukraine; [2]University of California San Diego, Division of Cardiovascular Medicine, San Diego, United States of America; [3]University College Dublin, Department of Nephrology, Dublin, Ireland

Background: Atrial fibrillation (AF) and/or atrial flutter (AFL) and heart failure (HF) frequently coexist. The clinical impact of AF/AFL has not been fully investigated in patients with acute HF (AHF), especially in relation to biomarker values.

Purpose: To characterize the trajectory of biomarkers among patients hospitalized for AHF with AF/AFL on admission.
Methods: The Acute Kidney Injury Neutrophil gelatinase-associated lipocalin (NGAL) Evaluation of Symptomatic heart fallure Study (AKINESIS) was a multicenter, prospective cohort study of AHF patients. We retrospectively analyzed the relationship between AF/AFL detected on admission electrocardiogram and relative changes in biomarkers during therapy. Brain natriuretic peptide (BNP), high sensitivity cardiac troponin I (hs-cTnI), urine and serum NGAL (uNGAL and sNGAL), and galectin 3 (Gal-3) were measured at admission, 4-hours, day 1, 2, 3 and discharge. Clinical outcomes were 60-day composite of death or HF hospitalization and death at 1 year.

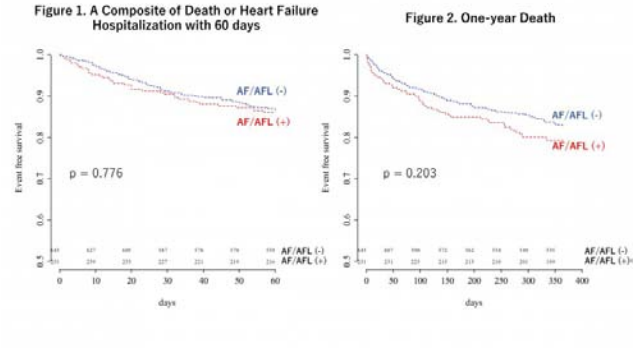


Figure
Results: Among 895 patients analyzed, 28% had AF/AFL. Patients with AF/AFL had smaller decreases in BNP and hs-cTnI during the first 3 days than those without AF/AFL. Levels of uNGAL trended higher in those with AF/AFL, while levels trended lower in those without AF/AFL. There was no association between AF/AFL and clinical outcomes (Figure). In multivariate Cox analysis, BNP and hs-cTnI were significantly associated with 60-day composite endpoint and BNP, hs-cTnI and Gal-3 were significantly associated with death at 1 year. AF/AFL did not predict these outcomes.
Conclusions: Presence of AF/AFL on admission for AHF was associated with unfavorable trajectories of BNP, hs-cTnI, and uNGAL; however, biomarkers, but not AF/AFL, were significantly associated with short- and long-term outcomes.

Prediction of 30-day readmission for Heart Failure by N-terminal pro-brain natriuretic peptides. Results of IMPEDANCE-HF extended trial

M Michael Kleiner Shochat[1]; D Kapustin[2]; M Fudim[3]; M Kazatsker[1]; Y Levy[1]; A Asif[1]; I Kleiner[4]; JM Weinstein[4]; G Panjrath[5]; A Roguin[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]University of Toronto, Internal disease , Toronto, Canada*; *[3]Duke University Medical Center, Cardiology, Durham, United States of America*; *[4]Saroka Medical Center, Cardiology, Beer Sheva, Israel*; *[5]George Washington University School of Medicine and Health Sciences, Cardiology, Washington, United States of America*

The aim of secondary analyses of the IMPEDANCE-HF extended trial was to find out if N-terminal pro-brain natriuretic peptides (NT-proBNP) on discharge for HF could predict 30-day readmission.
The analysis of IMPEDANCE-HF extended trial was based on the data collected during the index hospitalization for HF. The IMPEDANCE-HF extended trial was a randomized controlled single-blinded trial of HF with reduced LVEF patients. Inclusion criteria were LVEF ≤ 45%, NYHA class II-IV and patients were hospitalized for HF within 12 months (ClinicalTrials.gov NCT01315223). Half of the patients (N=145) were assigned to the active Lung Impedance (LI)-guided treatment arm where clinicians were based therapy on LI level. The other half was assigned to the control arm where LI values were recorded but not conveyed to the clinical treatment team. In the case of hospitalization, LI and NT-proBNP were recorded in all patients at discharge. The decisions regarding discharge and choice of treatment were at the discretion of the hospital staff .
Method. Values of NT-proBNP at discharge for HF hospitalization were divided according quartiles. Quartile 1: 800-3112, Quartile 2: 3113-5200, Quartile 3: 5201-7900, Quartile 4: > 7901 pg/ml.
Results: LI-guided patients were followed for 61.9.4±39.6 months and control patients for 46.7±33.3 months (p<0.01) accounting for 269 and 470 HF hospitalizations, respectively (p<0.01). Average NT-proBNP at discharge was 7351±5906 and 9060±7290 pg/ml in LI-guided and control groups, respectively (p<0.01). The distribution of study patients according to NT-proBNP level at discharge by quartiles was: 32%, 24%, 34%, 20% and 20%, 28%, 26%, 26%, in the LI-treated and control group, respectively (p<0.01). The probability to 30-day readmission calculated for both groups together according quartiles of NT-proBNP on discharge was: HR Quartile 2 to 1 = 1.7 [1.4 – 2.2, p <0.01], HR Quartile 3 to 1 = 2.5 [2.0 – 3.2, p <0.01], HR Quartile 4 to 1 = 4.1 [3.1 – 5.3, p <0.01].
Conclusion NT-proBNP at discharge for HF hospitalization is a reliable predictor for 30-day readmission.

P473

Catestatin serum levels are inversely associated with adverse structural and hemodynamic profile among patients with acutely decompensated heart failure: preliminary echocardiographic findings

JA Borovac[1]; J Bozic[1]; Z Susilovic Grabovac[2]; D Supe Domic[3]; T Ticinovic Kurir[1]; A Bradaric[2]; PM Zivkovic[4]; M Vilovic[1]; K Novak[5]; D Glavas[2]

Funding Acknowledgements: Nothing to declare.

Background: Catestatin is a novel peptide with pleiotropic roles in the cardiovascular system that might have pathophysiological implications in terms of structure and function of the left ventricle (LV) among acutely decompensated heart failure (ADHF) patients.
Purpose: This study tested associations of serum catestatin levels with structural and functional echocardiographic parameters of LV (Table 1).
Methods: Thirty-five patients diagnosed with ADHF according to ESC 2016 HF criteria were consecutively enrolled during January-April of 2018. Each patient underwent physical and transthoracic echocardiography examination and antecubital venous blood sampling. Catestatin serum levels were determined by using an enzyme-linked immunosorbent assay (ELISA).
Results: Mean age of the analyzed sample was 68 ± 10.2 years and 54.3% were men. Catestatin serum levels were in negative and significant correlation with LVEDd (r=-0.445, p=0.009), LVESd (r=-0.450, p=0.010), LVEDV (r=-0.407, p=0.021), LVESV (r=-0.407, p=0.009) and LV mass (r=-0.376, p=0.031) while they positively correlated with FS (r=0.422, p=0.016) and EF (r=0.311, p=0.039) (Figure 1). Remaining echocardiographic LV parameters did not significantly correlate with catestatin.
Conclusions: Higher levels of circulating catestatin measured at admission of ADHF patients are significantly associated with more favorable structural remodeling and hemodynamic performance of the left ventricle.

INTRODUCTION
The predictive role of an acid–base disbalance remains scarcely investigated in a broader population of acute dyspnea patients.
PURPOSE
To determine whether arterial blood gas test at the time of hospital admission can predict 1- and 3-month all-cause mortality of patients presenting with acute dyspnea due to different causes.
METHODS
Prospective multicenter observational cohort study enrolled 1457 dyspneic patients admitted with acute heart failure (AHF) and other diagnoses. Current analysis included 517 patients for whom arterial blood gas samples could be obtained. Patients were distributed into 3 groups: alkalosis group (pH > 7.45), a normal acid–base balance (normal ABB) group (7.35 pH 7.45) and an acidosis group (pH < 7.35). Chi-square test, logistic regression, Kaplan-Meier curves and Cox proportional hazard model were used to analyze survival differences in the groups. Multivariate analysis was adjusted to age, gender, history of chronic heart failure, coronary artery disease, diabetes mellitus, amount of C-reactive protein, anemia and eGFR < 60 ml/min/1.73m2.
RESULTS
In 517 patients of current analysis 57% were female, mean age was 69±13, mean pH value was 7.41±0.09, mean pCO2 38.4±13.0 mmHg, mean HCO3- 23.37±4.64 mmol/L, 59% were diagnosed with AHF. At admission, acidosis was found in 79 (15.3%), alkalosis in 121 (23.4%) and normal ABB in 317 (61.3%) patients. In-hospital mortality rates were: 12 (15.2%), 9 (7.4%) and 19 (6.0%) patients of the acidosis, alkalosis and normal ABB groups, respectively (p=0.02). Multivariate logistic regression showed that acidosis was associated with significantly increased in-hospital mortality risk with odds ratio 3.35 (95% confidence interval [CI]: 1.36 to 8.27, p=0.01). Meanwhile, mortality rates after 1 and 3 months were: 14 (17.7%) and 24 (30.4%) in acidosis; 15 (12.4%) and 27 (22.3%) in alkalosis; 26 (8.2%) and 46 (14.5%) patients in normal ABB group (p=0.04 and p<0.01, respectively). The presence of acidosis and alkalosis was associated with higher risk of 1- and 3-month mortality in univariate and multivariate analysis (Table 1).
CONCLUSIONS
Acid-base balance disorders at admission likely show more advanced disease stage in acute dyspnea patients. Alkalosis was associated with deteriorated survival, while acidosis was even worse increasing short-term all-cause mortality by three times.

Analysis for 1- and 3-month mortality

	Acidosis	Normal ABB	Alkalosis			
	HR (95% CI)	AHR (95% CI)	HR (95% CI)	AHR (95% CI)	HR (95% CI)	AHR (95% CI)
1-month mortality	2.34* (1.22-4.49)	2.79* (1.39-5.59)	1 (1-1)	1 (1-1)	1.55 (0.82-2.92)	1.58 (0.81-3.1)
3-month mortality	2.33* (1.42-3.82)	2.73* (1.61-4.62)	1 (1-1)	1 (1-1)	1.61 (0.99-2.59)	1.69* (1.02-2.79)

Introduction The usefulness of high-sensitivity Troponin T (hs-TnT) as a predictor of sudden cardiac arrest in patients undergoing valve surgery is currently unknown.
Methods A prospective study was conducted on a group of 815 consecutive patients with significant valvular heart disease that underwent elective valve surgery. The primary end-point was postoperative sudden cardiac arrest.
Results The postoperative sudden cardiac arrest occurred in 26 patients. At multivariate analysis hs-TnT measured immediately after surgery (hs-TnT I) and age remained independent predictors of the primary end-point.
The area under receiver operator characteristic curve for postoperative sudden cardiac arrest for hs-TnT I is 0.776 (95% CI 0.702–0.850)(Figure 1).
Conclusions Elevated postoperative hs-TnT was associated with a higher risk of postoperative sudden cardiac arrest.

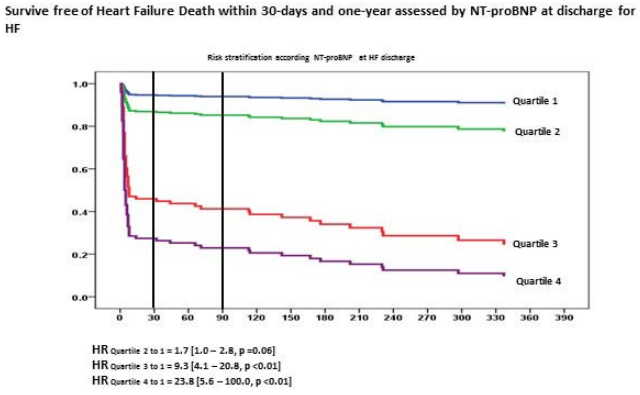
Introduction: Endothelial dysfunction contributes to the pathophysiology of heart failure (HF), being associated with adverse outcomes. Endocan has recently emerged as a novel biomarker of endothelial dysfunction but remains scarcely explored in HF. Resolvins (Rvs) are specialized proresolving mediators that actively contribute to the resolution of inflammation and tissue regeneration and appear to attenuate ventricular dysfunction after myocardial infarction and endothelial disruption. Nevertheless, their role in clinical settings of acute HF (AHF) has not been investigated.
Purpose: To evaluate serum endocan and RvD1, and to determine their correlation with each other and with ventricular dysfunction, lactic acidosis and prognostic scores in human AHF.
Methods: Patients with the diagnosis of AHF (n=11) and cardiogenic shock (CS) (n=9) were included and blood samples were collected at 3 time points: I - days 1-2 (admission), II - days 3-4 and III - days 5-7. Blood donors were used as controls (n=10). RvD1 and endocan were measured with ELISA kits. Ventricular dysfunction was assessed by echocardiogram and B-type natriuretic peptide (BNP) and lactic acid plasma concentration were evaluated using automated analyzers. Calculation of APACHE II and SAPS II scores were performed in all patients.
Results: Endocan (ng/mL) at admission was significantly increased in patients with AHF and CS when compared to control values (controls: 1.9±0.3; AHF: 8.8±3.7; CS: 20.0±3.8; controls vs AHF, p=0.036; controls vs CS, p<0.0001; AHF vs CS, p=ns). RvD1 (μg/mL) at admission was significantly higher in AHF than in CS although there were no significant differences compared to control values (controls: 1.8±0.3; AHF: 3.0±0.4; CS: 1.4±0.2; AHF vs CS, p=0.024; AHF or CS vs controls p=ns). Endocan and RvD1 values were not significantly different during hospitalization when comparing time points I, II and III. Within patients, we observed significant correlations between RvD1 and endocan (r=-0.38, p=0.009), RvD1 and lactic acid (r=-0.51, p=0.041), RvD1 and SAPS II (r=-0.50, p=0.029) and also between endocan and BNP (r=0.51, p=0.006) and endocan and lactic acid (r=0.55, p=0.024). Furthermore, when patients were stratified according to EF, endocan (ng/mL) significantly increased in line with the degree of EF impairment (preserved/mildly impaired:2.4±0.6; moderately impaired: 9.8±2.5; severely impaired:18.4±4.2; p=0.014, preserved/mildly impaired vs severely impaired).
Conclusions: Endocan is significantly associated with the deterioration of cardiac function and haemodynamics in human AHF. RvD1 appears to be exhausted or inactivated in worse clinical scenarios in the spectra of AHF and is probably a protective mediator, as inferred from its inverse correlations with endocan, lactic acidosis and SAPS II score.

P477

Thirty day and one-year risk stratification of Heart Failure Death According N-terminal pro-brain natriuretic peptide at discharge for Heart Failure hospitalization. Results of IMPEDANCE-HF extended t

M Michael Kleiner Shochat[1]; D Kapustin[2]; M Fudim[3]; M Kazatsker[1]; I Kleiner[4]; JM Weinstein[4]; G Panjrath[5]; A Roguin[1]; S Meisel[1]
[1]Hillel Yaffe Medical Center, Heart Institute, Hadera, Israel; *[2]University of Toronto, Internal disease , Toronto, Canada*; *[3]Duke University Medical Center, Cardiology, Durham, United States of America*; *[4]Saroka Medical Center, Cardiology, Beer Sheva, Israel*; *[5]George Washington University School of Medicine and Health Sciences, Cardiology, Washington, United States of America*

The aim of secondary analyses of the IMPEDANCE-HF extended trial was to find out if N-terminal pro-brain natriuretic peptide values (NT-proBNP) on discharge for HF could predict 30-day and one-year Heart Failure death.
The analysis of IMPEDANCE-HF extended trial was based on the data collected during the index hospitalization for HF. The IMPEDANCE-HF extended trial was a randomized controlled single-blinded trial of HF with reduced LVEF patients. Inclusion criteria were LVEF ≤ 45%, NYHA class II-IV and patients were hospitalized for HF within 12 months (ClinicalTrials.gov NCT01315223). Half of the patients (N=145) were assigned to the active Lung Impedance (LI)-guided treatment arm where clinicians were based therapy on LI level. The other half was assigned to the control arm where LI values were recorded but not conveyed to the clinical treatment team. In the case of hospitalization, LI and NT-proBNP were recorded in all patients at discharge. The decisions regarding discharge and choice of treatment were at the discretion of the hospital staff .
Method. Patient's NT-proBNP of both groups at discharge for HF were divided according quartiles. Quartile 1: 800-3112, Quartile 2: 3113-5200, Quartile 3: 5201-7900, Quartile 4: > 7901pg/ml.



Heart Failure associated death

Results: LI-guided patients were followed for 61.9.4±39.6 months and control patients for 46.7±33.3 months (p<0.01) accounting for 269 and 470 HF hospitalizations, respectively (p<0.01). Twenty-five (38%) and 57 (66%) HF-associated deaths

were recorded during follow-up (p<0.01) representing a mortality rate of 0.03 and 0.1 per patient×year follow up in the LI-guided and control group, respectively (p<0.01). Probability of HF death within 30-day and one year for both groups is presented on figure.
Conclusion The level of pre-discharge NT-proBNP is reliable predictor for 30-day and one-year HF death.

Short-term prognostic role of galectin-3 in Vietnamese patients with acute heart failure

T Toan Dang[1]; H Ta[2]
[1]University of Medicine and Pharmacy, Ho Chi Minh city, Medicine, Ho Chi Minh, Viet Nam; *[2]University of Medicine and Pharmacy, Ho Chi Minh city, Internal Medicine, Ho Chi Minh, Viet Nam*

Background: Galectin-3 as a biomarker has made its way to the ACC/AHA 2017 for prognosing patients with acute heart failure. In Vietnam, there hasn't been any study assessing this role of galectin-3.
Objectives: The aim of this study was to examine the role of plasma galectin-3 concentrations measured at time of admission in predicting 30-day all-cause mortality in patients with acute heart failure.
Methods: We performed an exploratory study including 113 patients diagnosed with acute heart failure. We measured galectin-3 in plasma at time of admission using a two-step immunoassay procedure . The primary endpoint was 30-day all-cause mortality.
Results: 32 patients (28,3%) died within 30 days. The median galectin-3 plasma concentration of patients with acute heart failure was 34.6 (27.35 – 44.1) ng/mL. Galectin-3 had an area under the ROC curve of 0.844 (95% CI, 0.763 – 0.925, p < 0.001) for predicting outcome with the best cut-off being 37.9 ng/mL (sensitivity: 81.3%, specificity: 70.4%). Patients with galectin-3 concentrations > 37.9 ng/mL had an OR = 10.3 (95% CI, 3.76 – 28.2, p < 0.001). This increased short-term risk remained statistically significant after adjustment for age, estimated glomerular filtration rate and BNP.
Conclusions: Galectin-3 had the ability to predict 30-day all-cause mortality with good discriminatory capacity.

Coincidence or connection: cardiac sarcoidosis in a patient with multiple benign naevi on a background of suspected rare somatic mutation

L J Eveson[1]; A Steriotis[1]; V Kouranos[1]; R Sharma[1]
[1]Royal Brompton Hospital, Cardiology, London, United Kingdom of Great Britain & Northern Ireland

A 37-year-old male with a background of extensive skin lesions originally attributed to giant benign compound naevus and neurofibromatosis presented with a four month history of exertional breathlessness and palpitations. Echocardiography revealed impaired left ventricular systolic function (40-45%) and an akinetic apex with apical thrombus. Coronary angiography excluded any coronary obstruction and the cardiac MRI showed extensive late gadolinium enhancement (LGE) involving both ventricles. The patient was referred to our centre for exclusion of cardiac sarcoidosis.
FDG PET found diffuse patchy activity matching the cardiac MRI LGE pattern. The chest CT findings were compatible with pulmonary sarcoidosis but not pathognomonic. The differential diagnosis of the cardiac MRI and FDG PET appearances included cardiac sarcoidosis, although a cardiac lymphoma could not be excluded. A right ventricular septal biopsy revealed non-caseating granulomatous inflammation accompanied by an atypical eosinophilia. Integration of all the above findings led to a multidisciplinary diagnosis of cardiac sarcoidosis.In an attempt to unify the skin with the cardiac abnormalities the patient was reviewed by dermatologists experts in neurofibromatosis who supported the diagnosis of benign naevi on a background of somatic kinase mutation after repeating a skin biopsy.An ICD was inserted for primary prevention of sudden cardiac death and the patient was commenced on immunosuppressive induction treatment with IV methylprednisolone infusions.
This case illustrates the importance of investigating new onset heart failure with advanced imaging modalities to exclude inflammatory cardiomyopathic processes such as cardiac sarcoidosis. The differential diagnosis may be wide and a myocardial biopsy may be considered when extra-cardiac sarcoidosis cannot be confirmed. Recently significant clinical response of another patient with cutaneous sarcoidosis with the use of a JAK inhibitor highlighted the potential role for JAK-STAT signaling in cutaneous sarcoidosis, which could represent pathogenetic association between the skin and cardiac abnormalities in this patient's case.

Benign naevi and cardiac sarcoidosis

Acute Heart Failure - Epidemiology, Prognosis, Outcome

Mortality predictors, in the first 24 hours, in patients admitted in Non-cardiac Intensive Care Unit with Cardiogenic Shock

H Hugo Miranda[1]; I Milet[2]; N Barros[2]; H Leite[2]; I Militao[2]; F Esteves[2]
[1]Hospitalar Center Barreiro-Montijo, Lisboa, Portugal; *[2]Hospital Center of Tras-os-Montes and Alto Douro, Intensive Medicine, Vila Real, Portugal*

Introduction: Cardiogenic shock (CS) is a state of critical end-organ hypoperfusion due to primary cardiac dysfunction. Most epidemiological data for CS focus on patients with acute myocardial infarction managed in intensive care units (ICUs) of cardiology departments.
Objectives: Identify main predictors of mortality in a general ICU, in the first 24h of cardiogenic shock, and evaluate their impact in the outcome.
Methods: Retrospective analysis of patients (P) admitted in our ICU, with confirmed diagnosis of CS, within a period of 5 years (January 2012- December 2016). We analyzed common epidemiological variables, evolution during ICU stay, established therapeutics and outcome.
Results: 90 P were included. The mean age of the population was 69,59 ± 12,23 years, with a predominance of males (56,7%). Majority of P coming from the Emergency Room (45,6%) and 26,7% presenting cardiopulmonary arrest at admission. Admission SOFA of 10,39 ± 3,19. The main cause of CS (defined by clinical and echo evaluation) was non-ischemic (66,7%). In 27,8% of P the presence of mixed shock was verified. 68,9% needed mechanical invasive ventilation in the first 24h. Maximum PEEP of 8,22± 2,76 and median weaning of 3 days during ICU stay, respectively. PaO2/FiO2 ratio and lactactes at admission of 178,5 and 2,85, respectively. All the patients needed aminergic support. 34,4% needed renal replacement therapy.
At discharge, the patients presented median ICU stay of 5 days with SOFA, APACHE II and SAPS II of 7.6±5,06, 24,5 and 56,61 ± 19,71, respectively. Hospital mortality of 45,6%.
We found a statistically significant association between outcome and: admission SOFA (p=0,006), APACHE II (p<0,001), etiology (p=0,024) and variation (v) of lactates in the first 24h (p=0,027). We also point out that after applying a logistic regression, only APACHE II (OR: 1,12; IC95%: ,049-1,196) and v24h lactates (OR 0,811; IC95%: 0,672-0,979) had relevant prediction power.
Conclusion CS requires rapid diagnosis and appropriate therapy to have a positive influence on the outcome. In our study, we found that APACHE II and v24h lactates were the best predictors of mortality.

P481

Predictors of all-cause mortality in patients hospitalized for acute heart failure

AM Lupan[1]; IC Daha[2]; C Delcea[2]; GA Dan[2]
[1]Institute of Cellular Biology & Pathology Nicolae Simionescu, Bucharest, Romania; *[2]Colentina University Hospital, Bucharest, Romania*

Introduction: Heart failure is increasingly prevalent worldwide, especially among old persons. It is associated with high mortality rates and high costs.

Purpose: Our aim was to evaluate the predictors for mortality in a population of hospitalized patients with acute heart failure.
Methods: We performed a retrospective cohort study on 489 patients admitted in the Cardiology department over a 6-months period for heart failure with NT-proBNP more than 300 pg/m. Demographic, personal history, clinical, biological and imagistic data were collected from internal registry and archive documents. After a 4.5 years-following period, we retrieved all-cause mortality data. We excluded the patients deceased in the hospital. We analyzed our data using the Cox regressive model to assess the predictors of mortality.
Results: During the study period, almost 40% of heart failure patients deceased. NT-pro BNP at admission was twice higher in the deceased's group, compared to the survivors' group. The mean age of the deceased patients was 74.35(±10.07) years, being older than the survivors whose mean age was 70.05(±10.55) years. Each additional year of age was associated with a 3.1% increase of the mortality hazard. There was no difference in survival of the young group (under 65 years) and the young-old (65-74 years), while the old group (75-84 years) and oldest-old group (over 84 years) was associated with an increase in all-cause mortality about twice and three-times, respectively, in the univariate analysis. Also, this analysis identified resting dyspnoea, atrial fibrillation, pulmonary rales, ejection fraction, pulmonary artery pressure in systole, maximal LV/aortic gradient, end diastolic volume of left ventricle, aortic and tricuspid valve regurgitation and hemoglobin level under 11.82 mg/dl as predictors for mortality. In the multivariate analysis, each unit increase of the ejection fraction and maximal LV/aortic gradient was associated with a decrease in mortality of 3.3% and an increase in mortality of 2.2%, respectively. Also, resting dyspnoea was an independent predictor, associated with a 2.5-times increase in mortality when compared to dyspnoea on exertion. Nonetheless, the old age over 85-years was associated with more the 5-times increase in mortality.
Conclusion: We identified four independent predictors of mortality in a population of hospitalized patients with acute heart failure: ejection fraction, maximal LV/aortic gradient, resting dyspnoea and age over 85-years old. For the oldest-old group, age was the most important predictor.

P482

Seasonal variation in Takotsubo syndrome compared with myocardial infarction in Sweden: A report from the Swedish Angiography and Angioplasty Registry

E Elmir Omerovic[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

AIM: Acute myocardial infarction (MI) shows well-defined temporal patterns in occurrence throughout the year characterized by a peak in winter and a trough in summer. Takotsubo syndrome (TTS) is a potentially life-threatening acute cardiac syndrome with a clinical presentation very similar to myocardial infarction (MI) and for which the natural history, management, and outcome remain incompletely understood. This study aimed to evaluate whether the incidence of TS varies throughout the year in Sweden.
METHODS AND RESULTS: Using the nationwide Swedish Angiography and Angioplasty Registry (SCAAR) we identified almost all (n=153,400) patients who underwent coronary angiography due to TTS (N= 2,673 [1.7%]), STEMI (N= 42,744 [27.7%]) or UA/NSTEMI (N=108,688 [70.5%]) in Sweden between January 2009 and February 2018. Patients with TS were more often women as compared with patients with STEMI or UA/NSTEMI. We calculated the number of cases of TTS, STEMI, UA/NSTEMI per month and used Edwards test to evaluate whether the occurrence of events differs throughout the year. The onset of TTS differed as a function of the season (p<0.001), with the events most frequent in winter (n= 696, 26.1%) and least in spring (n=625, 23.4%). The incidence of STEMI and UA/NSTEMI also varied by season (both p<0.001), with highest events in winter [(STEMI, n= 21,489, 26.7%) (UA/NSTEMI, n= 57,696, 26.5%)] and lowest in summer [(STEMI, n= 18,536, 23.0%) (UA/NSTEMI, n= 50,535, 23.2%)].
CONCLUSIONS: In Sweden, the pattern of seasonal variation in TTS is similar to STEMI and UA/NSTEMI with peaks during winter. While the lowest incidence of TTS was during spring, the incidence of STEMI and UA/NSTEMI was lowest during summer.

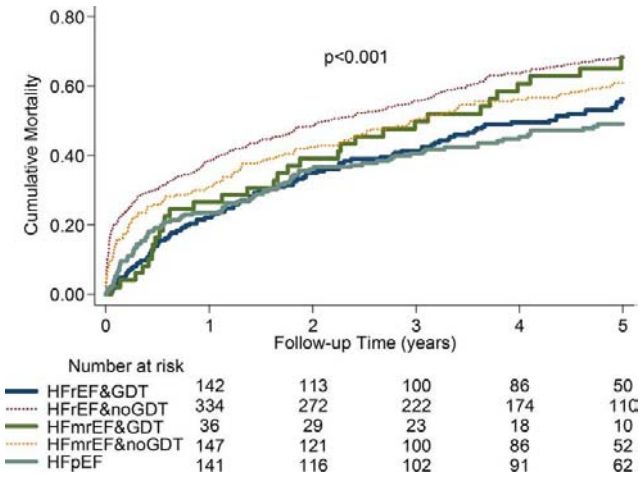
Introduction: Heart failure (HF) is emerging as an important cause of hospitalization in India, but long term longitudinal follow-up data are not available.
Objective: To evaluate the long-term outcomes of mortality and readmission rates in patients hospitalized for HF in India.
Methods: We enrolled consecutive admissions among patients with a diagnosis of HF defined by the European Society of Cardiology 2012 criteria from January to December 2013. We longitudinally followed-up these patients for five years and collected both hospitalisation and mortality data. "Guideline-directed therapy" (GDT) was defined as the combination of beta-blockers, angiotensin converting enzyme inhibitors or angiotensin receptor blockers, and aldosterone receptor blockers in patients with left ventricular systolic dysfunction.
Results: We collected data from 1,205 patients (69% males, mean [SD] age 61.2+13.7 years) during the study period. The most common etiology was ischemic heart disease (72%), followed by dilated cardiomyopathy (14%) and rheumatic heart disease (8%). More than half of the patients reported diabetes (52%) and hypertension (55%) at baseline. Smoking rate at baseline was 44%. One out of every six patients reported chronic kidney disease (stage III or greater). Heart failure with preserved ejection fraction (HFpEF: EF>45%) constituted 26% of the population.
Cumulative five-year mortality was 58.8% (n=709 deaths). Median survival time was 3.05 years and the overall mortality rate was 22.6 per 100 person years (95% CI: 21.0-24.3). Only one out of every six patients received GDT, which was associated with lower mortality and longer survival time (Figure 1). Sudden cardiac death (SCD) was the cause of death in 45.5% of the patients, while pump failure caused 49.4% of the deaths. The 5-year cumulative mortality rate among different types of HF were as follows: HFrEF=61.3%, HFmrEF=60.46% and HFpEF=46.84%.
The re-admission rate was 48.8%. The 5-year cumulative mortality rate in individual with no-readmission was 50.41%, while it was 69.22% in individual with >1 readmission.
CONCLUSIONS: Compared to previously published data from high-income settings, this younger cohort of HF patents from India report higher 5-year mortality rate. The uptake of GDT is very low and that leads to worse outcomes. Almost half of the patients experienced at least one re-admission over the 5-year follow-up period and they report higher mortality rate. Quality improvements programmes in evidence-based management may improve HF outcomes in this region.



GDT and Survival at 5 years follow-up

Background: Heart failure is emerging as a major public health problem in India. However, limited data are available on its presentation, practice patterns, and mortality data.
Methods: Kerala Heart Failure registry (KFHR) recruited acute decompensated heart patients from 50 hospitals in Kerala. The data collection period ranged from Jan 2016 to June 2018. Consecutive patients who satisfied ESC 2016 criteria were recruited from all participating hospitals. Data were captured using structured study tool.
Results: In total, 5789 patients (mean age 64.5 years; SD=12.9, women 37%) were included in the analyses. More than two-third (65%) belonged to heart failure with reduced ejection fraction, while the proportions of patients in the mid-range and preserved ejection fraction were 19.2% and 15.6%, respectively. Diabetes and hypertension was prevalent in 61% and 50% of the study population, respectively. Similarly, smoking and alcohol use was prevalent in 14% and 6% of the study population, respectively. More than one of ten (11.5%) reported atrial fibrillation. Nearly one of six (17.8%) patients presented with anaemia. Pulmonary hypertension was prevalent in one-tenth (9.2%) of the population, while chronic obstructive pulmonary disease and renal failure was prevalent in 18.3% and 20.1%, respectively. Nearly one of 20 patients (5.7%) were presented with history of stroke. Ischemic heart disease was the predominant etiology in over two third of the population (63.5%), while dilated cardiomyopathy and rheumatic heart disease were cited as the etiological factor in 10.4% and 3.4% of the study population, respectively. More than one-tenth (13%) reported hypertensive heart disease. Guideline directed therapies such as beta-blockers, ACEI, ARBs, aldosterone antagonists, angiotensin receptor-neprilysin inhibitors were prescribed during admission in 57.1%, 26.7%, 18.9%, 43.1% and 3.3%, respectively. The corresponding prescription rate at discharge were 58.9%, 26.5%, 18.9%, 42.7% and 2.8%, respectively. Combination of ACEI/ARB and BB were prescribed in 31.8%, 26.7% of patients in HFrEF and HFmrEF respectively. In hospital devise treatment was given in 3.1% (45 ICDs and 41 CRTs) of the patients. Only nine patients were listed in the heart failure transplant register. The in hospital mortality rate was 6.4% in the study population (7.0%, 5.7% and 5.0% in HFrEF, HFmrEF and HFpEF, respectively).
Conclusion: The heart failure population in India is relatively younger and predominantly men. Ischemic heart disease is the predominant etiology in over two-third of the study population. Prescription rates of guideline directed therapies were less than optimal. In hospital mortality rate was relatively higher than data reported from high-income countries. Less than optimal prescription of guideline directed therapies in the KHFR calls for innovative quality improvement programmes in the management of heart failure.

Background: High burden of heart failure remains major public health issue in India. Acute Decompensated Heart Failure (ADHF), in particular, is the leading cause of mortality and morbidity; hence, identifying clinical and treatment related factors that predict them, can guide optimal management and resource utilization. The Indian College of Cardiology National Heart Failure Registry (ICCNHFR) was started in August 2018 with the aim to assess prognostic factors and overall management of ADHF patients in real world setting in India.
Methods: This interim analysis of this prospective longitudinal registry was planned to evaluate data from the initial 1230 patients who were enrolled at 19 centers across India and completed follow-up at 30 days. The primary objective was to study the impact of comorbidities on all-cause mortality and re-hospitalization. A logistic regression analysis was performed to identify predictors of in-hospital and 30 days post-discharge mortality, and re-hospitalization. The prognostic factors included in the model were age, gender, comorbid diabetes, hypertension, ischemic heart disease, chronic kidney disease, pulse rate, blood pressure, Echo left ventricular ejection fraction (LVEF), medications.
Results: Mean age of patients was 61.2±14.4 years and majority were men (64.58%). Diabetes (52.4%), hypertension (49.5%), ischemic heart disease (58.3%), and left ventricular ejection fraction (LVEF)<40% (70.6%) were the most prevalent risk factors. Of 1005 patients, 88 died during index hospitalization leading to mortality rate of 8.8%. Increasing age (odds ratio[OR]: 1.078, confidence interval [CI]: 1.015-1.145, p=0.0149), male gender (OR: 5.512, CI:1.102-27.56, p=0.0376), abnormal ECG (OR: 9.39, CI:1.165-75.67, p=0.0354), and LVEF <40% (OR: 0.305, CI: 0.104-0.896 , p=0.0308) were independently associated with in-hospital mortality. During post-discharge follow-up at 30 days, 49 patients died (5.3%) leading to cumulative mortality rate of 13.6%. LVEF <40% (OR: 0.178, CI: 0.053-0.6, p=0.0054). Treatment with diuretics was found to reduce the in-hospital (OR: 0.007, CI:<0.001-0.058, p= < .0001) and post-discharge (OR: 0.002, CI:<0.001-0.034, p= < .0001) mortality risk, whereas use of β-blockers and aspirin was associated with reduction of in-hospital mortality. No prognostic factor was found to correlate with re-hospitalization.
Conclusion: Several comorbidities are associated with mortality risk in hospitalized patients with ADHF. LVEF<40% was a common risk factor predicting both, in-hospital and post-discharge mortality risk. Continued follow up will further inform and enhance our understanding of management practices in the real-world setting. Our data may help identify potential predictors which could guide optimal management and direct appropriate resource utilization.

P487

Predictive factors for all cause mortality and readmissions at follow up for patients presented with acute decompensated heart failure.

H B Hui Beng Koh[1]; SS Lim[1]; J Jaafar[1]; MS Sulong[1]; IS Sabian[1]; SH Ong[1]; KL Tan[1]; TJ Lee[1]; R Stanislaus[1]; CH Thum[1]; KC Teh[1]; A Roslan[1]; AA Abdul Rahim[1]; CK Teoh[1]; A Mohd Ghazi[1]
[1]National Heart Institute, Cardiology, Kuala Lumpur, Malaysia

BACKGROUND: The prevalence of heart failure continues to rise in tandem with an aging population, advent of disease-modifying heart failure drugs and survival from cardiac events. Unfortunately heart failure related morbidity and mortality remains unacceptably high.
PURPOSE: Identify predictive factors that influence outcomes of mortality and ADHF readmission after first admission for acute decompensated heart failure (ADHF).
METHODS: An observational cohort study of 2965 patients admitted to National Heart Institute from 2009 to 2017 were followed up retrospectively till end points of all cause mortality and/or ADHF readmission were met. Data was analysed using descriptive, ROC curve and cox regression.
RESULTS: 17.6% patients died, 38.5% patients were readmitted for ADHF during median follow up of 1.7 [0.7, 3.3] years. Independent predictors for increased mortality were presence of Coronary artery disease (CAD) (adjusted hazards ratio [aHR] 1.42; 95% CI 1.02-1.63; p 0.001), Systolic blood pressure at discharge (SBP)≤100mmHg (aHR 1.29; CI 1.02-1.63; p 0.035), NTProBNP≥3000pg/ml (aHR 1.65; CI 1.31-2.06; p<0.001), Urea >7mmol/L (aHR 1.34; CI 1.1-1.65; p 0.004). Predictors for reduced mortality were SBP 121-139mmHg, (aHR 0.75; CI 0.58-0.97; p 0.026), SBP≥140mmHg (aHR 0.69; CI 0.50-0.95; p 0.024), intake of Angiotensin-Converting Enzyme inhibitor (ACEi) /Angiotensin II Receptor Blocker (ARB) + Beta Blockers (BB) (aHR 0.50; CI 0.32-0.78; p 0.003), ACEi/ARB + BB + Mineralocorticoid Receptor Antagonist (MRA) (aHR0.61; CI 0.41-0.9; p 0.013). As for ADHF readmission, independent predictors for increased risk were CAD (aHR 1.33; CI 1.13-1.55O; p<0.001), Diabetes Mellitus (DM) (aHR 1.25; CI 1.08-1.45; p 0.003), Uric Acid ≥460μmol/L (aHR 1.25; CI 1.09-1.43; p 0.002), Urea >7mmol/L (aHR 1.23; CI 1.07-1.42; p 0.004), heart failure reduced ejection fraction (HFrEF) <40% (aHR 1.36; CI 1.15-1.59; p<0.001). Independent predictors for reduced ADHF readmission were SBP 121-139mmHg (aHR 0.79; CI 0.67-0.94; p 0.006), SBP ≥140mmHg (aHR 0.74; CI 0.59-0.92; p 0.006), intake of BB (aHR 0.70; CI 0.52-0.95; p 0.023), ACEi/ARB+BB (aHR 0.68; CI 0.50-0.92; p 0.012), ACEi/ARB+BB+MRA (aHR 0.57; CI 0.43-0.75; p<0.001), BB+MRA (aHR 0.71; CI 0.52-0.97; p 0.029).
CONCLUSIONS: At median follow up of 1.7 years from hospital discharge for ADHF, background CAD and raised urea were consistent at increasing the risk of both mortality and ADHF readmission, whilst SBP≥121mmHg and medications (ACEi/ARB+BB or ACEi/ARB+BB+MRA) at discharge were consistent at reducing those risks. Low SBP at discharge and raised NTProBNP increased the risk of mortality but not for ADHF readmission, whereas DM, hyperuricaemia and presence of HFrEF increased the risk of readmission but not for mortality. Although BB alone was enough to confer benefit in reducing ADHF readmission, this benefit was further increased with each addition of disease-modifying heart failure medication.

Patients with peripartum cardiomyopathy display a high incidence of subfertility and fertility treatments

25/05/2019 08:30M Manuel List[1]; TJ Pfeffer[1]; M Ricke-Hoch[1]; V Abou-Moulig[1]; D Berliner[1]; C Schippert[1]; J Bauersachs[1]; D Hilfiker-Kleiner[1]
[1]Hannover Medical School, Hannover, Germany

Background Over the past decades the use of assisted reproduction technology (ART) gradually increased worldwide. Pregnancies conceived by in vitro fertilisation (IVF) or intracytoplasmatic sperm injection (ICSI) have a higher risk for hypertensive complications, which in turn are a risk factor for peripartum cardiomyopathy (PPCM). PPCM is a devastating cardiomyopathy with acute or subacute heart failure and reduced ejection fraction in previously healthy women. Here we investigate the incidence and outcome of patients with reported reduced fertility (subfertility) with and without ART procedures in PPCM patients.
Methods and Results
Data were collected in n=108 PPCM patients in our outpatient clinic or by phone interview. Plasma levels of markers associated with infertility and preeclampsia were measured at diagnosis of PPCM (n=30), and in healthy postpartum matched controls (n=24), using Multiplex Immunoassays.
No history of subfertility was present in 70% (PPCM-f; n=76), whereas 30% (n=32) of the patients reported subfertility. Out of the subfertile PPCM patients 56% (n=18) received IVF/ICSI (PPCM-I), 34% (n=11) hormonal treatment and 9% (n=3) conceived naturally. The share of live births conceived by IVF/ICSI in the total number of live births of all interviewed PPCM patients was 12.1%, while it is 2.2% in the German total population (Federal Statistical Office of Germany, IVF registry).
Twin pregnancy (12/32 vs. 12/76; p=0.0213) and C-section rate (27/32 vs. 41/66; p=0.0347) were higher in subfertile PPCM patients, otherwise both groups had comparable clinical histories at diagnosis. In PPCM-I age (37±4 vs. 34±4; p=0.0160), twin pregnancy and C-section rate were significantly higher and gravidity as well as parity were significantly lower compared to PPCM-f. At PPCM diagnosis, plasma markers associated with impaired fertility and/or preeclampsia, i.e. PAI-1, VEGFA, IL-8, Endoglin were altered overall in subfertile PPCM patients compared to PPCM-f. At 12 months follow-up, LVEF was significantly higher in all subfertile PPCM patients (55±7% vs. 50±9%; p=0.0371) and also in the subgroup of PPCM-I (56±6% vs. 50±9%; p=0.0396) compared to PPCM-f.
Conclusion In the present PPCM collective one third of the patients had documented subfertility and the application of ART was high with more live births conceived by IVF/ICSI compared to the total population in Germany. The recovery rate of PPCM with reported subfertility is better compared to PPCM-f, which could be due to better clinical monitoring leading to earlier diagnosis and treatment. This holds also true for PPCM-I suggesting that IVF/ICSI may be a risk factor for PPCM but are not associated with adverse outcome in PPCM patients. The observed alterations in plasma markers may point to a specific pathophysiology in PPCM with subfertility. To examine whether ART procedures or subfertile conditions per se are risk factors for PPCM, more studies in this context are necessary.

Cleveland Clinic-Abu Dhabi,, Abu Dhabi, United Arab Emirates*; *[8]Mohammed Bin Khalifa Cardiac Centre, Bahrain, Bahrain*; *[9]Sana'a University, Sana'a, Yemen*

On behalf of: GULF-CARE group

Background: The prognostic impact of beta-blockers (BB) in coronary artery disease (CAD) without heart failure (HF) is controversial, specially in the reperfusion-era. Moreover, it is not known whether patients with CAD and heart failure (HF) without left ventricular dysfunction might benefit from BB use
Purpose: We sought to assess the impact of BB on cardiovascular outcomes in patients with CAD and no LV dysfunction, hospitalized for acute HF.
Methods: The Gulf-CARE (Gulf aCute heArt failuRe rEgistry) is a prospective multicenter cohort of acute HF in the GULF Middle East.We studied in-hospital cardiovascular events in patients hospitalized for acute HF, with a previous history of CAD and a LVEF ≥40%, in relation to BB on admission; and one-year outcome in relation to BB on discharge, in the GULF-CARE, a prospective multi-center cohort of acute HF.
Results: From a total of 5005 patients included in the GULF-CARE registry,824 had a previous history of CAD and a LVEF ≥40%. 303 patients on BB were propensity-matched to 303 patients without BB. Mean age was 65 (11) and 53% were males. BB did not reduce in-hospital mortality (OR= 0.82; 95%CI [0.35-1.94]), stroke, and cardiogenic shock. On discharge, 306 patients on BB – including the ones newly diagnosed for myocardial infarction as a precipitating cause of HF- were propensity-scored matched with 306 patients without BB. Mortality (OR= 0.86; 95%CI [0.51-1.45], hospitalization for HF or PCI/CABG at 12 months were also were also not reduced by BB use at discharge. Further sensitivity analysis showed that BB treatment was not an independent predictor of in-hospital and 12-month mortality.
Conclusions: In this cohort of patients with acute HF, BB do not reduce in-hospital and one-year cardiovascular outcomes in patients with a previous history of CAD and a LVEF ≥40%.

P491

Left atrial size and the risk of long-term all-cause mortality in patients with atrial fibrillation and heart failure

JM Jiameng Ren[1]; S Wu[1]; YM Yang[1]
[1]Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Emergency and Intensive Care Center, Beijing, China

Aim: Many studies had reported that left atrial size was associated with atrial fibrillation (AF). And left atrial size might be a predictor of adverse events in patients with AF. This study aimed to determine whether left atrial size was associated with long-term risk of all-cause death in patients with AF and heart failure.

Methods: Patients admitted with atrial fibrillation and heart failure in emergency room(ER) were included and followed up. The anteroposterior diameter of the left atrium was used to represent the size of the left atrium, which measured by using transthoracic echocardiography at ER. Univariate and multivariate Cox regression analysis was performed to explore the association between the anteroposterior diameter of the left atrium and the risk of all-cause death.

Results: Total 632 patients (48.6% female) were included in this study. The median and interquartile range of the anteroposterior diameter of the left atrium and age was 4.8(4.2-5.4) centimeter,63.0(55.0-72.0) years, respectively. During follow-up for 3.17(1.57-3.96) years, 202 patients (32.0%) died. In univariate analysis, an increased left atrial anteroposterior diameter (per 1 cm) was significantly associated with elevated risk of all-cause death (hazard ratio 1.170, 95% CI 1.038-1.319).After adjusted for age, sex, admission systole blood pressure, admission heart rate, serum creatinine at admission, history of diseases(acute coronary syndrome, revascularization, myocardiopathy, chronic obstructive pulmonary disease, valvular disease, rheumatic heart disease, valvular surgery, chronic kidney diseases, hypertension, diabetes, stroke, peripheral vascular disease, major bleeding, gout),medications(diuretics, beta blockers, angiotensin converting enzyme inhibitors or angiotensin receptor inhibitors, spironolactone, digoxin, anticoagulants),CHA2DS2-VAS score, the anteroposterior diameter of left atrium was still significantly associated with all-cause death(hazard ratio 1.267, 95% CI 1.1-1.459).

Conclusion: Patients with AF and heart failure were at high risk of all-cause mortality, and the risk increased with the enlargement of the anteroposterior diameter of left atrium.

P492

Regional differences in the incidence and outcome of acute ischemic heart failure after ST-elevation myocardial infarction in Sweden

B Bjorn Redfors[1]; S Volz[1]; O Angeras[1]; D Ioanes[1]; J Odenstedt[1]; C Ljungman[1]; C Dworeck[1]; T Jernberg[2]; J Jensen[3]; T Ramunddal[1]; P Petursson[1]; O Frobert[4]; S James[5]; D Erlinge[6]; E Omerovic[1]

[1]Sahlgrenska Academy, Univ. of Gothenburg, Dept of Molecular & Clinical Medicine/Cardiology, Gothenburg, Sweden; *[2]Danderyd University Hospital, Stockholm, Sweden*; *[3]Karolinska University Hospital, Stockholm, Sweden*; *[4]Orebro University Hospital, Orebro, Sweden*; *[5]Uppsala University Hospital, Uppsala, Sweden*; *[6]Skane University Hospital, Lund, Sweden*

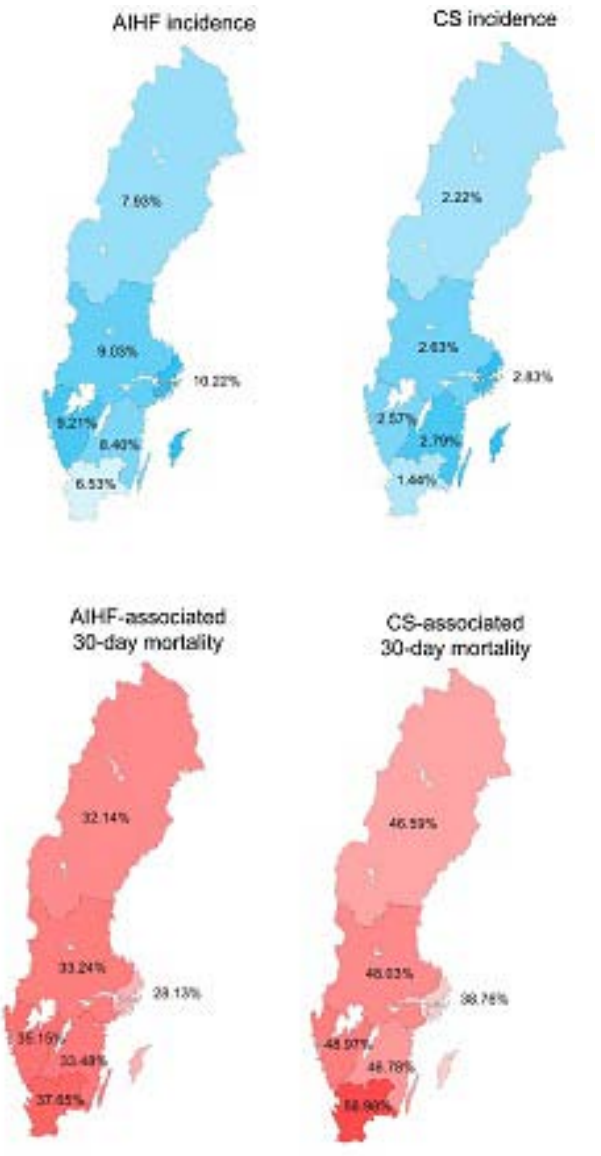
Background: Acute ischemic heart failure (AIHF) is the most common cause of death for patients with ST-elevation myocardial infarction (STEMI). The risk of AIHF in STEMI has been linked to factors such as choice of reperfusion strategy and time to reperfusion, and other patient-related factors that could theoretically differ between rural versus urban areas.

Purpose:We assessed whether the incidence and prognostic impact of AIHF in STEMI differ across the different health care regions in Sweden.

Methods: Using the nationwide Swedish Angiography and Angioplasty Registry (SCAAR) we identified patients who underwent primary PCI due to STEMI in Sweden between January 2010 and April 2018. Patients were grouped according to which of the six the health care region they were treated in. We defined IAHF as Killip class ≥2 and cardiogenic shock (CS), the most severe form of AIHF, as Killip class 4. The primary endpoint was mortality at 30 days.

Results: We identified 40,701 patients who underwent primary PCI during the study period with known vital status at 30 days, for whom Killip class was reported for 40,365 (99.2%). The highest number of patients were treated in the Western region (N=10,741 [26.6%]), followed by South (7,905 [19.6%]), Stockholm (6,505 [16.1%]), Northern (5,991 [14.8%]), Uppsala-Örebro (5,713 [14.2%]) and South-East (3,510 [19.6%). AIHF and CS incidences were highest in Stockholm and lowest in the South, whereas prognosis for patients with AIHF and CS was most favorable in Stockholm and least favorable in the South (Figure).

Conclusions: The incidence and prognosis of AIHF among patients with STEMI vary across health care region, with the lowest incidence and worst prognosis in the South and the highest incidence and best prognosis in Stockholm. These findings could be explained by less severely compromised patients being diagnosed with AIHF in Stockholm compared to the South.



P493

Comparing predictive factors for mortality between elderly and non elderly patients after an event of acute decompensated heart failure.

HB Hui Beng Koh[1]; SS Lim[1]; J Jaafar[1]; MA Sulong[1]; IS Sabian[1]; N Jaafar[1]; KL Tan[1]; SH Ong[1]; R Stanislaus[1]; CH Thum[1]; KC Teh[1]; TW Nay[1]; AA Abdul Rahim[1]; CK Teoh[1]; A Mohd Ghazi[1]

[1]National Heart Institute, Cardiology, Kuala Lumpur, Malaysia

BACKGROUND: The burden of heart failure (HF) continues to rise globally with increasing average life expectancy and improvement in cardiac event survival due to novel interventions. It is a common preconception that elderly patients fare worse when they have HF and most studies on HF focused on this group.

PURPOSE: To evaluate demographic differences and predictive factors which influenced the all-cause mortality between the elderly (EL≥6o years) and non-elderly (NEL<60 years) patients after admission for acute decompensated heart failure (ADHF).

METHODS: An observational study of 2965 patients admitted from 2009 to 2017 were followed up retrospectively till endpoint of mortality was met. Data was analyzed using descriptive, ROC curve, cross tabulation and Cox regression analysis.

RESULTS: Total of 17.6% of deaths were recorded during the median follow up of 1.7 [0.7,3.3] years. Majority were from the EL group (64%). The EL had more coronary artery disease (CAD) (46.4 vs 24.2% p<0.001), renal insufficiency (19.3 vs

8.2%, p<0.001), atrial fibrillation (14.1 vs 6.8%, p<0.001), diabetes (40 vs 22.7%, p<0.001), hypertension (48.3 vs 24.5%, p<0.001), dyslipidaemia (26.8 vs 15%, p<0.001), chronic obstructive pulmonary disease (6.3 vs 3%, p0.001). Interestingly, EL had more non-smokers (65.8 vs 34.2%, p<0.001). Amongst the EL, independent predictors which increased the mortality risk were CAD (adjusted hazard ratio [aHR] 1.44; 95% CI 1.05-1.99; p0.024), estimated glomerular filtration rate [eGFR (ml/min/1.73m^2)] 30-59 (aHR 1.80; CI 1.02-3.19; p0.04), eGFR <30 (aHR 2.54; CI 1.38-4.66; p0.003), ejection fraction (EF) < 40% (aHR 1.44; CI 1.10-1.89; p0.007). Predictors which reduced this risk were systolic blood pressure at discharge [SBP(mmHg)] 121-139 (aHR 0.72; CI 0.53-0.98; p0.037), SBP≥140 (aHR0.612; CI 0.42-0.90; p0.013). Angiotensin Converting Enzyme inhibitor (ACEi)/Angiotensin II Receptor Blocker (ARB) + beta blockers (BB) were the only drug combination to reduce mortality risk (aHR0.53, CI0.33-0.84; p0.007) in the univariate analysis. This was however not significant in the multivariate analysis. In the NEL group, independent predictors that increased mortality risk were SBP≤100 (aHR 1.49; CI 1.07-2.08; p0.018, heart rate at discharge [HR(bpm)] ≥100 (aHR 1.98; CI 1.14-3.44; p0.016), NTProBNP(pg/ml) ≥3000 (aHR 1.74; CI 1.23-2.46; p0.002), Urea(mmol/L) >7 (aHR 1.56; CI 1.15-2.10; p0.004). The risks were non-independently reduced by BB (aHR 0.36, CI 0.15-0.84; p0.02) and ACEi/ARB + BB (aHR 0.4; CI 0.17-0.91; p0.029) but not seen in multivariate analysis.

CONCLUSIONS: EL and NEL patients with ADHF are not identical. At median follow up of 1.7years from hospital discharge for ADHF, EL patients had more comorbidities and mortalities. Although predictive factors that influenced mortality risk were heterogenous between these 2 groups, SBP at discharge played a major role in both groups at discriminating mortality risks after discharge for ADHF.

Hyponatremia in acute heart failure

H Santos[1]; I Almeida[1]; H Miranda[1]; M Santos[1]; C Sousa[1]; L Almeida[1]; J Chin[1]; S Almeida[1]; L Santos[1]; J Tavares[1]
[1]*Hospital N.S. Rosario, Cardiology, Barreiro, Portugal*

Background: Hyponatremia is a common electrolyte abnormally in acute heart failure (HF), being associated with worst prognosis.

Purpose: Evaluate the impact of hyponatremia in the prediction of clinical gravity (Killip III and IV) at admission and the outcome in acute HF patients.

Methods: Single-centre retrospective study, engaging patients hospitalized for acute HF between 1/01/2008-31/12/2017. Demographic, clinical and blood work data at admission were collected. Hyponatremia was defined as serum sodium level of less than 135 mEq/L. T-student, U Mann-Whitney, Qui square test and Spearman's rank correlation coefficient were used to compare categorical and continuous variables. Logistic regression was performed to assess mortality rates based on the serum sodium levels.

Results: 423 patients were included, mean age 67.81±12.16 years, with 29.8% females, presenting a in-hospital mortality rate of 5.9%. Patients with hyponatremia (27.19%) were similar regarding gender, age, cardiovascular history and mortality rates compared to patients without hyponatremia. On the other hand, hyponatremia patients had higher levels of blood urea nitrogen (67.00±68 vs 54±36, p<0.001) (r= 0.097, p=0.049), creatinine (1.36±0.74 vs 1.15±0.51, p<0.001) (r= -0.239, p0.001) and B-type Natriuretic peptide (1850±2712 vs 1337±3574, p<0.001) (r= -0.216, p0.001) at admission. Also, at admission more patients presented with Killip IV (37.7 vs 18.8%) on the hyponatremia group, with an odds ratio 1.008, p=0.004 (confidence interval 1.002-1.013). Logistic regression revealed that hyponatremia was not a predictor of in-hospital, 6-months and 1-year mortality, as well of hospital readmission in the same period.

Conclusions: Hyponatremia was associated with higher Killip class at admission, however, without a direct mortality impact. Hyponatremia was weakly correlated with low hemoglobin values, and higher blood urea nitrogen, creatinine and B-type Natriuretic peptide levels.

P495

BAUN score, a predictive model of in-hospital mortality in acute heart failure

J Joao Santos[1]; G Pereira[1]; L Goncalves[1]; I Pires[1]; H Antunes[1]; E Correia[1]; L Abreu[1]; I Almeida[1]
[1]*Hospital Sao Teotonio, Viseu, Portugal*

Introduction Patients hospitalized due to heart failure (HF) compose a heterogeneous population whose prognosis and in-hospital mortality (IHM) are difficult to forecast. The purpose of this study was to create a simple model capable of accurately predicting IHM in these individuals.

Methods A retrospective analysis of 1052 patients admitted to a Cardiology ward due to decompensated HF was performed. 141 patients were excluded due to data omission. The variables systolic blood pressure (SBP), urea, brain natriuretic peptide (BNP) and sodium at admission were selected for score inclusion. The Mann-Whitney U and T-test were used for mean comparison between groups. Subgroups were created for each variable. For each subgroup, an odds ratio (OR) for the risk of IHM was calculated, and a numerical value proportional to the OR was subsequently attributed. The reference values for BNP, urea and sodium in healthy individuals were classified with 0 points, as well as an SBP>140 mmHg. A score (BAUN) was created, ranging from 0-28 points, corresponding to the sum of the classification attributed to each variable. A ROC curve analysis was then performed to evaluate the predictive value of the score for IHM.

Results Mean patient age was 77 (±10) years; 51% were men. Mean LVEF was 49% (±16,4). A LVEF<40% was present in 31% of patients. IHM was 6.5%. A statistically significant association between IHM and the variables SBP and sodium was found on T-test (p<0.001). The same was verified for BNP and urea in the Mann-Whitney U test (p<0.001). Pearson correlation test did not reveal significant correlation between variables; thus, an independent variation between them was assumed. ROC curve analysis revealed an AUC of 0.752 (p<0.001). The cut-off point with the most sensitivity (S) and specificity (E) obtained using the Youden index (IY=0.3626) was 4 (S≈92% e E≈45%). The analysis of mortality by score interval revealed an IHM of 1.3%, 7.5%, 17.6% e 35%, respectively, for the intervals <5, 5-15, 16-22, >22. A BAUN score>22 predicts death in 1 out of 3 patients hospitalized due to HF. A score <5 predicts a very low risk of IHM (≈1%).

Conclusion The BAUN score is a good predictive model of IHM in patients hospitalized due to HF. It is also objective and easy to apply. Its use may help to identify patients with a very high risk of IHM in need of specialized care, and those patients with very low risk of death, who might be candidates for early discharge.

P496

Incidence and prognostic value of residual pulmonary congestion by clinical data and lung ultrasound in decompensated heart failure

F Cabello Montoya[1]; A Safarova[1]; M Bayarsaikhan[1]; O Lukina[1]; Z Kobalava[1]
[1]*Peoples' Friendship University of Russia (RUDN University), Department of Internal Diseases, Moscow, Russian Federation*

Introduction: Recently lung ultrasound (LUS) based on B-lines measurement has been proposed as an effective tool for assessment of pulmonary congestion (PC) in patients with decompensated heart failure (DHF). The aim of this study was to assess the incidence and prognostic significance of residual PC by clinical data and LUS in DHF patients.

Material and methods: Routine clinical assessment and eight-zone LUS were performed in 162 patients with DHF (men 66%, age 69±12 years (M±SD), AH 97%, history of MI 44%, AF 60%, EF 40 (30;50)%, EF<40% 46%, baseline NT-proBNP 4246 (1741;6837) pg/ml) on admission and at the day of discharge. Sum of B-lines <5 was considered as normal, 6-15, 16-30 and >30 – as mild, moderate and severe PC, respectively. Presence of at least one clinical sign or sum of B-lines >5 at discharge were considered as residual PC. Mann-Whitney, McNemar and Wilcoxon tests, multivariable Cox regression analysis were performed. P<0.05 was considered significant.

Results: Using LUS on admission PC diagnosed in all patients (moderate and severe in 31 and 68%, respectively). During hospitalization the median of B-lines sum decreased from 35 (28;53) to 6 (3;12) (relative -82 (-90;-67)%), p<0.001. At discharge normal LUS profile was observed in 48% of patients, 52% patients sill

had PC (mild, moderate and severe PC in 33, 15 and 4% cases). Patients with vs without residual PC by LUS had higher median of B-lines sum on admission 43 (28;57) vs 35 (27;48), p=0.002) and at discharge (12 (8;21) vs 3 (3;4), p<0.001), lower relative B-lines (-69 (-80;-48) vs -91 (-94;-85)%, p<0.001), and surprisingly were characterized by lower incidence of dyspnea at exertion at discharge (29.8 vs 46.1% p=0.031).
Incidence of PC by clinical data decreased: orthopnoea from 78 to 15%, dyspnea at rest from 33 to 0%, dyspnea at exertion from 100 to 38%, bilateral pulmonary rales from 87 to 11%, p<0.05 for all. 46.3% of patients with at least one clinical sign of PC at discharge did not differ by B-lines sum neither on admission nor at discharge.
Residual PC was diagnosed in 76.5% of patients (only by clinical data in 32.3%, only by LUS in 39.5%, by both in 28.2% of patients).
Only residual PC revealed by LUS was characterized by negative prognosis. Sum of B-lines >5 was associated with higher probability of 12-month all-cause death (HR 4.30, CI 1.71-10.78, p=0.002). Sum of B-lines >15 – with higher probability of 12-month all-cause death (HR 2.99, CI 1.32-6.79, p=0.009) and HF readmission (HR 2.65, CI 1.45-4.85, p=0.002) after adjustment by age, gender, EF and clinical PC at discharge.
Conclusion: Residual PC by clinical data or LUS was revealed in 76.5% patients, in 39.5% of them only by LUS. Presence of at least one clinical sign of PC had no impact on outcomes. Sum of B-lines >5 at discharge was independently associated with higher risk of 12-month death, >15 – with higher risk of 12-month death and HF readmission.

P497
Impact of functional mitral regurgitation at discharge upon survival in patients with acute decompensated HFpEF, HFmrEF and HFrEF

T Castelein[1]; M Beles[1]; M Penicka[1]; M Goethals[1]; S Verstreken[1]; R Dierckx[1]; W Heggermont[1]; J Bartunek[1]; M Vanderheyden[1]
[1]*Cardiovascular Center Aalst, Cardiology, Aalst, Belgium*

Background: The relationship between the severity of functional mitral regurgitation (FMR) at discharge, left ventricular ejection fraction (LVEF), and outcomes in acute decompensated heart failure (HF) patients remains not fully understood. The aim of this study was to assess the impact of FMR at discharge upon survival in patients with acute decompensated HF with preserved, mid-range and reduced EF (HFpEF, HFmrEF, HFrEF, respectively).
Methods: We retrospectively analysed 1485 patients (mean age: 74 years, 60% were men) admitted with an episode of de novo, acute decompensated HF in a tertiary HF centre between February 2010 and March 2018. Mean follow-up time was 1045 ± 702 days. Based upon LVEF at time of the index hospitalization, 37%, 19% and 45% of patients were classified as HFpEF, HFmrEF and HFrEF respectively. FMR was assessed at time of discharge and graded as none/mild (grade 0, 0.5 and 1), moderate (grade 2) or severe (grade 3 and 4). Moderate or severe FMR was present in 41% of patients. The primary focus of this study was to determine the survival probability of the HF patients, according to the severity of FMR.
Results: HFpEF patients showed higher all-cause mortality as compared to HFmrEF and HFrEF patients (42%, 38% and 35% respectively; p = 0.034). Among all HF patients, the presence of severe FMR was associated with higher all-cause mortality as compared to moderate and mild FMR (44%, 42% and 35% respectively; p = 0.027). However, interestingly, the association between severity of FMR and outcome was only seen in HFrEF (see figure), not in HFpEF and HFmrEF (p < 0.001). HFrEF patients with moderate/severe FMR showed higher mortality as compared to those with none/mild FMR (p < 0.001).
Conclusion: According to our findings, it seems that although FMR is prevalent at time of discharge in all HF patients, it only bears prognostic information in HFrEF patients. Therefore, HFrEF patients with severe FMR despite optimal medical therapy, should be followed intensively in the HF clinic.

Overall survival of HFrEF patients ~ FMR

Coronary Artery Disease

P498
The antiplatelet therapy and pro-inflammatory cytokines with stable coronary artery disease: is there any connection?

A Andrey Vorobev[1]; VI Ruzov[1]; LG Komarova[1]; AS Komarov[1]
[1]*Ulyanovsk State University, Ulyanovsk, Russian Federation*

The connection between cytokine inflammation and atherothrombosis suggests evaluability of the antiplatelet effect by values of pro-inflammatory interleukins, notably IL-1β and IL-6.
Purpose. The goal is to study the connection between the antiplatelet effect and cytokine inflammation with stable CAD.
Methods. The evaluation of thrombocyte aggregation against mono- and dual antiplatelet therapy was carried out in 147 patients with stable clinical progression of CAD, of whom 121 patients received aspirin mono-therapy, while 26 patients received clopidogrel/aspirin therapy. The
platelet aggregation was assessed by a spontaneous and adenosine diphosphate (ADP) - induced aggregometry. IL-1β and IL-6 concentration was determined by a solid-phase enzyme immunoassay.
Results. The stable progression of CAD is characterized by the absence of activation of cytokine inflammation (in IL-1β and IL-6 levels) in 73% of patients. Subclinical inflammation was seen in 23% of patients during both mono- and dual antiplatelet therapy, which was reflected by higher-than-normal values of predominantly IL-6 (12% vs. 1%). Evaluation of the connection between the cytokine activity and the spontaneous and ADP-induced platelet aggregation in patients undergoing coronary revascularization showed insufficient anti-inflammatory effect of aspirin mono-therapy vs. the combined effect of aspirin and clopidogrel, which was expressed by higher levels of pro-inflammatory interleukins IL-1β and IL-6 (χ2=4.01, p=0.04). At the same time, spontaneous platelet aggregation activity was observed during mono or double antiplatelet therapy, mainly in stented patients (23%) vs. shunting patients (7%), and correlated with higher-than-normal values of pro-inflammatory interleukins.
Conclusion. The efficacy of antiplatelet therapy correlates with low ADP-induced platelet activity and cytokine inflammation. Persistence of high spontaneous platelet aggregation during antiplatelet therapy, mainly in stented patients, against the higher-than-normal values of pro-inflammatory interleukins indicates subclinical inflammation and thrombogenic risk retention.

P499
The prevalence of heart failure after acute coronary syndrome in patients with nonobstructive coronary atherosclerosis

SB Gomboeva[1]; VV Ryabov[2]; AE Baev[1]; YU V Rogovskaya[1]
[1]*Cardiology Research Institute, Tomsk National Research Medical Centre, Russian Academy of Sciences, Tomsk, Russian Federation*; [2]*National Research Tomsk State University, Tomsk, Russian Federation*

The aim of the study was to evaluate the frequency of heart failure during 1 year after acute coronary syndrome in patients with nonobstructive coronary atherosclerosis.
Material and methods: This non-randomized open controlled investigation (NCT02655718). The study included data of patients admitted at the Emergency Department of Cardiology due to ACS in 2015-2016. Inclusion criteria was nonobstructive coronary atherosclerosis (normal coronary arteries / plaques <50%), confirmed by invasive coronary angiography, age ≥ 18 years at the time of randomization. The exclusion criterion was previous revascularization of the coronary arteries. Forty two patients were underwent cardiac MRI.
Primary outcomes were hospital mortality, incidence of recurrent ischemia, stroke, and as final diagnosis acute myocardial infarction, unstable angina, Takotsubo syndrome, and myocarditis. Secondary outcomes were death, reccurent myocardial infarction, stroke, the development of heart failure during 1 year after presence of acute coronary syndrome. During 1 year after discharge visit was hold for assessment secondary outcomes. Descriptive statistics was used for analysis of data.
Results: Among 913 people who were hospitalized with acute coronary syndrome at the Emergency Department of Cardiology in 2015 - 2016, 4.8% (44) patients had nonobstructive coronary atherosclerosis confirmed by coronary angiography. One patient died. Forty two patients were underwent cardiac MRI. One year mortality was 2(5%). In 24 (55%) cases were diagnosed acute myocardial infarction, in 6(14%) - unstable angina, and 10(23%) cases had pseudo-coronary scenario of myocarditis, in 4(9%) cases was other causes of ACS, such as: ongenital heart disease - 1(25%), WPW-syndrom-1(25%), acute aortic dissection-1(25%), posttraumatic cardiosclerosis-1(25%).
During 1 year after discharge 17 (39%) cases of re-hospitalization was due to cardiac causes in 11(65%) such as: unstable angina- 4 (36%), recurrent myocardial infarction in 1 (9%), arterial hypertension-1(9%), cardiac arrhythmias - 4(36%),

planned hospitalization after surgical treatment of acute aortic dissection -1 (9%); noncardiac causes had 6 (35%) patients. The development of heart failure was observed on a half patients, 23(52%): NYHA I- 10(43%), II-3 (13%), III-8 (35%), NYHA IV-2(9%).
Conclusion: The proportion of patients with nonobstructive coronary atherosclerosis was 4.8% (44) in 2015-2016. Heart failure in patients with nonobstructive atherosclerosis in 1 year after acute coronary syndrome occurred on a half of the patients.

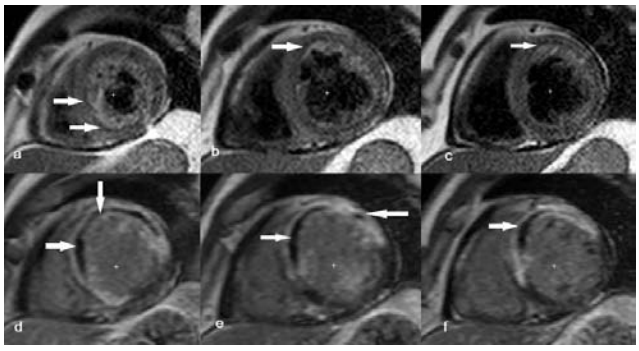
Impact of different reperfusion strategies in primary myocardial infarction on microvascular obstruction and intramyocardial haemorrhage

Y Alekseeva[1]; OV Mochula[2]; EV Vyshlov[1]; EN Pavlyukova[2]; VV Ryabov[1]; VY Ussov[2]; VA Markov[1]
[1]Cardiology Reseach Institute, Tomsk National Reseach Medical Centre, Russian Academy of Scince, Emergency cardiology, Tomsk, Russian Federation; *[2]State Research Institute of Cardiology of Tomsk, Tomsk, Russian Federation*

Background: Wide adoption of reperfusion strategies has led to decrease in mortality but remains still unresolved why postinfarction heart failure does progress unequally in various groups. There is suggestion the reperfusion therapy leads to ischemia-reperfusion injury and worsening of myocardial microcirculation. Intramyocardial haemorrhage (IMH) and microvascular obstruction (MVO) or no-reflow phenomenon represent components of reperfusion injury. Nowadays, contrast CMR is the optimal diagnostic technique to image and quantify these phenomena. Prevalence of IMH in patients with STEMI in primary PCI is as high as 40-50% and of MVO is 50-60%. There's not enough data on quota of these phenomena in patients who are treated with pharmacoinvasive strategies.
Purpose: To evaluate the prevalence of IMH and MVO with different reperfusion strategies in patients with primary STEMI.
Materials and methods: The study included 47 patients with primary STEMI in the first 12 hours of symptom onset. Exclusion criteria: pulmonary edema, cardiogenic shock, creatinine clearance <30 mL/min or dialysis, severe comorbidity, acute psychotic disorders and unability to undergo or contra-indications for CMR. According to the strategy of reperfusion, patients were divided into 2 groups at the admission. Patients of the 1st one (n=30) have been treated with pharmacoinvasive strategy. Fibrinolysis was performed in all patients at the pre-hospital stage. The 2nd group (n=17) was treated with primary PCI. CMR imaging was performed at 2nd day post-STEMI in everybody. MVO was imaged using late gadolinium enhancement and T2-weighted CMR imaging for IMH (Fig.1). The study was registered in ClinicalTrials.gov, with identification number NCT03677466.
Results: IMH and MVO were revealed in majority of the patients with primary STEMI. In group of primary PCI the IMH was observed in 11 of 17 patients (64,7%), whereas MVO – in 12 of 17 patients (70,5%). In group of pharmacoinvasive strategy IMH was revealed in 12 of 30 patients (40 %), MVO – also in 12 of 30 patients (40%). There was not difference between frequencies of IMH in two groups, whereas occurrence of MVO was significantly highly in the group of primary PCI (=0.05). The combination IMH with MVO were occurred in 14 patients (29,8%): in group of pharmacoinvasive strategy – 6 patients (20%) and in group of primary PCI – 8 patients (47%). The combination of IMH with MVO was presented also more frequently in group of primary PCI (p=0.03). LV ejection fraction was significantly lower in patients with combination of IMH and MVO, if compared to those without it (p=0.001).
Conclusion: IMH and MVO were common findings in patients with primary STEMI with different reperfusion strategies and were present from 40 % to 70% of the patients. There was no difference in the prevalence of IMH with different reperfusion strategies. On the contrary - the MVO occurred more frequently among patients treated with primary PCI.



Patient with IMH (a-c) and MVO (d-f)

P501
Association of rs2891116 polymorphism in CDKN2B gene with the extent of myocardial injury and left ventricular ejection fraction in patients after ST elevation myocardial infarction.

F A Magamedkerimova[1]; FA Magamedkerimova[1]; EN Ivantsov[1]; NR Khasanov[1]; M Ibrahim[2]
[1]Kazan State Medical University, Propaedeutics of internal medicine, Kazan, Russian Federation; *[2]Kazan State Medical University, Kazan, Russian Federation*

Background. History of previous myocardial infarction has significant impact on the development of heart failure. Genome-wide association studies reveal polymorphisms in the CDKN2B gene link to the susceptibility of coronary artery disease and myocardial infarction. Recent studies show there is an association of CDKN2B with the development of heart failure.
Purpose. To evaluate the extent of myocardial injury with regard to the Left Ventricular Ejection Fraction (LVEF) according to echocardiography data in patients with different genotypes of rs2891116 CDKN2B gene, after being diagnosed with ST elevation myocardial infarction (STEMI).Materials and Methods. A total of 113 patients diagnosed with STEMI were included in the study, composed of 41 females and 72 males. Female mean age was 69±11.7 years, male mean age was 60±11.3 years. All patients provided informed consent and a blood sample from each was taken for genetic testing. During hospitalization, echocardiography was conducted. Data was analysed using STATISTICA 10 software via nonparametric methods – Mann-Whitney test, Kruskal-Wallis test and Spearman rank correlation test.
Results. Significant differences were discovered among groups with different genotypes in CDKN2B gene, in terms of the number of affected segments and Wall Motion Score Index value (WMSI) (Table 1). Participants with TT genotype of CDKN2B gene had a higher rate of incidence of left ventricular contractile function impairment (5.5±0.8 (CI 3.4;5.9) in comparison to CT genotype carriers (3.5±0.4 (CI 2.2;3.2); p=0.032). The mean value for carriers of the CC genotype compared to CT and TT genotype carriers was not significantly different. WMSI mean value in patients with TT genotype in CDKN2B gene was 1.4±0.06 (CI 0.2;0.4); and in patients with CT genotype – 1.25±0.03 (CI 0.1;0.2), (p=0.025). In patients with CC genotype compared to CT and TT the mean value of WMSI was not significantly different. A significant correlation between WMSI and LVEF is evident in patients with TT (r = -0.48, p<0.05) and CT (r = -0.50, p<0.05) genotypes. In CC carriers group WMSI-LVEF correlation is indefinite.
Conclusions. Patients diagnosed with STEMI and carrying TT genotype in CDKN2B gene exhibited a higher number of affected segments and WMSI value compared to patients with CT genotype. In patients with TT and CT genotypes there is a strong association between WMSI and LVEF.

Table 1

	n=30 (26%)	CTn=55 (49%)	TTn=28(25%)	p
Mean amount of affected segments	4.07±0.4	3.47±0.4	5.46±0.8	0.042
Mean value of WMSI	1.32±0.05	1.25±0.03	1.41±0.06	0.036

Background: Coronary artery disease (CAD) is one of the most common causes of hospitalization, death and disability in Europe. Despite the knowledge of classical CAD risk factors, the morbidity and mortality associated with this disease remains high. As a consequence, new factors that may lead to CAD, like gut microbiome, are taking into consideration.

Purpose: To evaluate gut microbiota composition in CAD patients. To compare intestinal microbiome of patients with acute coronary syndrome (ACS) in relation to patients who underwent elective percutaneous coronary intervention (PCI).
Methods: The study included stool microbiome of 92 CAD patients, aged 64.6±7.6 years (72 males) who were hospitalized 12-18 months prior recruitment due to an ACS (ST-elevation myocardial infarction, n=22; non-ST elevation myocardial infarction, n=22; unstable angina, n=14) or PCI (n=34). All patients underwent detailed assessment of health status, including biochemical tests and stool sample collection.
Stool samples were collected in Stool Tubes with DNA stabilizer. DNA was isolated with the use of the PSP-Spin Stool-DNA kit. Further analyses were based on the V3-V4 region of the 16S rRNA gene (Next Generation Sequencing method).
Results: We identified 8 clusters of bacteria (Table). The analysis revealed that the gut microbiome consists mostly of Bacteroidetes, Firmicutes and Actinobacteria, with the largest abundance of reads for Bacteroidetes (Table). Study groups did not differ in terms of the most abundant bacteria (Table). There was no difference in Firmicutes/Bacteroidetes ratio between study groups (Figure).
Conclusions: Among CAD patients, there are no significant differences in gut microbiome composition between patients with ACS and PCI. The analysis in larger CAD population as well as patients without CAD is required.

Adiponectin and t-cadherin level in patients with coronary artery disease and heart failure.

KY Mikheeva[1]; EA Polyakova[1]; AS Draganova[1]; DA Kolodina[1]; OA Berkovich[1]
[1]Saint-Petersburg State Medical University named I.P.Pavlov, faculty therapy, Saint-Petersburg, Russian Federation

On behalf of: E. Polyakova

Introduction: Adiponectin, an adipocyte-derived circulating protein, accumulates in the heart, vascular endothelium, and skeletal muscles through an interaction with t-cadherin (t-cad), a unique glycosylphosphatidylinositol-anchored cadherin. Recent studies have suggested that this interaction is essential for adiponectin-mediated cardiovascular protection.
Adiponectin stimulates phosphorylation and amp (adenosin mono phosphate) kinase activation, exerting direct effects on vascular endothelium, diminishing the inflammatory response to mechanical injury and enhancing endothelium protection. : low adiponectin levels may be an independent risk factor for severe coronary artery disease(cad) and heart failure(hf).
Methods: 41 patients with cad after coronary artery bypass surgery were enrolled: 29 males (70,7 %) and 12 females (29,3 %), age 58,7±1,1 years. All patients with stable class ii to iii hf. Adiponectin and t-cad level and lipid profile were measured. Statistical analyses were performed with spss 20.0 for windows.
Results: the distribution of adiponectin(ad), t-cad levels and ad/t-cad ratio differed significantly between cad patients with class ii to iii hf(27,1±0,09 pg/ml vs 9,4±0,1 pg/ml; 34,2±0,9 pg/ml vs 6,6±0,8 pg/ml; 1,1±0,1 vs 1,8±0,1; accordingly, p<0,05). Adiponectin, t-cad levels was significantly lower in cad patients with myocardial infarction in history(25,5±0,1 pg/ml vs 31,1±0,09 pg/ml ; 32,7±0,8 pg/ml vs 40,0±0,9 pg/ml ; accordingly, p<0,05). Ad/t-cad ratio was significantly lower in post-infarction patients (1,8±0,2 pg/ml vs 0,8±0,1 pg/ml, p<0,05).
Among lipid parameters whereas the high-density lipoprotein cholesterol level correlated positively (r=0,684; p=0,01).
Conclusion: cad after coronary artery bypass surgery and myocardial infarction in history had a lower level cardioprotective adipocytokines.

The impact of short term amiodarone treatment on hsCRP level in patients with ischemic heart failure and paroxysmal atrial fibrillation

Al Grosu[1]; RA Mocan[2]; EC Buzdugan[1]; H Rosianu[3]; D Pop[2]
[1]Municipal Hospital of Cluj-Napoca, Cardiology, Cluj-Napoca, Romania; *[2]Rehabilitation Hospital, Cardiology, Cluj-Napoca, Romania*; *[3]Heart Institute Nicolae Stancioiu, Cardiology, Cluj-Napoca, Romania*

INTRODUCTION: The role of inflammation in the development of coronary heart disease (CAD) and atrial fibrillation(AF) is well established, high sensitivity C reactive protein (hsCRP) being the most studied biomarker of inflammation in patients with cardiovascular diseases. It can be used as a prognostic or risk factor in patients with heart failure (HF), CAD or AF. Despite the progress in pharmacology , amiodarone (AM) remains the only antiarrhythmic drug used for rhythm control in patients with depressed left ventricular ejection fraction. Its mechanism of action is still not entirely discovered.
PURPOSE The aim of this study was the impact of short term amiodarone treatment on hsCRP level in patients with ischemic heart failure and paroxysmal AF (PAF).
METHODS We have enrolled 50 patients with CAD, left ventricular ejection fraction(LVEF) <40% and PAF documented on baseline ECG or 24 hour Holter monitoring (Group A). Amiodarone treatment was initiated as a rhythm control strategy. In the control group we have selected 50 consecutive patients with CAD and no evidence of PAF (Group C). All patients underwent transthoracic echocardiography and dosage of serum hsCRP, both at study initiation and at 3 months. All patients received betablockers, ACE and statins at maimum tolerated dose.
RESULTS At baseline there was no significant difference in age, sex, renal function, thyroid stimulating hormone (TSH) and glycated hemoglobin between the two groups. The mean LVEF was similar in both groups (Group A= 34±5% vs Group C= 32±4, p=0.852), but mean atrial volumes were significantly higher in PAF group (Group A= 33±10 ml/m2 vs Group C= 27±8 ml/m2, p=0.0017). hsCRP values were similar regardless of group (Group A=0.524±0.312 mg/dl vs Group C=0.485±0.371 mg/dl, p=0.91).
At 3 months evaluation no statistically significant difference was reported in renal function and glycated hemoglobin. TSH level sufferred an insignificant increase in Group A (2.440±0.812 µUI/ml vs 3.189±1.383 µUI/ml, p=0.76) compared with Group C (2.19±1.042 µUIml vs 2.227±1.5 µUI/ml, p=0.68). Short term AM treatment had a neutral impact on LVEF (34±5% vs 35±4%; p=0.87), but significantly decreased the volume of LA from 33±10 ml/m2 to 29±8 ml/m2; p=0.031, CI 95% 5-23 in Group A. No important changes of LVEF (32±4% vs 34±3%; p=0.77) and LA volumes (27±8 ml/m2 vs 28±3 ml/m2; p=1.1) were observed in Group C. The level of hsCRP decresed to a median of 0.471±0.118 mg/dl (p=0.002 CI 95% 0.375-0.592) after 3

months of amiodarone treatment in Group A. No significant changes in hsCRP level were observed in Group C (0.485±0.371 mg/dl vs 0.451±0.187 mg/dl (p=0.715, CI 95% 1.64-16).
CONCLUSION Short term AM treatment significantly decreased the level of hsCRP and LA volume.

P507
Feasibility of single-photon emission computed tomography in the diagnosis of obstructive coronary artery lesions in stable coronary aretry disease

A Alexey Sumin[1]; EV Korok[1]; AA Korotkevitch[1]; EN Kachurina[1]; AN Kokov[1]; OL Barbarash[1]
[1]Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation

Background: Patients with suspected coronary artery disease (CAD) are recommended to undergo non-invasive tests (NIT) for detecting ischemia (stress echocardiography, myocardial scintigraphy, etc.). Since these tests are beneficial in early diagnosis of myocardial ischemia (before pathological ECG alterations and the presence of chest pain syndrome), their high sensitivity and specificity do not cause much doubt. However, recent study has shown that NIT data had minimal added value compared to clinical data in predicting obstructive CAD.
Purpose: To evaluate the diagnostic capabilities of single-photon emission computed tomography (SPECT) in the detection of obstructive CA, depending on the meeting appropriate use criteria.
Material and Methods: 107 patients with previously diagnosed CAD or with the need to exclude it, who were admitted to the inpatient departments in the period from 2012 to 2015, were included in the retrospective study. All the patients underwent coronary angiography (CAG) and SPECT to detect hemodynamically significant CA stenoses. All the patients were enrolled into two groups according to the scores for SPECT imaging: Group 1 – patients, who had 7-9 scores (in whom SPECT imaging was reasonable, n = 88), Group 2 – patients who had 1-6 scores (in whom SPECT imaging was questionable or did not have any indications for its performance, n = 19).
Results: Clinical signs and symptoms of angina pectoris were predominantly found in Group 1 patients (p = 0.499). Asymptomatic patients were more likely to be found in Group 2 (p <0.001). Group 1 patients commonly had high pre-test probability (PTP; p <0.001), whereas Group 2 patients commonly had low PTP (p <0.001). The mean PTP was 77% in Group 1 and 58% in Group 2 (p = 0.003). According to positive SPECT imaging, significant CA lesions were more often found in Group 1 (31.8%), compared to Group 2 (10.5%, p = 0.060). Two- and three-vessel disease prevailed in Group 1 (25% and 14.7%) according the analysis of the prevalence and the location of hemodynamically significant CA lesions, although the data did not reach the statistical significance (p = 0.057 vs. p = 0.073). Stenoses > 70% were more commonly detected in Group 1 patients, compared to Group 2: the anterior descending artery (52.3% vs. 5.3%, p <0.001), the circumflex artery (35.2% vs. 10.5% ; p = 0.034), and the right coronary artery (34.1% vs. 10.5%, p = 0.041). The sensitivity in both groups was rather low (40% vs. 25%), whereas the specificity was 83% in Group 1 and 93% in Group 2. Conclusion: According to the clinical examination, patients with CAD and the indications for SPECT imaging commonly had obstructive CA lesions (63.6%), compared to the patients with the lack of indications (21.1%). However, the rate of the positive findings during the stress tests with SPECT imaging was low in both groups and did not differ significantly (p = 0.06). Despite high specificity of SPECT imaging, its sensitivity was low in both groups.

Valvular Heart Disease

Edge-to-edge percutaneous mitral repair for functional ischemic and non-ischemic mitral regurgitation: a systematic review and meta-analysis.

M Chiarito[1]; M Pighi[2]; D Cao[1]; F Francesco Cannata[1]; J Sanz[1]; F Roccasalva[1]; D Pini[1]; B Reimers[1]; P Pagnotta[1]; G Condorelli[1]; C Di Mario[3]; C Grasso[4]; C Godino[2]; G Stefanini[1]
[1]Clinical Institute Humanitas IRCCS, Rozzano, Italy; *[2]San Raffaele Hospital of Milan (IRCCS), Interventional Cardiology, Milan, Italy*; *[3]Royal Brompton Hospital, Interventional Cardiology, London, United Kingdom of Great Britain & Northern Ireland*; *[4]University of Catania, Catania, Italy*

Aim: Recently published randomized controlled trial comparing the use of the Mitraclip device in addition to guideline directed medical therapy alone in patients with secondary mitral regurgitation (MR) have shown conflicting results. Only few studies have assessed if these differences could be due to the underlying secondary MR etiology; the aim of this study is to systematically review the available literature about percutaneous edge-to-edge repair outcome in patients with secondary MR and perform a meta-analysis of studies investigating the differences after percutaneous edge-to-edge repair in patients with ischemic and non-ischemic secondary MR.
Methods: PubMed, EMBASE, Google scholar database and international meeting abstracts were searched for all studies about MitraClip. Studies where results were not delineated between MR aetiology, with <25 patients or with overlapping population were excluded.
The prespecified primary efficacy endpoint was the composite of all cause death and heart failure related hospitalization. Secondary endpoints were the single components of the primary endpoint.
Results: A total of seven studies investigating the midterm outcome of percutaneous edge-to-edge repair in patients with ischemic versus non-ischemic MR were included in the meta-analysis (n=2,908).
At 2 years, the risk of the prespecified primary endpoint was similar among patients with ischemic and non-ischemic MR (risk ratio (RR) 1.06; 95% CI: 0.91 to 1.23).
Conversely, the rate of all-cause death was significantly higher in patients with ischemic MR compared to patients with non-ischemic MR (RR 1.26; 95% CI: 1.06 to 1.52), while the rate of rehospitalization for heart failure was similar in the two groups (RR 1.21; 95% CI: 0.91 to 1.61).
Conclusions: This meta-analysis suggests that percutaneous edge-to-edge repair is likely to be more efficacious in terms of mortality in patients with non-ischemic rather than ischemic MR, despite a similar rate of rehospitalization for heart failure.

P510
Heart failure in aortic stenosis: extra-valvular cardiac damage according to the novel 2017 staging classification is differentially reflected by certain biomarkers of cardiovascular remodelling

M Franz[1]; L Baez[1]; K Gruen[1]; S Moebius-Winkler[1]; A Berndt[2]; PC Schulze[1]
[1]University Hospital Jena, Department of Internal Medicine I, Jena, Germany; *[2]University Hospital of Jena, Institut of Legal Medicine, Section of Pathology, Jena, Germany*

Background: Heart failure is one of the leading clinical characteristics in patients suffering from severe aortic valve stenosis (AVS) and is mainly determined by extra-valvular cardiac damage. In 2017, a novel staging classification integrating left ventricular, left atrial, pulmonary vascular and right ventricular remodelling has been introduced. In this study, we aimed to analyse a panel of serum biomarkers reflecting cardiovascular remodelling in correlation to this classification.
Methods: A clinically well-characterized patients' collective of the Jenaer Aortenklappenregister (JAKR) was categorized according to the 2017 staging classification into stage 0 to 4. Serum levels of the following biomarkers have been determined by ELISA: MMP-9, TIMP-1, B and C domain containing Tenascin-C (B+ Tn-C, C+ Tn-C), ED-A and ED-B domain containing Fibronectin (ED-A+ Fn, ED-B+ Fn), Endothelin 1 (ET-1) and Neutrophil gelatinase associated lipocalin (NGAL). Results: The patients included in the current study (n=94; age: 78.3 ± 7.3 years; 46.8% males; STS-score (STS): 4.4 ± 2.2) could be divided in to the following stages: stage 0 (4.3%), stage 1 (16%), stage 2 (54.3%), stage 3 (16%) and STAGE 4 (9.6%). To investigate the association of the different biomarkers to disease progression, we firstly compared stage 0+1 with stage 2 and than dichotomized the entire collective into stage 0+1+2 and 3+4 to compare the cohort exhibiting left heart damage and the group additionally showing pulmonary hypertension ± right heart damage.
We could show significantly decreased serum levels of MMP-9 (p=0.038) as well as a reduced MMP-9/TIMP-1 ratio (p=0.024) and increased levels of B+ Tn-C (p=0.002) and C+ Tn-C (p=0.007) when comparing stage 0+1 with stage 2. For these markers, no significant differences could be proven between the stage 0+1+2 and the stage 3+4 group. On the contrary for TIMP-1 (p=0.028), ED-A+ Fn (p=0.009), ET-1 (p=0.004) and NGAL (p=0.013), significantly increased serum levels occurred in the stage 3+4 compared to stage 0+1+2 group. For these markers, no significant differences were detectable between the groups of stage 0+1 and stage 2. To elucidate the predictive value of TIMP-1, ED-A+ Fn, ET-1 and NGAL for the probability of stage 3+4, logistic regression analysis (backward elimination WALD) including 9 relevant covariates was performed. Only ED-A+ Fn (OR: 1.134; CI: 1.044 – 1.231; p=0.003) and ET-1 (OR: 1.674; CI: 1.029 – 2.723; p=0.038) could be identified as independent predictors.
Conclusions: This is the first study identifying novel biomarkers differentially reflecting left and right heart damage in patients suffering from AVS. MMP-9 and B+ as well as C+ Tn-C are associated especially with left atrial or mitral damage. In contrast, TIMP-1, ED-A+ Fn, ET-1 and NGAL are associated with pulmonary vascular or tricuspid ± right ventricular damage. These findings might contribute a more precise initial diagnosis and risk stratification.

P511

Response of right ventricular longitudinal and radial fiber contractility to mitral valve surgery: a PREPARE-MVR substudy

B K Lakatos[1]; M Tokodi[1]; Z Toser[2]; KB Koritsanszky[3]; K Racz[3]; AV Soltesz[3]; T Varga[3]; E Kispal[1]; B Merkely[1]; E Nemeth[3]; A Kovacs[1]
[1]Semmelweis University Heart Center, Budapest, Hungary; *[2]Argus Cognitive Inc., Dover, DE, United States of America*; *[3]Semmelweis University, Department of Anaesthesiology and Intensive Therapy, Budapest, Hungary*

Despite mitral regurgitation is a valvular disease primarily affecting the left ventricle, significant changes in right ventricular (RV) morphology and function are also expected. Elevated pulmonary pressures are the main drives of concomitant RV remodelling, which can be partially restored by mitral valve repair/replacement (MVR). Following MVR, RV deformation markedly changes, while the role of these alterations in context of RV contractility is less known. The PREPARE-MVR study (PRediction of Early PostoperAtive Right vEntricular failure in Mitral Valve Replacement/Repair patients) aims to determine parameters, which may predict the perioperative risk of acute RV failure.
In this preliminary analysis we aimed to investigate the changes of RV global, longitudinal and radial contractility pre- and postoperatively in patients undergoing MVR.
Our study group consisted of 22 MVR patients (mean age: 60±11 years, m/f: 16/6). Transthoracic 3D echocardiography was performed before the operation and following intensive care unit discharge. 3D beutel model of the RV was created and RV end-diastolic volume index (EDVi) among with RV ejection fraction (RVEF) were calculated using commercially available software. For in-depth analysis of RV mechanics, we have decomposed the motion of the RV using our custom software (ReVISION) to determine longitudinal (LEF) and radial ejection fraction (REF). Right heart catheterization was also performed before MVR and 24 hours after the procedure as well to measure pulmonary arterial systolic pressure (sPAP). Using the aforementioned parameters, we have calculated RV global end-systolic elastance (Ees), along with longitudinal (EesL) and radial end-systolic elastance (EesR), which represent load-independent contractility indices of the RV global, longitudinal and radial systolic function.
RV morphology was unaltered by surgery according to RVEDVi (preop vs. postop: 73±19 vs. 76±21 mL/m^2, p=NS). RVEF slightly decreased after MVR (50±6 vs. 48±7 %, p<0.05), however, RV motion pattern markedly changed. Postoperative LEF was significantly lower compared to preoperative values (25±5 vs. 16±6%, p<0.0001), among with an increase in REF (21±8 vs. 26±6%, p<0.01). As expected, sPAP decreased in response to MVR (38±15 vs. 34±11 mmHg, p<0.05), in parallel with global RV contractility (1.09±0.40 vs. 0.90±0.33 mmHg/mL/m^2, p<0.01). While EesL was significantly lower after the operation (0.72±0.25 vs. 0.56±0.20 mmHg/mL/m^2, p<0.0001), EesR did not change (0.70±0.29 vs. 0.63±0.23 mmHg/mL/m^2, p=NS).
MVR results in complex changes of RV function and hemodynamics. Novel parameters of RV contractility reveal different response of the longitudinal and radial fibers to the altered RV load, which may have significance in postoperative patient management. The PREPARE-MVR study aims to determine the role of perioperative parameters on patient outcome.

P512

Cardiac filling pressures in left-sided valvular regurgitation

J Oehman[1]
[1]Turku University Hospital, Cardiology , Turku, Finland

Background -Assessing left-sided valvular regurgitation (LVR) by transthoracic echocardiography (TTE) is rather difficult and time-consuming due to a required guideline based multiparametric approach
-In these conditions,ventricular remodelling is often a late sign of prolonged volume, and in case of aortic regurgitation (AR) also pressure overload, and possible interventions should mostly take place before remodelling has occurred-Evaluation of diastolic function including evaluation of left-sided cardiac filling pressures is often routinely done whenever TTE is performed
- Since both LVRs pool up elevated pressures in the left atrium, either directly in mitral regurgitation (MR) or via left ventricular diastolic pressure in AR, left-sided filling pressures might provide a rapid and sensitive method for detecting significant LVR
Methods -30 patients scheduled for LVR follow with TTE without significant structural heart disease other than LVR were enrolled in this prospective registry trial
-A guideline-based multiparametric evaluation of diastolic function including filling pressure assessment was done at the very beginning of each TTE exam, followed therafter by a thorough multiparametric guideline-based evaluation of valvular disease
Results - Medial E/e‘ with a cutoff of 15 reached a 100 % sensitivity and a 100 % specificity for detecting significant LVR, as did a multiparametric guidelined-based evaluation of filling pressures as well (p <0.001 for both)
-The sensitivity of left ventricular remodelling for detecting significant LVR was only 33.3 %
-Compared to the other two groups, the mean E-wave was larger in the MR-group (164 vs 121 cm/s, p<0.001) and the tissue doppler e‘-wave smaller in the AR-group (5.5 vs 7.5 cm/s, p=0.03), while systolic pulmonary pressure, Inferior Vena Cava measurements, LA size, E/A-ratio, tissue doppler velocities or dTE alone did not differ between groups (p=NS)Conclusions- Significant LVR seems to be very unlikely in the absence of elevated left-sided filling pressures on TTE-Evaluation of filling pressures at least by the E/e‘ ratio, which also is known to be feasible and rapid to perform, should thus probably be included in TTE exams evaluating LVR

Immediate changes on aortic hemodynamics and wave reflections after surgical aortic valve replacement

E Evangelia Sigala[1]; C Vlachopoulos[1]; C Triantafylloy[2]; N Koumallos[2]; V Lozos[2]; A Katsaros[1]; I Kouerinis[2]; N Giakis[2]; M Demosthenous[2]; D Terentes-Printzios[2]; K Fillis[3]; D Tousoulis[1]
[1]Hippokration General Hospital , Athens, Greece; *[2]Hippokration General Hospital , Cardiac Surgery, Athens, Greece*; *[3]Hippokration General Hospital , Propaedeutic Surgery, Athens, Greece*

Introduction: Aortic hemodynamics and wave reflections are predictors of adverse cardiovascular events. Surgical aortic valve replacement (SAVR) is the most effective treatment of patients with aortic stenosis. Purpose:Our aim was to evaluate the immediate changes on aortic hemodynamics and wave reflections after surgical aortic valve replacement.
Methods: ιn this pilot study, twenty-five patients (mean age 71.0±7.1 years, 11 female) with severe aortic stenosis undergoing SAVR were included. Aortic hemodynamics and wave reflections (aortic pressures, aortic augmentation index [AIx@75], augmented pressure, subendocardial viability ratio [SEVR]) were measured with Sphygmocor. Measurements were performed preoperatively and postoperatively.
Results: There was a statistically significant decrease in aortic systolic blood pressure (SBP) (134±24 vs 118±17mmHg with p=0.002, respectively) that was not apparent in peripheral SBP. We observed a marginally significant decrease in aortic AIx@75 (29±13 vs 22±12% with p=0.05, respectively) and a decrease in aortic AIx (p<0.001, Figure) and augmented pressure (20±10 vs 8±7 mmHg with p<0.001, respectively). Moreover, there was a marginally non-significant trend for an increase in SEVR (137±30 vs 149±35%, p=0.095).
Conclusions: The results of this study indicate that shortly after SAVR subjects show a decrease in aortic wave reflections with a small improvement of myocardial perfusion. These findings imply the short-term hemodynamic consequences of SAVR.

P514

Evaluation of the relationship between platelet indices and spontaneous echo contrast in patients with mitral prosthetic heart valves

M Kalcik[1]; A Guner[2]; E Bayam[3]; M Yesin[4]; S Kalkan[2]; MO Gursoy[5]; S Gunduz[2]; S Karakoyun[6]; M Ozkan[7]
[1]Hitit University Faculty of Medicine, Department of Cardiology, Corum, Turkey; *[2]Kosuyolu Kartal Heart Training and Reserch Hospital, Cardiology, istanbul, Turkey*; *[3]Umraniye Training and Research Hospital, Department of Cardiology, Istanbul, Turkey*; *[4]Kars Harakani State Hospital, Department of Cardiology, Kars, Turkey*; *[5] Izmir Katip Çelebi University Atatürk Training and Research Hospital, Department of Cardiology, Izmir, Turkey*; *[6]Kafkas University, Faculty of Medicine, Department of Cardiology, Kars, Turkey*; *[7]Ardahan University, Division of Health Sciences, Ardahan, Turkey*

Introduction: Spontaneous echo contrast (SEC) is defined as dynamic smoke-like echoes within the cardiac cavities with a characteristic swirling motion in echocardiography. Previous clinical studies have demonstrated that SEC is a risk factor for left atrial thrombus formation and an important indicator of potential systemic embolism. Platelet indices have been associated with the presence of SEC in patients with mitral stenosis previously. However, the relationship between platelet indices and SEC in patients with prosthetic heart valves has not been investigated yet.
Methods: This study enrolled a total of 89 patients [female: 38 (42.4%), median age: 52 (36-67) years] with SEC formation in the left atrium, and 257 control subjects [female: 123 (47.5%), median age: 56 (45-65) years] without SEC formation. All patients were evaluated by transthoracic and transesophageal echocardiography and laboratory tests including complete blood count and biochemical parameters.
Results: Patients with SEC formation had more frequent atrial fibrillation, higher left atrial diameter (LAD) and lower left ventriular ejection fraction values. Platelet indices including platelet count, platelet distribution width, mean platelet volume,

and plateletcrit did not differ between the groups (Figure 1). Increased LAD was detected as the only independent predictor of SEC development. In the receiver operating characteristic curve analysis, LAD values above 50.5 mm predicted SEC formation with a sensitivity of 78%, and a specificity of 61% (area under the curve= 0.641; 95% confidence interval: 0.571-0.712; p<0.001)

Conclusion: Platelet indices were not found to be associated with the presence of SEC formation in the left atrium in patients with mitral prosthetic valves. Therefore, it is debatable to use platelet indices with previously known echocardiographic and clinical risk factors to predict SEC development in patients with mitral prosthesis.

N-terminal of the prohormone brain natriuretic peptide is a predictor of hemodynamic instability in patients undergoing valve surgery

P Duchnowski[1]; T Hryniewiecki[1]; M Kusmierczyk[2]; P Szymanski[1]
[1]Institute of Cardiology in Anin, Department of Acquired Cardiac Defects, Warsaw, Poland; [2]Institute of Cardiology in Anin, Department of Cardiosurgery and Transplantology, Warsaw, Poland

Funding Acknowledgements: Statutary work at Institute of Cardiology, no 1705

Introduction The usefulness of N-terminal of the prohormone brain natriuretic peptide (NT-proBNP) as a predictor of perioperative hemodynamic instability is currently unknown.

Methods A prospective study was conducted on a group of 455 consecutive patients with significant valvular heart disease that underwent elective valve surgery. The primary end-point was postoperative hemodynamic instability. The secondary end-point was death from all causes in patients with perioperative hemodynamic instability.

Table 1.

Preoperative characteristics of patients (n=455)	Values
Age, years*	62 ± 12
NYHA, (classes)*	2.4 ± 0.5
LV ejection fraction, (%)*	57 ± 11
Pulmonary blood pressure, mmHg*	45 ± 18
Hs-TnT,ng/L*	19 ± 15
NT-proBNP,pg/mL*	1089 ± 874
Main procedures:	
AVR, n (%)	240 (30%)
MVR, n (%)MVR + AVR, n (%)MVP, n (%)	90 (19.7)46 (8.4%)79 (14.6%)

Results The postoperative hemodynamic instability occurred in 85 patients. At multivariate analysis NT-proBNP, NYHA classes and Glomerular Filtration Rate remained independent predictors of the primary end-point. Age and NT-proBNP were associated with an increased risk of death. The area under receiver operator characteristic curve for primary end-point for NT-proBNP is 0.802 (95% CI 0.756–0.842) (sensitivity: 74%; specificity: 78%) (Figure 1).

Conclusions Elevated preoperative NT-proBNP was associated with a higher risk of postoperative hemodynamic instability and death.

Background: left ventricular non-compaction (LVNC) is considered to be a separate form of cardiomyopathy often presented with heart failure, arrhythmic and embolic events. It often has developmental origin with a wide spectrum of genes being a cause of LVNC. The genetic landscape of LVNC crossovers with that of other types of cardiomyopathies with sacromeric gene mutations prevailing as a dominant cause of the disease. However, in paediatric and adolescent patients, LVNC is often associated with other types of cardiomyopathies such as restrictive and hypertrophic cardiomyopathy. Paediatric cases of LVNC are often associated with congenital heart defects and present with a higher proportion of familial cases with great phenotypic intrafamilial variability compared to adult LVNC. Recently, a wider genetic spectrum of pediatric/adolescent LVNC was demonstrated compared to adult cases with unexpectedly high proportion of causative genes encoding for structural and ion channel genes. There for the aim of our study was to identify the genetic spectrum of LVNC in paediatric and adolescent patients in Russian population.Material and methods: the study was approved by the Institute Ethical Review Board. On behalf of the children enrolled in the study, written informed consent was obtained from the next of kin. The study included 15children with LVNC presented with heart failure class II-IV. Patients with inborn errors of metabolism and congenital syndromes as Noonan and Barth syndrome were also included into the study. The genotyping was performed using HaloPlex target enrichment panel on MiSeq (Illumina). In those patients, where no pathogenic or likely pathogenic

variant as well as variant of unknown significance within a gene highly expressed in myocardium were not identified, exome sequencing was performed. The identified genetic variants were classified according to ACMG guidelines.
Results: Mean age of LVNC manifestation was 7,6 [1,1 – 10,1] with HF as a main clinical feature. In two patients the diagnosis of LVNC was established within the first year of life. Within 3 year follow up three patients reached endpoints such as cardiovascular death (1) and heart transplantation (1). In 8 patients pathogenic or likely pathogenic genetic variants were detected in TAZ, ACTN2, DSP, TTN, MYPN, MYH7, BRAF and MYBPC3 genes. In 6 patients, variants of unknown significance were detected in MYPN, OBSCN, ANK2, SCN1B, MYLK2, and SCN5A genes. In one patient no pathogenic, likely pathogenic or variant of unknown significance were detected.
Conclusions: In patients with LVNC presented in childhood (likely)pathogenic genetic variants were detected in 53% of the cases. Importantly, variants of unknown significance were mainly represented by structural and ion channel encoding genes, rather than sarcomeric genes with pathogenic role to be further determined.

Screening for transthyretin amyloid cardiomyopathy in everyday practice

P Pablo Garcia-Pavia[1]; S Bokhari[2]; T Damy[3]; P Elliott[4]; N Fine[5]; M Gospodinova[6]; L Obici[7]; C Rapezzi[8]; R Witteles[9]
[1]University Hospital Puerta de Hierro Majadahonda, Department of Cardiology, Madrid, Spain; *[2]Columbia University Medical Center, New York, United States of America*; *[3]Mondor Hospital, Paris, France*; *[4]University College London, London, United Kingdom of Great Britain & Northern Ireland*; *[5]Libin Cardiovascular Institute Of Alberta, Calgary, Canada*; *[6]Medical Institute of Ministry of Interior, Sofia, Bulgaria*; *[7]Amyloidosis Research and Treatment Center, Pavia, Italy*; *[8]University of Bologna, Bologna, Italy*; *[9]Stanford University Medical Center, Stanford, United States of America*

Funding Acknowledgements: Pfizer provided logistical support and funding to allow the expert group to meet. Editorial support was funded by Pfizer.

Background: Transthyretin amyloid cardiomyopathy (ATTR-CM) is a life-threatening, progressive, infiltrative disease caused by the deposition of transthyretin amyloid fibrils in the myocardium.
ATTR-CM is often overlooked as a cause of common cardiovascular conditions in older heart failure patients. Lack of disease awareness, misdiagnosis and misconceptions about the diagnostic process are, in part, responsible for a delay to diagnosis and application of appropriate patient management strategies, which can lead to a poor prognosis. Today, with the availability of bone scintigraphy as an inexpensive, non-invasive tool to diagnose ATTR-CM, the rationale to screen for this disease within certain populations of patients is increasingly warranted.
Purpose: Here, we aimed to develop a clinical framework to aid clinicians in identifying appropriate patients to be screened for ATTR-CM among the wider heart failure population.
Methods: An international panel of 11 amyloidosis experts convened to develop a consensus on the patient characteristics and clinical scenarios that further heighten suspicion or support the possibility of an underlying ATTR-CM, as well as a list of 'red flags' that should provide further evidence to support screening for ATTR-CM in general practice.
Results: The expert panel advised that men over 65 years or women over 70 years with heart failure and left ventricular wall thickness ≥14 mm should be screened for ATTR-CM. Some of the cardiac 'red flags', providing further evidence as to the possibility of ATTR-CM as an underlying condition, include: reduction in longitudinal strain with apical sparing; discrepancy between left ventricular wall thickness and QRS voltages; the presence of atrioventricular block and infiltrative features; and a diffuse late gadolinium enhancement with cardiac magnetic resonance. The presence of extra-cardiac symptoms such as sensorimotor polyneuropathy, dysautonomia and a history of bilateral carpal tunnel syndrome further support the possibility of ATTR-CM. Once a suspicion of ATTR-CM has been raised, a non-invasive diagnostic approach is recommended. The combination of bone scintigraphy and free light chain testing is the basis for the appropriate non-invasive screening of patients with suspected ATTR-CM.
Conclusion: This framework should assist clinicians in recognising patients at risk of having an underlying ATTR-CM. Awareness and timely diagnosis of ATTR-CM will facilitate the provision of optimal patient care.

P519

The left ventricular noncompaction and hypertrabecularity in adult patients: clinical classification and follow-up

EV Pavlenko[1]; O V Olga Blagova[1]; AV Nedostup[1]; VP Sedov[1]; NV Gagarina[1]; EA Mershina[1]; ME Polyak[2]; EV Zaklyazminskaya[2]
[1]I.M.Sechenov I Moscow State Medical University, Moscow, Russian Federation; *[2]Russian Research Center of Surgery, Moscow, Russian Federation*

Purpose: to study clinical variants and follow-up of the left ventricular noncompaction (LVN) in comparison with hypertrabecularity (HT) in adult patients.
Methods. The diagnosis of LVNC was established in 116 adults (67 males, 46.3±15.1 y.), diagnosis of HT (ratio noncompact to compact layer 1:1 – 1:2) - in 42 adults (24 males, 43.5±15.2 y.). To diagnose LVNC / HT were performed Echo-CG, CT (n = 77 / 24) and MRI (n = 51 / 11). In 31 / 10 patients three visual methods were used, in 77 / 27 patients using any two methods. The average LV EDD was 6.0±0.8 / 5.9±1.1 cm, LV EF 38.5±14.0 / 44.6±18.3%. We performed NGS sequencing, followed by Sanger sequencing and also investigation of anti-heart antibodies, virus genome by PCR, coronary angiography (n = 29), scintigraphy (n = 27), a morphological study of the myocardium in 22 patients (14 endomyocardial, 1 intraoperative biopsy, 3 explanted heart studies, 6 autopsies). The mean follow-up was 15 [5; 40] / 6 [2; 19] months.
Results. The pathogenic mutations / VUCS in the genes MYH7, MyBPC3, LAMP2, DES, DSP, TTN were found in 12 / 5 (15%) of patients with LVNC and 0 / 1 (2%) of patients with HT. We identified six clinical variants (forms, diagnostic scenarios) of the LVNC: 1. Asymptomatic ('accidental find', 2%). 2. Arrhythmic ('idiopathic' arrhythmias, 15%). 3. Ischemic ('coronary heart disease', 7%). 4. Dilated ('idiopathic' dilated cardiomyopathy, 42%). 5. Acute / subacute myocarditis in the patients with LVNC, 12%. 6. LVNC in association with other cardiomyopathy (hypertrophic, restrictive, arrhythmogenic right ventricular cardiomyopathy, myodystrophy, Danon disease), 22%. The mutation only in forms 4-6 were detected, VUCS – also in form 2. In patients with HT met the same six clinical forms with a frequency of 2.4%, 31.0%, 2.4%, 45.2%, 9.5% and 7.1% respectively. Myocarditis was diagnosed in 51.7% of patients with various forms of LVNC and in 59.5% of patients with HT. The main clinical manifestations of the LVNC / HT were CHF (82.7 vs 57.1%, $p < 0.05$), PVBs more than 500 / day (46.6 vs 31.0%, $p < 0.05$), sustained / unsustained ventricular tachycardia (49.1 vs 26.2%, $p < 0.05$), atrial fibrillation (31.0 / 14.3%), ischemia (angina pectoris in 20.7 vs 2.4% and myocardial necrosis in 13.8 vs 2.4%, $p < 0.05$), thromboembolism (22.4 vs 7.1%, $p < 0.05$). Initial clinical forms were stable over time. LV EF and LV EDD showed a significant improvement only in the group with acute / subacute myocarditis (EF increased from 27.3% to 39.2%, $p < 0.05$), most of which received basic therapy of myocarditis. In other groups, there was a nonsignificant improvement. The end-point "mortality + transplantation" was 18% in LVNC and 2% in HT.
Conclusions. LVN syndrome in adults is vary polymorphic and often associated with other cardiomyopathy (22%). LV HT may be a softer (latent) form of noncompact cardiomyopathy. The clinical forms of LVNC are stable over time. We have proposed an extended clinical classification of LVNC.

P520

Clinical spectrum and outcome of advanced heart failure in hypertrophic cardiomyopathy: from pathophysiology to contemporary unmet needs

G Galati[1]; S Zieroth[2]; A Di Lenarda[3]; N Aspromonte[4]; I Vranic[5]; M Gulizia[6]; A Margonato[1]
[1]San Raffaele Hospital and Scientific Institute (IRCCS), Heart Failure Unit and Division of Cardiology, Cardiothoracic and vascular Department, Milan, Italy; *[2]St. Boniface General Hospital, Heart Failure and Transplant Clinics, Section of Cardiology, Winnipeg, Canada*; *[3]Cardiovascular Center A.S.S. 1 of Trieste, Cardiovascular Department, Trieste, Italy*; *[4]Polyclinic Agostino Gemelli, Cardiology Unit, Rome, Italy*; *[5]Clinical Centre of Serbia, Cardiology Department, Belgrade, Serbia*; *[6]Garibaldi Hospital, Cardiology Unit, Catania, Italy*

On behalf of: Heart Failure in Hypertrophic Cardiomyopathy

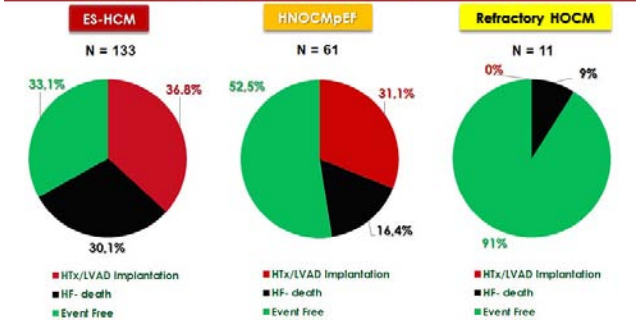
Background Advanced heart failure (AdvHF) in hypertrophic cardiomyopathy (HCM) was overlooked. Neither large case series nor clinical trials on this topic have been described. The main clinical-pathological profiles responsible for AdvHF in HCM are: 1) End-stage HCM (ES-HCM) defined by an ejection fraction (EF) ≤50%; 2) LV outflow obstruction despite optimal pharmacological and not pharmacological therapy (Refractory HOCM); 3) Nonobstructive HCM with preserved EF (HNOCMpEF).
Purpose
Based on a systematic revision of all published manuscripts on this topic, this study describes prevalence and outcomes of the 3 main HCM phenotypes responsible for AdvHF, heart transplantation (HTx), left ventricular assist device (LVAD) implantation and death for heart failure (HF-death) with the contemporary management of HCM.
Methods
The study screened 120 manuscripts in MEDLINE and EMBASE on AdvHF in HCM patients published from 2000 until December 2018, in adult patients (≥18 years old). The authors identified 8 manuscripts eligible for the analysis. 205 patients with AdvHF due to HCM, despite optimal therapy, were included in the main analysis. AdvHF was defined in presence of severe NYHA symptoms (class III and IV), because in all the manuscripts this definition was used. Mean follow-up = 7.6 years.
Results
Figure 1 shows the prevalence of phenotypes responsible for AdvHF and HTx/LVAD implantation/HF-Death. Please notice on the right the combined outcome split in two HTx/LVAD implantation separated from HF-Death. Of 205 HCM patients, 119 (58%) underwent HTx, LVAD implantation or died for HF.

Figure 2 shows the outcome per each clinical phenotype.

Conclusion

AdvHF in HCM has an ominous prognosis, indeed 58% of patients underwent HTx/LVAD implantation or died for HF. AdvHF in HOCM has a good outcome with the contemporary management. Less than 1/3 of cases of AdvHF in HCM was determined by HNOCMpEF due to massive hypertrophy and restrictive physiology and only 16.4% of them died due to HF. Nowadays, ES-HCM represents the main cause of AdvHF in HCM (64.9% of all HCM patients) and the major determinant for poor outcome (74.8% of Htx/LVAD/HF-death among all HCM patients). Although it has been managed with HTx or LVAD implantation, 1/3 of these patients died due to HF. This reflects poor attention and portrays an unmet need for HCM patients, in particular for ES-HCM patients that are younger than all others HCM patients. These findings reinforce the emphasis on long-term surveillance of HCM patient in order to timely identify patients at risk of ES evolution and early start the standard HF therapeutic (pharmacological and non-pharmacological) armamentarium. Finally, developing specific therapies for these HCM patients it is of paramount importance.

FIGURE 1	Adv HF (=205)	HTx/LVAD implantation/HF-Death (=119)	HTx/LVAD implantation (=68)	HF-Death (=51)
ES-HCM	133 (64.9%)	89 (74.8%)	49 (72.1%)	40 (78.5%)
Refractory HOCM	11 (5.4%)	1 (0.8%)	0 (0%)	1 (1.9%)
HNOCMpEF	61 (29.7%)	29 (24.4%)	19 (27.9%)	10 (19.6%)



P521

Echocardiographic deformation imaging improves assessment of structural disease progression in arrhythmogenic cardiomyopathy

K Taha[1]; TP Mast[1]; MJM Cramer[1]; J Van Der Heijden[1]; FW Asselbergs[1]; PAF Doevendans[1]; AJ Arco Teske[1]

[1]University Medical Center Utrecht, Department of Cardiology, Utrecht, Netherlands (The)

Background: Arrhythmogenic cardiomyopathy (AC) is an inherited cardiomyopathy characterized by both electrical and structural cardiac disease. Remarkably, progression of structural disease is uncommon during the early stages of AC, while progression of electrical disease is seen frequently. We hypothesize that this discrepancy is caused by the inability of conventional imaging methods to detect subtle changes over time. Echocardiographic deformation imaging may be more sensitive than conventional imaging techniques for detection of structural disease progression in AC.

Objective: To study the incremental value of serial echocardiographic deformation imaging over conventional imaging for detection of structural disease progression in AC.

Methods: We included patients who fulfilled criteria for AC diagnosis (i.e. definite AC) and their mutation-carrying relatives who did not fulfil criteria for definite diagnosis (i.e. early AC). All study participants underwent a baseline and follow-up cardiac evaluation, including conventional echocardiography and deformation imaging. Global right ventricular strain (RV-GLPS) and regional analysis in the right ventricular (RV) subtricuspid region. The deformation pattern in this region was scored as type I (normal deformation), type II (delayed onset, decreased systolic peak, and post-systolic shortening), or type III (systolic stretching and large post-systolic shortening). All measurements were compared between baseline and follow-up to assess disease progression.

Results: 81 subjects were included (50 definite AC, 31 early AC). The mean follow-up duration was 6.7±3.0 years. In definite AC, measurements by conventional echocardiography and deformation imaging both indicated disease progression ($p<0.001$). In early AC, conventional functional measurements did not reveal disease progression: left ventricular ejection fraction went from 57.5% [IQR 5.5] at baseline to 57.0% [IQR 4.7] after follow-up ($p=0.146$), and RV fractional area change went from 47.6 ± 6.6% to 47.1 ± 7.2% ($p=0.279$). However, with deformation imaging, a small but significant decrease in RV global strain was seen in early AC (from 24.9 ± 3.9% to 23.3 ± 3.8%, $p=0.035$). More pronounced was the deterioration of regional strain patterns, 14 subjects (45%) with early AC showed a change of the deformation pattern in the subtricuspid region ($p<0.001$), of which 12 subjects progressed to type II and two progressed to type III.

Conclusion: While conventional imaging approaches indeed lack sensitivity to detect disease progression in early AC, echocardiographic deformation imaging reveals progressive mechanical dysfunction in the RV in half off our study population. Serial evaluation by echocardiographic deformation imaging may therefore be helpful in risk stratification of patients during the earliest stages of AC. The prognostic implications of this finding warrants further investigation.

P522

Evaluation of myocardial gene expression profiling for superior diagnosis of idiopathic giant cell myocarditis in a large cohort of patients with acute cardiac decompensation

F Felicitas Escher[1]; HP Pietsch[2]; CS Siegismund[2]; UG Gross[2]; DL Lassner[2]; HPS Schultheiss[2]

[1]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; [2]Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany

Background –Idiopathic giant cell myocarditis (IGCM) diagnostics is based on differential patterns of inflammatory cell infiltration, and multinucleated giant cells (GCs) in histological sections of endomyocardial biopsies (EMBs). However, the sampling error is high for the detection of focally GCs by histopathology. We report on a clinical evaluation of a recently published method for improved differential diagnosis of this frequently fatal disease by myocardial gene expression profiling.

Objective – This is to improve the diagnostics of IGCM by gene expression profiling, and to demonstrate the feasibility of this method in clinical practice in a large cohort of patients.

Methods – In this multicenter study, EMBs of n=427 patients with clinically acute cardiac decompensation and suspected acute myocarditis were screened (mean age 47.03±15.69 years). In each patient, EMBs were analyzed by histology, immunohistology, molecular virology, and gene expression profiling.

Results – Out of the total of n=427 patient samples examined, GCs could be detected in 26 cases (6.0%) by histology. An established myocardial gene profile – consisting of 27 genes – was revealed resulting in a specified profile of 5 genes (chemokine receptor 5 (CCR5), chemokine receptor 6 (CCR6); carnitine palmitoyltransferase I (CPT1), toll-like receptor 8 (TLR8), and chemokine (C-C motif) ligand 20 (CCL20)) which identified histologically proven IGCM with high specificity in 25 of the 26 patients (96.2%). Applying this newly established profiling on the remaining patient samples, additional n=31 (7.3%) patients were identified for IGCM without any histological proof of myocardial GCs.

In a subgroup study we analyzed clinical hemodynamic outcome at follow-up (mean follow-up 6.4±4.3 months) of n=40 patients treated under immunosuppressive therapy after EMB- or geneprofil-based diagnosis. Immediate immunosuppressive treatment of patients with histologically diagnoses IGCM revealed a significant improvement of left-ventricular function (LVEF) ((19.0±14.22 to 47.25±12.27; $p=0.0049$) at follow-up). Similarly, a significant increase of LVEF (31.3±15.0 to 49.9±12.4; $p=0.0028$) in patients with positive myocardial gene profiling for GCs without histological proof was observed. Simultaneously, baseline highly deregulated genes were normalized in the follow-up EMBs after treatment. No treated patient died within the observation period.

Conclusions – Myocardial gene expression profiling is a reliable method in clinical practice to predict IGCM even without direct histological proof of GCs in EMB section. The gene profiling is of high clinical relevance to overcome the sampling error of purely histological examination, and to control the effectiveness of the therapy. The data clearly show the importance to take EMB in unexplained acute decompensation to get a diagnosis and improve the prognosis.

P523

Plasminogen activator inhibitor type-1 (PAI-1) expression relates to the presence of myocardial inflammation in patients with nonischemic cardiomyopathy

F Felicitas Escher[1]; ME Agirbasli[2]; DL Lassner[3]; GA Aleshcheva[3]; HPS Schultheiss[3]

[1]Charite - Campus Virchow-Klinikum (CVK), Berlin, Germany; [2]Medeniyet University, Cardiology, Istanbul, Turkey; [3]Institute of Cardiac Diagnostics and Therapy (IKDT), Berlin, Germany

Background: Plasminogen activator inhibitor type-1 (PAI-1) is an important inhibitor of the fibrinolytic pathway and an acute phase reactant in response to inflammatory cytokines, resulting in thrombosis, arteriosclerosis, and tissue fibrosis. It has been identified as a potential biomarker for coronary artery disease and metabolic

syndrom. However, so far, nothing is known about its importance in nonischemic cardiomyopathy.
Aims: To analyzed PAI-1 expression in patients with different forms of cardiomyopathies and evaluate possible influence of PAI-1-dependent pathomechanisms in patients with intramyocardial inflammation.
Methods and Results: In this study, endomyocardial biopsies (EMBs) from 309 patients (mean age 48.0±13.9 years) with different forms of cardiomyopathies were enrolled, including 123 patients with dilated cardiomyopathy (DCM) (mean LVEF 28.01+9.06%) and 186 patients with EMB-proven virus-negative inflammatory cardiomyopathy (DCMi) (mean LVEF 31.76+14.14%). 10 patients (mean LVEF 60.50+4.76%) without viral or inflammation in EMB served as controls. Hemodynamic parameters were measured by catheterization and echocardiography. EMBs were performed at first admission after exclusion of ischemic of valvular heart disease. In EMBs PAI-1 was assessed by immunohistology including digital imaging analysis. PAI-1 expression was significantly higher in patients with DCMi in contrast to DCM patients and controls (0.517+2.20 vs. 0.187+0.598 vs. 0.023+0.032 % Area Fraction; =0.0002). PAI-expression correlates significantly with lymphocytic infiltrates (for CD3 = 0.56, < 0.0001, and LFA-1 = 0.59, < 0.0001). This was found to be independent of hemodynamic parameters, and age.
Conclusion: Myocardial inflammation is associated with a significant increase in PAI-1 expression in DCMi independently of the hemodynamic conditions. This new pathophysiological axis could be a potiential therapeutic target in future treatment stategies in DCMi.

P524
Prognostic values of new biomarkers in patients with AL amyloidosis

D Kim[1]; JO Choi[1]; K Kim[1]; SJ Kim[1]; ES Jeon[1]
[1]*Samsung Medical Center, Internal medicine, Seoul, Korea (Republic of)*

Background Cardiac involvement is the most important prognostic marker in light-chain amyloidosis (AL). Revised Mayo staging, which is widely used staging system for prognosis in AL amyloidosis incorporated N-terminal pro-brain natriuretic peptide (NTproBNP) and troponin T (TnT) because of importance of cardiac involvement. Soluble suppression of tumorigenicity 2 (sST2), growth differentiation factor 15 (GDF15), and osteopontin (OPN) are currently emerging biomarkers in acute and chronic heart failure patients.
Purpose We investigated additive prognostic values of new biomarkers, sST2, GDF15, and OPN for overall mortality in AL amyloidosis.
Methods Levels of sST2, GDF-15, and OPN were assessed at time of diagnosis in 73 AL amyloidosis from 2010 to 2015. All patients were biopsy-proven amyloidosis confirmed by Congo red staining and immunohistochemistry of any tissue specimen. AL amyloidosis was diagnosed when at least 1 antibody stained the amyloid deposits (anti- lambda light chain, anti-kappa light chain). Cardiac involvement was defined by the presence of amyloid deposits on endomyocardial biopsy (n=50, 69%). Primary endpoint was all cause mortality. All patients underwent baseline assessment including 12-lead electrocardiogram, transthoracic echocardiography, and blood sampling.
Results During median follow-up duration of 18.0 (12.4-28.1) months, a total of 25 deaths occurred. sST2 and GDF-15 showed satisfactory predictive performances for both one-year and overall survival from ROC analysis and best cut-off values were selected. Elevated sST2 and GDF-15 levels showed significant incremental prognostic values in addition to NT-ProBNP and TnT for overall mortality (Figure 1). Patients were assigned 1 point for elevated sST2 or GDF-15. The mean values of NT-proBNP, TnT, mean LV wall thickness, and septal e' velocity differed significantly according to the scores (Figure 2). Patients with higher scores showed significantly worse prognosis even in patients with advanced revised Mayo staging (Figure 3). Conclusion sST2 and GDF-15 showed satisfactory prognostic value for overall survival of AL amyloidosis patients. Furthermore, sST2 and GDF-15 showed additive incremental values over conventional biomarkers and further discriminated prognosis of patients in advanced stages.

Figure 1.

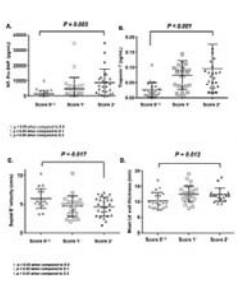

Figure 3.

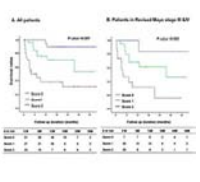


P525
Nitric oxide and kinins system plasma levels in patients with chronic Chagas heart disease and systemic arterial hypertension

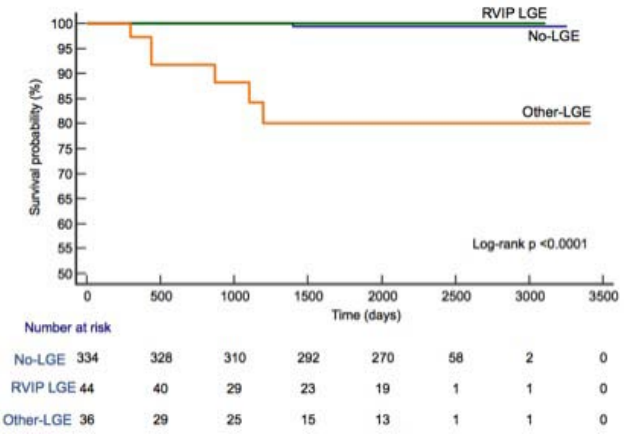
R Bestetti[1]; R Dellalibera-Joviliano[1]; G Lopes[1]; R Furlan-Daniel[1]; M Faria-Jr[1]; K Lopes[2]; N Iucif-Jr[1]
[1]*University of Ribeirao Preto, Ribeirao Preto, Brazil*; [2]*Clinica Sao Rafael, Piumhi, Brazil*

Background. Nitric oxide (NO) is one of the most important metabolic modulators of blood pressure and cardiovascular function. Its production can be stimulated by bradykinin, the main peptide generated by the kinins system (KS), as well as by inflammatory mediators such as cytokines. Purpose. Considering that, 30% to 40% of patients infected with T. cruzi develop chronic Chagas' Heart Disease (CCHD), and in previous studies, we observed increased cytokines serum levels in patients with CCHD and systemic arterial hypertension (SAH) (CCHD-SAH), the aim of this study was to determine the potential association between NO and the KS in patients with CCHD-SAH.
Methods. About 15 patients with CCHD, 22 with CCHD-SAH, 11 with SAH without Chagas disease, and 28 controls matched by age and sex were included in this study. The KS activity was assessed by kininogen levels, enzymatic activities of kallikreins, and kininase II (Kin II). The concentration of low molecular weight kininogen (LKg), high molecular weight kininogen (HKg), and NO were determined by ELISA. The activity of tissue kallikrein (Tkal), plasma kallikrein (Pkal) and Kin II were assessed by their activity upon selective specific substrates. A quantitative detection kit of nitrate and nitrite concentrations using colorimetric assay determined nitric oxide. Results. We observed increased plasma levels of all variables of the KS in patients with CCHD-SAH when compared with those with CCHD and controls (p<0,001). NO plasma levels were also higher in patients with CCHD-SAH and in those with CCHD in comparison with controls (p<0,001). No difference was observed between CCHD-SAH and CCHD patients regarding NO plasma levels. Median values observed in different groups are as follows: SAH (LKg: 0.7uEqBK/mL; HKg: 0.45uEqBk/mL; KinII: 0.75umLHis-Leu/mL; Tkal: 1.89uMPNa/mL; Pkal: 1.5U/mL; NO: 0.7umol/L). CCHD (LKg: 0.3uEqBK/mL; HKg: 0.4uEqBk/mL; KinII: 1.04umLHis-Leu/mL; Tkal: 2uMPNa/mL; Pkal: 1.55U/mL; NO: 1.6umol/L). CCHD-SAH (LKg: 0.15uEqBK/mL; HKg: 0.2uEqBk/mL; KinII: 0.8umLHis-Leu/mL; Tkal: 2.5uMPNa/mL; Pkal: 2.3U/mL; NO: 1.45umol/L). Control (LKg: 1uEqBK/mL; HKg: 0.6uEqBk/mL; KinII: 1.4umLHis-Leu/mL; Tkal: 1.3 5uMPNa/mL; Pkal: 1U/mL; NO: 1umol/L). Conclusion. In this study, we observed increased KS activity in CCHD-SAH compared to CCHD, in those with SAH, and in controls. Plasma levels of NO were higher in CCHD-SAH and CCHD patients in comparison with controls, but not between both groups. These data allow a better understanding of the inflammatory mechanisms occurring in patients with CCHC-SAH, thus suggesting a potential role for both the KS and plasma NO in the pathogenesis of patients with this condition.

P526
Late gadolinium enhancement at right ventricular insertion points, in subjects with structurally normal hearts, is prognostically irrelevant

C Grigoratos[1]; A Pantano[2]; L Ait-Ali[3]; A Barison[4]; G Todiere[4]; P Festa[4]; G Sinagra[2]; M Emdin[1]; G D Aquaro[4]
[1]*Sant'Anna School of Advanced Studies, Pisa, Italy*; [2]*University of Trieste, Trieste, Italy*; [3]*Institute of Clinical Physiology, CNR, Pisa, Italy*; [4]*Gabriele Monasterio Foundation, Pisa, Italy*

Aims: Late gadolinium enhancement (LGE) is the current non-invasive gold standard for fibrosis assessment. Diagnostic and prognostic significance of different LGE patterns have already been described but the clinical importance of isolated right ventricular insertion points (RVIP) LGE is yet to be defined.Methods and results: We retrospectively analyzed 420 patients (270 males, mean age 38±17 years) with structurally normal hearts except for the presence of RVIP-LGE (44 patients), other-LGE (midwall or subepicardial; 36 patients) or no-LGE (340 patients). Clinical follow-up was performed for a median of 2177 days. Primary composite endpoint included cardiac death, resuscitated cardiac arrest, and appropriate implantable cardiac defibrillator shock.
Prevalence of cardiac events was significantly lower in RVIP-LGE than those with other-LGE (p=0.006). Kaplan Meier curve analysis demonstrated no significant differences between patients with RVIP-LGE and no-LGE for the primary endpoint. On contrast, patients with other-LGE had worse prognosis than those with RVIP-LGE or no-LGE (p<0.0001). Among patients with other-LGE, midwall pattern of LGE distribution was associated with worse prognosis than subepicardial one (p =0.0044).
Conclusions: RVIP-LGE in subjects without additional evidence of cardiac damage does not convey worse prognosis when compared with subjects without LGE and it is therefore not to be considered a marker of disease. Its diagnostic and prognostic significance is to be considered irrelevant.



Primary endpoint Kaplan-Meier curves

Delayed diagnosis of Idiopathic Pulmonary Hypertension in woman with heart failure.

Y Yuliia Varava[1]; LV Sapozhnychenko[1]; OS Kalashnykova[1]; VV Panov[1]; OO Khanyukov[1]; LI Vasilyeva[1]
[1]*Dnipropetrovsk State Medical Academy, Internal medicine 1, Dnipropetrovsk, Ukraine*

Introduction Idiopathic Pulmonary Arterial Hypertension (IPAH) is a rare condition which usually presents with the nonspecific symptoms in which shortness of breath takes the first place. We present a case of a patient with the delayed diagnosis, whose first symptoms were cough and shortness of breath.
Purpose
To show the importance of early recognition and treatment of pulmonary hypertension.
Clinical case
A 36-year-old woman presents to our department with the one year history of cough and progressive shortness of breath. Her primary care physician assessed the X-ray and ECG as inconclusive one year ago and the patient‘s cough was connected with the occupational exposure at work and the trial of antihistamines were prescribed. The patient‘s condition continued to deteriorate. After several months she was admitted to the infectious clinic because of jaundice. Diagnosis of chronic Hepatitis C, 3a genotype, was established and woman underwent 3 months treatment with sofosbuvir and daclatasvir. Shortly after the treatment she was admitted to our clinic. On physical examination the patient was pale with mild acrocyanosis, marked leg edema, breathless at rest with the RR of 26 and mildly confused. The ECG showed right ventricle hypertrophy. On ECHO- RV size-6.0cm (N-0.5-2.8), RV EF<30%, LV EF-64%, marked tricuspid regurgitation with TAPSE-0.6cm (N>2.0). The right heart catheterization measured the mean pulmonary artery systolic pressure of 69 mm Hg, PCWP 7 mm Hg, PVR 2058,1 dyn.sec/m5. NT-pro-BNP was 9188 pg/ml. USG showed moderate ascites. Total bilirubin-52.0 mcmol/L (with indirect-27.1 mcmol/L). ALT 14,3, AST 29,8 mcmol/L. 6 MVT -195 meters with SaO2 98% at rest and exertional desaturation 89%. The diagnosis of IPH WHO FC III, high risk was made and the patient started with the specific treatment with inhaled Iloprost and oral Sildenafil, symptomatic treatment of congestive heart failure with furosemide and thorasemide. After 6 months of treatment patient admits the improvement of her symptoms. WHO FC from III to II and became euvolemic. NT-pro-BNP was 6034 pg/ml. On ECHO- RV size-5.6cm, TAPSE 1.5cm. 6 MVT-306 meters. Total bilirubin 16.6 mcmol/L. But the patient remained at high risk and the treatment with bosentan was added.
Conclusion Although Pulmonary Arterial Hypertension is not common condition the physicians from different areas should be aware of its most common symptoms and consider it after the common illnesses are excluded. The primary care providers should learn how to define early ECG and ECHO changes of PH early to avoid the progression of the disease to the terminal state.

P528

Prevalence of adverse pronostic factors in pulmonary hypertension

A Lescano[1]; A Rossi[1]; G Sorasio[1]; E Besmalinovich[1]; R Caprini[1]; C Musante[1]; M Vergara[1]; C Miranda[1]; J Farina[1]; R Skena[1]; GD G Dionisio[1]
[1]*QUILMES TRINIDAD CLINIC, BUENOS AIRES, Argentina*

Pulmonary hypertension (PH) is a multi-factorial condition associated with high morbidity and mortality. This requires for its diagnosis and treatment a multidisciplinary approach. There have been many advances in the epidemiological, pathophysiological and therapeutic knowledge of the disease in the past decades. However, there is little information available regarding clinical and prognostic factors in patients diagnosed with PH in Latin America.
Purpose: Determine the prevalence and clinical characteristics of adverse prognostic factors in a population with recent diagnosis of PH.
Methods: Patients with recent diagnosis of PH (< 7 days), confirmed by right heart catheterization, with a mean pulmonary-artery pressure (MPAP) ≥ 25 mm Hg (using a Swan Ganz Catheter) from three heart failure and pulmonary hypertension services were analyzed between March 2012 and December 2018. According to the recommendations of international guidelines, the following data were recorded: Personal data; PH group (G); clinical features: symptoms, functional class (FC); Direct hemodynamic parameters: pulmonary pressures (PP), wedge pressure (WP), right atrium pressure (RA) and cardiac index (CI); Functional: 6 minute walk (6MW) test distance; Echocardiographic variables: right ventricle systolic function (RVSF), systolic pulmonary pressure and presence of pericardial effusion (PE). Data obtained weas analyzed with STATA 14 program. Adverse prognosis factors identified were: history of heart failure (HF), syncope, advance functional class (III-IV), performance in the 6MW test < 440 m, presence of PE, RA ≥ 14 mm Hg e CI ≤ 2,2 litres/min/mt2
Results: Multicenter, observational, descriptive, consecutive and prospective study. 148 patients were included, from which 75% were women. Mean age was 57.8 (±19) years, 27% ≥ 70. The mean delay in diagnosis was 23 months after the first sign or symptom recorded. PH group distribution: GI 68%, GII 13%, GIII 7%, GIV 6% and GV 6%. FC of presentation: I 4%, II 39%, III 36% and IV 21%. History of HF in 79%, syncope in 24%. 6MW mean walked distance was 317 (±144) meters, 74% performed ≤ 440 meters. RHC: MPAP 48 (±16) mm Hg, RAP 9 mm HG (±5) and ≥ 14 mm Hg 19 %; CI 2,8 litres/min/mt2 (≤ 2,2 22%). Ecocardiographic data showed: 80 % impaired FSVD (40% slight, 19% moderate and 21% severe) and PE in 25%.
Conclusions: In our population with confirmed pulmonary hypertension, with a group I predominance, we had a high prevalence of presentation in patients over 70 years of age. At diagnosis time a high number of patients presented adverse prognosis factors. These findings remark the need of using early diagnosis and therapeutic strategies.

P529

Pulmonary arterial hypertension associated with corrected CHD vs Eisenmenger syndrome.

T Tatyana Ivanova-Razumova[1]; AI Baigalkanova[1]; A Janatkyzy[1]; DV Gorbunov[1]
[1]*National research cardiac surgery center, pediatric cardiology, Astana, Kazakhstan*

Background: Up to now question about necessity and advisability of surgical correction of borderline (operable/inoperable) left to right shunts congenital heart defects (CHD) remains a big problem. Due to recent dates children with pulmonary arterial hypertension (PAH) after CHD repair may have worse outcome than other forms of PAH.
Purpose: to compare disease course and quality of life in patients with PAH after CHD correction and Eisenmenger syndrome (ES).
Methods: from January 2012 up to August 2018 81 children’s were under observation in our center. Median age - 10,5 years (range 6 - 18 years). Boys 49 (60%), girls - 32 (40%). PAH was diagnosed according to ESC guidelines. For all patients standard clinical investigations, pro-BNP levels, 6-minute walk test (6-MWT) were performed every 6 month during follow-up. We have used PedsQl for estimation physical, emotional, social QoL aspects and school functioning. Mean follow-up period was 3,5 year (range 1-7 years).
Results: patients were devided for 2 groups: I - PAH after defect correction (37%), II - ES (63%). Patients with ES had worst exercise capacity at first admission 352 ± 83 m vs 392 ± 105 m in I group (p<0,005), but slow desiase progression. Patients in I group demonstrated rapid deterioration: during 3 year follow-up mean 6-MWT decrease was 24 ± 11,8 m/year, in ES patients - 13,5 ± 8.7 m (p<0,003). In contrast pro-BNP level increased averagely on 12 ± 7.8 pg/ml and 23.8 ± 10.1 pg/ml in ES and patients with PAH after defect closure respectively (p<0,003). Total QoI score in I group was significantly lower - 48,4 ± 3,8 scores vs. 60,78 ± 6,9 scores in patients with Eisenmenger syndrome (p<0,001). Analysis of QoL different aspects showed significantly lower scores in emotional and social scales in patients with PAH after defect correction (I group): emotional - 47.8 ±4.9 vs. 61.4 ± 10.1 in ES (p<0,005); social scale - 54.4 ± 7.6 and 62.2 ± 5.8 in I and II group accordingly. We didn’t find any significant difference in physical scale between two groups - 54.1 ± 4.9 and 58.6 ± 7.1 in I-st and II-nd group accordingly.

Conclusion: We receive convincing evidence that desiase course characterized by significuntly rapid
progression in patients with PAH after defect correction than in ES patients. Quality of life in this group was also significantly lower than in patients with Eisenmenger syndrome (p<0,001), especially in emotional and social aspects. Further evaluation is required for determine optimal operability criteria and time of correction.

P530

Lactate predicts short-term mortality in acute pulmonary embolism more accurately than shock index and modified shock index.

D David Roque[1]; JS Simoes[1]; DF Faria[1]; HF Hilaryano[1]; JB Ferreira[1]; MB Beringuilho[1]; CM Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*

Background: Increasing blood lactate concentrations are more closely related to outcome than blood pressure, particularly in sepsis. Shock index (SI) and modified shock index (MSI) have been shown to predict adverse prognosis in severe trauma, heart failure, and acute coronary syndromes. Data on lactate, SI and MSI as prognostic factors in acute pulmonary embolism (PE) are scarce.
Purpose: We aimed to (1) evaluate whether blood lactate, SI and MSI are associated with short-term mortality in acute PE patients; (2) determine the correlation between lactate concentration and SI and MSI; and (3) compare the prognostic accuracies for short-term mortality of lactate, SI and MSI in acute PE patients.
Methods: We retrospectively reviewed 483 consecutive patients admitted for acute PE in one single emergency department (ED) along 3 years until December 2016. Lactate concentration on arterial blood collected within the first 6 hours after ED admission was recorded. SI was defined as the ratio of heart rate to systolic blood pressure (SI=HR/SBP), and MSI was defined as the ratio of heart rate to mean arterial blood pressure (MSI=HR/MAP). Outcome was all-cause 7-day mortality. Differences in lactate, SI and MSI between non-survivors and survivors groups were analysed by $\chi 2$ (chi-square) test. Correlation of lactate to SI and to MSI was evaluated by Pearson correlation coefficient. Prognostic accuracy for all-cause 7-day mortality of lactate, SI and MSI was performed by C-statistical analysis.
Results: Among the 483 acute PE patients comprising study population, mean age was 66.3 ± 17.6 years and 40% (n=192) were male. Mean lactate concentration was 1.65 ± 1.14 mmol/L. Mean SI was 0.73 ± 0.24 and mean MSI was 1.01±0.33. All-cause 7-day mortality was 9.9% (n=48). Compared to survivors, non-survivors had significantly higher lactate concentration (6.80 ± 5.02 mmol/L in non-survivors, vs. 1.96 ± 1.59 mmol/L in survivors, p <0.001), SI (0.97 ± 0.36 in non-survivors vs. 0.71 ± 0.23 in survivors, p <0.001), and MSI [1.33 ± 0.55 in non-survivors vs. 0.97 ± 0.28 in survivors, p <0.001). Lactate had a significantly positive correlation with SI (r=0.353, p<0.001) and MSI (r=0.370, p<0.001). Prognostic accuracy for all-cause 7-day mortality of lactate, SI and MSI was as follows: lactate (AUC=0.856, CI 95% 0.788-0.923, p<0.001), SI (AUC=0.721, CI 95% 0.639-0.803, p<0.001), MSI (AUC=0.720, CI 95% 0.639-0.803, p<0.001). Lactate concentration >2.12 was the optimal cutt-off point (Youden´s index) for prediction of all-cause 7-day mortality (sensitivy=81.1%, specificity=71.5%).
Conclusions: In our analysis, higher lactate concentration, SI and MSI are all associated with higher short-term mortality in acute PE patients. Lactate prognostic accuracy for short-term mortality is superior to SI and MSI prognostic accuracies. Our study supports the role of lactate, SI and MSI as prognostic factors in acute PE.

P531

SaO2/FiO2 ratio is associated to short-term outcome in acute pulmonary embolism

D David Roque[1]; JS Simoes[1]; DANIEL Faria[1]; JB Ferreira[1]; HF Hilaryano[1]; MB Beringuilho[1]; CM Morais[1]
[1]*Hospital Prof Fernando da Fonseca EPE, Cardiology, Amadora, Portugal*

Background: SaO2/FiO2 ratio is an indicator of oxygenation status and has been shown to predict adverse outcome in some acutely-ill populations, such as septic patients. However, SaO2/FiO2 ratio is not so widely used in respiratory dysfunction assessment as the PaO2/FiO2 ratio. We aimed to know whether SaO2/FiO2 ratio and PaO2/FiO2 ratio are associated to prognosis in acute pulmonary embolism (PE).
Purpose: (1) To assess the association between acute short-term prognosis in acute PE patients and SaO2/FiO2 ratio and PaO2/FiO ratio; and (2) to examine correlation between SaO2/FiO2 ratio and PaO2/FiO ratio in acute PE patients.
Methods: We retrospectively studied 483 consecutive patients hospitalized for acute PE along 3 years. Arterial blood gas analysis was performed within the first 6 hours of hospitalization. SaO2/FiO2 ratio was the quotient between oxygen saturation of arterial haemoglobin and oxygen fraction in inspired air. PaO2/FiO2 ratio was the quotient between oxygen partial pressure in arterial blood gas and oxygen fraction in inspired air. Measured outcome was all-cause 7-day mortality.
Results: Among the 483 acute PE patients comprising study population, mean age was 66.3 ± 17.6 years and 40% (n=192) were male. Mean Pulmonary Embolism Severity Index (PESI) score was 116.9 ± 49.4 points. Mean SaO2/FiO2 ratio was 348.3 ± 114.5 and mean PaO2/FiO2 ratio was 272.4 ± 116.8. All-cause 7-day mortality rate was 9.9% (n=48). Non-survivors had significantly lower SaO2/FiO2 ratios (267.5 ± 139.7 in non-survivors vs 356.2 ±108.8 in survivors, p=0.002). On the other hand, PaO2/FiO2 ratio was not significantly different between non-survivors and survivors (p=0.195). SaO2/FiO2 and PaO2/FiO2 had a good correlation (r=0.714, p<0.001). In acute PE patients with SaO2/FiO2 <200, all-cause 7-day mortality rate was 23.8%, and significantly higher than patients with SaO2/FiO2 ≥200 (p=0.002). In acute PE patients with SaO2/FiO2 200-299, 300-399, and ≥400, all-cause mortality rate at 7 days was 11.7%, 4.7% and 5.5%; however, these mortality rates did not significantly differ from the remaining patients (p=0.455, p=0.455 and p=0.052, respectively).
Conclusions: Short-term mortality was higher in acute PE patients with lower SaO2/FiO2 ratio. All-cause 7-day mortality was as high as 23.8% in SaO2/FiO2 ratio <200. SaO2/FiO2 ratio is well correlated to PaO2 ratio. Our study suggests SaO2/FiO2 ratio within the first hours of hospitalization may be useful in prognostic assessment of acute PE patients.

P532

Pattern of anticoagulation therapies in pulmonary embolism in the current era of non antivitamin k anticoagulants (NOACs); experience of a tertiary emergency care hospital.

A Adrian Sturzu[1]; AM Balahura[1]; E Weiss[1]; E Badila[1]; D Bartos[1]
[1]*Clinical Electrophysiology and Pacing Laboratory Emergency Clinical Hospital Floreasca, Bucharest, Romania*

On behalf of: Emergency Clinical Hospital Floreasca

Introduction NOACs have emerged in the recent years as an useful alternative to unfractionated heparin (UFH)/vitamin K antagonists (VKAs) in non-high risk pulmonary embolism (PE), therefore we aimed to assess weather physicians from a tertiary emergency care hospital are prescribing NOAC in PE more lately compared with times when there was less evidence from studies.
Methods We conducted a retrospective study from 2014 to 2017, including all patients admitted for PE in a tertiary care emergency hospital. We retrieved demographic, clinical and treatment pattern data from the electronic charts. They were divided according to the period they were admitted in the E group (early, 2014-2016) and the L group (late, 2017). High risk (HR) PE was defined as shock/hypotension while all other cases as non HR PE.
Results We included in the study 339 patients with PE, 219 (64.6%) in the E (48.8% men, mean age 61.7±16.4 years) and 120 (35.4%) in the L (51.6% men, mean age 65.4±15.8). During hospitalization, in the non HR PE, 19.3% received NOAC in the E versus 16.6% in the L (p=0.59), 73.2% received UFH in the E versus 64.4% in the L (p=0.13) and 7.3% received LMWH in the E versus 15.5% in the L (p=0.03). In the HR PE, 96% received UFH in the E versus 77.2% in the L (p=0.054), 4% received LMWH in the E versus 22.8% in the L (p=0.054). At discharge, in the non HR PE, patients were recommended NOACs in 26.8% of case in the E versus 57.3% in the L (p=0.000001) while VKAs were recommended in 70.8% in the E versus 37% in the L (p<0.001). In the HR PE patients the recommended anticoagulant at discharge was VKA in 100% in the E versus 89.4% in the L. LMWH was recommended in 2.4% in the E versus 5.7% in the L (p=0.15) in non HR PE, while in HR PE in 0% in the E versus 10.6% in the L.
Conclusion Our results show that NOACs are becoming more popular as a first choice anticoagulant in the settings of non HR PE while UFH remains the first choice during hospitalization. NOACs however became the first choice for long term anticoagulation of non HR PE. In HR PE UFH remains the first choice for anticoagulation in the acute settings while AVK is the most frequent choice for long term secondary prevention.

Pre-hospital thrombolysis of high-risk pulmonary embolism- patient characteristics, management and outcome

J Harjola[1]; P Holmstrom[1]; M Kuisma[1]; V-P Harjola[1]
[1]*Helsinki University Central Hospital, Emergency medicine, Helsinki, Finland*

Funding Acknowledgements: Helsinki University Hospital, department of emergency medicine and services

Background: Massive, high-risk pulmonary embolism (PE) is manifested by shock or cardiac arrest. Rapid reperfusion is the key of therapy but data on prehospital thrombolysis are scarce.
Purpose: To assess the safety and outcome of prehospital thrombolysis of suspected high-risk PE.
Methods: All patients with clinically suspected PE treated with intravenous thrombolysis (92% tenecteplase) by EMS (prehospital emergency medical services) were

collected from EMS registry and hospital database. Diagnosis was confirmed in emergency department or by autopsy.
Results: Twelve patients were included. Characteristics, management and outcome are shown in Table. Eight (67%) had cardiac arrest and were resuscitated before thrombolysis. Four (33%) had cardiogenic shock. Five out of 8 resuscitated patients survived to hospital where two of them died. All three patients who suffered cardiac arrest at scene after arrival of EMS died whereas those with initial VF or PEA (2) survived to hospital. Altogether, five (42%) died.
Conclusions: Mortality of prehospitally suspected PE is high. Prehospital thrombolysis of PE may be life-saving and seems safe.

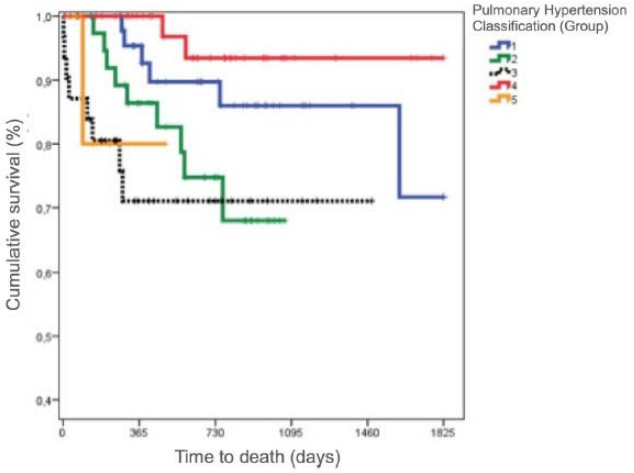
Clinical and hemodynamic 5-year mortality predictors in patients with pulmonary hypertension

A Nunes Ferreira[1]; R Placido[1]; T Guimaraes[1]; JR Agostinho[1]; J Rigueira[1]; I Aguiar-Ricardo[1]; R Santos[1]; T Rodrigues[1]; P Antonio[1]; PS Morais[1]; N Cortez-Dias[1]; A Mineiro[2]; S Martins[1]; N Lousada[3]; FJ Pinto[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal; *[2]Hospital Pulido Valente/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Pneumology department , Lisbon, Portugal*; *[3]Hospital Pulido Valente/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal*

Introduction: Pulmonary hypertension (PH) is associated with high morbidity and mortality rates, making early prognostic stratification essential. Although several predictors of mortality have already been established, the emergence of novel therapies and the evolution in the management of these patients makes it urgent to reassess and validate prognostic markers.
Purpose: To ascertain clinical and hemodynamic 5 year mortality predictors in patients with the diagnosis of PH.
Methods: It was made a retrospective single center study (PH reference center) of consecutive patients with hemodynamic diagnosis of PH. At diagnosis demographic and clinical data [WHO functional class and presence of right-sided heart failure (HF) signs], non-invasive diagnostic tests [6-minute-walk test (6MWT) and carbon monoxide diffusion capacity (DLCO)] and hemodynamic parameters [right atrial pressure (RAP) and mean pulmonary artery pressure (MPAP)] were collected. The association of these variables with any cause 5-years mortality was evaluated using Kaplan-Meier survival analysis and Cox regression analysis.
Results: A total of 176 patients were included, 69.9% (N = 123) female, with a median age of 68 years (IQR: 24). Based on the clinical classification, 28.4% (N = 50) belonged to group 4, 27.3% (N = 48) to group 1, 23.3% (N = 40 to group 2, 17.6% (N = 31) to group 3 and 3.4% (N = 6) to group 5. The 5-year mortality rate from any cause was 27.3%. Were identified as predictors of mortality being of male gender (p <0.001) and had group 2, 3 and 5 PH (p 0.017, p 0.004, p 0.042; versus group 4 and 1).
Conclusion: In this study, male sex and group 2, 3 and 5 PH were identified as 5 year mortality predictors. These results allow the identification of patients groups who may benefit from earlier multidisciplinary therapeutic interventions.



P536
Acute hemodynamic effects of inhaled nitric oxide during right heart catheterization in cardiac transplant candidates with and without pulmonary hypertension

CMF Christopher Strong[1]; L Raposo[1]; M Castro[1]; B Rocha[1]; C Aguiar[1]; A Tralhao[1]; MJ Rebocho[1]; A Ventosa[1]; M Trabulo[1]; JP Neves[2]; M Almeida[1]; M Mendes[1]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; *[2]Hospital de Santa Cruz, Cardiac Surgery, Lisbon, Portugal*

Background and Aim
Right heart catheterization (RHC) should be performed on all candidates evaluated for cardiac transplantation (CT) since elevated pulmonary vascular resistance (PVR) is associated with right heart failure and mortality after CT. A vasodilator challenge is recommended for those with pulmonary hypertension (PHT), to assess the reversibility of PVR. The effects of inhaled nitric oxide (NO) on pulmonary and systemic hemodynamics have been reported only in small series. Our purpose was to describe the response to NO in this population.
Population and Methods
From 167 right heart catheterization procedures performed between 2010 and 2018, vasodilator challenge with inhaled nitric oxide (NO) was used in 88 patients, of which 60 had end-stage cardiac disease under evaluation for CT (55±11 years old; 72% male gender; 42% with ischemic cardiomyopathy; LVEF 30±12%; peak VO2 of 11.9±3.1; 63% with systolic PAP≥50 mmHg). NO was administered through a tight-fitting facial mask at a mean dose of 34±10 ppm, regardless of baseline pulmonary pressure. LV pressures were measured simultaneously in all but 3 cases. Cardiac output was measured using the Fick method. Pressure measurements were made at end-expiration.
Results There were no relevant side effects of NO administration. Hemodynamic profiles at baseline and after NO are represented in Table 1. In summary, typical response consisted of a reduction in PVR, concordant with an increase in both PCWP and LV end-diastolic pressures and no significant change in mean pulmonary artery pressure (resulting in a lower mean transpulmonary gradient). Cardiac index and systemic vascular resistance were unaffected (p=NS). PVR fell to < 5 Wood units with NO in 11/20 pts with higher baseline PVR; in 2 cases (3.3%) PVR increased paradoxically. Patients with hypertrophic cardiomyopathy (n=13) displayed higher PVR (mean 5.4 ± 1.5; p<0.01), but responded similarly to NO.
Conclusions Inhaled NO is safe and produces a reasonably predictable response in patients undergoing vasodilator challenge prior to heart transplant listing. As opposed to patients with predominant type 1 pulmonary hypertension, the absence of significant reductions in pulmonary artery pressures may not mean that the PVR is fixed.

Table 1. Hemodynamic profile at baseline and during inhaled Nitric Oxide (NO)			
Variable (mmHg)	Baseline	NO	p
PAP systolic	58.7 ± 18.3	56.3 ± 16.6	0.01
PAP diastolic	26.6 ± 7.6	26.4 ± 7.7	0.79
PAP mean	39.6 ± 11.0	38.4 ± 10.5	0.05
PCWP (mean)	26.0 ± 7.5	30.3 ± 9.5	<0.01
LVEDP	23.3 ± 9.1	25.8 ± 10.4	<0.01
Mean TPG	13.5 ± 7.3	8.1 ± 6.0	<0.01
PVR (Wood Units)	5.0 ± 3.4	2.9 ± 2.5	<0.01
Cardiac Index (L/min/m2)	1.6 ± 0.4	1.76 ± 0.6	0.06

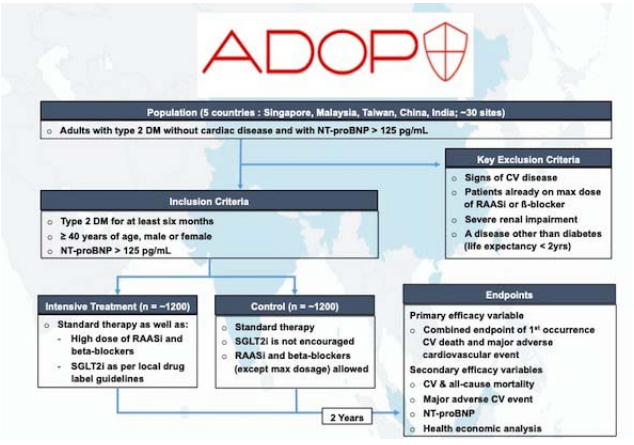
On behalf of: ADOPT Investigators
Funding Acknowledgements: National Medical Research Council of Singapore, Roche Diagnostics Switzerland

Background: Cardiovascular (CV) events are the leading cause of death among patients with type 2 diabetes (DM). Early biomarker-based identification of high-risk patients with DM for intensive preventive therapy (high dose renin-angiotensin-aldosterone system inhibitors [RAASi], beta-blockade and sodium-glucose co-transporter 2 inhibitors [SGLT2i]) may prevent CV events. No previous CV outcome trial has tested the strategy of targeting a high-risk DM population using biomarkers for primary prevention.
Purpose: Among biomarker (N-terminal pro-B-type natriuretic peptide, NT-proBNP)-identified high-risk DM patients without pre-existing CV disease, to test whether intensive preventive therapy (RAASi, beta-blockers, SGLT2i) may be associated with reduced cardiovascular events, compared to standard of care.
Method: Asian Diabetes Outcome Prevention Trial (ADOPT) is a prospective multinational randomized open-label, parallel group, active-controlled, two-arm, long-term morbidity and mortality trial involving 5 countries (Singapore, Malaysia, China, Taiwan, India; estimated 6 sites each) with patients followed for 2 years. The target population are adults with type 2 DM without CV disease (defined as history of coronary heart disease [prior myocardial infarction of significant coronary artery disease] or heart failure [reduced ejection fraction or hospitalization for heart failure]) and with NT-proBNP>125 pg/mL. Approximately 3000 patients to be screened to achieve the target of 2400 patients randomized. Patients will be randomized to either (1) Intensive Treatment group (high dose of RAASi and beta-blockers as well as SGLT2i) on top of standard therapy; or (2) Control group (standard of care). The primary endpoint is the combined endpoint based on the first occurrence of CV death and CV hospitalization.



ADOPT flow chart

Significance: Recruitment is expected to occur between March 2019 – March 2021. The trial is event driven, with total expected trial duration of four years (two years recruitment, two years follow-up). Results of this trial will present a treatment strategy that may change management of patients with DM in Asia, improve patients' outcomes and healthcare costs.

P538
Combined therapy with rosuvastatin and ezetimibe on inflammatory state and pro-inflammatory cytokines in patients with coronary heart disease and metabolic syndrome

JK Uzokov[1]; BA Alyavi[1]; AX Abdullaev[1]
[1]Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Tashkent, Uzbekistan

Background: Aim of the study was to investigate the influence of combined lipid lowering therapy with rosuvastatin and ezetimibe on lipid profile, inflammatory state and pro-inflammatory cytokines in dyslipidemic patients with coronary heart disease (CHD) and metabolic syndrome (MS).
Methods: 128 patients with CHD and MS were randomly divided into two groups per 64. First group was provided rosuvastatin (10 mg) + ezetimibe (10 mg) and the second group (control) was provided only rosuvastatin (10 mg). Plasma lipids, inflammatory state (hs-CRP), and pro-inflammatory cytokines (IL-1β, IL-6, TNF-α) were measured at baseline and in 12 weeks.
Results The level of TC, LDL-C was decreased significantly in combination group than controls (P<0.05), however there was not significant difference between 2 groups on HDL-C (P>0.05). Hs-CRP was decreased by 38% in the first group (P=0.003) vs. 31% in control group (P=0.005) from baseline, however there was no obvious changes between 2 groups. Even though, pro-inflammatory cytokines: TNF-α (from 1.42±0.98 to 0.87±0.18 in 12 weeks, P=0.018), IL-6 (from 7.8 pg/mL to 4.1 pg/mL, P=0.012), IL-1β (from 28.4±19.5 pg/ml to 17.5±15.8 pg/ml, P=0.010) in the combination group vs. TNF-α (from 1.48±1.12 to 1.12±0.25, P=0.047), IL-6 (from 8.0 pg/mL to 5.9 pg/mL, P=0.037), IL-1β (from 29.6±20.6 pg/ml to 20.6±17.4 pg/ml, P=0.040) significantly decreased in both groups from baseline however, there were statistically significant changes observed only in the first group (P<0.05) when compared two groups.
Conclusions: Therapy with rosuvastatin and ezitemibe is superior than rosuvastatin alone to improve TC, LDL-C and pro-inflammatory cytokines in patients with CHD and MS.

P539
Nesfatin-1 activity in hypertensive obese patients changes with the duration of hypertension

M Maryna Vizir[1]
[1]Kharkiv National Medical University, Kharkiv, Ukraine

Background: Nesfatin-1 was discovered in 2006 as a satiety peptide produced by hypothalamus and adipose tissue mainly. It was found that activity of nesfatin-1 may be related to the occurrence of hypertension, obesity, type 2 diabetes mellitus and thereby affect the cardiometabolic risk. However, the mechanisms which lead to progressive deterioration after long-term hypertension remain unclear.
Objective: The study aimed at identifying the relationship between nesfatin-1 activity and duration of elevated blood pressure in patients with arterial hypertension and abdominal obesity.
Methods: 83 patients with essential hypertension and abdominal obesity were divided by known hypertensive anamnesis into group A (< 5 years of hypertension), group B (5-10 years) and group C (> 10 years). The control group D consisted of 12 healthy individuals. The levels of nesfatin-1 (ng/ml) as well as parameters of carbohydrate and lipid metabolisms were determined by enzyme immunoassay method. Obtained data were analyzed with the methods of nonparametric statistics by Statistica10.0 software with the significance (p) < 0.05.
Results: The hypertensive patients had higher nesfatin-1 levels compared with the control group (7.51 [6.76;8.17] vs 4.53 [4.23;4.87], p < 0.001). Short-term hypertension was associated with higher activity of nesfatin-1 (7.74 [7.40;8.12]) compared with results of the group B (7.41 [6.70;8.10], p = 0.007) and the group C (7.21 [6.44;8,07], p = 0.04).
Cardiometabolic features of the group A showed lower levels of fasting glucose compared with both, B (p = 0.04) and C (p < 0.001), postprandial glucose compared with the group C (p < 0.001), higher levels of insulin compared with the group B (p = 0.007), higher index of insulin resistance HOMA-IR than in the group C (p = 0.009), lower index of β-cell activity HOMA-β than in groups B (p < 0.001) and C (p < 0.001) and higher levels of triglycerides compared with the group C (p < 0.001).
Nesfatin-1 correlated with systolic (r = 0.475; p < 0.01) and diastolic blood pressure (r = 0.486; p < 0.01), fasting glucose (r = 0.601; p < 0.001), insulin (r = 0.325;

p < 0.01), index of insulin resistance HOMA-IR (r = 0.334; p < 0.01), index of β-cell activity HOMA-β (r = -0.566; p < 0.001) and triglycerides (r = 0.431; p < 0.001) in patients with short-term hypertension (< 10 years) only.
Conclusions: Presence of hypertension is associated with higher levels of nesfatin-1 compared with those in healthy individuals and slight gradual decreasing of its levels with the duration of the disease. In case of concomitant abdominal obesity nesfatin-1 may be involved in metabolic control processes during first years of hypertension.

P540
Anthropometric measurements of central adiposity are superior predictors of heart failure in the general population - data of PREVEND

N Navin Suthahar[1]; SJL Bakker[1]; RT Gansevoort[1]; P Van Der Harst[1]; DJ Van Veldhuisen[1]; RA De Boer[1]
[1]University Medical Center Groningen, Cardiology, Groningen, Netherlands (The)

Funding Acknowledgements: Netherlands Heart Foundation, Netherlands Organization for Scientific Research, European Research Council

Background: Obese individuals have a greater risk of developing heart failure (HF), and prevalence of both obesity and HF are expected to rise greatly by 2030. However, It is not clearly known whether central obesity confers a greater risk of developing HF compared to general obesity.
Purpose: To evaluate whether associations between obesity and incident HF differ among anthropometric measurements of general and abdominal adiposity.
Methods: Observational study in general population setting; included 8567 community-dwelling individuals from the PREVEND (Prevention of Renal and Vascular ENd-stage Disease) cohort. Mean age = 49 years and 50% women. Measurements include BMI (body-mass index), WC (waist circumference), WHR (waist-hip ratio) and incident HF. HF cases were identified according to HF guidelines issued by the European Society of Cardiology. Cox proportional-hazards models were employed to evaluate the predictive utility of BMI, WC and WHR for incident HF. Models were adjusted for age, sex, classical HF-risk factors, EKG-assessed left ventricular hypertrophy and also for NT-proBNP (N-terminal pro-B-type natriuretic peptide).
Results: WC and WHR are stronger predictors of HF compared to BMI in the general population. During a mean follow-up of 12 years, 373 developed HF. Hazard ratio (HR) for one standard deviation (SD) increase in BMI was 1.47 (95% confidence interval: 1.25-1.72). Corresponding HR for WC was 1.52 (1.23-1.87) and for WHR was 1.59 (1.26-2.02); Pall<0.001. Even after excluding individuals with prevalent cardiometabolic disease, WC and WHR outperformed BMI in predicting HF; HRWC-1.69 (1.11-2.58) and HRWHR-1.66 (1.11-2.48) vs HRBMI-1.47 (1.09-1.99]; Pall<0.05.
Conclusions: Measures of abdominal obesity are stronger predictors of HF compared to general obesity measures. Primary HF prevention strategies should focus on curbing obesity and screening individuals with abdominal obesity.

P542
Diabetes mellitus is a predictor of development of heart failure independent of HTN, CAD and diastolic function: a population based study

H Horng Chen[1]; M Klajda[1]; C Scott[1]
[1]Mayo Clinic, Rochester Mn, United States of America

Funding Acknowledgements: National Institutes of Health [R01HL84155, and R01-HL136440]

Background: Diabetes mellitus (DM) is associated with comorbidities such as hypertension (HTN), coronary artery disease (CAD) and diastolic dysfunction (DD) resulting in adverse cardiovascular (CV) outcomes. The impact of DM has on CV outcomes independent of HTN, CAD and DD in the general population is not well defined.
Methods: Cross-sectional survey of 2,042 randomly selected residents of Olmsted County, aged 45 years or older from June 1997 through September 2000. All subjects underwent clinical, echocardiographic and humoral assessment. This cohort included all subjects with DM and were compared to a group of non-DM subjects matched 1:2 for age, gender, HTN, CAD and diastolic dysfunction. Multi-variable proportional hazards regression analysis was applied to identify predictors of heart failure.
Results: 116 subjects with DM were compared to 232 matched non-DM subjects. Subjects with DM had higher BMI (31±5 vs 29±5, kg/m2; p=0.001), plasma insulin (8.5 [5,15]vs 5.8 [4,9], uU/ml; p<0.001), and triglycerides (183±121 vs 146±80,mg/dL p<0.001) as compared to the non-DM subjects. E/e' ratio (9.7±2.9 vs 8.5±2.9, p=0.001) was higher in DM vs non-DM suggesting increased LV filling pressure in DM.
Over a median follow-up of 10.8 years (IQR: 7.8-11.7), DM subjects had higher incidence of CHF, 21% vs 12%; HR 2.13(1.25, 3.62;p=0.012) as compared to non-DM. Using multivariate cox regression analysis adjusted for age and gender, DM was predictive of HF, HR 1.92(1.11, 3.32; p=0.02). We also examined the subgroup of subjects without diastolic dysfunction. In this subgroup of DM subjects and matched non-DM subjects, DM subjects had higher incidences of CHF, HR 2.52 (1.01, 6.27; p=0.04) over 10.9 years.
Conclusions: In this community-based cohort, subjects with diabetes have increased incidence of HF over a 10-year follow up period even in the absence of underlying diastolic dysfunction. These findings suggest that DM is an independent risk factor for the development of heart failure and supports the concept of DM cardiomyopathy.

P543
The receptor for advanced glycation end products and its ligands modulate cardiovascular cell apoptosis in diabetic patients

J James Tsoporis[1]; E Hatziagelaki[2]; I Rizos[3]; S Izhar[1]; A Tsiavou[2]; V Salpeas[3]; TG Parker[1]
[1]St. Michael's Hospital, Toronto, Canada; [2]Attikon University Hospital, Second Department of Internal Medicine, Research Institute and Diabetes Center, Athens, Greece; [3]2nd Academic Department of Cardiology, Attikon Hospital, University of Athens Medical School, Athens, Greece

Introduction The accumulation of ligands of the receptor for advanced glycation end products (RAGE) and the soluble form of the receptor sRAGE may play key roles in cardiovascular remodeling in diabetic patients.
Purpose: We aimed to determine whether the concentration of RAGE ligands and soluble form present in the serum of individuals with and without type 2 diabetes modulates their pathogenic potential.
Methods: Individuals were stratified according to normal glucose tolerance (control) (n=10, 5 male (M), 5 female (F), mean+SEM age 59.6+1.23 yrs), impaired glucose tolerance (n=10, 5M, 5F, age 59.4+2.2) and type 2 diabetes (n=10, 7M, 3F, age 59.8+1.6). The titers of sRAGE, the RAGE ligands, AGEs (quantified by N-carboxymethyllysine (CML)), S100B, S100A1, S100A6, and the apoptotic marker Fas ligand (FasL) were measured by enzyme-linked immunosorbent assay in plasma. We also measured the apoptotic potential of circulating concentrations of RAGE ligands and sRAGE in cultured rat aortic smooth muscle (AVSMC) and cardiac myocytes (CM).
Results: Circulating levels of RAGE ligands and sRAGE were not different among individuals with normal and impaired glucose tolerance. Type II diabetics had a 3-5 fold increase in circulating CML and FasL compared to individuals with normal or impaired glucose tolerance tests. Type II diabetics also demonstrated an approximate 35-70 per cent decrease in circulating sRAGE, S100B, S100A1 and S100A6 compared to subjects with normal or impaired glucose tolerance. Treatment of AVSMCs or CMs with CML (0.5 μg/mL –quantified in the plasma of type 2 diabetics) for 24 hrs induced cellular apoptosis measured as DNA fragmentation, increased FasL and caspase-3/9 activation, responses attenuated by concomitant administration of sRAGE, S100B, S100A1, or S100A6 at concentrations measured in the plasma of subjects with normal glucose tolerance.
Conclusion: In type 2 diabetes, a decrease in circulating sRAGE may no longer decoy and trap the accumulating deleterious pro-apoptotic RAGE ligands (CML) thereby contributing to diabetic complications including cardiovascular apoptosis.

P544
Impact of antidiabetic treatment on mortality and heart failure readmissions: beyond hipoglucemic effect

L Laura Rodriguez[1]; AM Iniesta[1]; LA Martinez[1]; JM Garcia De Veas[1]; J Caro Codon[1]; SO Rosillo[1]; I Marco[1]; C Merino[1]; L Martin[1]; L Pena Conde[1]; O Gonzalez[1]; JR Rey[1]; JL Lopez-Sendon[1]
[1]University Hospital La Paz, Cardiology department, Madrid, Spain

Introduction: In recent years we have witnessed a growing interest on antifiabetic treatment, especially in patients with heart failure (HF), following the publication of the trials EMPAREG, CANVAS and the latest DECLARE, due to the proven benefits of SGLT2 inhibitors (SGLT2i).
Purpose: The aim of our study was to asses the antidiabetic treatment in patients with HF with reduced ejection fraction (HFrEF) and its impact on mortality and cardiovascular events.
Methods: Diabetic patients with a hospitalization due to HF who had HFrEF were consecutively included between september 2016 and april 2018 and then follow-up. A survival analysis was performed using the Kaplan-Meyer method.

Table 1.

Age (years) mean±SD	71.8±11.1
Women n (%)	33 (24.4)
Hypertension n (%)	117 (88)
Dyslipemia n(%)	104 (79.4)
Smokers n(%)	28 (21.4)
Left ventricular ejection fraction mean±SD	29.6±7.0
Charlson index mean±SD	6.6±1.9
HbA1C mean±SD	7.1±6.8
glomerular filtration rate ml/min/Kg mean±SD	62.1±26.7

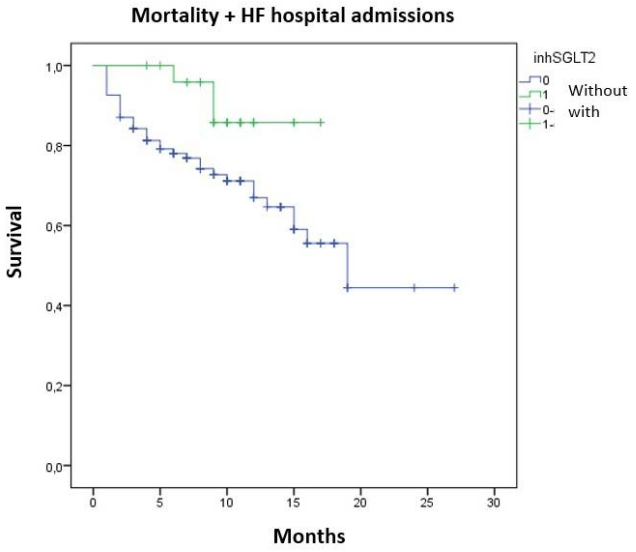


Image 1

Results: Of a total of 453 patients with HFrEF, 135 with type 2 diabetes were included (baseline characteristics are shown in table 1). At discharge the most used antidiabetic drug (AD) was metformin 88 (67.7%), followed by insulin 55 (42.3%). SGLT2i were used only in 26 patients (19.3%), with 34 (26.2%) being treated with other AD. Patients with SGLT2i were younger (65.3 ± 11.1 vs 73.3 ± 10.6 years, p = 0.001), had lower comorbidity (Charlson index 5.8 ± 1.9 vs 6.8 ± 1.9, p = 0.018), better renal function (glomerular filtration rate 71.9 ± 23.9 vs 59.7 ± 26.9 ml /min/1.73m2 p = 0.036) and had higher HbA1c (7.0±1.3 vs 7.6±1.3p=0.024). During follow-up, which was of a median of 12 months (RIQ 8-14.5), the composite endpoint of mortality or HF hospitalization was higher in patients without SGLT2i p = 0.05, analyzed by the method of Kaplan-Meier. The survival graph is shown in Image 1. Furthermore, the use of insuline was a predictor of poor prognosis with higher mortality and more hospitalizations (HR 3.6 95% CI (1.7-7.8) p=0.001)
Conclusion: There is no still enough widespread use of SGLT2i despite of its proven benefit in patients with HF. Treatment with SGLT2i in diabetic patients with HF was associated in our cohort with lower mortality and HF hospitalizations

P545

The incidence of the first onset diagnosed type 2 diabetes mellitus in patients with cardiovascular diseases

VV Medovchshikov[1]; NB Yeshniyazov[1]; EA Tereshchenko[1]; ER Khasanova[1]; ZD Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), Department of internal diseases, Moscow, Russian Federation

Introduction: The development of type 2 diabetes mellitus (T2DM) and cardiovascular diseases (CVD) is parallel. However, there is a high incidence of undiagnosed diabetes, reaching 45.8% globally, and 20% among patients with heart failure. Undiagnosed diabetes is an unfavorable and expensive condition due to the development of complications for individuals and the health care system.
Purpose: To estimate the incidence of the first onset diagnosed T2DM among patients with CVD.
Methods: The registry included patients ≥40 years with established CVD admitted to the city hospital from 08/01/2018 to 08/31/2018 (n=256). 39.1% (n=102) patients had the diagnosis of T2DM at admission. All patients, except those with pre-diabetes or T2DM, were screened for T2DM and pre-diabetes. Glucose metabolism was measured by glycated hemoglobin (HbA1c), fasting plasma glucose and glycemic profile or 2-hour plasma glucose if need. The diagnosis of T2DM required at least two measurements above the diabetes cut-off point according to current American Diabetes Association and World Health Organization criteria. HbA1C and glucose were evaluated within 1-3 days after admission. Statistical analysis was performed with STATISTICA 10.0 software package.
Results: Among patients with CVD, the first onset T2DM was diagnosed in 10.9% (n=27). The median age was 55 [52;63] years, men 42.9%. The median HbA1c was 9,4 [7,6;11,7]%, median fasting glucose was 11,4 [7,5;13,1] mmol/l. The incidence of CVD in this group was the following: hypertension 94.4%, chronic heart failure (CHF) 83.3%, coronary heart disease (CHD) 55.6%, atrial fibrillation (AF) 33.3%, previous myocardial infarction (MI) 27.8%, a history of stroke 22.2%.
Pre-diabetes was diagnosed in 17.4% (n=44) of patients. The median age was 77 [57;85] years, men 38.4%. The median HbA1c was 6,1 [5,5;6,4]%, median fasting glucose was 7,1 [6,4;7,8] mmol/l. The incidence of CVD in this group was the following: hypertension 95.9%, CHF 79.6%, CHD 65.3%, previous MI 36.7%, AF 30.6%, a history of stroke 18.4%.
For comparison, in the group of patients with previously established T2DM, the median age was 67 [58;81] years, men 44%. The incidence of CVD in this group was the following: hypertension 97.6%, CHF 88%, CHD 73.5%, previous MI 45.8%, AF 28.9%, a history of stroke 20.5%.
Conclusions: Thus, the incidence of the first onset diagnosed T2DM among hospitalized patients with CVD was 10.9%, and the overall incidence of T2DM and pre-diabetes among patients with CVD was 67.4%. Our data suggest a high incidence of disorders of carbohydrate metabolism and patients with CVD need for careful screening for the detection of T2DM and pre-diabetes.

P546

Reduced coronary flow reserve is associated with impaired ventriculoarterial interaction in patients with obstructive sleep apnea

H Chung[1]; JML Lee[1]; JSW Woo[1]; JBK Kim[1]; SJK Kim[1]; SKR Ryu[2]; WK Kim[1]; KSK Kim[1]; WSK Kim[1]
[1]Kyunghee University, Cardiology, Seoul, Korea (Republic of); [2]Eulji University School of Medicine, Cardiology, Seoul, Korea (Republic of)

Backgrounds: Obstructive sleep apnea (OSA) is associated with cardiac and arterial damage, and adverse cardiovascular outcome. Microvascular dysfunction is subclinical pathologic condition.
Purpose: We aimed to whether coronary flow reserve (CFR), which represents microvascular dysfunction, might be associated with ventricular-vascular coupling index (VVI), which represents the afterload-adjusted contractility.
Methods: 315 patient (282 males, mean 4311 years) with newly diagnosed OSA were enrolled. Transthoracic echocardiography was performed, and adenosine-associated coronary flow reserve (CFR) was measured in left anterior descending (LAD) coronary artery. We evaluated the differences between the patients with

	Normal CFR group (n=243)	Reduced CFR group (n=72)	P-value
Age, years	42±12	43±10	0.752
LA volume index, ml/m^2	20.2±5.8	20.9±5.9	0.432
LV EF, %	64±5	64±6	0.764
E/e'	8.1±2.0	7.7±2.0	0.148
DT, ms	188.8±40.8	188.7±41.7	0.980
Ed, 1/ml	0.16±0.06	0.15±0.06	0.362
Ees, m/^{2}	8.17±2.30	7.26±2.29	0.007
VVI	2.76±1.16	3.18±1.58	0.023
Tricuspid annular velocity ,cm/s	13.93±2.33	12.67±2.09	0.029
LA strain, %	44.45±13.36	44.39±12.29	0.971
LV GLS, %	-19.57±2.14	-19.67±2.17	0.732

Baseline characteristics according to CFR

normal CFR (≥2.5) and reduced CFR (<2.5). VVI was calculated using effective arterial elastance (Ea) and left ventricular end-systolic elastance (Ees).
Results: Normal CFR group (n=243) showed increased Ees compared with reduced CFR group (n=72) (8.17±2.30 vs 7.2±2.29m/s2, p=0.007) and preserved VVI (2.76±1.16 vs 3.18±1.58, p=0.023). Normal CFR group showed higher systolic tricuspid annulus peak velocity (13.93±2.33 vs 12.67±2.08cm/s, p=0.029) compared to reduced CFR group. There were no differences in LV dimension, LV ejection fraction, left atrial (LA) volume index, E/e', LA strain and LV global longitudinal strain between two groups (all p>0.05).
Conclusions: Reduced CFR is associated with decreased Ees and impaired VVI in OSA patients. Microvascular dysfunction might affect myocardial contractility, which supports the necessity of more intensive observation in OSA patients with reduced CFR to improve cardiovascular outcome.

P547

Ischemic preconditioning, a potential cardioprotective mechanism of sleep apnea during acute myocardial infarction

O Ludka[1]; R Stepanova[1]; T Kara[2]; J Spinar[3]; P Kala[3]
[1]International Clinical Research Center, St. Anne´s University Hospital, University Hospital Brno, Masaryk University, Brno, Czechia; *[2]Division of Cardiovascular Diseases, Department of Internal Medicine, Mayo Clinic and Foundation, Minnesota, United States of America*; *[3]Department of Internal Medicine and Cardiology, University Hospital Brno, Brno, Czechia*

Funding Acknowledgements: Supported by the project no. LQ1605 from the National Program of Sustainability II and FNUSA-ICRC (No. CZ.1.05/1.1.00/02.0123)

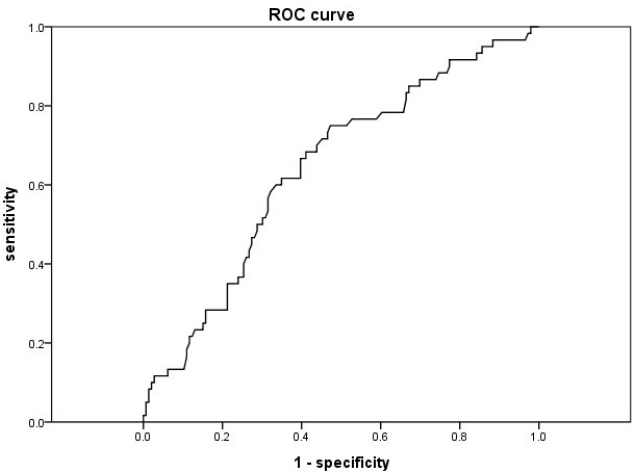
Background: Sleep apnea (SA) is associated with intermittent hypoxemia that may lead to ischemic preconditioning in the myocardium. This potential cardioprotective effect of SA may play a role in the development of non-ST-elevation myocardial infarction (NSTEMI) versus ST-elevation myocardial infarction (STEMI) during acute ischemia. Purpose: We prospectively investigated the prevalence of these two types of MI in patients with SA. Methods: We prospectively studied 607 consecutive patients admitted with the diagnosis of acute MI (both NSTEMI and STEMI). All subjects underwent sleep evaluations using a portable diagnostic device after at least 48 h post-admission, provided they were in stable condition. Results: SA was present in 65.7% and NSTEMI in 30% of patients. The prevalence of NSTEMI increased with increasing severity of SA (p<0.001). The relative frequency of NSTEMI vs STEMI in patients without SA and with mild SA was 59.4% vs 70.1% respectively (p=0.01). In patients with moderate to severe SA (AHI ≥ 15 events/hour), the relative frequency of NSTEMI and STEMI was 40.6% vs 29.9% respectively (p=0.01). Moderate to severe SA was an independent predictor of having a NSTEMI (p=0.021). In moderate to severe SA patients, those with NSTEMI had lower peak troponin T than those with STEMI (1.538±2.771 μg/l vs 3.085±3.127 μg/l, p<0.001) and similar left ventricular ejection fraction (49.07±13.43% vs 47.60±11.53%, p=0.413).
Conclusion: The prevalence of NSTEMI increases with increasing severity of SA. This finding may suggest a cardioprotective role of SA, which may attenuate the development of STEMI, perhaps through ischemic preconditioning.

P548

Respiratory arousal index independently predicts the presence of hypertension in patients with obstructive sleep apnea rather than apnea-hypopnea index (AHI)

H Chung[1]; JM Lee[1]; R Heo[2]; JS Woo[1]; JB Kim[1]; SJ Kim[1]; YS Byun[3]; SK Ryu[4]; W Kim[1]; WS Kim[1]
[1]Kyunghee University, Cardiology, Seoul, Korea (Republic of); *[2]Hanyang University, Cardiology, Seoul, Korea (Republic of)*; *[3]Inje University, Cardiology, Seoul, Korea (Republic of)*; *[4]Eulji University School of Medicine, Cardiology, Seoul, Korea (Republic of)*

Backgrounds: The prevalence of hypertension (HTN) is higher in OSA patients. Increased sympathetic drive might be the leading mechanism of HTN in OSA.
Purpose: We aimed to identify the association between the sleep-related indices and hypertension, and the predictive value of these indices for prevalent HTN in OSA patients.



ROC curve respiratory arousal index

P548: Determinants of hypertension

	Univariate analysis			Multivariable analysis			Multivariable analysis		
	OR	95% CI	P	OR	95% CI	P	OR	95% CI	P

Lowest saturation <85%	1.880	0.947-3.735	0.071				1.364	0.629-2.959	0.432
RAI, per events/hour	1.026	1.008-1.044	0.005	1.040	1.001-1.081	0.043	1.041	1.003-1.082	0.035
ODI, per events/hour	1.014	0.999-1.029	0.069	1.016	0.944-1.095	0.669			

Methods: 206 patients (197 males, 44±11 years) with newly diagnosed moderate-to-severe OSA (AHI≥15) were enrolled from May 2009 to September 2012. All patients underwent full-night laboratory polysomnography and transthoracic echocardiography.
Results: Among 206 patients, 32% (65/206) had HTN. HTN group was older, and had a higher AHI, oxygen desaturation index (ODI), respiratory arousal index (RAI), and lower e' velocity, higher E/e' than non-HTN group (all p<0.05). Multivariate logistic regression analysis revealed that RAI and age were significantly associated with HTN after adjustment of AHI, ODI or lowest saturation <85%. The area under the receiver operating curve for RAI was 0.642 (p=0.001).
Conclusions: This results suggests that respiratory arousal index better reflects the contribution to the activation of sympathetic tone leading to the prevalent HTN rather than AHI, ODI or lowest saturation.

P549
The relation of obstructive sleep apnea syndrome with acute coronary syndromes

S Savvas Grigoriadis[1]; A Samaras[1]; I Vogiatzis[1]; P Stiropoulos[2]
[1]General Hospital of Veria, Veria, Greece; *[2]University Hospital of Alexandroupolis, Alexandroupolis, Greece*

Purpose: Obstructive Sleep Apnea Syndrome (OSA) is a clinical entity that is often under-diagnosed, although it has been associated with many cardiovascular complications. Polysomnography is the method of choice for the diagnosis of obstructive sleep apnea, but it has been shown that the use of appropriately weighted questionnaires is a reliable alternative. The study aimed to investigate the correlation between the possibility of obstructive sleep apnea in a patient who suffered an acute coronary event.
Method and results: Eighty patients who were hospitalized for an acute coronary event in our hospital clinic were weighted for the likelihood of sleep apnea with the STOP-Bang questionnaire and Berlin questionnaire, and assessed for Epworth sleepiness within thirty days of the onset of the syndrome. Depending on the questionnaire used, 48 (Berlin) and 45 (STOP-Bang) patients were found to be at high risk for OSA, while 32 (Berlin), 35 (STOP-Bang) patients were not at risk of suffering from OSA. Also, 38 patients were likely to suffer from excessive daytime sleepiness and 42, probably, did not run such a risk according to the Epworth scale.
Conclusions: The high proportion of high-risk patients for OSA among ACS patients is a serious indication of a pathophysiological correlation between the two entities. By using easy-to-use questionnaires, it is possible to timely risk stratification for OSA in patients who suffered an ACS, with a possible effect on the course of their treatment.

Sacubitril valsartan in real life: tolerance, clinical evolution and remodeled long term

C Martin Dominguez[1]; R Rafael Bravo Marques[1]; S Lopez Tejero[1]; A Valle Alberca[1]; FE Mesa Prado[1]; E Mariscal Lopez[1]; F Rivas Ruiz[2]; N Oliva Damaso[3]; PA Chinchurreta Capote[1]; C Corona Barrio[1]; JR Siles Rubio[1]; E Timonet Andreu[1]; F Ruiz Mateas[1]; F Torres Calvo[1]
[1]Hospital Costa del Sol, Cardiology, Marbella, Spain; *[2]Hospital Costa del Sol, Investigation, Marbella, Spain*; *[3]Hospital Costa del Sol, Nephrology, Marbella, Spain*

1. INTRODUCTION: The introduction of Sacubitril / Valsartan (S/V) has led to a paradigm shift in patients with heart failure with reduced ejection fraction. There are few data on its use and long-term follow-up in real life and no specific data are available to improve echocardiographic parameters during follow-up.
2- MATERIAL AND METHOD: An observational, prospective study of patients with HFrEF in a non-acute situation, seen in a HF clinic and who began treatment with S / V between October 2016 and December 2018. We analyzed the baseline characteristics, functional class, analytical and echocardiographic parameters, and long-term follow-up.
3-RESULTS: The sample consists of 202 patients 68 ± 10 years of age. 83% males. Prevalence of HBP and DM 64.4% and 45% respectively. The most frequent cause of myocardiopathy was of ischemic origin (61.9%), followed by idiopathic origin (30.2%). 20.3% were carriers of DAI +/- TRC. The initial LVEF was 33.6%. Prior to the start of S / V, patients received optimal medical treatment (Beta-blocker 98%, mineralocorticoid receptor antagonists 93%, Ivabradin 31.7% and diuretics 84%); with ACEI 64.9% and the rest with ARA II. The patients started with S / V at low doses 43%, average doses 42.1% and high doses 9.9%. Table 1 shows the parameters of SBP, DBP, functional class and analytical parameters with more relevance.
After one month there was a significant decrease in SBP figures (120.6 vs 116.5mmHg, p = 0.008), without changes in DBP. There was a slight decrease in GFR attending to CKD EPI (68.8 vs 66.5ml / min / 1.73m2) without major changes in long-term follow-up. No significant differences were found in levels of Na and K.
Regarding echocardiographic parameters in 6 months, an inverse remodeling of the LV and the size of the LA was observed (LV diastolic diameter61.8 vs 60.3mm, p = 0.021, AI 44.9 vs 44.1mm, p = 0.042) and improvement of LVEF (33.6 vs 37.2, p <0.001) that leads to the non-indication of ICD in 39.72% of patients who had an initial LVEF of less than 35%. Figure 1 shows the significant improvement of the functional class from the beginning of treatment with S / V during the follow-up. During follow-up, despite the slight decrease in BP, S / V titration was achieved with medium doses in 40.5% and high doses 32.7%. Only 10 patients presented intolerance to the drug, most of them due to arterial hypotension followed by economic problems.
In a follow-up of 12.5 ± 7.9 months, cardiovascular mortality 10.4% and admission due to heart failure were registered in 18.3%, data similar to the pivotal study, our series presenting patients with greater age and comorbidity .
4-CONCLUSIONS: The treatment with S / V in real life is well tolerated, achieves a clinical improvement of the functional class maintained long-term. There are a inverse remodeling of the LV and improvement of the EF that leads to a decrease in the indication of ICD in a high percentage of patients.

Introduction: After the onset of sacubitril / valsartan (S/V) studies have been developed with oral antidiabetics such as iSGLT2 that have shown an improvement in the prognosis of patients with heart failure (HF). There is little evidence on tolerability and safety in patients with HF who are on combined S/V, iSGLT2, MRA and diuretic therapy.
Material and method: This is a prospective, observational study of patients with HF and type 2 diabetes mellitus with S/V and iSGLT2. We analyzed the baseline characteristics, tolerability and safety of the combination of both drugs.
Results: A total of 29 patients were treated with S/V and iSGLT2, 93.1% males of mean age 66.7 ± 10.5 years. 62.1% had HBP and 24.1% AF. The cause of HF in 72.4% was ischemic origin. Table 1 shows the figures for both SBP, DBP and analytical parameters. 93.1% of patients were under treatment with MRA (72.4% low doses). S/V is started with low-doses in 37.9%, medium-doses 55.2% and rest high-doses. 75.9% were treated with loop diuretic therapy (6.9% low-dose, 48.3% medium-dose and 20.7% high-dose). In the month and year follow-up, there was a decrease in SBP, DBP, HbA1C, weight and a slight decrease in GFR atrending to CKD-EPI (Table 1). We found slight significant increase in K. In 6 months of treatment, loop diuretics were reduced to a small number of patients in a non-significant way and the MRA and S/V were increased to a maximum dose in 31% and 31.7% respectively. In a mean follow-up of 8±5 months, 17.2% were admitted due to HF and 6.9% of patients had death due to cardiovascular causes.

Conclusions: In patients with HFrEF and DM the combined use of S/V+MRA+iSGLT2 in the short term is safe, well tolerated, with a slight initial increase in K, not maintained over time and weight loss. The potential risk of the association of S/V+iSGLT2+MRA is not observed in our cohort in the medium term. More long-term studies are needed to confirm whether this group of patients would have a better cardiovascular prognosis than those without S/V or iSGLT2.

P554

Improvement of NT-proBNP and NYHA values in patients with HFrEF and Sacubitril/Valsartan treatment

C Goena[1]; V Escolar[2]; A Laskibar[2]; C Gomez[3]; R Natividad[4]; A Romero[5]; M Perez De Nanclares[6]; I Rilo[7]; L Quintas[1]; I Solla[7]; G Zugazabeitia[5]; P Gil[6]; I Rodriguez[5]; I Urreta[8]; A Lozano[2]
[1]Mendaro Hospital, Cardiology, Mendaro, Spain; [2]Basurto University Hospital, Cardiology, Bilbao, Spain; [3]Cruces University Hospital, Cardiology, Barakaldo, Spain; [4]San Eloy Hospital, Cardiology, Barakaldo, Spain; [5]Galdakao Hospital, Cardiology, Galdakao, Spain; [6]Araba University Hospital, Cardiology, Vitoria, Spain; [7]Donostia University Hospital, Cardiology, Donostia, Spain; [8]Donostia University Hospital, Epidemiology, Donostia, Spain

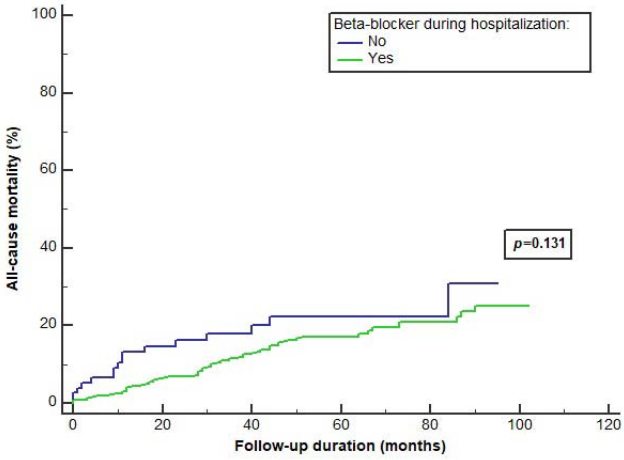
Introduction: Sacubitril/Valsartan (SV) has shown to reduce symptoms and improve survival in patients with HFrEF.
Objective: Analyze in real life if outpatients with HF, NYHA≥II and LVEF<40% treated with loop diuretics have improvement of the NYHA class and the NTproBNP values 3 months after reaching the SV maximum dose.
Methods: Retrospective and multicenter study in outpatients with optimized medical treatment and implantable devices at the time of onset of SV and loop diuretic intake (≥20 mg of Furosemide or ≥5 mg of Torasemide). Doses are recorded before and 3 months after reaching the maximum tolerated SV (low (L) <150 mg/24h, moderate (M) 150-200 mg/24h or high (H) ≥300 mg/24h). Admissions, diuretic dose adjustments and prerenal events were recorded during follow-up.
Results: 260 patients included (75% men, mean age 69±10 years, mean LVEF: 28±6 %). Comorbidities: 64.5% HBP, 35% DM, 49.4% ischemic cardiomyopathy (IC) and 13.5% severe MR. Base treatment: 89% BB, 76% MRA and 86.7% ACEi/ARA. 96% patients took ≥ 20 mg of furosemide and 4% ≥ 5 mg of torasemide. Reached dose of SV: L=65 (25%), M=100 (38.46%), H=95 (36.53%). Final SV doses were higher in men (p=0.003), IC (p=0.02), use of BB (p=0.03) and previous ACEi/ARA intake (p=0.006). Adverse events such as non-HF admissions: 25(9%), HF admissions: 37(13%), diuretic adjustment: 73(27%) and prerenal event: 34(12.5%) did not show significant differences between groups or depending on the SV reached dose. Baseline NYHA was II:120 (44%), II-III:95 (35%), III:58 (21%).Functional class 3 months after reaching the maximum SV dose improved significantly although there were no differences depending on the SV dose: 12 patients (4.4%) worsened, 107 (39%) did not change and 154 (56%) improved: I:46 (16.8%), II:162 (59.3%), II-III:46 (16.8%), III 19 (7%). Patients who presented greater improvement were the most symptomatic at the beginning of treatment with SV: NYHA III and II-III have a 7-fold and 5-fold improvement respectively (p<0.0001). Baseline NTproBNP mean values were 2563±4017 pg/ml and 1753±3552 at the end of the study. The percentage of NTproBNP reduction was 14% and 79% of patients reduced their baseline values regardless the achieved dose of SV. Significant differences in baseline NTproBNP values were recorded (p=0.001): L: 4413±7315, M: 2168±2216, H: 1871±1905). NTproBNP decreased in all groups and differences between them were maintained depending on the dose (p=0.03): L:2870±6468, M:1671±2620, H:1182±1073. Improvement in NYHA class and decrease in NTproBNP levels matched with a decrease in loop diuretic dose in 42% of the patients in the sample.
Conclusions: SV treatment improves the functional class and NT-proBNP values within 3 months of reaching the optimal dose. This improvement is associated with a decrease in loop diuretic requirements and is independent of the SV dose achieved but is more pronounced in advanced functional status (NYHA III) and with higher baseline NT-proBNP values.

P555

Long-term prognostic impact of beta-blocker prescription during hospitalization for acute myocardial infarction

F M Fernando Manuel Fonseca Goncalves[1]; JP Guimaraes[1]; PS Mateus[1]; JI Moreira[1]
[1]Hospital Center of Tras-os-Montes and Alto Douro, Cardiology, Vila Real, Portugal

Introduction: The use of beta-blockers (BB) was classically considered a sine qua non condition in ischaemic heart disease treatment. However, some recent studies question its use in this setting nowadays. This study aimed to assess the long-term impact of the prescription of BB during hospitalization for an acute myocardial infarction (MI).
Methods: This was a retrospective study of patients with non-fatal MI, included periodically in our center registry between October 2010 and November 2017. The endpoints evaluated were MI, decompensated heart failure (DHF), death and MACE (MI, coronary revascularization and cardiovascular death), in a median follow-up of 42 months (IQR 24-59). The endpoint analysis was adjusted for age, left ventricular ejection fraction, MI subtype, angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers prescription during hospitalization and at discharge and BB prescription at discharge.
Results: A total of 544 patients were selected, 74.4% male, of which 45.2% had ST-segment elevation MI and 86% had BB prescribed during hospitalization. These latter patients also had increased prescription of BB at discharge (86.9% vs 34.8%, p <0.001).
During follow-up the group of patients medicated with BB during hospitalization was not associated with significant lower mortality rate (14.7% vs. 21.1%, p = 0.131).
In the multivariate analysis, the prescription of BB during hospitalization was not associated with a statistically significant reduction of endpoint events, including MI (HR 0.84, 95% CI 0.28-2.48), DHF (HR 95% CI 0.41, 0.91-2.02), death (HR 0.84, 95% CI 0.38-1.85) and MACE (HR 0.73, 95% CI 0.37-1.43).
Conclusion: The prescription of BB during hospitalization was not associated with an independent and significant decrease of long-term cardiovascular events.



BB Mortality Kaplan Meier curves

Diabetic patients need higher loop diuretic doses: a report on acute and chronic heart failure patients

FM Cunha[1]; J Pereira[2]; P Marques[2]; A Ribeiro[2]; P Bettencourt[3]; P Lourenco[4]
[1]Hospital Centre do Tamega e Sousa, Endocrinology, Penafiel, Portugal; [2]Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal; [3]Hospital CUF, Department of Internal Medicine, Porto, Portugal; [4]Sao Joao Hospital, Department of Internal Medicine - University of Porto Medical School, Porto, Portugal

INTRODUCTION: Diuretics are first line drugs in symptomatic heart failure (HF) treatment. Diabetes mellitus (DM) has been suggested to be determinant of diuretic resistance. Studies comparing the dose and efficacy of diuretics in patients with and without DM are lacking. We aimed to study if furosemide dose differed according to DM status.
METHODS: We studied two cohorts of HF patients: a cohort of acute HF patients consecutively hospitalized with the primary diagnosis of HF and a cohort of stable and optimized patients followed in a specialized HF clinic. Data on comorbidities and medication were abstracted from patients' files. High diuretic dose was considered as the use of ≥80mg of furosemide per day. Use and doses of the furosemide were compared between diabetic and non-diabetic patients. Regression analysis was used to determine the association of variables with diuretic dose. The independent association of DM with loop diuretic dose was assessed using multivariate models.
RESULTS: We studied 865 HF patients: 601 acute HF patients and 264 chronic stable HF patients. Acute HF patients with DM were more likely to be medicated with loop diuretics and in higher doses; diabetics were more likely to need intravenous diuretic therapy and they were also more often discharged under higher doses of loop diuretics. The presence of DM was independently associated with use of higher dose of loop diuretic both at admission as well as at discharge. Diabetic patients were under additional 8mg furosemide upon admission when compared with non-diabetics independently of gender, hypertension history, atrial fibrillation, left ventricular systolic dysfunction and ischemic aetiology. Also, diabetic HF patients needed multivariate adjusted extra 6mg furosemide at discharge in

comparison with their non-diabetic counterparts. Diabetic acute HF patients had an independent 24% higher odds of being under high furosemide dose upon admission and an also independent 26% higher odds of being discharged with high loop diuretic. Chronic patients were also more prescribed loop diuretics and on higher doses, however, and diversely from what was documented in the acute HF setting, neither in the crude nor in the multivariate approaches was diabetes associated with the use of higher doses of loop diuretics

CONCLUSIONS: Diabetic patients are more intensively treated with loop diuretics. In acute HF, diabetes is an independent predictor of loop diuretic dose. For yet to uncover reasons, DM does not appear to be an independent predictor of the loop diuretic dose in patients with chronic HF under optimized medical therapy.

Background: Elevated B-type natriuretic peptide (BNP) in asymptomatic patients with cardiac abnormalities can provide a protective response to fibro-inflammation. The PARABLE study is investigating the hypothesis that augmenting BNP pharmacologically with sacubitril/valsartan versus valsartan alone can modulate progression of left atrial volume index (LAVI) over 18 months measured using cardiac Magnetic Resonance Imaging (cMRI). In addition, all patients in PARABLE undergo Doppler-echocardiography at baseline, 9 months and 18 months. The purpose of this report is to evaluate overall, blinded progression of cardiac structural and functional abnormalities in the first 100 patients over 9 months and the first 74 patients at 18 months.

Methods: PARABLE is an investigator-led, prospective, randomised, double blind, double dummy, phase II trial comparing treatment with sacubitril/valsartan versus valsartan alone. PARABLE will enroll 250 patients aged over 40 years with hypertension and/or diabetes, with BNP from 20-280 pg/mL or NTproBNP from 100 to 1000 pg/mL) and with LAVI above 28 mL/m2. We excluded patients with a history of heart failure, left ventricular systolic dysfunction, haemodynamically significant mitral and /or aortic valve disease, persistent atrial fibrillation, hepatic dysfunction and severe chronic kidney disease. The primary endpoint is change in LAVI measured by cMRI over 18 months. We evaluated blinded Doppler-echocardiographic measures of left ventricular structure, systolic function and diastolic function at baseline, 9 months and 18 months.

Results. Of the first 100 patients to complete the study, 35% were female, average age 72.7 ± 8.0 years, 94% had hypertension and 22% had Type 2 diabetes. Population baseline blood pressure was 136/78 ± 21/13 mmHg, heart rate was 63.5 ± 10.8 bpm and body mass index was 28.8 ± 4.9 kg/m2. Other baseline medical history included dyslipidaemia (83%), coronary artery disease (52%), other vascular disease (5%), stroke/TIA (10%), paroxysmal atrial fibrillation n (7%) and chronic kidney disease (2%). Median BNP was 79 pg/mL [interquartile range 47, 117 pg/mL] and baseline Doppler-echocardiography showed the average ejection fraction was 68.5 ± 6.5%, left ventricular mass index was 113.3 ± 28.2%, E/e' was 11.3 ± 3.2 and LAVI was 34.3 ± 4.9 mL/m2. There were no changes from baseline in Doppler-echocardiography measures at 9 months. At 18 months, in the subgroup that completed the study, the only observed change was a significant increase in LAVI from 34.0 ± 4.6 mL/m2 to 36.0 ± 5.0 mL/m2 ($p<0.01$).

Conclusions: Participants in the PARABLE clinical trial with elevated BNP and LAVI at baseline show significant progression of LAVI abnormalities over an 18-month time period. The PARABLE study is on target to define the impact of preserving circulating BNP using sacubitril on LAVI progression as a personalised therapy for prevention of progression of left ventricular diastolic dysfunction.

P558

Comparative efficacy of renin-angiotensin aldesteron system modulators and angiotensin receptor neprilyzin inhibitor in chronic heart failure with mid-ranged and preserved ejection fraction

LR Liana Tumasyan[1]; KG Adamyan[1]; AL Chilingaryan[1]; LG Tunyan[1]; VA Mkrtchyan[1]
[1]Institute of Cardiology, Yerevan, Armenia

The aim of study was to compare efficacy of long-term therapy with ramipril (R, up to 10 mg) + spironolacton (S, up to 25 mg), valsartatan (V, up to 160 mg) + spironolacton (S, up to 25 mg) and sacubitril/valsartan (S/V, up to 97/103 mg) on prognosis, left (LV) and right ventricular (RV), left (LA) and right atrial (RA) functional parameters by Doppler and tissue echocardiography, transforming growth factor-beta (TGF-β, ng/ml) and high sensitivity C reactive protein (hsCRP, ng/ml) levels by EIISA method

IHD: Ischemia heart disease; HFrEF: Heart Failure with reduced ejection fraction

in patients (pts) with III NYHA functional class (FC) chronic heart failure in relation to mid-ranged (HFmEF) or preserved (HFpEF) ejection fraction (EF).

Methods. 82 pts (mean age 59.9) with HFmEF (40% ≤EF<50%) and 79 pts (mean age 63.1) with HFpEF (EF≥50%) in sinus rhythm were randomly assigned to groups, receiving R+S (n=28 and n=27), V+S (n=27 and m=26) and S/V (n=27 and m=26) in addition to diuretics and beta-blockers.

Results. 1-year mortality and hospitalization rates were 35.7% and 57.1%; 40.7% and 59.3% and 25.9% and 40.7% in pts with HFmEF, receiving R+S, V+S and S/V, respectively. 1-year mortality and hospitalization rates were equal to 33.3% and 55.5%; 38.5% and 57.7% and 23.1% and 38.5% in pts with HFpEF, receiving R+S, V+S and S/V, respectively. Survival analysis revealed relative risk (RR) reduction of 1-year mortality and hospitalization rate at 27.5% and 28.7% (p<0.05) and 36.4% (p<0.01) and 31.3% (p<0.05) in pts with HFmEF, treated by S/V, compared to groups, receiving R+S and V+S, respectively. Similarly, significant reduction of 1-year mortality and hospitalization at 30.6% and 30.6% (p<0.05); 40.4% (p<0.01) and 33.3% (p<0.05) was revealed in V/S treatment group with HFpEF, compared to groups, using R+S and V+S, respectively. 1-year S/V treatment significantly (p<0.01 for all) decreased levels of TGF-β at 31.3% and 33.3%, e' at 30.2% and 30.6%, Ar-A at 55.1% and 57.2%, increased PV SC at 42.1% and 43.4%, RAFI at 32.9% and 33.6%, LAFI at 34.9% and 35.2%, LV EF at 22.1% and 23.4% in pts with HFmEF, and significant changes (p<0.01 for all) of hsCRP at 34.6% and 35.2%, levels of TGF-β at 30.2% and 31.2%, TAPSE at 42.2% and 43.4%, e' at 26.2% and 28.2%, PA ET at 19.8% and 20.3% in pts with HFpEF, compared to groups, receiving R+S and V+S, respectively. .

Conclusions: 1) V/S treatment associated with significant reduction of morbidity and mortality compared to use of R+S and V+C in pts with both HFmEF and HFpEF. 2) Changes of Ar-A, RAFI and LAFI, e'≥40%, TGF-β≥30% identified pts with cardiovascular risk reduction in HFmEF group, while changes of TGF-β, hsCRP≥30%; PAET ≥30% revealed pts with improvement of morbidity and mortality in pts with HFpEF. 3) Prognostic improvement in pts treated by V/S has related to improvement of TGF-β, LV systolic and diastolic functional parameters, LA and RA functional parameters in HFmEF and to TGF-β hsCRP, LV diastolic functional and RV functional parameters changes in HFpEF

Combined therapy with angiotension receptor-neprilysin inhibitor and sodium-glucose transport protein 2 inhibitors, a real life register data

M Singh[1]; M Galvan Ruiz[1]; M Sanmamed Giron[1]; M Groba Marco[1]; M Lopez Perez[1]; C Camacho Godoy[1]; B Hernanez Meneses[1]; J Medina Suarez[1]; D Rua-Figueroa Erausquin[1]; P Bujanda Morun[1]; P Pena Ortega[1]; V Quevedo Nelson[1]; H Mendoza Lemes[1]; E Caballero Dorta[1]; A Antonio Garcia Quintana[1]
[1]University Hospital of Gran Canaria Doctor Negrin, Las Palmas De Gran Canaria, Spain

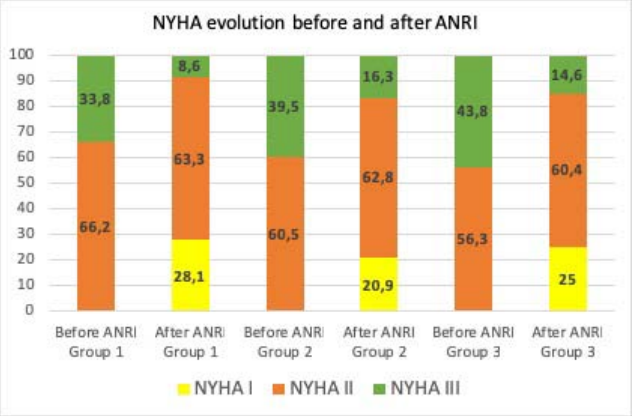
On behalf of: SAVE-RLife group

Background: Angiotensin receptor-neprilysin inhibitor (ARNI) and Sodium-Glucose Transport Protein 2 inhibitors (iSGLT2), beside there different targets, have shown reduction in cardiovascular mortality in patients with heart failure. Few data is known about the efficacy and safety of their combination. Purpose: To analyse the clinical and analytical evolution of patients with HFrEF under combined therapy with ANRI and iSGLT2.

Methods: SAVE-RLIFE (SAcubitril-Valsartan Evidence in Real Life) is an observational, ambispective, multicentre study that included patients with HFrEF under treatment with ANRI between SEP2016 and DEC2018. A subanalysis of 3 groups of patients was performed: Group 1 non-diabetic patients, Group 2 diabetics with iSGLT2 and Group 3 diabetics without iSGLT2.

Results: 276 patients were included, 50% were diabetics, 18.5% of them received combined therapy and 31.5% only ANRI. The mean age was 66.16±11.23 and ischemic cardiomyopathy the main etiology, without significant differences between the three groups. Clinical evolution assessed by NYHA classification, was similar in all groups (Figure 1). No significant difference was observed in terms of side effects between the groups (Table 1). Glomerular Filtration Rate (GFR) before and after ANRI initiation shows similar progression (in group 1 70.41 to 67.6ml/min, group 2 69.8 to 65.2ml/min, group 3 63.6 to 63.2ml/min), without a statistically or clinically relevant reduction.

Conclusions: ANRI and i-SGLT2 seem to have good security profile with their combined usage, without any significant increase in the side effects, neither decrease in their clinical efficacy. Further follow-up of these patients is necessary.



NYHA progression after ANRI

P560

Long-term treatment with inotersen and potential improvement of amyloid transthyretin cardiomyopathy

NR Dasgupta[1]; MD Benson[2]
[1]Indiana University School of Medicine, Division of Cardiology, Indianapolis, United States of America; *[2]Indiana University School of Medicine, Department of Pathology and Laboratory Medicine, Indianapolis, United States of America*

Introduction: Amyloid transthyretin (TTR) amyloidosis cardiomyopathy (ATTR-CM) is a progressive and fatal disease caused by deposition of TTR in the heart. ATTR-CM may be caused by mutations in TTR (hereditary ATTR [hATTR]) or misfolding of normal TTR in older individuals (wild-type ATTR [wtATTR]). Natural history data show a progressive decline in cardiac functional and structural parameters including a reduction in 6-minute walk test (6MWT) distance and increase in left ventricular mass (LVM). Inotersen, an antisense oligonucleotide inhibitor of TTR production, showed efficacy in treating neuropathy in the NEURO-TTR study in patients with hATTR, including those with cardiac involvement. We previously reported stabilization of hATTR-CM and wtATTR-CM after 1 year of treatment with inotersen. We now report updated results for patients treated for up to 3 years.

Purpose: To study whether longer-term treatment with inotersen improves CM in patients with hATTR-CM and wtATTR-CM

Methods: Patients with biopsy proven hATTR-CM or wtATTR-CM, interventricular septum (IVS) thickness ≥ 1.3 cm on echo, and evidence of congestive heart failure [CHF]) received 300 mg inotersen by subcutaneous injection weekly in a single-center, ongoing, open-label, investigator-initiated study. Safety monitoring included platelet counts, serum creatinine, and urine protein. Efficacy assessments included plasma TTR levels, 6MWT distance, B-type natriuretic peptide (BNP) and echocardiograms and cardiac MRIs.

Results: As of October 2018, 35 patients (10 hATTR, average age 63.4 years and 25 wtATTR, average age 76.1 years) have enrolled. Of the 35 patients, 5 are newly enrolled, 21 completed 1 year, 17 completed 2 years, 14 completed 3 years, 3 completed 4 years, 8 voluntarily withdrew, and 1 died from a nondrug related cause. Inotersen was well-tolerated. No drug-related serious adverse events (AEs), cases of severe thrombocytopenia, or renal AEs occurred. Sustained TTR reduction resulted in a mean decrease in LVM by 0.54%, 8.5%, and 11.4% and improvement in 6MWT of 5.6, 23.2, and 18.6 meters compared to baseline at 1, 2, and 3 years respectively in all patients. Improvement in 6MWT was more striking in the hATTR subgroup, who demonstrated a mean improvement of 29. 3, 40.9, and 50.2 meters compared to baseline at 1, 2, and 3 years respectively. BNP and IVS thickness decreased or remained stable in most patients and left ventricular ejection fraction (LVEF) increased or remained stable in most patients.

Conclusions: Long-term treatment with inotersen was well-tolerated and resulted in improvement or stabilization in cardiac function and structure in patients with hATTR-CM and wtATTR-CM. Our findings showing that long term inotersen therapy resulted in an increase in 6MWT distances, stabilization of the LVEF and BNP, and decreased LVM suggest that inotersen has the potential to decrease amyloid burden, reverse amyloid cardiomyopathy, and improve quality of life and survival.

Introduction . Serum levels variability (SLV) of calcineurin inhibitors (CNI) has been associated with poor outcomes in solid-organ transplantation. Its impact on heart transplantation (HTx) outcomes remains unestablished.
Purpose. To evaluate the relation of SLV with HTx outcomes.
Methods. Study population: patients aged ≥18 years with a first HTx performed between 2000 and 2014, and surviving > 1 year. Information regarding recipient's and donor's characteristics and outcomes was gathered retrospectively from the Spanish Heart Transplantation Registry database. SLV was assessed by the coefficient of variation (CV) of serum levels from 4 to 12 months post-HTx. End-points were death and treated rejection 1 to 5 years post-HTx. Cox regression models were used for analysis.
Results. Study population comprised 1581 patients (median age, 56 years; Females, 21 %). 1-year immunosuppression was Cyclosporine (50%), standard-release Tacrolimus (33%), prolonged-release Tacrolimus (17%), Prednisone (87%), Mycophenolate (80%). Median CV was 27.8%. Predictors of mortality and rejection are summarized in Table. SLV showed a marginal statistical significance (p = 0.06) for both 5-year mortality and treated rejection.
Conclusion. SLV of CNI over the first year post-transplantation has a marginal impact on mid-term mortality and rejection incidence in HTx.

Variable	Univariate		Multivariate	
	Hazard Ratio	P value	Hazard Ratio	P value
MORTALITY				
CV > 27.8 %	1.50 (1.08-2.09)	0.02	1.41 (0.98-2.02)	0.06
Donor's age > 39 y	1.78 (1.27-2.50)	0.001	1.95 (1.35-2.82)	<0.001
CNI type		0.10		0.02
Cyclosporine	1		1	
Tacrolimus standard-release	0.78 (0.54-1.13)	0.19	0.69 (0.46-1.04)	0.07
Tacrolimus prolonged-release	0.56 (0.39-1.00)	0.05	0.45 (0.24-0.84)	0.01
Diabetes prior to HTx	1.97 (1.34-2.84)	<0.001	1.55 (1.03-2.33)	0.03

Sacubitril/Valsartan and SGLT2i: a safe combination?

C Goena[1]; R Natividad[2]; I Rilo[3]; C Gomez[4]; M Perez De Nanclares[5]; A Lozano[6]; L Quintas[1]; G Zugazabeitia[7]; I Solla[3]; V Escolar[6]; I Rodriguez[7]; P Gil[5]; A Laskibar[6]; I Urreta[8]; A Romero[7]
[1]Mendaro Hospital, Cardiology, Mendaro, Spain; *[2]San Eloy Hospital, Cardiology, Barakaldo, Spain*; *[3]Donostia University Hospital, Cardiology, Donostia, Spain*; *[4]Cruces University Hospital, Cardiology, Barakaldo, Spain*; *[5]Araba University Hospital, Cardiology, Vitoria, Spain*; *[6]Basurto University Hospital, Cardiology, Bilbao, Spain*; *[7]Galdakao Hospital, Cardiology, Galdakao, Spain*; *[8]Donostia University Hospital, Epidemiology, Donostia, Spain*

Introduction: SGLT2i have been shown to reduce HF hospitalization and have become the second step after Metformin in the treatment of type 2 DM. Sacubitril/Valsartan (SV) is indicated in the treatment of symptomatic HFrEF, however SGLT2i were not included among the drugs co-administered in the PARADIGM-HF assay.
Purpose: Estimate the prevalence of treatment with both drugs and adverse events in SV titration.
Methods: Diabetics under treatment with SGLT2i and SV are selected retrospectively from a multicenter registry. The inclusion criteria were: outpatient, optimized medical treatment and devices at the time of onset of SV and loop diuretic intake (≥20 mgr Furosemide or ≥5 mgr Torasemide). SV doses (low (L) low <150 mgr/24h, moderate (M) 150-200 mgr/24h or high (H) ≥300 mgr/24h), admissions, diuretic dose adjustments and prerenal events were recorded during follow-up.
Results: From a sample of 260 patients: 35% have DM type 2 (N=97). 17 of them were treated with iSGLT2 during SV titration. Baseline characteristics: 14 (82%) men and 3 (18%) female, HBP 13 (76%), CAD 6 (35%), CRT 3 (17%), Severe MR 2. Adverse events during follow-up were 5 HF admissions, 1 non-HF admission, 5 diuretic adjustments and 1 prerenal event. The treatment at the beginning of the study showed no difference compared to the rest of the patients in the registry: Torasemide (N=1), Furosemide (N=16), BB (N=14, 82%), MRA(N=14, 82%), previous ACEi/ARAII (N=13,76%). Baseline NYHA was II (N=3, 17.6%), II-III (N=12, 70.6%), III (N=2, 11.7%) and at the time of analysis there was a very remarkable improvement: 12 patients improved functional class and NYHA became II (N=14) in 82% and III (N=3) in 18%. Diuretic requirements were reduced by > 30% compared to basal dose in 6 patients and 3 patients discontinued it entirely. All but 2 patients reduced NT-proBNP levels. There were no statistically significant differences in renal function. High doses of SV were achieved in most patients: 6 (35%) ≥300 and 9 (53%) 150-200. In none of the cases the SGLT2i was a limiting factor to increase the SV dose.
Conclusions: Although the sample size is small, initial data suggest that administration of SGLT2i and SV is not associated with serious adverse effects and does not delay correct titration of the SV. Improvement in NYHA and NT-proBNP levels is documented along with decrease in diuretic dose.

Method of the logistic regression analysis in forecasting of development of atrial fibrillation

A Anna Chernova[1]; S Nikulina[1]; A Kuskaeva[1]
[1]Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation

Introduction . The method of carrying out multiple logistic regression analysis was used for forecasting of emergence of atrial fibrillation.
Purpose. By means of a method of logistic regression to predict development of AF.
Methods. Research object – the main group of a research was made by 234 persons, from them 86 men (36.8%) and 148 women (63.2%). Average age of men was 39.60±18.65 years, women of 50.93±16.78 years. In group of patients with primary AF of 40 patients, from them 26 (65.0%) men and 14 (35.0%) women. From them 90 probands with the confirmed diagnosis of AF. From them it was distinguished: 40 probands with primary AF (this group of patients had no communication of developing of arrhythmia with cardiovascular pathology); 50 probands with secondary AF (in this group the accurate interrelation of emergence of an attack of arrhythmia with existence of the accompanying cardiovascular pathology prolezhivatsya).
Results. Existence of atrial fibrillationis presented in the form of a binary variable where 0 – absence of arrhythmia, 1 – heart beat disorder.At creation logistic regression models with step-by-step inclusion of each predictor the assessment of value of coefficient of determination of R2 (Naydzhelkerk's square) which shows a share of influence of all predictive factors of model on dispersion of dependent variable was carried out.
The assessment of parameters was carried out on the basis of the value exp (b): if b coefficient positive, then exp(b) more than 1 and chances increase if coefficient negative – decrease.Check of the importance of model of logistic regression was estimated with use of value $\chi 2$. At <0,05 a hypothesis of insignificance of model. By means of Hosmera-Lemeshev's indicator compliance of model to basic data was defined. The hypothesis of coherence of model was accepted at >0,05.
Statistically significant model only for a genotype of the II gene of ACE was received. This model is presented by the equation: where – probability of development of

AF, x – existence of a genotype of the II gene the ACE (is – 1, is not present - 0) (b = 0.654), constant b0 =-0.297. – mathematical constant 2.72. The model is statistically significant (=0.04).
Among the main group of patients as the most probable predictors of development of heart beat disorder rare genotypes of the following genes were evaluated: ACE, AGTR1, AGT.
The dependence of a logarithm of chance of approach of the predicted event (logit) on linear combination of factor variables represents a mathematical model of logistic regression:
Conclusions. For this model an indicator of determination R2=0.024, therefore statistically significant definition by this genetic factor of probability of development of AF in the studied group of patients only for 2.4%. At the same time the model correctly predicts lack of AF in 83.3% of cases, and existence of AF in 27.8%. In total 57.7% of forecasts were correct.

P564

Numerous published biomarker prognostic models for heart failure exist, but none is officially recommended in clinical guidelines:a paradox or a research scandal/failure?

NPE Kadoglou[1]; M Vazquez-Montes[2]; K Taylor[2]; R Perera[2]; B Speich[1]; CJ Taylor[2]; T Debray[3]; G Collins[1]; FDR Hobbs[2]; K Moons[3]; N Roberts[2]; J Parissis[4]; M Trivella[1]
[1]University of Oxford, Centre for Statistics in Medicine, Oxford, United Kingdom of Great Britain & Northern Ireland; *[2]University of Oxford, Oxford, United Kingdom of Great Britain & Northern Ireland*; *[3]University Medical Center Utrecht, Utrecht, Netherlands (The)*; *[4]Attikon University Hospital, Athens, Greece*

Funding Acknowledgements: The project is funded by the British Heart Foundation (grant no. PG/17/49/33099)

Background/Introduction: Heart failure (HF) is a major public health problem. Risk stratification along with tailored intensive therapy may alter HF patients' prognosis. Two decades of biomarker research highlighted the prognostic ability of certain markers, and encouraged the development of prognostic models. Despite numerous publications with a prognostic theme and ESC's recognition of the need for prognosis information, no such models have been adequately established in clinical practice.
Purpose: To systematically assess the quality of published prognostic models and the evidence they present, for the first time. This is a complex time-constrained project with potential to advise on future HF prognostic model design and reporting, and contribute to improved HF research resources and clinical management.
Methods: We applied Cochrane methodology for searching and assessing published studies on prognostic HF models. Using validated prognostic filters in a sensitive search, more than 40,500 titles with at least one HF-related biomarker and prognosis-related information were initially identified. Of these only 10% (4224) were relevant to HF biomarker prognostic models and factors. We used established tools of prognostic methodology to assess the eligible studies3.
Results: Despite the extensive research on prognostic HF-biomarkers, only a maximum of 200 papers (5% of 4224 and only 0.5% of 40500) hinted on employing appropriate prognostic methodological processes, but less than 50 adequately reported their methods. As a preliminary result the adequately developed and validated models would not exceed 10.
In the vast majority of the papers there was a rather confusing marriage of HF-biomarker research and prognostic modelling methodology. Most were based on a simple logistic regression, which is merely explanatory of a causal or association hypothesis but doesn't qualify as a prognostic model on its own. Prediction research aims to provide an estimate of outcome probability to assist clinical management; it is independent of a causal hypothesis, and needs to be validated and if necessary, calibrated. The development and reporting of prognostic models was often misunderstood and/or misreported, while the adequate conduct and reporting of models' validation and calibration was usually absent.
Conclusions: Our project is the first known attempt to assess systematically the evidence from HF prognostic models. We found largely inadequate use of prognostic methodology leading to multiple papers, with very little prognostic information for HF. This area of HF research would benefit from adopting REWARD alliance initiatives on avoiding research waste. Research teams should consider prognostic methodology training, before embarking on such projects. Responsibility also lies with the Journals for ensuring the quality of conduct of prognostic research through their peer review processes. Until such time use of prognostic models would be limited.

Artificial intelligence (AI) and machine learning (ML), which is a subset of AI that allows for systems to autonomously learn through data and experience, have been of increasing use in the field of cardiology and heart failure (HF). These systems allow for the detection of patterns and signs used in early detection, monitoring and treatment with a higher degree of accuracy in comparison to human capability. In theory, this improvement in accuracy combined with the technological nature of these systems allows for efficient and quick intervention to be delivered, improving prognosis and allowing human resources to be spent elsewhere, increasing the efficiency of the entire healthcare system. Hence, attempts at incorporating AI and ML feasibly in heart failure treatment have been increasing.
We conducted a systematic review, across the three primary databases, Embase and Medline and the most comprehensive machine learning database Arxiv. The search strategy yielded a total of 235 results, after which two independent authors filtered out publications according to the clinical relevance. We performed a quantitative meta-analysis and qualitative assessment of both published and unpublished literature of AI in HF in a real-world clinical setting that we plan to present at the conference to inform the general HF community about this rapidly developing field.
Selected uses of AI in HF include the improvement of detection of HF using ECGs by incorporating a newly proposed algorithm which can classify whether the patient has HF using a mere 2 second segment to an impressive accuracy. Telemedicine interfaces that have been developed with the aim of integrating at home health monitoring, using connected wearable devices and Bluetooth instruments such as weighing scales, with the aim of improved monitoring and early detection of relapse post release. Furthermore, these platforms also have the capability of using coding clinical guidelines in the treatment of HF, incorporating the patient information that was collected and producing treatment recommendations to the clinicians. Wearable devices have also been a new fitness trend that has shown variable successes when incorporated into HF management, with learning algorithms showing an improvement over conventional predictive readmission guidelines while allowing for consistent patient monitoring and prompt intervention upon any alarming signs suggesting relapse, thus reducing hospitalisations. Lastly, we reviewed some of the ethical and regulatory challenges of implementation of these new technologies. In conclusion, we aim to present the findings of our recently conducted systematic review and meta-analysis to allow busy clinicians to stay up to date with the developments of AI in HF.

Guideline recommended therapies in HFrEF, online medical education improves cardiologists' knowledge and competence

L Lionel Thevathasan[1]; R Miller[2]; N Ashley[3]; P Schoonheim[1]
[1]Medscape LLC, Medical Strategy, Paris, France; *[2]Medscape LLC, Medical Strategy, New York, United States of America*; *[3]Medscape LLC, Scientific Direction, New York, United States of America*

Funding Acknowledgements: Developed through independent educational funding from Novartis

Introduction Clinicians who treat patients with chronic heart failure require education on current guideline recommendations for the treatment of heart failure with reduced ejection fraction (HFrEF) and on the appropriate use of established and new therapies.
Purpose We sought to assess whether online education, based on the latest evidence, directed at cardiologists, could improve knowledge and competence on the application of guidelines-recommended therapies – mineralocorticoid receptor antagonists (MRA) and angiotensin receptor neprilysin inhibitors (ARNi) – in HFrEF.
Methods The education consisted of a 30-minute, case-based, online video discussion between 2 heart failure experts, with synchronised slides. Educational effect was assessed using a 3-question repeated pairs, pre/post assessment survey. A chi-squared test assessed changes pre- to post-assessment. P values < 0.05 were statistically significant. Cramer's V test was used to calculate the effect size (<0.05 modest; 0.06-0.15 noticeable effect; 0.16-0.26 considerable effect; >0.26 extensive effect) overall and for each question. The activity launched on 11thMay 2017 and data were collected through 14thJune 2017.
Results 376 cardiologists completed the pre- and post-assessment. Overall, education had an extensive impact on cardiologists' knowledge/competence (V=0.264). At baseline, 6% of cardiologists answered all 3 questions correctly, which, on post-assessment, increased six-fold to 36%. For each of the three questions, there was a greater than 50% relative improvement for (57%, 84% and 57%). Specific observations include:
• There was a low level of baseline knowledge (35% pre-assessment) on selective MRAs having a better safety profile in men with a significant absolute increase of 20% (to more than half of cardiologists correctly answering this question) post-assessment ($p<0.001$; V=0.201).

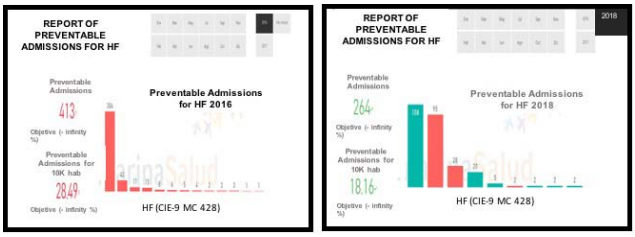
• On the benefit of ARNi vs ACE inhibitor therapy in the PARADIGM-HF trial, there was a low level of baseline knowledge (37%) which increased to 68% post-assessment (p<0.001; V=0.311).
• Nearly half of cardiologists were aware of the percentage of hyperkalaemia in clinical trials with ACE inhibitors and an MRA pre-education, which increased to nearly three-fourths post-education (p,0.001; V=0.286).
Conclusion This study demonstrates an extensive impact of case-based, online video discussion on cardiologists' knowledge of HFrEF and guidelines-recommended therapies.

P567

Reduction of potentially preventable hospitalization rates with a multidisciplinary program of heart failure

JSM Seller Moya[1]; HMC Morillas Climent[1]; AVL Vicedo Lopez[1]; EMJ Galcera Jornet[1]; EAT Alania Torres[1]; YRP Rodriguez Pichardo[1]; ALR Larumbe Rodriguez[1]; CNP Nunez Piles[2]; AVM Valle Munoz[1]
[1]Hospital Marina Salud, Cardiology, Denia, Spain; *[2]Hospital de la Ribera, Alzira, Spain*

INTRODUCCION: Potentially preventable hospitalization rates (PPH) have been used as an indicator of access to primary care since these are hospital admissions that could be prevented through accessible, effective and high-quality outpatient care.Heart failure (HF) is often the final stage of heart disease and currently one of the most relevant public health problems. Its prevalence has increased due to an aging population and the improvement of acute myocardial infarction treatment, among others.Patient or medical care preventable precipitating factors represent 30-60% of the causes of HF, and 40% of HF hospitalizations could be potentially preventable. Among all these factors, surveillance to recognize early HF decompensation, and the role of health care to ensure continuity after hospital discharge play a key role.
OBJECTIVES: to evaluate the PPH rate and the cost effectiveness of the development of a multidisciplinary program such as the heart failure unit (HFU) over the last two years.
METHODS: development and implementation of the community multidisciplinary HFU, including primary care, cardiology, internal medicine and palliative care. Programs are developed for early follow-up at discharge, outpatient clinic, home hospitalization and palliative care, remote patient follow-up, nursing consultation, available for patients during the 5 working days of the week. The PPH rate is analyzed using the indicator provided by Health department.
RESULTS: In 2016, with the start of the HFU activity, a total of 304 PPH were recorded in HF. In 2018 the PPH has been reduced to a total of 108. Therefore, with the development of the care integration programs of the HFU a total of 196 PPH have been reduced in two years. The average stay in the cardiology service is 5.3 days (expected 6.15). With an average cost per Law of 2017 Fees of the Department of Health of 310.17 €/day, (€ 1644 /admission). Therefore a potential reduction of € 322,224 in 2018 vs. 2016.
CONCLUSIONS: The clinical interventions which lead to the integration and coordination of the different levels of health care involved in HF affect the number of admissions, patient quality of life and health care efficiency.



Report of preventable admissions for HF

P568

Optimising guideline recommended medical therapy for heart failure, impact of medical education on cardiologists knowledge and competence using case simulations

L Lionel Thevathasan[1]; R Miller[2]; N Ashley[3]; P Schoonheim[1]
[1]Medscape LLC, Medical Strategy, Paris, France; *[2]Medscape LLC, Medical Strategy, New York, United States of America*; *[3]Medscape LLC, Scientific Direction, New York, United States of America*

Funding Acknowledgements: Developed through independent educational funding from Novartis

Introduction Application of evidence-based guidelines recommendations to clinical practice is not always optimally achieved. Clinicians who treat patients with chronic heart failure frequently fail to optimise medical therapies. It is important to educate them on the inclusion of an ARNi in the 2016 European HF guidelines, considerations on dose-titration, discontinuation and modification of treatment strategy in HF patients with moderate renal impairment.
Purpose: We sought to assess whether online education, directed at cardiologists, could improve knowledge and competence on optimising medical therapy for heart failure patients.
Methods: The educational activity consisted of a 20-minute online video patient-case simulation interspersed with expert commentary provided by a European heart failure expert. Educational effect was assessed using a 3-question repeated pairs, pre-/post-assessment survey. A chi-squared test assessed changes pre- to post-assessment. P values < 0.05 were statistically significant. Cramer's V test was used to calculate the effect size (<0.05 modest; 0.06-0.15 noticeable effect; 0.16-0.26 considerable effect; >0.26 extensive effect) overall and for each question. The activity launched on 18thMay 2017 and data were collected through 21stJune 2017.
Results: 319 cardiologists completed the pre- and post-assessment. Overall, education resulted in considerable impact on cardiologists' knowledge and competence (V=0.244). At baseline, 10% of cardiologists answered all 3 questions correctly and this, on post-assessment, increased nearly five-fold to 48%. Specific observations include:
• There was a good level of baseline knowledge (66% pre-assessment) on the importance of adding an MRA to beta-blocker and ACEi to optimize medical therapy and reduce CV outcomes in heart failure patients. This increased to 71% post-education (p=0.233; V=0.047)
• On determining the rationale to stop or not uptitrate an ARNi, there was a good level of baseline knowledge (62%) which increased to 80% post-assessment (p<0.001; V=0.193).
• Only 27% of cardiologists correctly identified that reduction of diuretic dose might help to compensate for reduced renal function in HF patients taking an ARNi. Post-education, there was a near three-fold increase to 76% correct responses (p<0.001; v=0.486).
Conclusion: This study demonstrates the positive effect of an online video patient-case simulation, interspersed with expert commentary, on cardiologists' knowledge and competence regarding practical application of HF guidelines. Despite improvements in knowledge and competence, implementation into clinical practice is still suboptimal and application-based education in different formats may be required to truly improve patient outcomes.

P569

Key changes to the 2016 European heart failure guidelines, effect of medical education on cardiologist knowledge

L Lionel Thevathasan[1]; R Miller[2]; N Ashley[3]; P Schoonheim[1]
[1]Medscape LLC, Medical Strategy, Paris, France; *[2]Medscape LLC, Medical Strategy, New York, United States of America*; *[3]Medscape LLC, Scientific Direction, New York, United States of America*

Funding Acknowledgements: Developed through independent educational funding from Novartis

Introduction Clinicians who treat patients with chronic heart failure require education on the latest updates to guidelines recommendations for the treatment of heart failure to improve clinical practice and patient outcomes.
Purpose We sought to assess whether online education directed at cardiologists could improve knowledge of the key changes to European heart failure guidelines.
Methods The educational activity was a 30-minute online video discussion between 4 heart failure experts, with synchronised slides. Educational effect was assessed using a 3-question repeated pairs, pre-/post-assessment survey. A chi-squared test assessed changes pre- to post-assessment. P values < 0.05 were statistically significant. Cramer's V test was used to calculate the effect size (<0.05 modest; 0.06-0.15 noticeable effect; 0.16-0.26 considerable effect; >0.26 extensive effect) overall and for each question. The activity launched on 16thMay 2017 and data were collected through 21stJune 2017.
Results 326 cardiologists completed the pre- and post-assessment. Overall, cardiologists experienced a considerable impact from the education (V=0.187). At baseline, 10% of cardiologists answered all 3 questions correctly which, on post-assessment, more than doubled to 25%. Specific observations include:
• There was a modest level of baseline knowledge (48% pre-assessment) on key changes to the 2016 European heart failure guidelines which increased to 60% at post-assessment (p=0.002; V=0.123).
• There was a modest level of baseline knowledge (51%)on assessing the characteristics of natriuretic peptides, which increased to 63% at post-assessment (p=0.002; V=0.124).
• At baseline, only 28% of cardiologists correctly responded to a question on BNP or NT-proBNP levels as a criterion for ACEi or ARNi use in patients with HFrEF.

Following the programme, this increased to 60% correct responses (p<0.001; V=0.318).
Conclusion This study demonstrates the positive effect of online medical education in the form of video discussion with slides on cardiologists' knowledge of key changes to the 2016 European heart failure guidelines. Remaining gaps were also identified that require further educational initiatives.

The correlation analysis of polymorphisms system renin-angiotensin-aldosteron system with development of atrial fibrillation

A Anna Chernova[1]; S Nikulina[1]; A Kuskaeva[1]
[1]*Krasnoyarsk State Medical University named prof. V. F. Voino-Yasenecky, Krasnoyarsk, Russian Federation*

Introduction: Methods of the mathematical analysis given for forecasting of emergence of atrial fibrillation. The correlation analysis of the genes of renin-angiotensin-aldosterone system with indicators of the electrocardiogram and an echocardiography at probands from primary AF was carried out.
Purpose. Studying of correlation bonds of polymorphisms of genes of ACE, AGTR1, AGT with indicators of the electrocardiogram and echocardiography at probands from primary and secondary AF.
Methods. Research object – the main group of a research was made by 234 persons, from them 86 men (36.8%) and 148 women (63.2%). Average age of men was 39.60±18.65 years, women of 50.93±16.78 years. In group of patients with primary AF of 40 patients, from them 26 (65.0%) men and 14 (35.0%) women. From them 90 probands with the confirmed diagnosis of AF. From them it was distinguished: 40 probands with primary AF (this group of patients had no communication of developing of arrhythmia with cardiovascular pathology); 50 probands with secondary AF (in this group the accurate interrelation of emergence of an attack of arrhythmia with existence of the accompanying cardiovascular pathology prolezhivatsya).
Results. When carrying out the correlation analysis of the studied genes with indicators of the electrocardiogram and an echocardiography at probands from primary AF it was established that left ventricular ejection fraction decreases at carriers of a widespread homozygous genotype of the CC polymorphism T174M and widespread homozygous genotype of a TT of polymorphism of M235T of a gene of AGT. Among probands from secondary AF at carriers of a homozygous genotype of the II gene the ACE of duration of a P wave increases while at carriers of a homozygous genotype the DD P wave remains the normal sizes.
Conclusions. Studying of polymorphic allelic variants of genes of RAAS (I/D of polymorphism of a gene of ACE, A/C of polymorphism of a gene AGTR1, T174M of polymorphism of a gene of AGT and M235T of polymorphism of a gene of AGT) in families of AF will allow to reveal molecular and genetic distinctions, to carry out the genetic forecast of development of diseases and also to define risk groups on development of AF for dispensary observation and implementation of prevention.

Swallow syncope: a review of the current evidences

K Kelvin Shenq Woei Siew[1]; MP Tan[1]; I Hilmi[1]; A Loch[1]
[1]*University Malaya Medical Centre (UMMC), Kuala Lumpur, Malaysia*

Background: Syncope is defined as transient loss of consciousness due to cerebral hypoperfusion. Swallow or deglutition syncope is an unusual type of neurally-mediated syncope associated with life-threatening bradyarrhythmia and hypotension. It is a difficult condition to diagnose, often missed by the physician, resulting in delayed diagnosis and treatment. We reviewed and summarized literature available regarding this rare condition, providing guidance for physicians encountering swallow syncope.
Purpose: To elucidate the basic demographic, clinical characteristics and management of swallow syncope based on the published literature.
Methods: A PubMed search for English language manuscripts published at any point in time using the MeSH terms "swallow syncope" and "deglutition syncope" was conducted. A total of 117 articles on swallow syncope were identified between 1949 and 2018. Sixteen cases were either reported in non-English literature or were not retrievable. 101 suitable case reports were statistically analyzed with regards to clinical presentation, underlying diseases and management. The statistical software SPSS, version 24 was used.
Results: A total of 101 swallow syncope patients reported in the literature were reviewed. The demographics were as follows: mean age 57.7 years at presentation, more common in older age groups (55.4%, n= 56, more than 60 years old); and males (59.4%, n=60). Presyncope or syncope was the most common presenting symptom (99%, n=100) followed by dysphagia (11.9%, n=12). Types of arrhythmia associated with swallow syncope were reported as follows: Atrioventricular (AV) conduction blocks (34.7%, n=35) including first, second and third-degree AV blocks were the most common electrophysiological problems; followed by sinus node dysfunctions (33.7%, n=34) including sinus bradycardia, sinus arrest and asystole. Any type of food (54.5%, n=55) be it liquids or solids were the most common trigger factor. Swallow syncope is frequently associated with underlying gastrointestinal diseases (32.7%, n=33). For instances, Hiatal hernia (18.8%, n=19), esophageal stricture (3%, n=3), achalasia (3%, n=3) were the most common gastrointestinal disorders. Followed by cardiac diseases (32.7%, n=33) and metabolic diseases (27.7%, n=28). More than half of the patients (55.5%, n=56) were treated with a permanent pacemaker, (98.1%, n=52) of them reported to had complete resolution of syncopal symptom. Second most common treatment modality was the treatment of an underlying causative factor (15.8%, n=16), all (100%, n=4) cases of hiatal hernia that were corrected surgically had a complete resolution of swallow syncope.
Conclusions: Swallow syncope is extremely rare, but still needs to be considered during diagnostic workup. Permanent pacemaker implantation is usually the first line treatment, with the exception of underlying gastrointestinal disease, where treatment of underlying diseases has more favourable outcomes.

P573
Lifestyles as risk for cardiovascular diseases in medical students

V Sonja Smiljic[1]
[1]*Medical faculty, Deaprtment of Physiology, Kosovska Mitrovica, Serbia*

The aim of this study was to show the connection between the lifestyles, physical activity, BMI and risk for cardiovascular diseases.
Material and methods: This was a prospective study, which was included 150 medical students within the regular systematic review. Self-administered questionnaires provided family history of hypertension, daily energy expenditure, smoking habit, daily fat intake, and socioeconomic status.
Results: Both genders were equally represented among the students. A significant difference was found between the values of BMI of males and females examined (p<0.001). Male students is more overweight then the female students. The majority of students (41.3%) are feeding in the student cafeteria, almost none are vegan (2.7). Students with higher value of BMI are consuming sweets on daily basis (p=0.006). Only 3.3% drink alcohol every day, energy drinks are consumed daily by 4.7% and coffee by 46.7% of students. There is a statistically significant difference in BMI in smoking (p = 0.019). Students with elevated systolic blood pressure were more likely to be overweight (OR = 1.22), and with a personal history of cardiovascular disease (OR = 3.68). No significant difference was established between physical activity and nutritional status of the students.
Conclusion: The main predictor for cardiovascular disease is overweight, consumed energy drinks and daily fat intake.

P574
Quality of life in patients with transthyretin amyloidosis accompanied by congestive heart failure

A Lovley[1]; A Sikora Kessler[1]; A Yarlas[1]; SD Guthrie[2]; M Pollock[2]; MK White[1]; KL Mccausland[1]

Funding Acknowledgements: Funded by Akcea Therapeutics.

Background: Transthyretin (ATTR) amyloidosis is a rare, systemic, progressive, and fatal disease in which transthyretin proteins misfold and deposit as amyloid in the tissue. Amyloids can infiltrate cardiac tissues, resulting in cardiomyopathy and eventually congestive heart failure (CHF). ATTR amyloidosis is a significantly undiagnosed cause of CHF, possibly representing 15% of patients with CHF with preserved ejection fraction. The burden of ATTR amyloidosis with CHF on quality of life (QOL) is not well known.
Purpose: To examine the QOL burden of patients with ATTR amyloidosis and CHF.
Methods: Adult patients with ATTR amyloidosis were enrolled in an online, longitudinal observational survey study. The current analysis is based on data collected at the initial assessment; patients included were a subset of the full sample who self-reported CHF. Measures administered included the 12-item Kansas City Cardiomyopathy Questionnaire (KCCQ-12), which captures the impact of CHF and its symptoms on patients' functioning and QOL, and the SF-36v2 Health Survey, a measure of generic physical and mental QOL. To examine the burden of ATTR amyloidosis and CHF, SF-36v2 scores for the current sample were compared to scores from age- and gender-matched benchmark samples of the United States general population and of patients with CHF. Cardiac-specific burden was examined by linking KCCQ-12 mean scores to the New York Heart Association (NYHA) Functional Classification.
Results: SF-36v2 scores from 25 patients with ATTR amyloidosis and CHF were significantly lower than that of the general population, particularly for physical

domains (physical functioning and role limitations due to physical health problems), general health, and the physical component summary score (all p < 0.01). Scores were also significantly lower for patients with ATTR amyloidosis and CHF on vitality and social functioning domains (both p<0.05), although not for the mental component summary score (p=0.72). The burden on QOL of patients with ATTR amyloidosis and CHF did not statistically differ from that of the CHF benchmark sample on any SF-36v2 domain or summary scores (all p>0.05). Patients with ATTR amyloidosis and CHF had a mean KCCQ-12 score of 57.8 (standard deviation = 18.6), which corresponds most closely to NYHA class III, marked limitation of physical activity. Conclusion: Patients with ATTR amyloidosis and CHF show significant burden on both generic and cardiac-specific QOL. Furthermore, patients with ATTR amyloidosis exhibit similar QOL burden as patients with CHF, with both patient populations showing significant burden compared to the general population. Therefore, patients with ATTR amyloidosis and CHF would greatly benefit from new treatments targeting physical functioning and overall physical health.

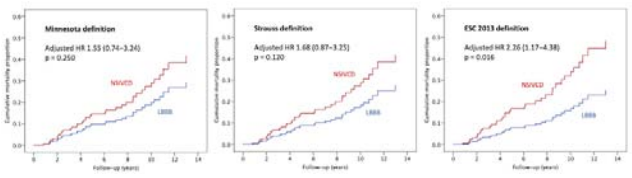
Funding Acknowledgements: The Finnish Cultural Foundation

Background: Left bundle branch block (LBBB) may represent a benign intraventricular conduction disorder, but it is also a well-established marker of structural heart disease. The definition of LBBB is known to influence the response to cardiac resynchronization therapy, but the significance of the definition of LBBB in the general population is not well-known. A broad QRS complex not typical for right bundle branch block (RBBB) or LBBB is defined as non-specific intraventricular conduction delay (NSIVCD), which has also been associated with worse outcome. The definition of LBBB influences the number of subjects classified as NSIVCD.
Purpose: We determined the prevalence and prognostic impact of three different definitions of LBBB and of NSIVCD in the standard 12-lead ECG in a Finnish population cohort.
Methods: Data were collected from a large nationally representative (random sample) health examination survey of 6,299 subjects. Three different definitions of LBBB were applied: Minnesota, Strauss et al and ESC 2013 definition. NSIVCD was defined as QRS duration ≥120 ms not meeting RBBB or LBBB criteria. Subjects were followed up for 16.5 years with primary study end points of all-cause and cardiovascular (CV) death.
Results: Minnesota, Strauss and ESC 2013 definitions identified LBBB in 59 (0.9%), 47 (0.7%) and 50 subjects (0.8%), and NSIVCD in 33 (0.5%), 45 (0.7%), 42 (0.7%) subjects, respectively. Chronic heart failure was present in 20.7% and NYHA class II-IV in 34.8% of subjects. After adjustment for age and gender, the hazard ratio (HR) for CV mortality for different definitions of LBBB was 1.93 (p = 0.003) for Minnesota, 1.62 (p = 0.058) for Strauss and 1.56 (p = 0.079) for ESC 2013 criteria. The HR for CV mortality for different definitions of NSIVCD was 2.83 (p = 0.004) for Minnesota, 3.18 (p < 0.001) for Strauss, and 3.47 (p < 0.001) for ESC 2013 criteria. In multivariate analysis, NSIVCD remained as an independent predictor of all-cause (HR 2.02, p = 0.003) and CV mortality (HR 3.39, p < 0.001); the ESC 2013 definition had the highest HR. Compared to LBBB, subjects with NSIVCD were associated with increased CV mortality only for the ESC 2013 definition of LBBB (HR 2.26, p = 0.016).
Conclusions: The definition of LBBB determines the number of subjects in the general population. Regarding mortality, the ESC 2013 definition of LBBB identifies NSIVCD subjects with the worst outcome better than two other LBBB criteria.



Multivariate Cox curves for def. of LBBB

P576

Evolution of diastolic dysfunction of patients with acquired heart diseases in the postoperative period

I I Irina Averina[1]; OL Bockeria[1]; MY Mironenko[1]
[1]Bakoulev Center for Cardiovascular Surgery RAMS, Cardiosurgical , Moscow, Russian Federation

Background: There are only a few studies concerning diastolic dysfunction (DD) in perioperative period. We examined the development of left ventricular DD after cardiac surgery.
Purpose: Assessment of DD dynamic, revealing of the newly emerging DD in patients with acquired heart diseases in the postoperative period
Methods: The study involved 112 patients (90 men and 22 women) with aortic and mitral valve diseases. The median age was 51 years Q1-Q3 (35-57). All patients underwent echocardiography, tissue Doppler, speckle tracking prior to surgery, in the early postoperative period (8 - 14 days) and 12 - 36 months after surgery. The patients were divided into group 0 - patients without complications, group 1 - patients with heart failure with preserved ejection fraction (HFpEF) after surgery. Initially, patients with DD 1, 2, 3 types were identified. DD was determined using the following parameters: septal velocity es < 7 cm/sec, lateral el < 10 cm/sec, average E/e ratio > 14, left atrial (LA) volume index > 34 ml/m2, peak tricuspid regurgitation (TR) velocity> 2.8 m/sec and appropriate /A ratio.

Results: Initially, patients with DD had shortness of breath (80% of patients), high blood pressure (70%), atrial fibrillation (52%). The worsening of diastolic function and appearance of HFpEF after surgery was associated with: dyspnea, severe pulmonary edema, prolonged ventilation, atrial fibrillation, reduced O2 consumption, encephalopathy, renal dysfunction. Diastolic function deteriorated in 15 patients (19%) after surgery. Normal diastolic function was determined primarily in 34 of 112 patients. DD occurred in 9 (26.5%) of 34 patients with originally normal diastolic function and was due to surgery. In these patients, the septal diastolic velocity es decreased immediately after surgery and continued to reduce progressively from 8.50± 0.71 to 4.60±0.53 cm/sec (p=0.005) in the long-term period. LA volume index declined from 28.49±6.9 to 13.8±5.4 ml/m2 (p=0.05), the lateral el increased from 6.9± 1.8 to 11±2.3 cm/sec (p=0.037) in patients with type 1 DD after surgery. The lateral el also significantly enhanced from 6.48±1.5 to 8.46±2.8 cm/sec (p= 0.0007), the septal es increased less from 5.3±1.5 to 6.4±2.0 cm/sec (p= 0.004), the E/e ratio decreased in the group with type 2 DD. A falling in the E/A ratio from 2.6 ± 0.6 to 1.6 ± 0.6 (p = 0.007) was typical for type 3 DD. Thus, the septal function has not improved to the normal indicators. The lateral el accomplished to normal from 6.5 ± 1.5 cm/sec to 10 ± 2.8 cm/sec (p = 0.0001) only in long-term period.
Conclusions: Patients with HFpEF after surgery have a severe clinical picture. There was positive diastolic function dynamics after surgery during 1 - 2 years, but the septal function did not reach the normal values. The emerging and worsening of diastolic function was due to damage of the septum function and subsequent progressive decreasing in the long-term after surgery.

P577

Correlation between the occurrence of cardiac arrhythmias and symptoms of heart failure in pregnant women with underweight

S Salma Hisamo[1]; A Prystrom[1]; E Gaishun[2]
[1]Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus; *[2]1st City Hospital, Minsk, Belarus*

Purpose: To evaluate the correlation between the occurrence of cardiac arrhythmias and symptoms of heart failure in pregnant women with underweight.
Methods: We examined 90 pregnant women in the II-III trimester of pregnancy. The first group consisted of 45 (50%) pregnant women with body mass deficiency (body mass index less than 18.5), the second group included 45 (50%) pregnant women with normal body weight (body mass index 18.6-24.9). The median age of the patients included in the study in 1st group was 27.4±1.2 years, in 2nd group it was 26.8±1.9 years. In order to asses the state of the cardiovascular system, all patients underwent echocardiography, 24-hours ECG Holter monitoring, the 6-min walk test (6 MWT).
Results: According to echocardiography, mitral valve prolapse was detected in 92% of pregnant women with underweight and in 30% of pregnant women with normal body weight. In pregnant women with a deficiency of body weight, mitral regurgitation of the 1st degree (35.6% vs 17.8%, p<0.05) and 2nd degrees (48.9% vs 8.9%, p<0.05) were more often registered. According to the results of ECG monitoring, ventricular premature beats were significantly more frequently recorded in pregnant patients with a body weight deficit (37.8% vs 6.7%, p<0.05). Episodes of ventricular tachycardia were recorded in 11.1% of pregnant patients with underweight. In the group of patients with underweight, more patients with supraventricular extrasystoles (71.1% vs 33.3%, p<0.05) and episodes of supraventricular

tachycardia (62.2% vs 20%, p<0.05) were identified. According to the 6 MWT, class 1st by NYHA (48.9% vs 77.8%, p<0.05), 2nd class (46.7% vs 20%, p<0.05) and 3d class (4.4% vs 2.2%, p<0.05).
Conclusions: In pregnant patients with a deficiency of body weight, mitral valve prolapse with mitral regurgitation, ventricular and supraventricular extrasystoles, supraventricular tachycardia and the severity of heart failure were significantly more common. The correlation between the number of rhythm disturbances and the severity of heart failure was traced by NYHA (r=0.45, p=0.042).

P578
CHA2DS2-VASc score and B-type natriuretic peptide in predicting stroke, transient ischemic attack,thromboembolism and death in at-risk patients without atrial fibrillation-the STOP-HF experience

B Kerr[1]; K Mcdonald[1]; M Ledwidge[1]; C Watson[1]; J Gallagher[1]
[1]St Vincent's healthcare group/St Michaels Hospital , STOP-HF unit, Department of Cardiology, Dublin, Ireland

Background In recent years, use of the CHA2DS2-VASc score in predicting stroke/TIA has extended beyond AF. It is recognized that the cluster of multiple stroke risk factors included within the CHA2DS2-VASc score increases the risk of stroke/TIA whether or not AF has been defined. Similarly, natriuretic peptides have gained interest as a marker of cardiovascular risk. Increased blood levels of natriuretic peptides have been repeatedly associated with cardioembolic stroke.
Purpose: To determine the accuracy of the CHA2DS2-VASc score and BNP separately for predicting stroke or transient ischaemic attack (TIA) and the composite endpoint of Stroke/TIA/Thromboembolism (TE) and Death in patients without a history of atrial fibrillation or flutter, and to evaluate the incremental benefit of adding BNP to CHA2DS2-VASc for predicting stroke or TIA, in a community-based population.
Methods The study included 801 patients without known AF enrolled in the STOP HF follow-up study between 2012 and 2017. The end points measured were stroke/TIA and the composite end point of ischaemic stroke/TIA/TE and death.
Results: The study population (N=801) had a mean age (SD) of 64.4 years (10.4) with 381 (47.6%) male. The median B-type Natriuretic peptide was 24pg/ml (Interquartile range:12- 52). A total of 33 (4.1%) patients had a CHA2DS2-VASc of 1, while 175 (21.9%), 282 (35.2%), 186 (23.2%), 94 (11.7%), 31 (3.9%) had CHA2DS2-VASc score of 1,2,3, 4 and ≥5 respectively.
The composite endpoint of stroke/TIA/TE/Death occurred in 115 (14.4%) of the population. The incidence of stroke/TIA/TE and death occurred more frequently as the CHA2DS2-VASc score increased. The outcome occurred in 1 (3%), 15(8.6%), 33 (11.7%) and 35 (18.8%) 19 (20.2%), 12 (38.7%) of those with a CHA2DS2-VASc score of 0, 1, 2, 3, 4 and ≥5 respectively. Separately, at baseline, both the CHADS2-Vasc score and the BNP predicted Stroke/TIA. The adjusted odds ratio for Stroke/TIA using the CHADS2-Vasc score and the baseline BNP were 2.05 (95% CI, 1.43 -2.93) and 1.33 (95% CI, 0.88- 2.0) respectively. Both the CHA2DS2-VASc score and the BNP had a respectable discrimination performance in this group with a c-statistic of 0.72 for the former and 0.67 for the latter. Adding the BNP to the CHADS2Vasc score improved the stroke/TIA predictive value further, producing a c-statistic of 0.75.
The adjusted odds ratios for Stroke/TIA, TE and Death using the CHA2DS2-VASc score and the baseline BNP were 1.35 (95% CI, 1.12 -1.63) and 1.5 (95% CI, 1.21-1.87) respectively (both p<0.01). Addition of BNP to the CHA2DS2-VASc improved c- statistics from 0.64 to 0.68 for stroke/TIA/TE and death.
Conclusion: Both the CHA2DS2-VASc tool and BNP predict Stroke and TIA and the composite end-point of stroke/TIA/TE and death in patients with out atrial fibrillation at baseline. The predictive value of CHA2DS2-VASc is further enhanced with the addition of BNP for outcome measures.

Funding Acknowledgements: GINOP-2.3.2-15-2016-00039

Background: Left ventricular non-compaction cardiomyopathy (LVNC) is characterized by prominent left ventricular trabeculae and deep inter-trabecular recesses. The myocardial wall is often thickened with a thin, compacted epicardial layer and a thickened endocardial layer. In some patients, LVNC is associated with left ventricular dilatation and systolic dysfunction. LVNC is frequently familial and genetic studies identified causative mutations in genes encoding taffazin, alpha dystrobrevin, ZASP, actin, and lamin A/C.
Aims: We performed genetic analysis of Hungarian patients with LVNC using next-generation sequencing.
Patients and methods: We examined 9 patients with non-compact cardiomyopathy (3 males, avg. age 58±20 years). Five of the patients were in the dilated phase of LVNC. Using next-generation sequencing we screened 103 known causative cardiomyopathy genes covering a target region of 500.000 base pairs.
Results: Pathogenic or likely pathogenic variants were identified in 6 patients (6/9, 67%). Two of these variants were identified in the beta myosin heavy chain gene (MYH7, Gly181Val, Tyr283Cys), and four in the titin gene (TTN, Gln34219*, Glu16261fs, Glu19847fs, Lys22311fs). TTN variants (all novel) were truncating variants, mostly affecting LVNC patients in the dilated phase (3/5, 60%).
Summary: Our results suggest that pathogenic variants can be found in a large proportion of Hungarian patients with LVNC. These variants mostly affect the titin gene and are associated with LVNC in dilated phase.

P580
It's not so rare to have a rare disease- single centre experience with wild type transthyretin amyloid cardiomyopathy

M Monika Gawor[1]; A Sioma[1]; Ł Mazurkiewicz[1]; P Michalek[2]; M Marczak[3]; A Teresinska[4]; J Grzybowski[1]
[1]Institute of Cardiology, Department of Cardiomyopathies, Warsaw, Poland; *[2]Institute of Cardiology, Emergency Room Rapid Diagnosis Department, Warsaw, Poland*; *[3]Institute of Cardiology, CMR Unit, Warsaw, Poland*; *[4]Institute of Cardiology, Department of Nuclear Medicine, Warsaw, Poland*

Background: Transthyretin (TTR) amyloid cardiomyopathy is caused by mutations in the TTR gene or by the deposition of wild-type TTR protein (wild type TTR amyloidosis-ATTRwt). According to literature, ATTRwt may present as heart failure with preserved ejection fraction, severe aortic stenosis, hypertrophic cardiomyopathy (HCM) or resctrictive cardiomyopathy.
Purpose: We describe the clinical heterogeneity of ATTRwt patients from our centre diagnosed in 2018.
Methods: All patients were diagnosed histologically and/or non-invasively (intensive cardiac uptake at 99mTc-DPD scintigraphy -Figure 1C). Light chain amyloidosis and mutations in TTR gene were excluded.
Results: Six patients (5 males) were diagnosed with ATTRwt (Table 1). Age of onset differed among the patients. Characteristic clinical features included cardiomyopathy with increased left and right ventricular wall thickness. Only one patient had

Table1

Patient	1.	2.	3.	4.	5.	6.

Paediatric DCM is characterised by rapid progression and high mortality. More than 70 genes have been associated with DCM, but new genes and mechanisms are still being discovered. Recently a novel form of syndromic DCM associated with mild ectodermal abnormalities was described in five children from a large consanguineous Arab-Christian pedigree who were homozygous for a loss-of-function variant in the PPP1R13L gene (Falik-Zaccai 2017).
Purpose. To expand the phenotypic spectrum of biallelic loss-of-function variants in the PPP1R13L gene using clinical data from three unrelated families of different ethnic backgrounds.
Methods. DNA samples extracted from venous blood or formalin-fixed paraffin-embedded post mortem tissue from probands with DCM were subjected to either whole genome sequencing (WGS) through The 100,000 Genomes Project Protocol v3 or whole exome sequencing (WES). Cases were brought together using GeneMatcher, a tool for connecting investigators with an interest in the same gene. Detailed clinical evaluation and archive clinical data analysis were performed for the 3 families.
Results. Biallelic loss-of-function variants in the PPP1R13L gene were identified in 3 children from 2 unrelated DCM families. A homozygous missense variant c.2167A>C p.(T723P) was identified in a proband3. This variant affects a highly conserved ANK2 repeat within iASPP, and was predicted as probably damaging by in silico prediction tools. This patient had a mild learning disability and no ectodermal findings. Clinical and genetic findings are summarised in Table.
Conclusion. Loss-of-function mutations in the PPP1R13L gene cause an autosomal recessive form of severe paediatric DCM with variable extra-cardiac involvement. This is the first genetic form of DCM where an abnormal inflammatory response appears to play a key role in cardiomyopathy pathogenesis. These additional presentations provide sufficient evidence for a robust gene-disease association and the PPP1R13L gene should be included in targeted panel-based genetic testing for DCM.

CD68+ and M2 macrophage infiltration in the human brain following myocardial infarction

B Kim[1]; A Gombozhapova[2]; M Rebenkova[2]; Y Rogovskaya[2]; Y Prohorova[3]; Y Kzhyshkowska[1]; V Ryabov[2]
[1]National Research Tomsk State University, Tomsk, Russian Federation; *[2]State Research Institute of Cardiology of Tomsk, Tomsk, Russian Federation*; *[3]Siberian State Medical University, Tomsk, Russian Federation*

Background. Myocardial infarction (MI) remains the leading cause of mortality all over the world. The development of acute organic brain syndrome significantly increase lethality rate. However pathogenesis of acute organic brain syndrome is less clear. One of available mechanism is low-grade neuroinflammation. Glial macrophages are key cells which may perform inflammation in the brain.
This study investigated the temporal dynamics of common macrophage population and M2 macrophages in brain following fatal MI type 1.
Materials and Methods. The study included 31 patients with fatal MI type I. The control group comprised 10 persons of 18-40 age group who died from injuries incompatible with life. Patients with MI were divided into two groups. Group 1 comprised patients who died during the first 72 hours of MI; group 2 comprised patients who died on days 4-28. Macrophage infiltration in the brain was assessed by immunohistochemical analysis. We used CD68 as a marker for the cells of the macrophage lineage and CD163, CD206, stabilin-1 as M2-like macrophage biomarkers.
Results. The number of CD68+ macrophages in the group 1 was significantly higher than in the control group. In the group 2 the intensity CD68+ cells infiltration was lower than in the group 1 and higher than in the control group. Small number of CD163+, CD206+ stabilin-1+ M2 macrophages were observed in all three groups. There were no significant differences in the number of CD163+, CD206+ and stabilin-1+ cells between group 1 and group 2. Correlation analysis revealed the presence of positive correlation between the number of CD68+ macrophages in the infarct, peri-infarct, and non-infarct areas of the myocardium and the number of CD68+ macrophages in the brain in patients with MI. There were not correlations between the number of CD68 + and stabilin-1+ cells and the presence of diabetes mellitus, history of stroke, history of MI, and pre-infarction angina.

Conclusions. The number of CD68+ macrophages in brain significantly increased during the first three days of MI. The number of brain CD163+, CD206+, stabilin-1+ M2 macrophages did not differ between groups. We observed a positive correlation between the number of CD68+ macrophages in brain and myocardium following MI.

P583
Circulating pro-inflammatory intermediate monocytes relate to right ventricular pressure in heart failure of adult congenital heart disease

LM Wienecke[1]; D Fraccarollo[1]; P Galuppo[1]; F Kockelmann[1]; J Treptau[1]; J Bauersachs[1]; M Westhoff-Bleck[1]
[1]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany

Funding Acknowledgements: Deutsche Herzstiftung e.V. (German Heart Foundation)

Background: Heart failure (HF) is a leading cause of mortality in adults with congenital heart disease (ACHD). ACHD is characterized by predominant right heart disease. In non-congenital heart disease inflammation and its mediators such as monocytes/ macrophages play an important pathophysiological role in HF. We aimed to evaluate the role of monocyte subsets in ACHD-HF.
Methods: This cross-sectional study includes 209 ACHD outpatients (mean age: 35.3±11.0 years; NYHA class I/II/III-IV 58.3%/19.6%/13%; male: 59.8%) and 21 healthy controls (age: 29.8±12.6 years; male: 47.6%). Patients with clinical signs of infection, inflammatory diseases or malignancies were excluded. Multivariate analysis was used to relate monocyte subsets to NYHA class and echocardiographically derived parameters of right and left ventricular function.
Results: Compared to control, ACHD had significantly higher circulating levels of HLA-DR+CD14++CD16+ intermediate monocytes (43.6±1.7 vs. 23.97±3.3 cells/μL; p<0.001). Independent predictors of NYHA class were intermediate monocytes (p=0.022), plasma noradrenaline (p=0.002), albumin (p=0.001) and NT-proBNP (p<0.001). NT-proBNP was independently associated with reduced left (p<0.001) and right (p<0.001) ventricular function, diastolic dysfunction (p<0.04) and vena cava diameter (p<0.02).
Elevated right ventricular pressure (upper tertial >35 mmHg) was independently associated with both, higher intermediate monocyte counts (OR 1.36; 95% CI: 1.13–1.62; p=0.001) and lower oxygen saturation (OR 0.8; 95% CI: 0.7–0.92; p=0.001).
Conclusions: Right ventricular pressure and low oxygen saturation are related to elevated intermediate monocytes, suggesting an important link between inflammation and HF in ACHD. Intermediate monocytes represent a promising biomarker in ACHD.

P585
Association between NT-proBNP and common carotid artery intima-media thickness in young healthy adults

AG Sorokina[1]; A Anna Alexandrova[1]; E Borisov[1]; Y Orlova[1]; I Strazhesko[1]
[1]M.V. Lomonosov Moscow State University, Moscow, Russian Federation

The intima-media thickness (IMT) of the common carotid artery is considered as a predictor of cardiovascular events and is associated with cardiovascular risk factors. Elevated serum level of N-terminal fragment of B-type natriuretic peptide (NT-proBNP) is also well-known risk factor for future cardiovascular events. The association between NT-proBNP and IMT is still unclear, especially in young healthy people without hypertension. The aim of this study was to investigate the association between NT-proBNP and IMT in young apparently healthy adults.
Material and methods: We investigated 282 healthy young adults, mean age 18,5±1,7 years, 47% male. NT-proBNP, blood pressure (BP), body mass index, fasting plasma glucose, glycated haemoglobin (1), lipid profile, growth hormone (GH), C-reactive protein, interleukin−6 (IL-6) were evaluated. IMT was measured with High-resolution B-mode carotid ultrasonography.
Results: IMT was 0,60±0,10 mm (M+ SD), NT-proBNP level was 58, 61+2,39 pg/ml (M+m). Multivariate regression analysis showed positive association between IMT and NT-proBNP, systolic BP, 1 and negative association between IMT and IL-6, GH (see table).
Conclusions: IMT of the common carotid artery is appeared to be associated with serum NT-proBNP level even in the young people with normal blood pressure.

Predictor	*β*	Standard Error	p
Systolic BP	0,003±0,001	0,111	0,009
NT-proBNP	0,001±0,0004	0,100	0,013
IL-6	-0,002±0,001	0,073	0,032
1	0,061±0,016	0,207	<0,001
GH	-0,013±0,006	0,071	0,035

Alterations of serum metabolites in patients with endothelium dysfunction associated with cardiovascular diseases.

M Maria Kozhevnikova[1]; EO Korobkova[1]; AV Kuharenko[1]; NE Moskaleva[1]; EV Larcova[1]; SA Appolonova[1]; IS Ilgisonis[1]; GA Shakaryants[1]; EV Privalova[1]; YUN Belenkov[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Purpose: The aim of the study was to identify the metabolic features of endothelial dysfunction associated with cardiovascular diseases (CVD).
METHODS Blood samples from two groups of individuals (n=51): 36 patients with cardiovascular diseases and 15 controls was analyzed. Endothelial function was evaluated by photoplethysmography (PPG): occlusion index, stiffness index (m/s). Untarget metabolic profiling was performed by gas-chromatography quadruple mass-spectrometry (GC\MS) and target analysis were made by liquid chromatography -triple quadruple mass-spectrometry (LC\MS\MS). Untarget results were analyzed by multivariate statistics with SIMCA-P. Statistical analyses for target data were performed with STATISTICA® 8.0. The distribution of the variables was checked with the Shapiro-Wilk test. Unpaired t-test for normally distributed and Mann-Whitney U-test for nonnormaly distributed metabolites were used to compare differences across groups.RESULTS A total of 106 metabolites were identified. Orthogonal projection to latent structurediscriminant analysis (OPLS-DA) identified metabolic clusters related to the studied groups (R2 0,991 and Q2 0,245). According to the results of the target analysis, statistically significant differences (p <0 05) of proteins, such as cysteine, alanine, valine, leucine, serine, threonine, proline, aspartic acid between ED group and controls are revealed. This alterations may be associated with impaired metabolic pathways of cysteine and glutathione synthesis. The levels of some acylcarnitines in patients with ED, which are caused by impaired energy metabolism, are elevated.
CONCLUSIONS We observed significant alterations of serum metabolites in patients with endothelium dysfunction. The alteration in phospholipids and cysteine metabolic pathways was revealed. Acylcarnitines were strongly related to ED.

Clinical Cases

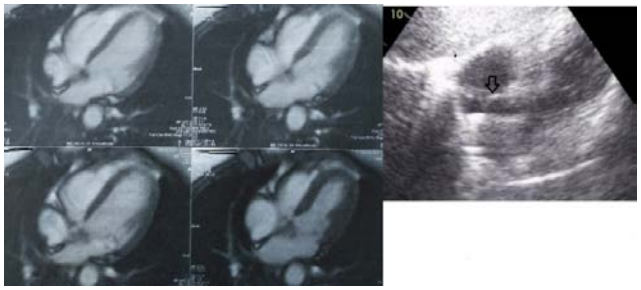
A rare case of atrial septal defect with mitral valve papillary fibroelastoma

A Filias[1]; D Stathopoulou[1]
[1]St Andrews General Hospital of Patras, Cardiology, Patras, Greece

We report on a 40-years old female patient who referred at our department for further investigation after a neurological examination (asymptomatic). She has a history of smoking, hepatitis C, drug use and ischemic stroke (3 years ago).
Taking into consideration the history of ischemic stroke, we performed ecg, 24hours holter monitoring and transthoracic echocardiography (TTE) to exclude arrhythmias, thrombus and septal defect. Ecg and holter were unremarkable. TTE revealed atrial septal aneurysm, patent foramen ovale (PFO) and a small echogenic mobile formation on the atrial surface of the posterior mitral leaflet. The patient was sent for a transesophageal echocardiography test which confirmed these findings. The patient underwent cardiac MRI which also confirmed PFO with left to right flow, without RV or LV dilation, without RV volume overload, and a small mobile elongated formation (11mm) with minor local turbulent jet. On SSFP sequences the signal was low. LGE did not show any visible nodule/formation.
So, was the atrial septal defect or the mobile lesion responsible for the ischemic stroke? Is this formation vegetation, myxoma or papillary fibroelastoma?
Our patient has no clinical signs of possible endocarditis. From the images we do not have significant mitral regurgitation and the mass is not attached on the edge of



Fibroelastoma-asd

the leaflet (in favor of endocarditis). On the other hand myxomas tend to be larger and have multi-focal LGE. So, from the TEE and the MRI images the most probable diagnosis is mitral valve papillary fibroelastoma (small size, minor MR, low signal on SSFP, high mobility).
From bibliography fibroelastomas are more common in aortic valve. There are cases with atrial septal defect associated with aortic valve fibroelastomas but very few associated with mitral valve fibroelastomas. Papillary fibroelastoma in the left heart which is mobile and/or larger than 10mm is treated surgically (in asymptomatic patients). Atrial septal defect with embolism without other cause should be considered for intervention. Because our patient is symptomatic (ischemic stroke) we decided that surgery (PFO closure and fibroelastoma resection) is the most suitable solution and the operation has been set for the next month.

Belated diagnosis of non-ischemic dilated cardiomyopathy in a patient with previous bypass surgery

MA Maria Anna Bazmpani[1]; G Tziatzios[1]; D Konstantinou[1]; H Karvounis[1]; T Karamitsos[1]
[1]Ahepa University Hospital, 1st Cardiology Department, Thessaloniki, Greece

Introduction and Background: Accurate identification of heart failure etiology is important for risk stratification and treatment planning. Cardiac magnetic resonance (CMR) is a well-established imaging modality for investigating heart failure etiology primarily due to its ability to provide tissue characterisation.
Case report description: A 67-year-old man with previous bypass surgery (2009) but no history of myocardial infarction presented with decompensated heart failure (NYHA class III). He had no evidence of ischemia on myocardial scintigraphy. His past history included dyslipidemia and he was an ex-smoker. Twenty years ago, left bundle branch block was found on ECG (panel A). At that point the patient had a mildly dilated left ventricle (LV) with preserved ejection fraction on echo. A second angiogram eight years ago revealed three-vessel coronary artery disease and surgical revascularization was performed.Description of the problem, procedures and patient management: Despite a technically successful bypass surgery, the patient continued to complain for breathlessness on exertion with further LV dilation and systolic dysfunction on echo. Multiple SPECT scans over the past 7 years failed to demonstrate any degree of myocardial ischemia. A CMR study showed a markedly dilated LV with severely reduced ejection fraction (EF 20%), global hypokinesis and dyssynchrony, and moderate mitral regurgitation. Late gadolinium enhancement showed no previous myocardial infarction. Some patchy midwall fibrosis was noted in the inferior wall (panel B) and septum (panel C). A diagnosis of non-ischemic dilated cardiomyopathy was entertained which together with functional mitral regurgitation could explain patient's heart failure symptoms. Patient's initial treatment included small doses of ACE inhibitor, b-blocker and mineralocorticoid receptor. The patient remained symptomatic (NYHA II) despite uptitration and fine-tuning of his HF treatment with the replacement of ACE inhibitor by sacubitril/valsartan. We therefore proceeded to cardiac resynchronization defibrillator therapy. An echocardiogram post CRT-D implantation revealed significant increase in LV stroke volume and ejection fraction rendering the patient an excellent responder to cardiac resynchronization therapy.
Conclusions and implications for clinical practice: The ischemic etiology of heart failure should be questioned in a patient who continuous to have symptoms despite complete and successful revascularization for coronary artery disease (CAD), or if the extent of CAD is not sufficient to explain the degree of systolic dysfunction. CMR offers unique insights into the etiological diagnosis of heart failure and may have a decisive role for treatment planning.

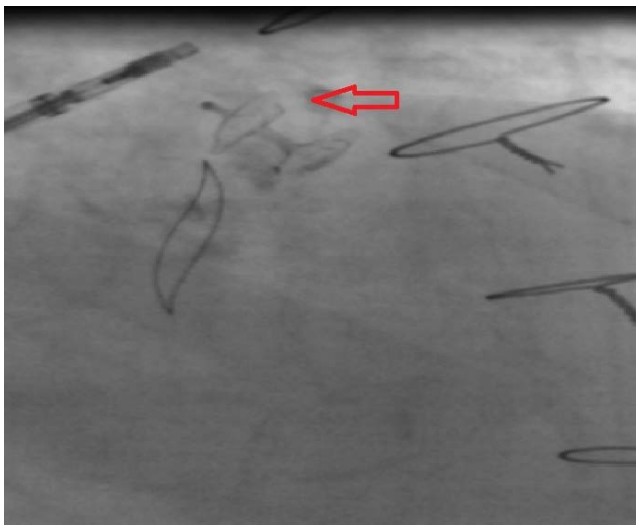
Successful percutaneous transcatheter closure of a prosthetic mitral paravalvular leak causing heart failure

R Gal[1]; G Fontos[2]; A Temesvari[2]; M Vertesaljai[2]; L Ablonczy[2]; B Magyari[3]; J Keller[3]; L Toth[4]; K Toth[1]; T Habon[1]
[1]University of Pecs, Division of Cardiology and Angiology, 1st Department of Medicine, Medical School, Pecs, Hungary; *[2]Gottsegen Gyorgy Hungarian Institute of Cardiology, Budapest, Hungary*; *[3]University of Pecs, Heart Institute, Medical School, Pecs, Hungary*; *[4]University of Pecs, Department of Radiology, Medical School, Pecs, Hungary*

Introduction: Paravalvular leak (PVL) is a known complication after valvular replacement. Although most paravalvular leaks are asymptomatic (depending on its size and location), 1–5% of patients exhibit serious clinical consequences, including hemolysis, infective endocarditis or heart failure.
Case report: A 70-year old male patient with a history of diabetes, significant coronary artery disease and severe mitral insufficiency was treated with ACBG (4x) and mitral valve replacement (Sorin 27 pericarbon bioprosthesis) at 2016. Transesophageal echocardiography (TOE) was performed due to postoperative fever, but it showed a well-functioning bioprosthesis without complications. During the 2-year follow-up the outpatient transthoracic echocardiographies (EF: 55%) showed preserved ejection fraction and normally functioning mitral bioprosthesis. In 2018 the patient was hospitalized twice with heart failure. TTE and TOE revealed previously unknown left ventricle dysfunction (EF: 40%), mild central mitral valve regurgitation and lateral paravalvular leak (outside the sewing ring) with 9x5 mm jet diameter. Lab tests didn't show hemolysis or elevated inflammatory parameters. Cardiac MRI revealed viable myocardium and confirmed the anterolateral paravalvular leak with 30 ml regurgitant volume. Coronarograpy was performed without stenosis enabling intervention. After that the PVL was successfully treated with transseptal, catheter closure technique (Occlutech PVL occluder - 12x5 mm). Follow-up TTE and chest X-ray showed optimal position of the device without significant regurgitation. After the intervention the patient's condition improved, he was in NYHA class II. stage at the last outpatient visit.
Conclusion: Our case report demonstrated, that PVL can be undiagnosed or develop late after surgery. Transcatheter PVL closure is a safe, effective and less invasive alternative to surgical re-intervention.



Mitral PVL occluder

Significant reduction of insulin dose after administration of sacubitril/valsartan in the patient with heart failure due to dilated cardiomyopathy, a case report.

M Marketa Hegarova[1]; I Malek[1]; V Melenovsky[1]; J Kautzner[1]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Department of Cardiology, Prague, Czechia*

Background: Diabetes is considered to be an independent risk factor for heart failure progression. Sacubitril/valsartan (S/V) is able to augment glucagon-like peptid-1 (GLP-1) pathway, because of GLP 1 receptor analogues are degraded not only by dipeptidyl peptidase 4, but also by neprilysin. In adition, it has been documented that S/V improves peripheral insulin sensitivity. With the wider use of S/V fot the heart failure treatment, it turns out that S/V appears to have the potential to improve diabetes compensation. We present a case report with a significant reduction in insulin doses with a subsequent weight reduction after S/V treatment in patient with heart failure due to dilated cardiomyopathy (DCM).
Case report :
We present case of 61-old man with a type 2 diabetes on insulin and metformin treatment, with diagnosis of DCM (documented since 2010), with normal coronary angiography, with severe left ventricle systolic dysfunction , EF 20%, mild mitral regurgitation and sustained good right ventricular function. He has been treated for the last four years in our out-patient heart failure department. We have up-titrated doses of heart failure medication. Achieved medication: ramipril 7,5mg, spironolacton 50mg, metoprolol 100mg, FSM 60mg per day. By the end of 2017, the patient worsened clinically to NYHA class III. In 2/2018 we replaced ramipril with S/V in dose 49/51mg twice a day. Already after two months of treatment with S/V, there was not only clinical improvement, but also a reduction in the long-term insulin dose by 35%. For the next 3 months the patient lost 4kg, BMI fell from 34,7 to 33,5. In November 2018 the patient was in NYHA class II, with total weight loss of 10 kg and BMI of 31,7. Weight loss did not occur due to diet or lifestyle change.
Conclusion: We present the clinical case, where the introduction of Sacubitril/valsartan treatment led not only to the clinical improvement of heart failure but also to a favorable metabolic effect in patient with type 2 diabetes. Treatment with S/V resulted in reduced insulin dose requirements and significant weight loss. Based on previous experience, it would be beneficial to initiate a study with S/V in patients with heart failure and diabetes.

[2]*Klinikum Passau, Internal Medicine and Cardiology, Passau, Germany*;
[3]*Semmelweis University, Budapest, Hungary*

Background: Heart failure is even today a life-limiting disease throughout the world. Mortality and morbidity of heart failure with reduced ejection fraction (HFrEF) is comparable with malignancies, despite the available pharmacological and non-pharmacological treatment possibilities. Over the last few years, a new, very promising family of substances – angiotensin receptor neprilysin inhibitors (ARNi) – has appeared. Sacubitril/valsartan, first-in-class of ARNi, has been proven effective, surpassing all expectations in a PARADIGM HF study published in 2014. Based on the evidence from this study, the current ESC guidelines for the diagnosis and treatment of acute and chronic heart failure published in 2016 recommend the use of the drug for stable HFrEF patients. However the drug became available worldwide very recently.
Cases: We report the cases of 9 patients (NYHA: 3.3±0.5; LVEF: 26.2±3.7%; age: 51.3±13.7years; male: 88.9%; ischemic: 55.6%; atrial fibrillation: 33.3%; diabetes: 11.1%; systolic blood pressure: 103.9±8.3mmHg; eGFR: 54.3±16.1ml/min/1.73m^2) who were suffering from advanced HFrEF in spite of optimized therapy (ACEi/ARB: 100%; at target dose (TD) of ACEi/ARB: 55.5%; βB: 100%; at TD of BB: 77.8%; MRA: 100%; ICD: 100%; CRT-D: 22.2%) and were referred to our heart failure clinic for heart transplantation (HTx) evaluation. After baseline non-invasive (6 minute-walking test (6MWT), cardiopulmonary exercise test) and invasive evaluation (right heart catheterization) for heart transplantation (NTproBNP: 3608.5±2375.5pg/ml; peakVO2: 11.1±2.1ml/kg/min; 6MWT: 424.2±162.9m; CI: 1.83±0.44l/min/m^2) sacubitril/valsartan was initiated and successfully titrated to the maximal tolerated level (275mg±116.5mg/die). After 3 months of follow-up the non-invasive and invasive tests were reapplied showing significant improvement in the clinical condition (NTproBNP: 1589.9±692.9pg/ml; peakVO2: 13.8±3,31ml/kg/min; 6MWT: 500.7±71.5m; CI: 2.91±0.1l/min/m^2). Based on these results only 3 out of 9 patients remained eligible for HTx and were referred to the HTx Committee.
Conclusions: HFrEF even nowadays is a deadly disease. In case of its progression in spite of optimized therapy and without the presence of any contraindication, HTx should be performed. However the time on the waiting list can be quite long, potentially resulting several complication. Based on our preliminary experience, with sacubitril/valsartan as part of a complex heart failure treatment, significant improvement could be achieved even among HTx candidates, which improvement in the clinical status could make the HTx temporary unnecessary or the time on the waiting list safer.

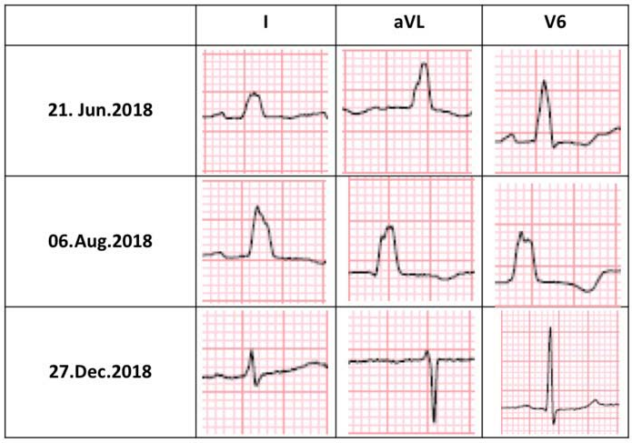
P592

Reversible left bundle branch block after sacubitril/valsartan in patient with severe heart failure

PL Lin[1]; YM Liu[1]; YH Lee[1]
[1]*Mackay Memorial Hospital, cardiovascular center, Taipei, Taiwan, Province of China*

Funding Acknowledgements: no

Background A complete left bundle branch block (CLBBB) is often encountered in patients with structural heart disease. Currently, a severely reduced left ventricular (LV) function with CLBBB can be treated with cardiac resynchronization therapy (CRT). We report a case with reversible CLBBB following sacubitril/valsartan.
Case report A 38-year-old woman presented herself at our hospital with increasing complaints of dyspnea on exertion. Electrocardiogram (ECG) demonstrated sinus rhythm, 115 bpm, with complete LBBB and QRS duration of 133 ms. No previous ECGs were present. Laboratory findings were non-contributory expect high NT-pro BNP (852 pg/mL). Echocardiography showed left ventricular (LV) dyssynchrony and severely compromised LV function with a LVEF ejection of 33%. 99mTC MIBI scintigraphy revealed diffusedly reduced uptake of the myocardium, most notably anterior wall and apex. Coronary angiography showed no significant coronary artery disease. Result was consisted with non-ischemic cardiomyopathy. The patient was started with standard heart failure (HF) medications including angiotensin II receptor blocker, aldosterone antagonist, diuretic and beta blocker. After beta blocker was continued for 2 weeks, her resting heart rate (HR) was around 100 bpm then Ivabradine was administered. After Ivabradine was administered for 1 month, repeated ECG showed sinus bradycardia (HR 57 bpm) with wide QRS duration (157 ms). According to 2016 ESC guidelines for the diagnosis and treatment of acute and chronic HF, cardiac resynchronization therapy was indicated but patient hesitated it. ARNI was administered after stabilization of acute decompensated HF. Within five months after ARNI initiation, her complaints disappeared and cardiac function and disturbance of the conduction system dramatically improved. The LVEF increased to 57%, LBB resolved and QRS duration shortened to 97 ms.
Discussion The mechanism of narrowing of QRS duration in the present case was unclear. It may be due to either changes in specialized cardiac conduction system, or changes in intra-myocardial impulse transmission. The neprilysin inhibitor of sacubitril/valsartan could block the degradation of natriuretic peptide (NP). NPs have potential beneficial actions in HR including decreasing cardiac fibroblast proliferation. Both of cardiac fibroblast and connexin hemichannels could modulate cardiac electrophysiology, ventricular conduction system and lead to blockage of cardiac fibrosis. The idea of reversible LBBB after sacubitril/valsartan in non-ischemic cardiomyopathy warrants further investigation.



QRS duration

P593

Reversal of pulmonary hypertension with sacubitril-valsartan in a candidate to heart transplantation.

D Cocco[1]; G Garau[1]; D Pasqualucci[1]; N Sanna[1]; PP Orru[1]; M Corda[1]; M Porcu[1]
[1]*G. Brotzu Hospital, SC Cardiologia con Unità di Terapia Intensiva Cardiologica, Cagliari, Italy*

In patients with end-stage heart failure (HF) severe pulmonary hypertension (PH) represents a contraindication to heart transplantation (HT). We describe the effect of sacubitril/valsartan in a HT candidate with PH. A 48-year-old male, ex smoker, underwent an anterior myocardial infarction (MI) treated with primary PCI on the LAD. Nevertheless, 5 months later he developed a severe LV dysfunction (LVEDD 73mm, akinesia of the apex, anterior and septal walls, EF 20%). ECG did not meet the criteria for resynchronization therapy and an ICD was implanted. Despite optimal medical therapy he progressively deteriorated towards end-stage HF and was evaluated for HT. Right heart catheterization (RHC) showed low cardiac index (1.93 L/min/m2) with pharmacologically reversible PH (baseline PVR 4.15 UW, after enoximone 2.04 UW) and in 2015 the patient was listed for HT. Unfortunately, he waited for 2 years, showing a progressive worsening of the hemodynamics. In 2017 a diagnosis of irreversible PH was made with mPAP=41mmHg, CPWP=20mmHg, DPG=12mmHg and PVR=8.6 UW, CI=1.15L/min/m2, which did not respond to multiple acute pharmacological challenges. For that reasons the patient was removed from the HT list and the HT Team considered him for LVAD. Concomitantly, following the access to the angiotensin receptor-neprilysin inhibitors (ARNI), medical therapy was optimized with sacubitril/valsartan, up-titrated to the maximal tolerated dose (24/26 mg bid). After 3 months the patient reported symptoms amelioration and hemodynamics improved dramatically (RHC after pharmacological challenge: mPAP=25mmHg, CPWP=15mmHg, DPG=5mmHg, PVR=3.3UW, CI=1.44L/min/m2). Seven months later basal RHC showed normalization of the PVR and DPG with only mild PH (mPAP=29mmHg, CPWP=20mmHg, DPG=2mmHg, PVR=2.6UW, CI=1.64L/min/m2). The patient was consequently readmitted on active HT list. Although the clinical effects of ARNI in advanced stable HF and in secondary PH are still under investigation, this report suggests that this new drug should be considered as a tool to reverse severe PH in candidates to HT. A better understanding of the pharmacological effect on the pulmonary circulation is needed. Moreover, apart from European Society of Cardiology group 2 PH, the use of ARNI should also be tested in different PH categories.

P594

Familial cardiomyopathy with a high risk of sudden cardiac death

L Gaztanaga Arantzamendi[1]; C Cristina Asla Ormaza[1]; E Zamarreno Golvano[1]; A Elorriaga Madariaga[1]; A Arregui Lopez[1]; A Andres Morist[1]; PM Mendoza Cuartero[1]; I Bravo Martinez[1]; G Aurrekoetxea Bajeneta[1]; R Saez Moreno[1]
[1]*Hospital de Basurto, Bilbao, Spain*

A 38-year-old woman with personal history of ventricular extrasystole was diagnosed with dilated cardiomyopathy (DCM) and moderate left ventricular (LV) systolic dysfunction. Magnetic resonance imaging (MRI) revealed intramyocardial enhancement in the basal and mid septum, suspecting previous myocarditis as first diagnosis. One year later she was admitted to hospital for sustained ventricular tachycardia (VT) that required electrical cardioversion. Coronary angiogram confirmed absence of coronary lesions. During electrophysiological study right bundle branch block and inferior axis VT was induced. Single-chamber defibrillator was implanted but one year later the patient was admitted to the coronary care unit (CCU) for arrhythmic storm due to same morphology VT. Radiofrequency ablation of multiple morphologies of VT was made in the mitroaortic continuity.

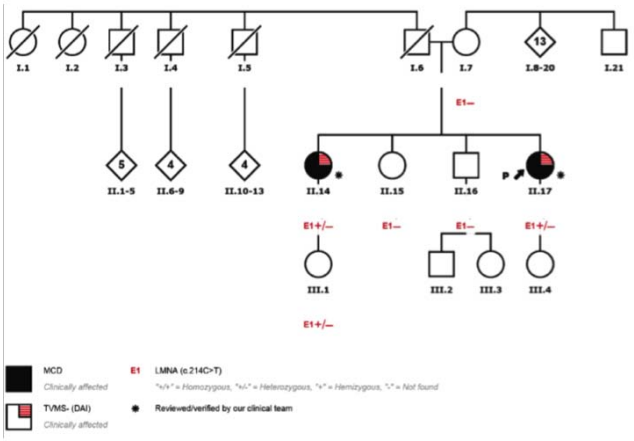
Index patient's sister was also referred for paroxysmal atrial fibrillation (AF) at the age of 51, after presenting a cerebrovascular accident. Echocardiogram displayed mild-to-moderate LV systolic dysfunction due to diffuse hypokinesia, markedly at the septal level. Catheter ablation of AF was practiced with early recurrence. Two years later she was admitted to the CCU for right bundle branch block VT clinically poorly tolerated. MRI showed dilated cardiomyopathy with septal intramyocardial enhancement. VT ablation was performed, being the arrhythmia located in the mitroaortic continuity. Single-chamber cardioverter defibrillator was implanted.

In outpatient follow-up study of familial cardiomyopathy was completed. Their father had passed away at the age of 43 because of cardiopathy, but no history was available. Two aunts and one uncle had also passed away at a relatively young age; history was neither available. They had other two uncles who had died older and who had children awaiting study.

Our second patient's daughter is a completely asymptomatic 32-year-old woman with a normal echocardiogram, although MRI reveals small focal myocardial enhancement of the septum. Holter recordings do not show any evidence of premature ventricular complexes. Index patient's daughter is 7 years old and she has not been studied yet.

Genetic study demonstrated a pathogenic heterozygous mutation in the LMNA gene in the index patient, her sister and sister's daughter.

LMNA encodes for proteins of the nuclear membrane and it is one of the most prevalent mutated genes in DCM, causing up to 10% of familial DCM. The earliest cardiac finding is usually conduction system disease, associated with atrial or ventricular arrhythmias, atrioventricular conduction abnormalities and myocardial dysfunction. Carriers of LMNA mutations are at a high risk of arrhythmias, heart failure and sudden cardiac death, even in absence of left ventricular dysfunction, emphasizing the importance of being recognised at an early stage, which may lead early implantation of an automatic cardioverter defibrillator.



P595

Early paradoxical steroid induced ventricular tachycardia in cardiac sarcoidosis

C Mccune[1]; L Dixon[1]
[1]*Royal Victoria Hospital, Cardiology, Belfast, United Kingdom of Great Britain & Northern Ireland*

A 39 year old former athlete was admitted with recurrent shocks from his ICD (implantable cardiac defibrillator). Medication history included sotalol, eplerenone and an angiotensin receptor neprilysin inhibitor. Electrolytes were within normal range and his ECG (electrocardiogram) was unremarkable.

A year prior he had been diagnosed with a dilated cardiomyopathy (left ventricular ejection fraction 40%) after an out of hospital VF (ventricular fibrillation) arrest. A secondary prevention ICD was implanted. PET-CT (Positron emission tomography–computed tomography) was suggestive of cardiac sarcoidosis (CS) and this diagnosis was later confirmed on a second cardiac biopsy.

The patient completed a three day course of intravenous steroids (methylprednisolone 970mg followed by oral prednisolone) two days prior to the ICD therapies. Device interrogation revealed two episodes of VF (ventricular fibrillation) each successfully terminated by defibrillation. The device EMG (electromyography) revealed a slow rhythm with an occasional PVC (premature ventricular contraction) leading to polymorphic VT (ventricular tachycardia) and subsequent VF. Sotalol was changed to bisoprolol and amiodarone. The lower rate of his pacemaker was increased to supress PVCs and prevent a long cycle post PVC. He experienced frequent runs of NSVT (non sustained ventricular tachycardia) and on day seven of steroid use he experienced VT with successful ATP (anti tachycardia pacing). The patient was unable to tolerate a higher base rate of 70bpm due to marked anxiety. His mood improved with clinical psychology input and his symptoms and arrhythmias abated with steroid reduction and commencement of methotrexate. He maintained sinus rhythm and has had no further ICD shocks since discharge.

Problem: Cardiac sarcoidosis is a multisystem infiltrative condition characterised by non-caseating granuloma. It is termed the "great masquerader" due to the diverse range in presenting symptoms and the difficulty in diagnosis. CS carries a higher risk of life-threatening tachyarrhythmia and can manifest as VT without any prior clinical features. There is a high recurrence rate of VT and it is notoriously difficult to control with antiarrhythmic therapies. Inflammation and re-entry due to scar are postulated mechanisms of VT, however there are currently no models to predict risk. Gallium scintigraphy, reduced ejection fraction and a prior VT have been suggested as predictors of VT recurrence. Firstline steroid therapy reduces the progression of myocardial inflammation and fibrosis, however steroid commencement is also associated with VT in the first year. This case illustrates an

early paradoxical proarrhythmic effect of steroid use in CS. In this case arrhythmias abated after antiarrhythmic adjustment, pacing at a higher rate and with persistence of steroid use. We advise close monitoring on a cardiac unit for patients with cardiac sarcoidosis commencing steroid therapy.

His bundle pacing, an alternative to CRT? Our first experience

F Filip Malek[1]; N Chovanec[1]; J Petru[1]; L Sediva[1]; J Skoda[1]; L Dujka[1]; P Hala[1]; K Koscova[1]; P Neuzil[1]
[1]*Na Homolce Hospital, Prague, Czechia*

Funding Acknowledgements: Supported by MH CZ - DRO (Nemocnice Na Homolce – NNH, 00023884), IG170501

Background: first temporary pacing of His bundle (HBP) was reported in 1970 in an experimental study, the permanent HBP was reported in clinical series from 2000 in several clinical scenarios. Several studies has reported lower incidence of heart failure after HBP compared to conventional right ventricle pacing in patients with A-V block. HBP was also used as an alternative to cardiac resynchronization therapy (CRT) in patients with LBBB and cardiomyopathy. We report our first experience with HBP in our center.
Patients and method: HBP was realized between 6th October 2017 to 11th December 2018 in eight patients (two males and six females) with mean age 65 (range 38 to 77 years). In two patients, HBP was indicated in prevention of pacing-induce cardiomyopathy, in six patients HBP was indicated as an alternative to CRT. The mean QRS width before HBP was 160 ms (92-200 ms range). The special HBP lead was used and the lead was navigated by quadripolar catheter to His bundle area, catheter was inserted from right femoral vein.
Results: implantation of the lead for HBP was succesfull in all subjects without any complication. In patients with LBBB at baseline, QRS width immediately decreased from mean 160 ms to 112 ms.
We report a case study of a 77 years old female patient with ischemic cardiomyopathy, with with LV EF 25% and atrial fibrillation and advanced HF symptoms (NYHA IV). The patient was indicated for CRT-D, implantation of LV lead was unsuccesull. Surgical implantation was contraindicated because of un acceptable risk and patient stayed long term in the hospital (long-term facility) because of recurrent episodes of decompensation. After succesfull HBP QRS width decreased from 156 ms to 110 ms. The patient was discharged from the hospital and is followed on outpatient basis with clinical improvement to NYHA III.
Conclusion: HBP is a relatively young method of physiological pacing. Indication for HBP is prevention of paceding induced cardiomyopathy and an alternative to CRT. We have to think of possibility of HBP in subjects with LBBB and cardiomyopathy, when CRT cannot be implanted because of anatomical or clinical issues.

P597

Sudden cardiac death in a patient with complicated peripartum cardiomyopathy and long QT syndrome

E Elena Reznik[1]; YP Yamka[1]; SN Avdeykin[2]; SV Borisovskaya[1]; LV Brylev[2]; TM Padzheva[2]; OA Ettinger[1]; IG Nikitin[1]
[1]*Pirogov's Russian National Research Medical University, Moscow, Russian Federation*; [2]*12 Moscow's Clinical Hospital, Moscow, Russian Federation*

Introduction: Peripartum cardiomyopathy with long QT syndrome is extremely rare. linical case. A 38-year-old woman, who had delivered her child 5 months previously, was admitted after resuscitation in connection with ventricular fibrillation, circulatory and respiratory arrest. Her condition was extremely acute - coma, tonic seizures, crepitation present upon palpation of the front of the neck, bilateral diffuse wheezing, blood pressure 70/50 mm Hg, SpO2 84%. Sinus rhythm of 124 per min, SIQIII, inverted T wave in V3-V6, and a long QTc of 518 ms were recorded on ECG.
Artificial ventilation was commenced with BIPAP after tracheal intubation with bronchoscope, which revealed aspiration signs of gastric material and blood. Gastrointestinal bleeding was excluded during esophagogastroduodenoscopy. CT chest scan revealed an infiltration in S1, S2, S6 right, and S6 left, lung segments, pneumomediastinum. CFP10-ESAT6 test was negative. CT abdomen scan revealed a pneumoperitoneum, and an absence of organ perforation. The reason for the hemoaspiration, subcutaneous emphysema, pneumomediastinum and pneumoperitoneum, was probably due to microtrauma of the trachea, resulting from unsuccessful pre-hospital attempts at intubation.
Blood tests showed leukocytosis 23x109/L, CK total 263 IU/L, MB 174 IU/L, creatinine 128 μmol/L, lactic acid 4.6 mmol/L, NTproBNP 33300 mg/L, troponin I 0.8 hg/mL, D-dimer 14325 pg/mL, procalcitonin 11 mg/mL, and CRP 125 mg/L.
ECHO indicated an akinesis of the apical and middle segments of the anterior wall and of the ventricular septum, and the apex, a left ventricle (LV) volume of 84 ml, and an LV ejection fraction (EF) of 32%. Angiopulmonography, coronary angiography excluded pulmonary embolism and coronary heart disease. CT brain scan did not reveal any acute pathology. CSF liquor test showed cytosis, elevated level of protein, therefore secondary meningitis was suspected. Markers for rheumatological diseases were normal.
Fluid, antibacterial, inotrope, anticoagulant therapy and hemodiafiltration lead to the regression of the heart, renal, respiratory, brain failure. After 5 days, artificial ventilation and inotropic support were stopped, treatment with ACE inhibitors, beta-blockers (BB), and antagonists of mineralcorticoid receptors was started. LVEF increased to 40% in 10 days, and to 56% in 20 days, and local contractility was restored. Control X-ray revealed the resolution of the pneumonia. The patient was discharged after 27 days. After 4 months, she was feeling well and continued to take BB. A cardioverter-defibrillator implantation was planned.
Conclusions. The simultaneous presence of a peripartum cardiomyopathy and long QT syndrome, with the development of ventricular fibrillation, sudden death and multiple complications was discovered. The management of multimorbid patients should be carried out by a multidisciplinary team, in strict accordance with guidelines for the successful treatment of rare, severe diseases.

P598

Prosthetic mitral valve thrombosis during extracorporeal membrane oxygenation treated with functional closing of aortic valve

G Giosafat Spitaleri[1]; JM Dominguez[1]; B Keller[1]; S Vazquez[1]; MA Castel[1]; M Farrero Torres[1]; F Perez Villa[1]
[1]*Hospital Clinic de Barcelona, Advanced heart failure and cardiac transplant unit, Barcelona, Spain*

We report a case of 25-year-old woman with Marfan syndrome who was admitted at our hospital for acute cardiogenic shock. In her past medical history, the patient suffered from valvular dilated cardiomyopathy who had undergone mitral valve replacement with a prosthetic mechanical valve at age 14, Bentall intervention (prosthetic mechanical aortic valve and Dacron graft) at age 22 and CRT-D implantation at 23.
During admission, the patient remained hypotensive and progressed to INTERMACS level 1 cardiogenic shock despite treatment with inotropes, vasoactive drugs and intra aortic ballon pump. Therefore, we decided to implant a peripheral veno-arterial extracorporeal membrane oxygenator (ECMO) and the patient was included in heart transplantation waiting list with highest priority. Despite an initial clinical improvement, the patient developed prosthetic mitral valve thrombosis 24 hours after ECMO implantation. We decided to remove the mitral valve and to perform functional closing of the prosthetic aortic valve with a supra anular bovine pericardial patch and extensive atrial septostomy (Figure 1). Six days after ECMO implantation the patient underwent successful heart transplantation with no further complications.

P599

High-dose insulin therapy of acute heart failure during left ventricular reconstruction surgery

E V Elena Dzybinskaya[1]; E Vlasova[1]; RS Akchurin[1]
[1]*National medical research center of cardiology, Cardiovascular Surgery, Moscow, Russian Federation*

High-dose insulin is not a well known therapeutic method of refractory myocardial failure. Insulin has been known to have positive cardiac inotropic properties, although the mechanisms are not fully understood [1]. Only a minor experience of this technique has been reported in cardiac surgery [2].
A 75 years old man was scheduled for left ventricular (LV) reconstruction with myocardial revascularization. Eleven months before, he had suffered a myocardial infarction, complicated by rupture of the inferior wall of the LV, followed by the formation of a pseudoaneurysm (Fig., RV - right ventricle, IVS - interventricular septum). Preoperative examination revealed a reduction of the ejection fraction to 32% and an increase in pseudoaneurysm size to 4 cm as well as the three-vessel coronary artery disease. Dyspnea was the most significant symptom in the patient's condition. LV repair using a patch and triple coronary artery bypass grafting were performed. Aorta was clamped for 164 min.
During trial weaning from cardio-pulmonary bypass (CPB), despite the infusion of increasing doses of epinephrine (>400 ng•kg•min-1), severe myocardial failure was detected. The inability to wean from CPB and the lack of technical opportunity of hemodynamic mechanical support were recognized as an indication for the administration of totally 1000 units of insulin. We relied on its previously described cardioprotective and inotropic effects [1,2]. This led to a visible improvement in ventricular contractility, a decrease in epinephrine doses down to 100 ng•kg•min-1, and successful weaning from CPB. Despite the high-dose insulin therapy the blood glucose level varied within 8-14 mmol•l-1 without its additional administration, which is consistent with previously published data [1,2]. Duration of postoperative

inotropic therapy was 82 hours; mechanical ventilation time – 21 hours. The patient was discharged from hospital 18 days after surgery.
Thus, in present case of refractory post-CPB acute heart failure, high-dose insulin therapy was an effective tool to restore myocardial contractility.

PreCPB transoesophageal echocardiography

P600
A rupture of cardiac pseudoaneurysm - Devastating complication

D Balkute[1]; G Burneikaite[1]; B Petrauskiene[1]
[1]Vilnius University, Clinic of Cardiac and Vascular diseases, Centre of Cardiology and Angiology, Vilnius, Lithuania

Background/Introduction
Left ventricular (LV) pseudoaneurysm is usually associated with myocardial infarction and rupture of ventricular wall. The clinical presentation of these patients is non-specific, making the diagnosis challenging. It needs to be differentiated from a true aneurysm by the fact that there is lack of myocardial tissue in the wall of a pseudoaneurysm. There are no treatment guidelines considering the exact time of the surgery, which may be complicated due to the necrosis of the myocardium as well as risk of thromboembolic events prevention.
Case presentation
A 42-year-old previously healthy male presented to emergency department with abdominal pain for 7 day before hospitalization. In addition, he reported an attack of acute chest pain that lasted ≥ 24 hours 3 weeks ago. Upon examination, the patient had stable vital signs (heart rate 65/min, blood pressure 130/70mmHg), no murmurs, crackles bilateral over lower lung field.
Confirmation of diagnosis
An electrocardiogram showed deep Q waves and 2 mm ST elevation with biphasic T wave in V1-V4. His white blood cell count: 8.71 x 10*9 /L, hemoglobin: 143 g/L, troponin I: 12.8 ng/mL, BNP: 308.9 ng/L. Transtoracic echocardiograpram (TTE) revealed a poor LV systolic function due to an akinetic anterior wall, dyskinetic apex containing a thrombus (19 x 12 mm) and massive pericardial effusion with signs of right ventricle compression. The acute abdominal patology was excluded, hepatomegaly was comfirmed by ultrasound.
Procedures
Aspirin, clopidogrel, ramipril, metoprolol, atorvastatin, spironolactone, intravenous furosemide were initiated. The patient refused for angiographic investigations. The Heart Team decided to proceed to surgery in order to graft the left coronary artery in addition to pseudoaneurysm repair after a few days. We discontinued clopidogrel before the surgery and added low molecular weight heparin to the treatment. Patient was stable and TTE was performed daily. Unfortuantelly, on the 7th day the patient collapsed due to cardiac arrest. During the cardiopulmonary resuscitation, pericardiocentesis was performed and 1 liter of the blood was drained. The patient was operated urgently the same day. Intra-operatively a ruptured apical LV pseudoaneurysm was idetified; the rupture was covered with thrombus. Dor's operation was performed. Postoperative period was without complications, but the patient suffered from post-hypoxic encephalopathy due to the long duration of brain's hypoperfusion. On the 3 months follow up patient had heart failure symptoms NYHA class I.
Questions/problems: As this condition is lethal, prompt diagnosis and timely treatment is life preserving. This case reveals the dilemma of anticoagulation prescription in patients with LV pseudoaneurysm against the risk of bleeding or rupture of pseudoaneurysm.

Additional LV systolic functional recovery after PVC ablation in a peripartum cardiomyopathy patient

S Simon Vanhentenrijk[1]; D Dilling-Boer[1]; O Ghekiere[2]; P Koopman[1]; P Timmermans Jr[1]

[1]Heart Centre Hasselt, Hasselt, Belgium; *[2]Virga Jesse Hospital, Hasselt, Belgium*

Case

A 32-year old woman suffered from severe dyspnoea days after delivery of her first child. A transthoracic echocardiography (TTE) presented a new onset of major left ventricular dysfunction (ejection fraction (EF) of 30%) with signs of congestion. Nor electrocardiogram (ECG) or TTE showed sings of acute myocardial ischemia.

Patient management

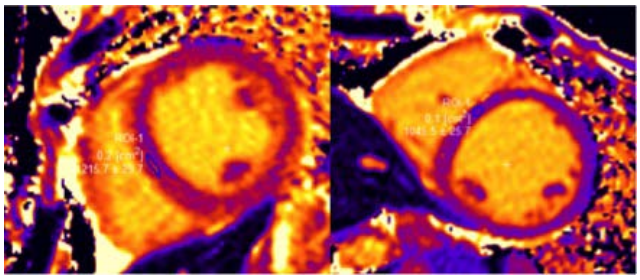
The patient was admitted to Intensive Cardiac Care Unit (ICCU), were supportive medical treatment was started. Subsequent, a seven-day treatment with bromocriptin 2,5mg daily was initiated in addition to standard heart failure treatment. Coronary angiography excluded significant coronary atherosclerosis. Cardiac magnetic resonance imaging (MRI) showed an enlarged myocardial relaxation time (T2 value of 65 milliseconds and T1 value of 1215 milliseconds (image)). Focal myocardial fibrosis was excluded using late gadolinium enhancement imaging. There was a good response to the medical treatment with gradual functional recovery (LV EF 40-45%). Due to low blood pressures, a combination of maximal tolerated carvedilol therapy and ivabradin associated with enalapril and spironolactone was used.

One month after the initial diagnostic implications, an ambulatory check-up showed no signs of congestion, however the TTE showed only partially improved LV function (EF 45%). Moreover, a 24-hour Holter analysis, conducted at that time, demonstrated highly frequent unifocal premature ventricular complexes (PVC's) (39029/24-hour, under maximal tolerated beta-blocker treatment) originating from the right ventricular outflow tract. Therefore the patient was sent for a PVC-ablation because medical treatment was limited.Differential diagnosis

Three months after treatment for PPCM and one month after PVC-ablation, new TTE revealed complete recovery of the LV EF (55%). A control 24-hour Holter monitoring measurement showed only eight PVC's. At that time, a second cardiac MRI showed a LV EF of 57 percent, myocardial relaxation T2 native and myocardial relaxation T1 native of respectively 50.5 milliseconds and 1045 milliseconds. Due to ventricular extrasystoles seen in her newborn child, a genetic analysis was performed in our patient, but could not conceal any abnormalities. Possibly a tachycardiomyopathy due to frequent PVC's was responsible for the incomplete recovery of systolic function after an initial PPCM cardiomyopathy.

Implications for clinical practice

This case report demonstrates an additional recovery of the LV function after PVC ablation in a PPCM patient suffering from residual pathologic burden located at the right ventricular outflow tract on top of standard heart failure and bromocriptin treatment. Referring PPCM patients to a specialized heart failure and electrophysiological centre for optimal medical treatment, genetic testing and potentially, in presence of a significant amount of PVC's, ablation is therefore indicated to obtain full functional recovery and good clinical outcomes.



P602

A case of cardiomyopathy with severe reversible systolic dysfunction

C Acatrinei[1]; O Fronea[1]; S Onciul[1]; D Zamfir[1]; M Dorobantu[1]

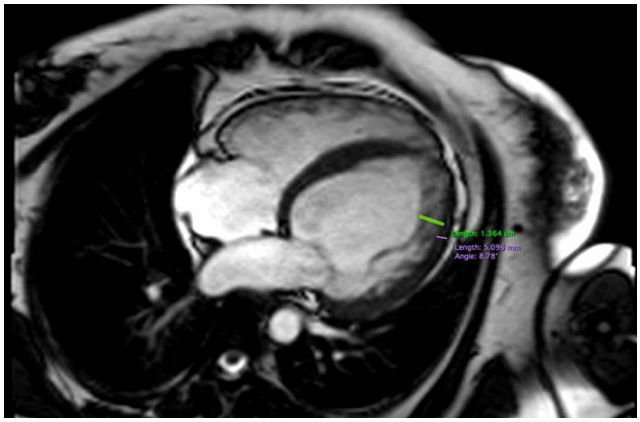
[1]Clinical Electrophysiology and Pacing Laboratory Emergency Clinical Hospital Floreasca, Bucharest, Romania

A 35-year-old female presented to the emergency room with severe dyspnea with orthopnea and anterior chest pain. She denied any personal or family history of cardiovascular disease, but reported two recent episodes of pneumonia for which she was treated with empirical antibiotic therapy with cefuroxime and clarithromycin. Physical examination revealed an overweight patient, mild bibasilar crackles, a systolic cardiac murmur over the mitral area and bilateral leg edema. Her blood pressure was 190/100 mmHg and heart rate 120 bpm. Initial laboratory data showed elevated CK-MB and NT-proBNP, elevated liver enzymes and normal renal function. There were no particular findings on the surface ECG.

The echocardiography revealed a dilated left ventricle (LV), severe systolic dysfunction (ejection fraction 20%) due to global hypokinesia, intraventricular dyssynchrony despite a narrow QRS complex on the surface ECG and moderate secondary mitral regurgitation. To clarify the cause of chamber dilation, a CMR was pursued which confirmed both left and right ventricle (RV) dilation (LV 171 ml/m2, RV 136 ml/m2) and severe systolic dysfunction. In addition, no oedema or areas of focal myocardial fibrosis were noticed. The apical region of the LV was hypertrabeculated with a non-compacted/compacted myocardium radio of 2.2 in long axis views suggestive of non-compaction. No thrombus was seen. In this context, the optimal treatment for heart failure with reduced ejection fraction was initiated (at first perindopril then combination sacubitril-valsartan, metoprolol, spironolactone, furosemide). On follow-up echocardiographic examinations, the ejection fraction gradually increased up to 45% at 8 months examination.

Several diagnoses were discussed as the underlying cause of left ventricle dysfunction. First of all, we excluded an ischaemic etiology considering the absence of coronary lesions, the diffuse hypokinesia on echocardiography and the lack of ischaemic changes on CMR. In addition, acute myocarditis was unlikely due to the non-suggestive CMR aspect. Finally, the 24-hour ECG monitoring showed very rare ventricular extrasystoles accounting for only 0.5% of total ventricular beats and no tachyarrhythmia, making a diagnosis of tachycardiomyopathy improbable.

In conclusion, myocardial non-compaction may be the expression of a genetic cardiomyopathy or may be the phenotypic appearance of other causes of left ventricle dysfunction. The reversibility of the disease in our patient does not support the diagnosis of genetic non-compaction cardiomyopathy. The patient was nonetheless programmed for genetic testing given the psychological burden that



CMR- left ventricle non-compaction

this diagnosis implies. So far, we were not able to determine a trigger for the reversible ventricular dysfunction in this patient. A question remains whether the optimal medical treatment for heart failure with reduced ejection fraction could nowadays reverse even a genetic form of non-compaction.

P603

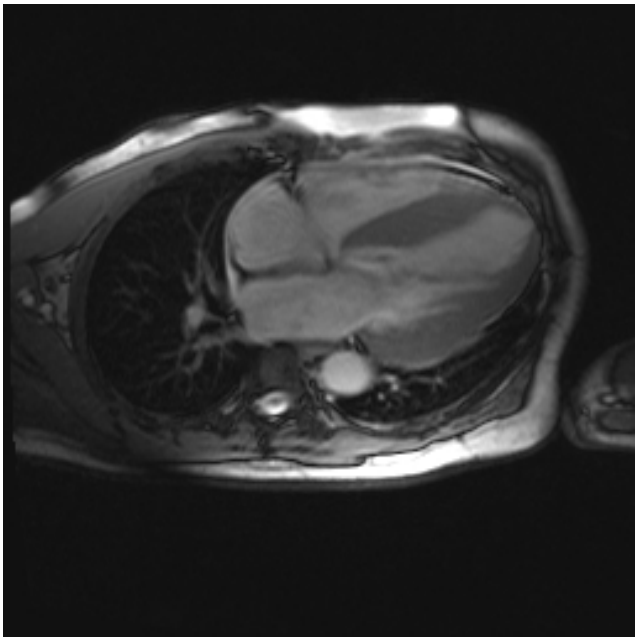
Hypertensive hypertrophic cardiomyopathy with low ejection fraction.

M Michail Siarkos[1]; P Giannakopoulou[1]; N Gouliaros[1]; E Eykarpidis[1]; I Zarifis[1]
[1]*General Hospital G. Papanikolaou, Cardiology, Thessaloniki, Greece*

Introduction: Hypertensive cardiomyopathy is a structural cardiac disorder, generally accompanied by left ventricular hypertrophy, associated with diastolic or/and systolic dysfunction, in patients with persistent systemic hypertension. We present a case of a patient with hypertrophic cardiomyopathy, and signs and symptoms of heart failure with no prior history.
Case report and description: A 46 years old male was admitted to our hospital with deteriorating shortness of breath, excessive tiredness and legs oedema. His medical history was unremarkable. The physical examination revealed the presence of a third sound, absence of murmurs, wheezing on pulmonary auscultation, distended neck veins and large oedema of the lower extremity. His blood pressure was 210/100 mmHg. Findings from electrocardiography showed sinus rhythm and signs of LV hypertrophy. Echocardiography showed LVH, mildly dilated LV, reduced EF and mildly dilated LA. The blood test results revealed impaired renal function, elevated liver transaminase levels and negative troponin.
The differential diagnosis included all of the following: hypertensive hypertrophic cardiomyopathy, hypertrophic cardiomyopathy with hypertension, amyloidosis and Fabry's disease.
The patient underwent CMR, which confirmed the hypertrophy with low EF, full scanning for detecting lesions in target organs due the hypertension. Secondary causes of hypertension, amyloidosis and Fabry's disease were excluded.
The patient was discharged with antihypertensive treatment and was reevaluated regularly. After a year of optimal blood pressure control findings from ECG were improved. The echocardiogram showed significant reduction in LV wall thickness and normal EF, which were also confirmed by CMR.

CMR results	EDV (ml)	ESV (ml)	EF%	SV (ml)	LVmass (g)
LV (during hospitalization)	336	234	30	102	416
LV (after a year)	223	70	69	153	238

CMR, LV volume and mass during hospitalization and a year after



4 chamber view, CMR

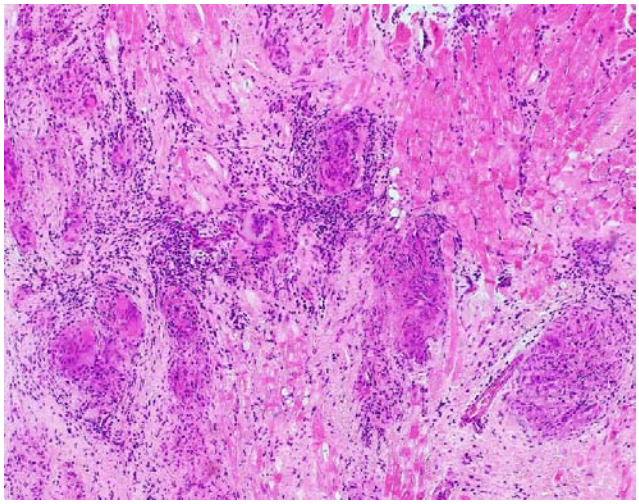
Conclusion: Hypertension is a major global health issue and can cause structural and functional myocardial abnormalities. The finding of severe LVH in hypertensive patients may sometimes create difficulties: Is a coexistent cardiomyopathy present? Or is LVH a secondary consequence of severe chronic hypertension? A definitive diagnosis may be difficult to resolve. Reduction of LVH by optimal blood pressure control after antihypertensive treatment reveals hypertension as the underlying cause of LVH, excluding hypertrophic cardiomyopathy.

P604

The great masquerader strikes again: cardiac sarcoid, an unusual cause of sudden cardiac arrest in a 37 year old athlete

C Mccune[1]; O King[2]; L Dixon[1]
[1]*Royal Victoria Hospital, Cardiology, Belfast, United Kingdom of Great Britain & Northern Ireland*; [2]*Royal Victoria Hospital, Department of Pathology, Belfast, United Kingdom of Great Britain & Northern Ireland*

A 37 year old athletic male with a history of asthma suffered an out of hospital VF arrest whilst playing Gaelic football. He was resuscitated after 8 minutes of bystander cardiopulmonary resuscitation and defibrillation with the club's automated external defibrillator. The patient had a recent history of a viral illness but was otherwise asymptomatic prior to this. A three generation family history was unremarkable. ECG and chest x-ray were normal. His echocardiogram revealed a dilated left ventricle (diastolic diameter 6.5cm) and an ejection fraction of 25%. Right ventricular function was normal. Initial cardiomyopathy screening bloods including serum ACE (angiotensin converting enzyme) were within normal limits. Coronary catheterisation showed angiographically smooth arteries. Cardiac magnetic resonance imaging demonstrated moderate-severe left ventricular systolic dysfunction (ejection fraction 40%) with partial wall thinning and inferior hypokinesis. Midwall contrast was noted in the basal anterior, mid inferior walls in addition to the right ventricular aspect of the mid septum. Transmural contrast was noted in the basal inferior wall. Cardiac biopsy was normal. Cardiac genetics screened for a dilated cardiomyopathy phenotype. He received a secondary prevention implantable cardiac defibrillator and after heart failure medication optimisation his device was upgraded to a cardiac resynchronization therapy defibrillator. The differential diagnosis of this non-ischaemic dilated cardiomyopathy was myocarditis, arrhythmogenic left ventricular cardiomyopathy or cardiac sarcoidosis. Subsequent high-resolution computerised tomography chest disclosed numerous confluent areas of nodularity prominent in the upper zones highly suspicious of parenchymal sarcoidosis. Cardiac PET revealed lung, liver and spleen lesions in keeping with sarcoid. A second cardiac biopsy confirmed granulomata formation, confirming a diagnosis of sarcoidosis. He was commenced on methotrexate and steroids with ongoing respiratory and cardiology specialist input.Problem: The prevalence of cardiac involvement in systemic sarcoidosis is approximately 1 in 4, yet it is often clinically silent. The range of clinical manifestations include asymptomatic ECG abnormalities, heart failure and sudden cardiac death. Serum ACE has a low sensitivity and specificity and therefore has limited utility as a diagnostic test. Cardiac biopsy is the gold standard for diagnosis however due to the patchy infiltration pattern of sarcoidosis and predisposition for the left ventricle it has a relatively low sensitivity. This case highlights the importance of having a high suspicion for sarcoidosis, particularly in younger patients with newly diagnosed atrioventricular block, VT or unexplained syncope. Current diagnostic



Biopsy confirming cardiac sarcoidosis

methods are flawed and this condition is likely underdiagnosed. Furthermore, this case highlights the success of community defibrillator schemes and public education in resuscitation.

P605

Left anterior fasicular ventricular tachycardia induced stress-iInduced cardiomyopathy

SH Seol[1]; YJ Song[1]; DK Kim[1]; S Kim[1]; KH Kim[1]; DI Kim[1]
[1]*Inje University College of Medicine, Haeundae Paik Hospital, Busan, Korea (Republic of)*

A 35-year-old man with no risk factors presented to the emergency room with palpitation and dyspnea. His clinical signs were blood pressure, 100/50 mmHg; heart rate, 180 beats/min (bpm); respiratory rate, 20/min; and body temperature, 36°C. His 12-lead ECG showed wide QRS tachycardia of 190 bpm (Fig. 1A). After administration of repeated electrical shock, the Electrocardiogram showed sinus tachycardia with ST-segment depression, and T-wave inversion in leads II, III, avF, and V3-V6 (Fig. 1B). Chest X-ray finding was normal. The levels of serum Creatinine kinase-MB (3.0 ng/mL) was within normal limits. And hs-troponin-I (0.04 ng/mL) was mild elevation. However, plasma N-terminal pro-brain natriuretic peptide (2,502 pg/ mL) were elevated. Kidney and liver enzymes were elevated (total bilirubin : 4.0, aspartate aminotransferase 1310 IU/L, alanine aminotransferase 1125 IU/L, γ-guanosine triphosphate 130 IU/L, lactate dehydrogenase 1320 IU/L, blood urea nitrogen 24.9 mg/dL, Creatinine 1.43 mg/dL). Transthoracic echocardiography revealed an ejection fraction of 38%, with hypokinesia of the left ventricular apical and anterior, lateral wall with apical ballooning (Fig. 2A). Coronary angiography with spasm test showed no significant stenosis (Fig. 3). The patient was treated with aspirin, perindopril, and torasemide. A follow-up ECG on the one month showed a normal sinus rhythm and normalized ST-segment and T-wave (Figure1C). Follow-up echocardiography revealed normalized left ventricular wall motion and systolic function (Fig. 2B). The patient underwent successful catheter ablation for left anteroseptal fascicular ventricular tachycardia. He was followed for 3 years without any medication.

Pulmonary edema following acute ischemic stroke

I Bravo Martinez[1]; A Elorriaga[1]; A Arregui[1]; G Aurrekoetxea[1]; P Mendoza[1]; C Asla[1]; A Andres[1]; JR Saez[1]
[1]*Hospital de Basurto, Bilbao, Spain*

Neurogenic pulmonary edema (NPE) is defined as acute pulmonary edema that develops after a significant nervous system insult. NPE following ischemic stroke is rare and few cases have been reported. We report a twice repeated NPE in the same patient.

A 71 year old woman with history of arterial hypertension and atrial fibrillation with normal ejection fraction, was brought to the emergency department by ambulance because of acute onset dyspnea. At admission she suddenly presented disturbance of consciousness. Lung auscultation disclosed bilateral rales and neurologic examination revealed right side weakness. Oxygen saturation decreased below 85% needing emergent intubation. Non-contrast CT showed no significant abnormality in the head but marked interlobular septal thickening and diffuse ground glass opacities. Angiography revealed occlusion of the right M2 proximal segment(A). The echocardiography showed a preserved biventricular systolic function with no valvular disease (D). Thrombolytic treatment with recombinant tissue plasminogen activator was initiated.

She was admitted to the Cardiology Intensive Care Unit. She was maintained with mechanical ventilation and intensive diuretic treatment was started. Pulmonary wedge pressure was rapidly normalized and pulmonary infiltrations were solved in 2 days. She was weaned from the ventilation a week after admission. She underwent rehabilitation therapy without any residual disability after it.

One year later, she was admitted again with a new onset left superior limb weakness and short of breath that lead to emergent intubation. The CT revealed again an acute ischemic stroke of the right medium cerebral artery (C) and pulmonary edema. The clinical course this time was similar to the previously described.

NPE usually occurs within minutes to hours after cerebral injury. The possible mechanisms of NPE after cerebral infarction include abrupt increase of intracranial pressure by large infarction or direct damage of so called "NPE trigger zones" including insular cortex, hypothalamus and medulla. This can lead to activation of the sympathetic nervous system. Massive sympathetic discharge can cause direct myocardial injury, pulmonary vascular bed injury, indirect left ventricular failure caused by increased systemic and pulmonary pressures and pulmonary endothelial injury with increased endothelial permeability.

Sudden disruption of blood supply toward left insular cortex could suggest as a possible etiology of NPE in this case. The initial management should focus on treating the underlying neurological insult. Some NPE patients require mechanical ventilation but with adequate treatment NPE resolves in 48-72 hours.

NPE is a rapidly developing and sometimes life-threatening complication of acute ischemic stroke. The clinicians should consider NPE as one of the possible etiologies of sudden respiratory compromise after acute cerebral infarction, when other causes have been excluded.

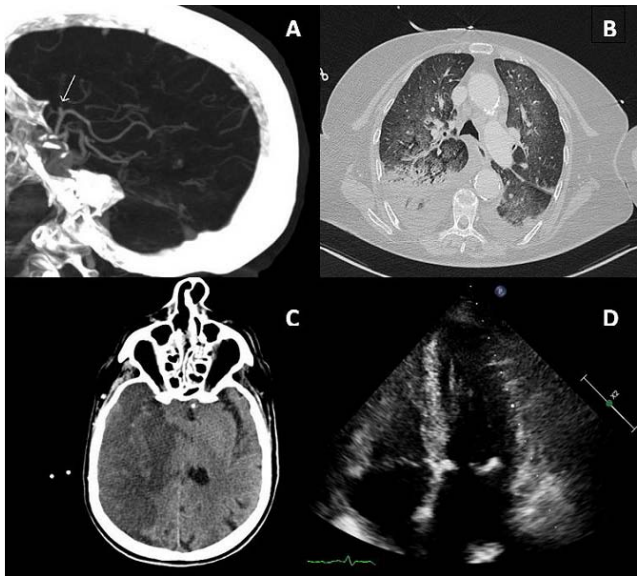

Figure 1.

P607

A case of systemic lupus erythematosus myopericarditis

TH Thai Hao Phan[1]
[1]*Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam*

Introduction: Systemic lupus erythematosus (SLE) is a chronic, recurrent multi-systemic auto-immune disease characterised by the production of auto-antibodies that cause widespread tissue damage. The most common diagnostic features of SLE include mucocutaneous lesions, nephritis, arthritis and haematological disorder. Serositis in the form of pericarditis is an uncommon first-line clinical manifestation. We report on an 31-year-old Vietnamese man who presented with myopericarditis as the initial clinical manifestation of SLE.

Case Report: An 31-year-old man was referred to us with a complaint of central chest pain of 1 months' duration with severe worsening over the past 2 weeks. Intermittent excruciating chest pain lasting a few minutes to an hour often radiated to the back and shoulder. He was neither pale nor cyanosed, but was in severe intermittent agonising chest pain. The jugular venous pressure was not elevated. The apex beat was located to the 5th intercostal space, mid-clavicular line; percussion suggested a normal area of cardiac dullness. There was neither pericardial nor pleural friction rub and no cardiac murmurs. There was no peripheral oedema, and

neither finger nor toe clubbing. None of the joints was tender. His weight, height, and body mass index at baseline were 60 kg, 168 cm, and 21.26 kg/m2 , respectively. The temperature, respiratory rate, pulse (regular and of good volume), blood pressure were 37oC, 25 cycles/min, 118 beats/min, 115/75 mmHg, respectively, at baseline. Patient was previously healthy, referring no prior cardiac surgery, chest radiotheray or tuberculosis. His family were normal.

Results: Electrocardiogarphy showed sinus tachycardia with diffuse ST elevation (except avR and V1) and depression of PR segments in leads (except avR and V1). Chest X-ray: showed showed cardiomegaly and moderate left pleural effusion and mild right pleural effusion. Echocardiography: moderate pericardial effusion (12mm), EF: 62%, PASP: 30mmHg. Hemoglobin was low 10.5g/dl. TSH mild elevated 5.31μUI/ml (0.35-4.94) but normal fT4 1.41 ng/dL (0.89-1.76); Troponin T elevated 1018 ng/L (<14ng/L); hsCRP: 264.31 mg/L(<5mg/L); ANA test; Anti-dsDNA were positive. C3: low 64.36 mg/dl (80-170); C4: low 8.84 mg/dl (15-45)Pericardial effusion analysis depicted exudate fluid, adenosine deaminase (ADA) 26.74 UI/l (<30) with mild cellularity and without atypical cells. Polymerase chain reaction (PCR) for detection of Mycobacterium tuberculosis was negative. Blood and plericardial effusion cultures were negative. Urinary protein 0.6g/24h. A diagnosis of systemic lupus erythematosus myopericarditis and pericardial effusion was made.

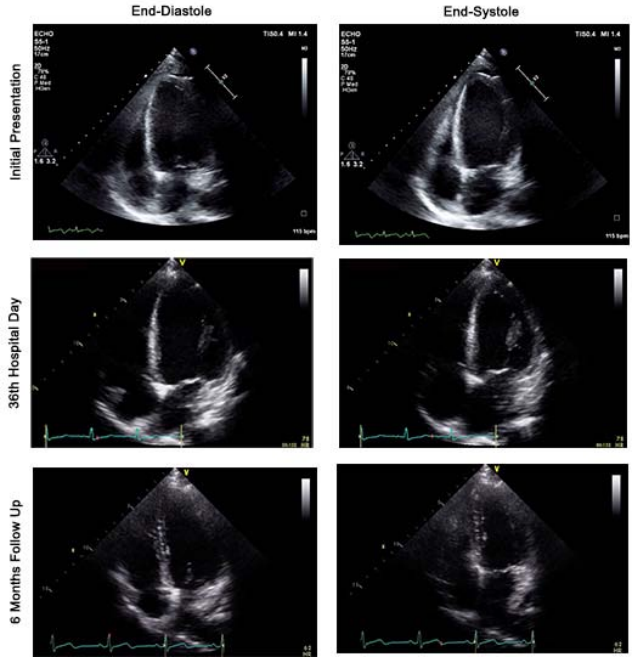
Conclusion: Myopericarditis with a pericardial effusion as the initial presenting feature of SLE is uncommon. The timely recognition and early steroid administration are imperative in SLE-related myopericarditis with cardiomyopathy to prevent the mortality associated with this condition.

P608

Systemic lupus erythematosus initially presented as acute heart failure

CS Chan Seok Park[1]; AM Gwon[1]; GH Kim[1]; JS Cho[1]; HJ Youn[1]
[1]*Catholic University Medical College, Seoul, Korea (Republic of)*

37 years old female visited emergency department due to dyspnea, peripheral pitting edema and decreased mentality. She delivered second baby without complications



Lupus myocarditis

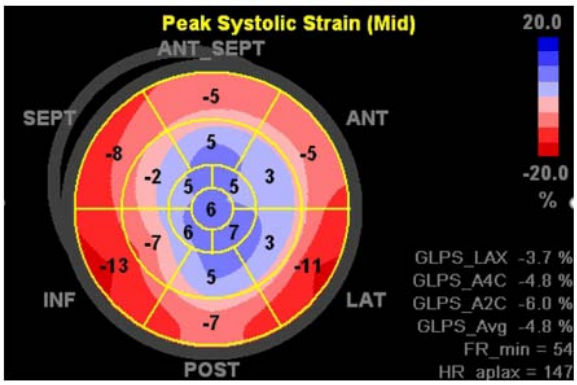
4 months before the presentation. After the delivery, she experienced fatigue and quitted the job. Peripheral edema and dyspnea developed 1 week before the presentation. Her past history showed thrombocytopenia 2 years ago during her first pregnancy. Upon arrival, her blood pressure and heart rate were 120/60 mmHg and 118/min, respectively. Mentality was stupor. Laboratory findings were as follows: Hemoglobin 7.8 g/dL, creatinine 1.21 mg/dL, Na/K/Cl 125/4.2/95 mEq/L, CPK/LDH 787/1560 IU/L. The level of NT proBNP was >35000 pg/mL. Chest roentgenogram and electrocardiogram showed cardiomegaly and sinus tachycardia, respectively. Chest and abdominal computed tomography showed edema. Left ventricular ejection fraction (LVEF) was decreased (24%) and volume was increased (end-diastole volume index (LVEDVi) /end-systolic volume index (LVESVi) 99/68 mL/m2). Further laboratory findings showed that anti-nuclear antibody (1:3200) and Coomb's test were positive. According to the diagnostic criteria, she was diagnosed as systemic lupus erythematosus. She underwent steroid pulse therapy. During the therapy, renal failure was developed so she also undertook continuous renal replacement therapy (CRRT). At 36th hospital day, CRRT was removed and her echocardiogram showed improved LVEF (51 %) although there were no differences in left ventricular volumes. Cardiac magnetic resonance imaging (cMRI) did not show late gadolinium enhancement. 6 months after the initial presentation, echocardiogram was followed and it showed normal LVEF (60%) and cardiac volume (LVEDVi/LVESVi 59/24 mL/m2). In this case, appropriate diagnostic procedures and therapy resulted in the complete recovery of heart failure due to lupus myocarditis. cMRI was useful tool to predict the complete recovery of the cardiac function.

P609

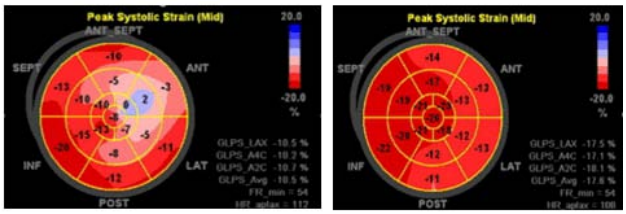
A young lady's fight or flight during the cardiogenic shocking

Y Yu Wang[1]; HW Fei[1]; ZZ Su[2]
[1]*Guangdong General Hospital Guangdong Cardiovascular Institute, Guangzhou, China*; [2] *Jiangmen hospital of sun yatsen university, cardiology, Jiangmen, China*

Introduction: A 31-year-old housewife was admitted to the emergency room with recurrent choking feeling exacerbating with nausea and vomiting for 24 hours.She mentioned blood pressure surged sometimes but could return to normal.On admission,she was sweaty with cold limbs.Blood pressure ranged from 90/50 to 159/122mmHg. Heart rate ranged from 70 to 140 bpm.Oxygen saturation was above 95%.EKG showed 1–2 mm ST segment elevation in leads II/ III/ aVF. Troponin I and BNP were elevated (50 pg/ml; 10683 pg/ml).Coronary artery obstruction was excluded by coronary angiography.She went to sudden dyspnea,extracorporeal membrane oxygenation (ECMO) was employed immediately.Cardiac magnetic resonance imaging(CMR) was held back because she could not finish it.Following EKG showed ST segments dropped gradually and T waves of all leads except aVR inverted.Serial following TTE showed gradually improved LV contraction. Speckle tracking echocardiography(STE) depicted restoration of contractile activity in a "patchy" way. Taketsubo cardiomyopathy (TTC) was suspected.Blood catecholamines were elevated.Abdominal computed tomography showed a right adrenal tumor.The final diagnosis was TTC associated with pheochromocytoma(TTC-pheo).Patient was put on β-blocker and phenoxybenzamine and finally underwent removal of the adrenal mass.Pheochromocytoma was confirmed on histopathology.In the follow-up,patient was asymptomatic and TTE was normal.Conclusion:Diagnosis of TTC-pheo has important implications for clinical management. CMR becomes widely acceptable to differentiate troponin positive chest pain associated causes. However, when the situation was unfitted for CMR,



a STE of patient on the day of admission



b STE changes during the following days (noticing the "pathy" recovery)

Speckle tracking echocardiography

echocardiography is an important method to track the pathophysiological changes. Besides,clinical routine tests can provide information: the EKG changing pattern and bizarre BNP to troponin I ratio. TTC-pheo may cause crisis. Commonly used vasoactive drugs may cause worsening of hemodynamics in TTC patients while ECMO can stabilize the patients and extend the diagnosis time window.

TTE findings					
	LA(mm)	LV(mm)	IVS(mm)	EF(%)	Decreasedleft ventricular wall motion
Day2	32	52	10	33	GeneralLV ventricle
Day3	33	52	11	16	GeneralLV ventricle

Myocarditis as a cause of reversible dilated cardiomyopathy

G Gorka Aurrekoetxea Bajeneta[1]; PM Mendoza Cuartero[1]; I Bravo Martinez[1]; C Asla Ormaza[1]; M Castellanos Alcalde[1]; A Andres Morist[1]; A Arregui Lopez[1]; A Elorriaga Madariaga[1]; R Saez Moreno[1]
[1]Hospital de Basurto, Bilbao, Spain

We report the case of a 37 year-old-male with a clinical background of arterial hypertension and a sporty lifestyle. In January 2018, patient was admitted to emergency department complaining of shortness of breath related to exercise, weakness and progressive dyspnea for almost a week. He referred cold symptoms four weeks prior to admission. He denied drug or alcohol abuse. No family history of cardiomyopathy was reported. On initial examination, patient was hypertensive (147/111 mmHg), tachycardic with 110 rpm heart rate and slightly tachypneic.

ECG showed sinus rhythm and negative T waves in precordial and lateral leads, without alterations on ST segment. Chest X-ray (Figure A) demonstrated cardiomegaly with mild bilateral pleural effusion and blood tests showed the following: mildly increased CRP (12 mg/L), acute renal failure with a mild increase of creatinine (1.4 mg/dl) and increased levels of hepatic parameters (bilirubin 2 mg/dl and GPT 504 U/L).

Echocardiography (Figure B) demonstrated a severely dilated left ventricle with global left ventricular hypokinesia, ejection fraction (EF) 15% and two masses, one located in the left atrium and another attached to the LV apex. During his hospital stay, anticoagulation was initiated with heparin and he was treated with diuretics and heart failure treatment, including IECAs, B –blockers and spironolactone, improving his clinical course.

Coronary angiography was made with normal coronary arteries. Cardiac MRI was also performed, finding dilated cardiomyopathy (DCM) with severely reduced EF and intracardiac masses suggestive of thrombus without pathological enhancements. Considering the MRI findings, diagnosis of myocarditis versus idiopathic DCM was suspected.

Finally, an endomyocardial biopsy detected parvovirus B19 IgG antibodies. Parvovirus B19 IgM and other antibodies were negative. Additionally, a subcutaneous ICD was implanted because of the severe dilatation and dysfunction. During the following weeks, patient clinically improved and was discharged under periodical follow-up by Cardiology. Four months later, an echocardiogram (Figure C) was repeated showing complete recovery of the diameter and EF of heart. Nowadays, patient remains asymptomatic with good functional capacity.

Our differential diagnosis was between myocarditis and idiopathic DCM. However, the evolution and complete recovery of heart diameters and EF only four months later made the diagnosis of myocarditis more probable.

Myocarditis is a complex disease which can present in various ways rendering diagnosis and treatment difficult. During the last years there is growing evidence that myocarditis and DCM are closely related due to the existence of an important inflammatory component in the pathogenesis of DCM.

Our patient represents a case of reversible DCM in the context of myocarditis.

P611

A case of arrhythmogenic right ventricular cardiomyopathy

TH Thai Hao Phan[1]
[1]Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam

Introduction: Arrhythmogenic right ventricular cardiomyopathy (ARVC), also known as arrhythmogenic right ventricular dysplasia, is a heritable heart-muscle disorder that predominantly affects the right ventricle. Progressive loss of right ventricular myocardium and its replacement by fibrofatty tissue is the pathological hallmark of the disease. ARVC is one of the leading causes of arrhythmic cardiac arrest in young people and athletes. We present a clinical case of Arrhythmogenic right ventricular cardiomyopathy

Case Presentation: A 25-year-old female presented with a one year dyspnea after being diagnosed as systemic lupus erythematosus by a hospital in our city one year ago. She was diagnosed with brain tumor 17 years ago at the age of 8. Her treatments for brain tumor were surgery, chemotherapy and radiation therapy And then her family history decided for her to stop taking medicine and did not to follow treatment plan. Since then she has noticed she has no period. Her symptoms include fatigue, weakness, inability to lose weight (or weight gain), puffiness, constipation, Physical examination may, periorbital puffiness, brittle hair and eyebrow loss. Other findings were normal.

Results: Echocardiogram: EF 53%, normal size and wall thickness of the left ventricle, slightly dilated left atrium, enlargement of the right ventricular 50mm and RVOT 47mm with reduced contractile function TAPSE 11mm, apical, aneurysm-akinesia and endocardial ventricular hypertrabeculation especially at apex. Mild mitral regurgitation and severe tricuspid regurgitation. Medium pericardial effusion without right ventricular depression. Cardiac MRI showed normal volume and function of the left ventricle (EF 55%), right ventricle with 114 ml/m2 indexed end diastolic volume, reduced right ventricular function (EF 29.6%), areas of dyskinesia of the free wall at the mid and apex. Late gadolinium enhancement of the free wall right ventricular at the mid and apex. Hypertrabeculation of septal wall at the apex. Medium pericardial effusion, no cardiac tamponade.

Discussion: Diagnosis of ARVC relies on a scoring system, formulated in 2010 by the revisited Task Force, with two major or one major and two minor criteria or four minor criteria based on the demonstration of a combination of defects in right ventricular morphology and function, characteristic depolarization/repolarization electrocardiogram abnormalities (negative T waves and/or "epsilon" waves in right precordial leads), characteristic tissue pathology, typical arrhythmias, family history, and the results of genetic testing.

Conclusion: In ARVC symptoms usually appear between the ages of 30–50. Especially in young patients the most common clinical presentation of ARVC are palpitations and syncope due to ventricular tachycardia with left bundle branch morphology. Cardiac magnetic resonance (MRI) is considered the best imaging modality in evaluating the RV in ARVC

P612

Case of dual mechanism for tacotsubo cardiomyopathy (ttc) (migraine and ergothamine toxicity), presented with atrial fibrillation and tachycardia induced systolic dysfunstion

T Tsenka Boneva[1]; L Vladimirova[1]; K Karamfilov[1]; R Ivanova[1]; M Shumkova[1]; KT Stoyanova[1]; G Zlatancheva[1]; T Yaneva Sirakova[1]; P Dunev[1]; N Mileva[1]; D Vassilev[1]
[1]University Hospital Alexandrovska, Sofia, Bulgaria

Case presentation: 69 year old female with arterial hypertension, atrial fibrillation (AF) and migraine was admitted in Emergency Departement, due to chest pain, dizziness,

palpitations, dyspnea. The day before hospitalization with severe migraine crisis, treated with 12 mg Ergothamine tartarate (maximal daily dose is 6 mg). At hospital admission BP 80/60 mmHg, irregular rhytm, HR 120 bp/min. Blood tests are normal exept high-sensitive cardiac troponin T 0,037; 0,042 ng/ml (normal range<0,014 ng/mL). ECG showed atrial fibrillation, ST elevation 2 mm in V2,V3, inverted T waves in I, aVL, V4 and V6. Transthoracic echocardiogram (TTE) demonstrated systolic dysfunction with ejection fraction (EF) 37%, apical akinesia and basal hyperkinesia. Sinus rhytm was restored after 300 mg amiodarone with HR 50/min. Coronary angiography showed normal coronary arteries with no stenosis, but ventriculography was demonstrative for an apical balooning. Thus, according clinical and imaging findings TTC was established as diagnosis. Pre-discharge 5 days after admission TTE showed recovery of LV systolic function EF 54%(with mild apical hypokinesia) and without symptoms. Two years later with heart failure III functional class of NYHA. ECG - AF, HR 130bp/min, EF 36% and diffuse hypokinesia.
Discussion: the current knowledge gives a connection between increased catecholamine levels in migraine and TTC. Although the trigger is mostly endogenous, some drugs with sympathetic effect have also been reported. Ergotamine is a commonly used drug in the treatment and prevention of migraine. It is structurally similar to endogenous catecholamines. In toxic doses the proposed mechanisms of TTC is vasoconstriction and neurogenic myocardial stunning. Differential diagnosis is made by acute coronary syndrome and myocarditis. The evidence of normal coronary arteriography, nonsignificant increase of troponine levels, ECG, TTE and ventriculography makes a diagnosis most likely TTC. AF is a common arrhythmia in TTC. The pathogenesis involves electrical, structural remodeling of the left atrium and excessive sympathetic activity with high catecholamine levels.
Conclusion: TTC has been described in the setting of intense physiologic or emotional stress. It has also been reported in a number of acute neurological illnesses. We report a case of TC apparently precipitated by two triggers (migraine and ergothamine toxicity) presented with AF. In our patient despite recovery of EF, lately diagnosed permanent AF, leads to tachycardia induced cardiomyopathy. TTC is a reversible condition, but the association between TTC and AF, is associated with poor clinical outcome.

P613
Left ventricular involvement in arrhythmogenic right ventricular cardiomyopathy assessed by cardiac magnetic resonance imaging: a case report

H Sisakian[1]; S Pepoyan[1]; A Barkhudaryan[1]; Z Kartoyan[2]
[1]Yerevan State Medical University after M. Heratsi, University Hospital N 1, Clinic of General and Invasive Cardiology, Yerevan, Armenia; [2]Astghik Medical Center, Department of Cardiology and Arrhythmology, Yerevan, Armenia

Introduction: Arrhythmogenic right ventricular cardiomyopathy (ARVC) is an inherited myocardial disease characterized by fibro-fatty replacement of the right ventricle (RV) and is considered the second most prevalent cause of sudden cardiac death (SCD) in young and athletes. The disease is usually manifested by paroxysms of life-threatening ventricular arrhythmias. We reported a case of a man affected by this rare cardiomyopathy which was manifested by left ventricular (LV) involvement.
Case report : We describe a case of a 46-year-old male who referred to our clinic presenting with complains of palpitations and irregular heartbeats. The patient presented with a history of palpitations for many years for which he received amiodarone and bisoprolol. During hospital treatment, the patient developed a paroxysm of hemodynamically unstable wide complex ventricular tachycardia (VT) which was treated by electrical cardioversion. He underwent coronary angiography which did not detect any hemodynamically significant stenoses of coronary arteries. The family history was unremarkable. The 24-hour Holter ECG monitoring revealed sinus rhythm with an episode of monomorphic VT consisting of 5 ventricular complexes with a ventricular rate of 120 bpm and without clinical manifestation. The transthoracic echocardiography revealed concentric hypertrophy of LV, enlargement of RV and right atrium (RA). The left ventricular ejection fraction (LVEF) was estimated 45% with no regional LV asynergy. The RV diameter at the basal level was 60 mm. The aneurysm was present in the subvalvular region and along the lateral wall of RV. The Doppler examination revealed 1st degree mitral regurgitation and 3rd degree tricuspid regurgitation. The patient was preliminary diagnosed with stable ventricular tachycardia, syncope, arrhythmogenic shock, status after electrical cardioversion and arrhythmogenic right ventricular dysplasia/cardiomyopathy. The cardiac magnetic resonance imaging (MRI) study was performed for confirmation of clinical diagnosis which revealed the presence of LV aneurysm, RV free wall aneurysm and dilatation (Fig. 1A). The late gadolinium enhancement (LGE) showed the presence of RV fibrosis (Fig. 1B). The patient underwent the implantation of a dual-chamber implantable cardioverter defibrillator (ICD) for the secondary prevention of SCD. Conclusion: Possible biventricular involvement should be considered in ARVC in radiological studies and may be misdiagnosed by echocardiography. The cardiac MRI has a key role in finding biventricular involvement in this form of cardiomyopathy.

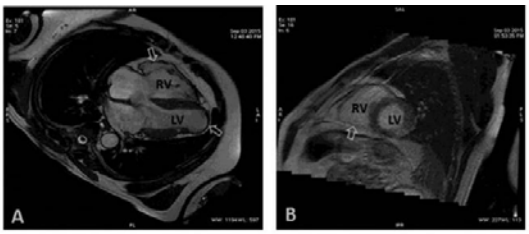

Figure 1. Cardiac magnetic resonance imaging. A-Cine study: Long axis view shows RV dilatation with dyskinesia and LV aneurysm (arrows); B-short axis view after LGE reveals RV wall fibrosis (arrow). LV=left ventricle; RV=right ventricle

P614
A case of cardiac fibroma

TH Thai Hao Phan[1]
[1]Pham Ngoc Thach University of Medicine, Ho Chi Minh City, Viet Nam

Introduction: Cardiac fibroma is a rare benign primary tumor of the heart, which has been reported as the second most common benign cardiac tumor following rhabdomyoma in the pediatric population. Fibroma accounts for between 12 and 16% of primary cardiac tumors in children. Signs and symptoms are nonspecific, including arrhythmias, dyspnea, cyanosis, chest-pain and sudden mortality. However, a number of patients with cardiac fibroma are asymptomatic. The prevalence of cardiac fibroma is rare in the adult population. Echocardiography is the initial diagnostic modality for evaluating cardiac fibroma, and computed tomography (CT) or magnetic resonance imaging (MRI) can be as supplementary diagnostic techniques. The present case report describes an adult with cardiac fibroma arising from the left ventricle.
Case Presentation: A 34-year-old man presented with chest pain, which continued for 1 months and no association with regular activities such as walking. Physical examination revealed normal blood pressure and regular pulse. Patient was previously healthy, referring no prior cardiac surgery, chest radiotheray or tuberculosis. His family were normal.
Results: Electrocardiogram indicated normal sinus rhythm. Subsequently, echocardiography was performed, and revealed a large mass located in the left ventricular lateral wall. Cardiac magnetic resonance imaging (MRI) indicated a large mass located in the lateral wall of the left ventricle. The mass was regular and well defined, with a size of 7×4 cm are MRI images captured of the T1 transaxial section, T2 transaxial section, T2 coronal section and T2 sagittal section, respectively. The mass was T1 iso-intense compared with cardiac muscle and T2 hypo-intense compared with cardiac muscle. Myocardial first-pass perfusion images indicated an enhancement in the mass compared to the myocardial wall and in delayed phase perfusion images, the mass showed homogeneous enhancement. In addition, MRI functional analysis reported mild reduction in cardiac function.
Discussion: Echocardiography is non-invasive, fast and does not involve the use of radiation. It is generally the initial diagnostic modality for evaluating cardiac fibroma. Supplementary diagnostic techniques include computed tomography (CT) or MRI. CT and MRI can provide the location of the tumor, as well as identifying its surrounding structures and hemodynamic effects. In addition, MRI can provide additional functional data. Therefore, cardiac MRI is the modality of choice for further evaluation of cardiac fibroma. In this case, the cardiac MRI showed a regular solid lesion, which was iso-intense relative to muscle on T1-weighted and hypo-intense on T2-weighted images, which suggested fibrosis.
Conclusion Cardiac fibroma is very rare in adults. Echocardiogram, CT and cardiac MRI can provide valuable findings. Surgical excision is a reliable and effective method for treatment.

P615
Role of cardiac resynchronization therapy in optimizing the recovery of left ventricular function in a patient with peripartum cardiomyopathy and left bundle branch block

H A Farhan[1]; G F Haji[1]; G M Mahmood[1]; I F Yaseen[1]
[1]Baghdad Medical City, Cardiology, Baghdad, Iraq

Introduction: Peripartum cardiomyopathy (PPCM) is presenting at the end of pregnancy or within 6 months postpartum with left ventricular dysfunction with EF <45%. Incidence is estimated to be 1:1000-4000. Rates of recovery ranging from 29 – 72% and mortality 25%.Management including medical therapy, cardiac devices, and heart transplant. Available published data showing three reported cases of PPCM with LBBB for whom Cardiac resynchronisation therapy [CRT] was implanted

Case Presentation: A 36-year-old woman, presented 3 months postpartum with severe dyspnea (NYHA III), she has non relevant past medical history. Echocardiography showed LVEF 25% and severe MR, diagnosed as PPCM
Management: Medical therapy was started with carvedilol, ramipril, indapamide, and spironolactone. After 17 months, despite the maximum tolerated dose of medical therapy, LV function did not improve and her symptoms worsen. Her ECG showed LBBB. Post CRT implantation, her LVEF recovers after 3 months, reaching 60% at 7 month follow up with dramatic improvement in her symptoms (NYHA I).
Conclusion and implication for clinical practice
CRT could be considered for optimizing LV function recovery in patients with PPCM despite optimal medical therapy. Comparing with the other two published cases, first case was refractory for medical therapy for 9 years with EF 28%, reached 55% six-month after CRT. Second case, her EF was 25% over 6 years, then 45% six-month post CRT. According to the current guideline in heart failure, eligibility for CRT should be evaluated after 6 months, however, the possibility of PPCM recovery make the early decision of CRT challenging. Moreover, the current data regarding use of CRT in PPCM is limited and there is a lack of precise follow up. Therefore, we need focus and orientation regarding this topic to bridge the gap of evidence to determine predictor factors for optimum time of CRT implantation in patients who are refractory to medical management

P617
The pineal hormone melatonin inhibits doxorubicin-induced mitochondrial dysfunction and apoptosis in cardiomyocytes

T Kasi Ganeshan[1]; JD Bell[1]; NW Chong[1]
[1]*University of Westminster, School of Life Sciences, London, United Kingdom of Great Britain & Northern Ireland*

Background: Heart failure (HF) is a major end-point of cardiovascular diseases (CVD). The pathogenesis of HF is mostly unresolved but involves metabolic alterations. Treatment of animals and cardiomyocytes with β-adrenergic receptor agonists induces HF. Mitochondrial dysfunction and HF are common complications of anticancer drugs such as doxorubicin (DOX). Melatonin synthesis dramatically decreases with age and in patients with CVD.
Purpose: The aim of this study was to investigate whether DOX-induced cardiac dysfunction can be attenuated by melatonin.
Methods: The Seahorse XF analyser was utilised (with the XFp Cell Energy Phenotype kit) to measure oxygen consumption rate [OCR; oxidative phosphorylation (OXPHOS)] and extracellular acidification rate (ECAR; glycolysis) in living rat cardiomyocyte-derived H9c2 cell line. Mono-layers of cells were treated with cardiotoxic drugs [isoproterenol (ISO, 100μM) or DOX (0.1μM)] for 24hr with and without melatonin co-treatment (MEL, 1μM). Cyan ADP flow cytometry was used to examine the anti-apoptotic properties of MEL (1μM) on DOX-treatment (0.5μM, 24hr). Data are given as mean$\pm$SEM (n=separate experiments) and analysis was performed using ANOVA and two-tail unpaired Student's T-test, as applicable.
Results: Isoproterenol-treatment increased peak OCR of H9c2 cells by ~30% which was inhibited by MEL [CON, 384$\pm$17; ISO, 496$\pm$33; ISO+MEL, 412$\pm$31pmol/min; n=3 (six replicates); CON vs. ISO, $p<0.05$; ISO vs. ISO+MEL, $p<0.05$; CON vs. ISO+MEL, $p>0.05$]. Doxorubicin-treatment decreased OCR by ~40% which was reversed by MEL. [CON, 934$\pm$69; DOX, 554$\pm$52; DOX+MEL, 858$\pm$97pmol/min; n=3 (six replicates); CON vs. DOX, $p<0.05$; DOX vs. DOX+MEL, $p<0.05$; CON vs. DOX+MEL, $p>0.05$]. ISO and DOX significantly increased (~30%) and decreased (~25%) ECAR respectively (n=3, $p<0.05$) which was not inhibited by MEL. Melatonin alone had no significant effect on OCR and ECAR. Melatonin inhibited DOX-induced apoptosis in H9c2 cells [CON, 6.3$\pm$0.8%; DOX, 22$\pm$1.8%; DOX+MEL, 11$\pm$1.7%, n=4 (two replicates); CON vs. DOX, $p<0.001$; DOX vs. DOX+MEL, $p<0.004$; CON vs. DOX+MEL, $p>0.05$].
Conclusions: ISO and DOX-treatment induced mitochondrial dysfunction in H9c2 cells by alteration of OXPHOS and glycolysis; changes in OXPHOS were prevented by MEL. These data indicate that DOX-induced apoptosis in cardiac cells may be mediated, at least in part, by OXPHOS dysfunction which was attenuated by MEL treatment.

P618
Reactivation of fetal gene program, cardiomyocyte dedifferentiation and hypertrophy in heart failure

T Tatiana Kulikova[1]; O Stepanova[1]; A Voronova[1]; M Valikhov[1]; I Zhirov[1]; V Masenko[1]; A Samko[1]; S Tereshchenko[1]
[1]*Russian Cardiology Research and Production Complex, cardiology department, Moscow, Russian Federation*

Funding Acknowledgements: RFBR: 18-015-00198 "Studying of energy cardiac metabolism and cardiomyocyte dedifferentiation in chronic heart failure"

In heart failure (HF) cardiomyocyte remodeling includes: restructuring of the contractile apparatus; changes in energy metabolism. Dedifferentiation represents a key feature of cardiomyocyte remodeling. It is characterized by reactivation of the fetal gene program. Compared to normal myocytes, dedifferentiated cells become more fetal with increased diameter and surface area. Dedifferentiation arises in vivo, in fibrillating atria, ischemic myocardium, and in the border zone of myocardial infarcts. Such dedifferentiated myocytes are not apoptotic and presumably reflect adaptations to abnormal myocardial stress. Re-expression of alpha skeletal actin (alpha SKA) is a marker of cardiomyocyte dedifferentiation but in the same time it is a marker of cardiomyocyte hypertrophy too. Cell dedifferentiation is accompanied by a shift from oxidative phosphorylation to glycolysis. A key regulator of cardiac energy metabolism is transcription factor peroxisome proliferator-activated receptor alpha (PPAR alpha).
The aim of the work to study cardiomyocyte dedifferentiation and hypertrophy in dilated cardiomyopathy (DCM) and HF, the expression of alpha SKA, PPAR alpha and of myosin protein kinase zipper interacting protein kinase (ZIPK) in cardiomyocytes. Endomyocardial biopsies (EMB) were obtained from 28 patients with DCM and HF. Transmission electron microscopy was used to detect cell ultrastructure. The gene expression levels of PPAR alpha, alpha SKA and ZIPK were determined using real time PCR.
Revealed cardiomyocytes have main features of dedifferentiated cardiomyocytes - increased diameter and surface area, sarcomere disorganization, enhanced glycogen content. Gene expression levels of PPAR alpha decreased, gene expression levels of alpha SKA and ZIPK increased in DCM and HF.
PPAR alpha expression level decrease shows shift from oxidative phosphorylation to glycolysis, a transition to dedifferentiated state of cardiomyocytes. Our results demonstrate the reactivation of the fetal gene program, features of fetal heart include the preference of carbohydrates over fatty acids as energy substrate. ZIPK expression level is elevated, perhaps ZIPK is involved in sarcomerogenesis during hypertrophy in HF. The level of alpha SKA may be a useful determinant for the degree of dedifferentiation in HF and an indicator for possible redifferentiation. Since the reactivation of the fetal cardiac gene program is also a characteristic feature of hypertrophic cardiomyocytes during HF, it is possible that the main distinction between hypertrophy and dedifferentiation was made by the presence or absence of glycogen accumulation. We propose that cardiomyocytes detected in our study are dedifferentiated cardiomyocytes. Dedifferentiated cardiomyocytes may take part in cardiac regenerative processes in HF and the understanding of the mechanisms of dedifferentiation, proliferation and redifferentiation of cardiomyocytes is important for heart regeneration and repair.

P620

Desmin s head domain is important for interaction with mitochondrial and lysosomal proteins: implications for cardiomyopathy

K Tsilafakis[1]; D Vlachakis[2]; I Kostavasili[1]; S Kossida[3]; M Manolis Mavroidis[1]
[1]Biomedical Research Foundation Academy of Athens, Greece, Athens, Greece; *[2]University of Athens, Athens, Greece*; *[3]University of Montpellier, Montpellier, France*

Posttranslational modification of serine residues 27 and 31 in desmin head domain have been implicated in heart failure by preamyloid oligomers (PAO) formation (1). To better understand the functionality framework of desmin's head domain interactions, in health and disease we have used a yeast two hybrid system in order to identify new binding partners. We described a mitochondrial and a lysosomal protein, NDUFS2 and saposin D respectively, as direct desmin binding partners. The protein-protein interactions were confirmed in vitro by GST-pull down assays. A homology modeling approach was employed to determine 3D structure of desmin and NDUFS2, as for saposin D an actual crystal structure already existed. These 3D structures were further used as an input for protein-protein docking analysis by which we observed that both interactions occur in a very similar pattern by forming a three helix bundle that comprises one α-helix from desmin's head domain and two α-helical domains from NDUFS2 or saposin D. The desmin interacting part of both NDUFS2 and saposin D is almost identical. The latter adds up to the confirmation of the reliability of our 3D homology model of NDUFS2 protein, since its identical saposin-D counterpart is an actual crystal structure of high reliability. Deletion of desmin's head domain (aa 1-35) and GST-pull down analysis confirmed its importance for desmin binding to NDUFS2 and saposin D. Analysis of cell lines transfected with truncated desminΔ1-35 (missing aa 1-35) indicated increased aggregate desminΔ1-35 co-localization with Rab5, suggesting possible dysregulation of protein and/or organelle trafficking.
Conclusions: Our results indicate that desmin's head domain is necessary for the interaction with NDUFS2 and saposin D, proteins of key organelles for cardiomyocytes function in health and disease. Also cleavage of desmin head domain increases desmin-positive protein aggregates, a mechanism that has been linked to PAO formation.

The novel butyrate derivative phenylalanine-butyramide protects from doxorubicininduced cardiotoxicity

M Russo[1]; F Guida[1]; L Paparo[1]; G Trinchese[2]; C Avagliano[3]; F Napolitano[4]; V Sala[5]; M Li[5]; A Ghigo[5]; D Sorriento[6]; P Abete[1]; D Bonaduce[1]; A Calignano[3]; RB Canani[1]; CG Tocchetti[1]

Introduction: With advancements in cancer survival, an increasing number of patients are at risk of anticancer drug-cardiotoxicity. Butyric acid (BUT), a short chain fatty acid produced daily in nanomole concentrations by the gut microbiota, has proven beneficial in models of cardiovascular diseases, but its translation into clinical practice is difficult because of its unpleasant organoleptic properties and its rapid degradation that alters its stability.
Purpose: Here we assess whether the novel BUT-derivative Phenylalanine-butyramide (FBA) protects from doxorubicin (DOXO) cardiotoxicity, by decreasing oxidative stress and improving mitochondrial function.
Methods: C57/BL6 mice (2-4 mo. old) were randomly divided in four groups. At day 0, mice in the FBA and FBA + DOXO groups were pre-treated with FBA daily for 21 days by oral gavage, while SHAM and DOXO mice received vehicle as control. At day 15, DOXO and FBA+DOXO mice were injected with Doxorubicin (1 mg/kg day, 1h after daily pre-treatment with vehicle or FBA) for the next 7 days, while SHAM and FBA mice were treated with saline solution. At day 21, mice were sacrificed for ex-vivo analysis. Heart function was monitored by echocardiography analysis at days -1, 14, 17 and 21.
Results: In C57BL6 mice, DOXO produced LV dilation assessed by echocardiography. FBA prevented LV dilation, fibrosis (assessed by PicroSirius Red staining) and cardiomyocytes apoptosis (assessed by TUNEL) when co-administered with DOXO. DOXO increased atrial natriuretic peptide, brain natriuretic peptide, connective tissue growth factor, and matrix metalloproteinase 2 mRNAs significantly, which were not elevated on co-treatment with FBA. DOXO, but not FBA+DOXO mice, also showed significantly higher nitrotyrosine levels, and increased iNOS expression. Accordingly, DOXO hearts showed significantly lower levels of intracellular catalase vs SHAM, while pretreatment with FBA prevented this decrease. We then assessed for ROS emission: DOXO induced significant increased activity of mitochondrial SOD and higher production of H2O2, which were blunted by FBA pretreatment. FBA also ameliorated mitochondrial state 3 and state 4 respiration rates that were significantly compromised by DOXO. Furthermore, in DOXO animals the mitochondrial degree of coupling was significantly increased vs SHAM, while FBA was able to prevent such increase, contributing to limit ROS production, Finally, FBA significantly reduced the toxicity of DOXO in hiPSC cardiomyocytes as measured by relative LDH release, protected HUVEC against DOXO-induced mortality and increased the tumor-killing action of DOXO in MCF7 cancer cells
Conclusions. FBA protects against experimental doxorubicin cardiotoxicity. Such protection is accompanied by reduction in oxidative stress and amelioration of mitochondrial function. Thanks to its organoleptic and pharmacokinetic features, oral assumption of FBA could be easily tolerated by
oncological patients.

Catalpol ameliorates neointimal hyperplasia in streptozotocin induced diabetic rats

C-M Chiu-Mei Lin[1]; K-G Shyu[2]; B-W Wang[3]
[1]Shin Kong Wu Ho-Su Memorial Hospital, Emergency Medicine, Taipei, Taiwan, Province of China; *[2]Shin Kong Wu Ho-Su Memorial Hospital, Cardiology, Taipei, Taiwan, Province of China*; *[3]Shin Kong Wu Ho-Su Memorial Hospital, Central Laboratory, Taipei, Taiwan, Province of China*

On behalf of: Skin Kong Hospital
Funding Acknowledgements: non

Background/purpose: Diabetes is a prime risk factor of cardiovascular diseases, and results from the glucose and lipid metabolic dysregulation attribute to vascular and myocardial damage, then lead to heart failure. Catalpol, an iridoid glycoside, is an isolated natural product of Rehmannia glutinosa, which has been reported to have antidiabetic properties. This study investigated the vascular protective effects of catalpol in hyperglycemic rats with balloon-injured carotid arteries. Methods:Balloon injury stress led to the upregulation of monocyte chemoattractant protein-1 (MCP-1) expression in rats with streptozotocin (STZ)-induced diabetes. Western blotting, and real-time polymerase chain reaction (PCR), immunohistochemistry and confocal analyses were performed. Results: MCP-1 levels were increased through STZ induction or balloon injury. Catalpol and MCP-1 siRNA treatment significantly ameliorated the neointima after balloon injury. The area of neointima decreased by 58.8% after MCP-1 siRNA delivery and 54.8% after administrating catalpol treatment compared with the control group after 2 weeks. The lumen size increased by 90.2% and 91.1% after catalpol and MCP-1 siRNA treatment, respectively. Real-time PCR and immunohistochemical analysis demonstrated reduced levels of MCP-1 2 weeks after balloon injury. MCP-1 expression was significantly increased in balloon-injured rats compared with the control groups. Thus, treatment with catalpol affected MCP-1 expression. Conclusion:This study demonstrated that catalpol downregulated MCP-1 expression in carotid artery and ameliorated neointimal hyperplasia in hyperglycemic rats. The results imply that catalpol play an important role in neointimal hyperplasia and potentially effective for preventing hyperglycemia related ischemic cardiac diseases.

Resveratrol and sacubitril/valsartan reduce cardiac oxidative stress, inflammation and fibrosis in myocardial infarction induced rats

P Pema Raj[1]; L Yu[2]; J Wigle[1]; T Netticadan[1]; S Zieroth[1]
[1]University of Manitoba, Winnipeg, Canada; *[2] Canadian Centre for Agri-Food Research in Health and Medicine, Winnipeg, Canada*

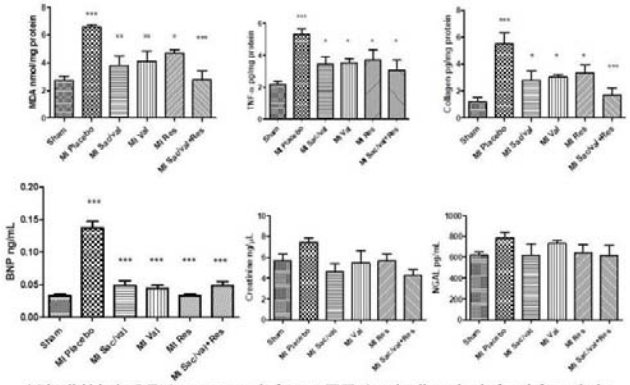
Funding Acknowledgements: The study was funded by an unrestricted research grant from Novartis.

Background: Resveratrol (res) is a plant polyphenol which offers cardioprotection as reported by both pre-clinical and emerging clinical studies. Our previous work showed that sacubitril/valsartan (sac/val), valsartan (val) and resveratrol (res) alone improved cardiac function and remodeling linked to heart failure (HF) in myocardial infarction (MI) induced rats. In addition combination therapy with sac/val+res was found to be more cardioprotective with a trend towards improving LVEF.
Objective: To investigate the mechanism of action of standalone and combination treatment with sac/val and res in MI rats. To delineate the post-MI renal changes and effects of sac/val, and res on renal function and injury following an MI.
Methods: The left anterior descending coronary artery was occluded in young male Sprague Dawley rats. Sham-operated male rats served as age-matched controls. Sham and MI study groups received either, placebo alone, sac/val alone

(68mg/kg/day), val alone (31mg/kg/day), res alone (2.5mg/kg/day) or sac/val+res combination (68+2.5 mg/kg/day) daily for 8 weeks and blood plasma and heart tissues were obtained at the endpoint. All treatments were started immediately after surgery to simulate clinical scenarios. Malondialdehyde (MDA), tumor necrosis factor (TNF-α), and collagen levels were determined from left ventricular tissue from all groups. Plasma brain natriuretic peptide (BNP), creatinine and neutrophil gelatinase associated lipocalin (NGAL) levels were also measured. The study was approved by the Animal Ethics Board.

Results: The MI group that previously showed significant improvement in cardiac remodeling and dysfunction with sac/val, val, res and sac/val+res treatment had significantly lower levels of MDA compared to MI placebo group (6.59 vs 3.786±0.72, 4.11±71($p < 0.01$), 4.68±0.24 ($p < 0.05$), and 2.78±0.64, ($p < 0.001$)). Sac/val, val, res, and sac/val+res also significantly reduced the level of TNF-α in MI rats compared to MI placebo (5.33±0.31 vs 3.44±0.45, 3.52±0.28, 3.67±0.64, and 3.06±0.61, ($p < 0.05$)). MI rats treated with sac/val, val, res, and sac/val+res had significantly decreased levels of collagen compared to MI placebo (5.50±0.80 vs 2.78±0.71, 3.09±0.20, 3.35±0.59, and 1.67±0.58 ($p < 0.05$). Sac/val, val, res, and sac/val+res also significantly reduced the level of BNP in MI rats (0.13±0.01 vs 0.05±0.007, 0.04±0.005, 0.03±0.002, and 0.05±0.006 ($p < 0.001$)). Creatinine and NGAL levels comparable between the groups.

Conclusion: Sac/val, val, res and sac/val+res prevented cardiac remodeling and dysfunction in MI rats via cardioprotective mechanisms mitigating oxidative stress, inflammation and fibrosis. These findings further support the study of sac/val and resveratrol as treatment strategies in post-MI patients with HF and warrants consideration of future translational clinical trials. In addition, there was no evidence of post-MI renal dysfunction or injury with the standalone or the combination treatments.



Malondialdehyde (MDA), tumor necrosis factor-α (TNF-α), and collagen levels from left ventricular tissue and plasma brain natriuretic peptide (BNP), creatinine and neutrophil gelatinase associated lipocalin (NGAL). All values are expressed as mean±SEM, n=4-6. *** $p<0.001$ vs Sham; ***$p<0.001$, **$p<0.01$ and *$p<0.05$ vs MI Placebo.

Parathyroid hormone causes endothelial dysfunction by inducing mitochondrial ROS and specific oxidative signal transduction modifications

J Gambardella[1]; M De Rosa[1]; D Sorriento[1]; N Prevete[2]; A Fiordelisi[1]; M Ciccarelli[3]; B Trimarco[1]; N De Luca[1]; G Iaccarino[1]

[1]Federico II University of Naples, Naples, Italy; *[2]Federico II University Hospital, Dept of Translational Medical Sciences, Naples, Italy*; *[3]University of Salerno, Medicine and Surgery, Salerno, Italy*

Background: Vitamin D deficiency contributes to cardiovascular risk (CVR), with subsequent hyperparathyroidism advocated as a putative mechanism. Indeed, mounting evidence supports the hypothesis that parathyroid hormone (PTH) impairs endothelial function, even though mechanisms are not fully elucidated. Purpose: The present study was designed to verify in vitro the ability of sustained exposure to PTH to cause endothelial dysfunction, exploring the underlying mechanisms. Methods: In bovine aortic endothelial cells (BAEC) in response to acetylcholine (Ach) and Bradykinin (BK) we evaluated Ca2+ handling and NO production using Fluo4/Rhod2 and DAF-FM respectively. The production of mitochondrial ROS (mROS) and total ROS (tROS) was assessed by cytofluorimetry using MitoSOX and DCFH respectively. The oxidation levels of Ach, BK and VEGF receptors was determined using oxiblot kit. The angiogenic competence was assessed determining the formation of capillary like structures on matrigel. Results: we evaluated the effects of PTH exposure ([0,1 nM]-24 hours) on both endothelial responsiveness to vasodilators, such as Bk [30 nM] and Ach [1 μM], and angiogenic competence. Pretreatment with PTH impaired endothelial response to Bk, but not to Ach, in terms of cytosolic Ca2+ fluxes and NO production. In order to explore the underlying mechanisms, we assessed the production of tROS and mROS in response to PTH (at 1 and 3 hours). PTH increased ROS generation, in a minor extent when compared to hypoxia, but enough to determine oxidation of Bk-receptor B2. Conversely, oxidation of Ach-receptors M1 and M3 was not affected by PTH. A mROS selective scavenger (MitoTEMPO, [5 μM]) restored the endothelial responsiveness to Bk while Vitamin D ([100 nM]) failed to counteract PTH-mediated oxidative stress, although its antioxidant properties are well-established. PTH determined mitochondrial calcium fluxes ([Ca2+]mt) and the inhibition of Mitochondrial Calcium Uniporter with Ru360 [10 μM] reduced mROS production and prevented the following PTH-mediated endothelial dysfunction. The evaluation of Angiogenic competence was impaired in PTH-pretreated cells ([0,1 nM]-24 hours), despite the increase in VEGF transcriptional levels. VEGF-R2 oxidation occurred in response to PTH, suggesting that even the impairment of angiogenesis was due to ROS surge.

Conclusions: These results indicate that PTH affects endothelial function through ROS production, driven by mitochondrial calcium overload. PTH-induced oxidative stress might act as signaling modifiers, altering specific pathways (Bk and VEGF) and preserving others (Ach).

Increasing the intensity of preconditioning training reduces the systolic right ventricle pressure in the heart of rats with pulmonary hypertension

N Natalia Medvedeva[1]; N Pankova[1]; M Artemieva[1]

[1]M.V. Lomonosov Moscow State University, Biology Department, Moscow, Russian Federation

Objective. For many diseases recommended physical activity, but not in the case of pulmonary hypertension (PH). It is known that exercise increases the postload on the right ventricle of the heart, which is risky for PH patients. However, recently there is more and more evidence of improving the overall physical condition of a patient with pulmonary hypertension in response to physical activity. The aim of this work was to study the effect of different types of exercise preconditioning on the degree of hPH on female Wistar rats.

Design and method. Female Wistar rats were used. Animals were divided into 4 groups. Two groups were with exercise preconditioning. For exercise preconditioning rats were subjected to exercise training by everyday swimming for a period of 2 weeks to hypoxia. First group was with aerobic swimming during 30 min/day without additional weight (hEx0). Second group was with swimming during 15min/day with additional weight equal to 4% of body weight (hEx4). The other two groups were not trained (and hC). 14 days after the start of exercises all rats except half untrained were exposed to hypoxia 10h/day, 2wk. with 10% in hypobaric chamber. Two weeks after the onset of hypoxia systolic right ventricle pressure (SRVP) was measured as indices of hPH.

Results. Two weeks after the onset of hypoxia all groups of rats developed hPH with different extent of the disease. Thus, hypoxia was accompanied by an increase in SRVP by 38% between C and hC groups ($p<0,05$). Aerobic exercise resulted in an increase in SRVP from 54±2 (hC) to 67±4 (hEx0) mmHg ($p<0,05$). The increase in training intensity caused a decrease in SRVP by 40% in the hEx4 group compared to the hEx0 group ($p<0,05$) and was 46±3,4 mmHg. Between hypoxic rats of all groups were not difference in RV hypertrophy.

Conclusions. Increasing the intensity of exercises training preconditioning from aerobic swimming to swimming with additional weight is accompanied by a decrease in SRVP but does not affect RV hypertrophy in the rat with hypoxia pulmonary hypertension.

P627

Protective effects of soluble ubiquinol in monocrotaline model of pulmonary hypertension in rats

O Oleg Medvedev[1]; S Abdullaev[1]; T Kuropatkina[1]; M Artemieva[2]; N Medvedeva[2]

[1]M.V. Lomonosov Moscow State University, Pharmacology, Moscow, Russian Federation; *[2]Lomonosov Moscow State University, Biology, Moscow, Russian Federation*

Objective: Due to its high antioxidant activity ubiquinol (U) potentially could be used for the treatment of cardiovascular diseases coupled with the development of oxidative stress and inflammation. There are several papers, showing the positive effect of ubiquinol on endothelium-dependent vasodilation. Pathogenesis of pulmonary hypertension (PH) is associated with inflammation and endothelial dysfunction. Effects of ubiquinol on PH development has not been studied before. Therefore, the aim of this work was to investigate the possible effects of ubiquinol on PH development in experiments on rats.

Design and method: Experiments was performed on male Wistar rats divided into 3 groups. All animals were subcutaneously injected with a solution of monocrotaline (MCT) (60 mg/kg, 0.5 ml) on the first day of the experiment. On 7th and 14th days

after the start of experiment animals of the group 1 were injected with a solution of solubilized U (30 mg/kg, iv), group 2 – with vehicle (V) and group 3 - physiological saline, (PS) in appropriate volumes. On the 21st day after MCT injection rats of each group were anaesthetized (urethane, 1.2 g/kg) and systolic right ventricular pressure (SRVP) and arterial blood pressure were measured. For testing vascular reactivity phenylephrine (PE) (6 μg/kg) and sodium nitroprusside (SNP) (6 μg/kg) were injected iv. After decapitation of narcotized rats the weight of right ventricle (RV) was measured and RV hypertrophy (RVH) was calculated as RV weight/body weight. Endothelium-dependent vasodilatation (evoked by acetylcholine (ACh) of isolated segments of pulmonary and systemic vessels were investigated as well.
Results: PH developed in all groups of animals 3 weeks after injection of MCT, that was confirmed by the increase in SRVP and RVH. Differences between of SRVP levels between groups (44.4 mmHg for U-group, 45.7 mmHg for V-group, and 44.5 mmHg for PS-group) were not significant Values of RVH demonstrated a significantly lower degree of hypertrophy development in U group compared to PS group (0.00076 vs 0.00085, $p<0.05$). The response of systemic blood pressure to intravenous injection of SNP in group U was 5.27% higher than in PS group and 18.29% higher than in the V group. A similar pattern was found for reaction to PE, that shows the capability of U to restore reactivity of blood vessels of systemic circulation to vasoactive factors. Study of reactivity of isolated segment of pulmonary artery at ACh showed that in group U compared with V-group there was a statistically significant increase in vasodilator response to ACh at concentrations of 10-7M(23% vs 17.2%), 10-6M (30.3% vs 25.1%), 10-5M (36.9% vs 30.9%) ($p<0.05$ for all).
Conclusions. Double intravenous administration of ubiquinol on an MCT model of PH on rats was able to inhibit the degree of RVH, being one of the major symptoms. In addition, it contributes to the restoration of reactivity of both systemic and pulmonary vessels.

P628

In the sugen/hypoxia model of pulmonary arterial hypertension in mice, abrogation of S100A1 exacerbates right ventricular dilation and fetal gene expression

J James Tsoporis[1]; K Teichert-Kuliszewska[1]; JF Desjardins[1]; S Izhar[1]; TG Parker[1]
[1]*St. Michael's Hospital, Toronto, Canada*

Introduction: The calcium sensor protein S100A1 is expressed in myocardium and endothelial cells and regulates cardiac muscle contractility. Previously, we demonstrated that under basal conditions in vivo, S100A1 knockout mice (KO) exhibited an elevation in right ventricular systolic pressure (RVSP), accompanied by an increase in RV hypertrophy.
Purpose: Since RV dysfunction occurs with progression of pulmonary arterial hypertension (PAH), we aimed to determine the impact of deleting S100A1 on progression of PAH in the Sugen-hypoxia (SUHx) model in mice.
Methods: C57BL6 (WT) and S100A1 KO mice (n=10 per group) were injected once weekly subcutaneously with SU (20mg/kg) and exposed to chronic Hx (10% O2) for 3 weeks. PAH was assessed by hemodynamic parameters, RV morphology and echocardiography. RV and lung tissue were collected for molecular analysis.
Results: In WT and S100A1 KO mice exposed to SUHx, RVSP was similar 31.0±1.90 vs.31.4±2.08, (mean+SEM) respectively. In RV and lung tissue of WT mice, S100A1 mRNA and protein decreased approximately 40% in response to SUHx. SUHx induced similar increases in RV weight calculated as the Fulton index (0.43±0.06 in WT vs. 0.41±0.04 in S100A1KO) but in contrast to WT, S100A1 KO demonstrated a 3.7-, 2.5-, and 1.5- fold increase in the mRNA levels of the hypertrophic genes, atrial natriuretic factor, β-myosin heavy chain and skeletal α-actin, respectively ($p<0.05$). In S100A1 KO mice SUHx reduced heart rate (S100A1KO - 305.41±54.69 vs. WT-443 ±54.82 bpm, $p < 0.001$) compared to WT. Furthermore, serial echocardiographic assessment indicated increased RV dilation in the S100A1KO compared to the WT in response to SUHx as assessed by increases in RV internal diameter in both diastole (S100A1KO, 1.92±0.08 vs. WT, 1.53 ±0.08, p=0.004) and systole (S100A1KO, 1.34±0.1 vs. WT, 0.97±0.01, p=0.02) .
Conclusion: Our results show that PAH is associated with decreased expression of S100A1 in the RV and lack of S100A1 increases RV dilation and expression of fetal gene markers in the SUHx model. S100A1 may serve to limit severity of RV structural changes in PAH and represents a potential therapeutic target in this disease.

P629

Impact of sympathectomy upon myocardium

F Fernanda Pessoa[1]; MR Jordao[1]; KCB Fonseca[1]; F Zanoni[2]; VMC Salemi[3]; ON Ribeiro[1]; LE Souza[3]; F Fernandes[1]; MC Irigoyen[3]; LFP Moreira[2]; C Mady[1]; FJA Ramires[1]
[1]*Heart Institute of the University of Sao Paulo (InCor), Cardiomyopathy Unit, Sao Paulo, Brazil*; [2]*University of Sao Paulo, Sao Paulo, Brazil*; [3]*Heart Institute of the University of Sao Paulo (InCor), Sao Paulo, Brazil*

Funding Acknowledgements: FAPESP

Rationale:Studies suggest that sympathectomy could be used to treat heart failure. However, its physiological effects on the heart have been minimally studied. Objective:We sought to evaluate the effects of sympathectomy on myocardium in an experimental model. Methods and Results:The study evaluated 3 groups of male Wistar rats: control (CT) (15), left unilateral sympathectomy (UNI) (15), and bilateral sympathectomy (BIL) (31). We assessed chronotropic properties at rest and stress, cardiovascular autonomic modulation, myocardial and peripheral catecholamines, and beta-adrenergic receptors in the myocardium. The proposed variables for analysis were obtained by resting ECG, echocardiography, maximal exercise test, heart rate (HR) and systolic blood pressure (BP) variability measured in the time and frequency domain. The information regarding β-receptors and myocardial and peripheral catecholamines was obtained by PCR, ELISA and HPLC, respectively. The BIL group had basal tachycardia immediately before the exercise test and more tachycardia at peak exercise (CT: 387±47 vs BIL: 461±22 bpm, $p<0.01$). Blood pressure had the same pattern (CT: 104±13 vs BIL: 121±8 mmHg, P=0.0365). The variables related to autonomic modulation had no statistical significance except the high frequency (HF) variable, which had significant differences in CT vs UNI. We observed that beta receptor expression had no statistical difference between groups. Despite no statistical significance difference β2 receptor had 1/3 expression in the base and apex compare to control, and β1 at the apex had the double expression. There was a higher concentration of peripheral norepinephrine in the BIL group (CT: 1.08±1.22 ng/mL vs BIL: 3.94 ±1.73 ng/mL, P=0.0001). There was no difference in myocardial norepinephrine (P=0.09). It may suggest that the animals in the bilateral group had higher levels of peripheral catecholamines, consequently a higher heart rate, and blood pressure levels.
Conclusions: These findings suggest an extra cardiac compensatory pathway increases the sympathetic tonus and maintains a higher HR, higher levels of peripheral norepinephrine, and downregulation of beta 2 receptors in the procedure groups. The increase in HF activity can be interpreted as an attempt to increase the parasympathetic tonus to balance the greater sympathetic activity.

P630

Pulmonary infarction in acute pulmonary embolism: a sign of poor prognosis?

J Joao Santos[1]; G Pereira[1]; H Antunes[1]; L Abreu[1]; I Pires[1]; L Goncalves[1]; I Almeida[1]; E Correia[1]
[1]*Hospital Sao Teotonio, Viseu, Portugal*

Introduction Pulmonary infarction (PI) is a common complication in patients with pulmonary embolism (PE), and its impact on prognosis is still uncertain. The main purpose of this study was to evaluate the association between the presence of PI and clinical characteristics and prognosis in patients with PE.
Methods A retrospective analysis of 209 patients admitted to a Cardiology ward due to PE was performed. Patients without data on PI were excluded (n=143). The Mann-Whitney U or T-test were used to compare means of selected variables: leukocytes, neutrophils, C-reactive protein (CRP), troponin I, BNP, heart rate (HR), oxygen pressure in arterial blood gas analysis (pO2), right ventricle diameter (RVD), pulmonary artery diameter (PAD), days of hospitalization (DH) and PESI score. The Chi-square test ($\chi 2$) was used to evaluate the association between fever, chest pain, hemoptysis, tachypnea or syncope at presentation and PI, as well as the association with in-hospital mortality. Mortality at 2 years of follow-up was evaluated with a Kaplan-Meier survival analysis. A multivariable logistic regression (MRlog) model was used to assess the predictive value of the significant variables for the presence of PI.
Results Mean patient age was 63 (±18) years. 60% were female. PI was present in 25%. There was no significant association between PI and neutrophil count, troponin I, BNP, HR, RVD, PAD, DH and PESI score. Higher leukocyte count (p=0.02) and CRP value ($p<0.001$) revealed significant association with PI. There was a trend towards association between higher pO2 and PI (p=0.052). Chi-square test test revealed a significant association with hemoptysis (p=0.001) and chest pain (p=0.014). There was no difference between patients in terms of fever, tachypnea or syncope. There was no significant association between the presence of PI and the risk of in-hospital mortality. The logrank test in Kaplan-Meier survival curves did not reveal a significant difference in mortality after 2 years of follow-up (p=0.17). In MRlog model, only CRP (p=0.001), hemoptysis (p=0.015) and chest pain (p=0.049) retained statistically significant association with PI.
Conclusion PI might be related with a more pronounced inflammatory process, associated with greater rise in CRP levels. Patients with PI appear to present more often with hemoptysis and chest pain than patients without PI. There is no apparent association between PI and in-hospital mortality or mortality at 2 years of follow-up.

P631

HFWM: Inhibition of the pro-inflammatory neutrophil mediator S100A8/A9 alleviates heart failure development post-myocardial infarction

A Alexandru Schiopu[1]; G Marinkovic[2]; L Decamp[3]; L Winkler[3]; R Mares[4]; IA Szabo[4]; I Goncalves[2]; I Nilsson[2]; S Jovinge[3]
[1]Lund University, Cardiology Clinic, Skane University Hospital, Lund, Sweden; *[2]Lund University, Department of Clinical Sciences Malmö, Malmo, Sweden*; *[3]Van Andel Institute, Grand Rapids, United States of America*; *[4]University of Medicine and Pharmacy of Tirgu-Mures, Tirgu-Mures, Romania*

Funding Acknowledgements: Swedish Research Council, Marianne and Marcus Wallenberg Found, Swedish Heart and Lung Found, CNCS - UEFISCDI proj PN-III-P4-ID-PCCF-2016-0172

Background: The potent immune and inflammatory response to myocardial infarction (MI) aggravates myocardial damage and precipitates the development of heart failure (HF). The pro-inflammatory alarmin S100A8/9 rises rapidly in blood and myocardium after MI and has been linked with increased risk for recurrent MI and CV death in these patients.
Purpose: In MI patients, we studied whether S100A8/A9 at the time of the MI is associated with impaired cardiac function and incident HF. Further, we assessed whether inhibition of S100A8/A9 activity in the acute phase can improve cardiac function post-MI in mice.
Methods: In a cohort of 524 MI patients, we studied the associations between S100A8/A9 and incident HF during a 2-year follow-up. In a subgroup of 114 of these patients we also examined the correlations between S100A8/A9 and left ventricular function at 1 year after MI, measured by echocardiography. To assess the role of S100A8/A9 in HF development, we induced MI by permanent left coronary artery ligation in C57BL/6 mice. The mice were subsequently treated with the S100A8/A9 blocker ABR-238901 (30mg/kg) or PBS for 3 days. ABR-238901 inhibits the binding of S100A8/A9 to its receptors RAGE and TLR4. Immune cell populations in blood and myocardium were analyzed by flow cytometry, and cardiac function was assessed by magnetic resonance on days 3, 7 and 21 post-MI.
Results: In a Cox proportional regression analysis adjusted for age and sex, patients with acute S100A8/A9 values in the highest tertile had a 1.3 (95%CI 1.0 – 1.7) higher risk to develop HF compared to the lowest tertile (P=0.026). Higher acute S100A8/A9 also correlated with lower left-ventricular ejection fraction (r=-0.332, P=0.001) and larger end-systolic volume (r =0.201, P=0.037) at 1 year. In mice, S100A8/A9 blockade post-MI had potent local and systemic anti-inflammatory effects, leading to significantly reduced numbers of neutrophils and inflammatory Ly6C(hi) monocytes in blood and myocardium on days 3 and 7 post-MI. Left ventricular ejection fraction was significantly higher on day 7 (25% vs 16%, P<0.01) and on day 21 (26% vs 12%, P<0.001) in mice treated with ABR-238901 compared to the PBS control. We recorded a remarkable hemodynamic recovery in the ABR-238901-treated mice, with an approximately 40% increase in cardiac output from 6.4mL/min on day 3 to 8.9 mL/min on day 21. On day 21 post-MI, the average cardiac output in the ABR-238901-treated group reached 83% of the baseline pre-MI value, compared to 51% in the control mice.
Conclusions: Our study identifies a deleterious role of S100A8/A9 in the immediate post-ischemic phase, mediating the development of cardiac dysfunction and chronic HF. We identify S100A8/A9 as an important target for immunomodulatory therapies aiming to ameliorate the development of post-ischemic HF, as S100A8/A9 blockade led to significant gains in cardiac function and hemodynamic parameters.

P632

Sleep-disordered breathing is associated with ventricular arrhythmias in postmenopausal women with hypertension and coronary artery disease.

V Tsareva[1]; N Nikolay Novitskii[2]; K Sundukova[3]
[1]Smolensk State Medical University, Therapy, ultrasound and functional diagnostics, Smolensk, Russian Federation; *[2]City Clinical Hospital 2, Kaluga, Russian Federation*; *[3]Smolensk State Medical University, Research center, Smolensk, Russian Federation*

Background: Arterial hypertension (AH) and coronary artery disease (CAD) hold leading position in the structure of cardiovascular morbidity. High risk of developing AH and CAD becomes clinically significant after a woman enters menopause. The problem of sleep-disordered breathing is also being actively studied recently, as more and more information is accumulating about the negative effect of sleep apnea on the cardiovascular system.
Purpose: To study the role of sleep-disordered breathing on ventricular arrhythmias (VA) in postmenopausal women with AH and CAD
Methods: 144 postmenopausal women with AH 1–2 degrees and chronic forms of CAD (mean age 66.6 ± 7.5 years) were examined. 27.1% of women had heart failure (NYHA I-II). The first group included 96 patients with VA. The second group consisted of 48 women without VA. The groups were divided into subgroups: A - index of apnea / hypopnea (AHI) <5 per hour of sleep; B - AHI ≥ 5 per hour of sleep. Patients underwent holter monitoring of ECG and respiratory monitoring.To characterize the VA, the Lown and Wolf classification was used in the Ryan modification. VA 3 and higher gradations were taken to arrhythmias of high gradations.
Results: Patients with sleep-disordered breathing (AHI ≥ 5 per hour of sleep) were found in the I (36.5%) and II (22.9%) groups, but in the group with VA of such patients there was a 13.6% increase (χ^2 with the Yates correction = 1.9 p> 0.05). Patient didn't significantly differ in the frequency of detection of VA I, III, IV and V grades (> 0.05). Frequent ventricular extrasystole (VE) by 22.2% (p <0.01 in the Fisher test) was more often recorded in patients in the IA subgroup (29.9% and 5.7% accordingly). Polymorphic pair VE more often (by 20.8%; p <0.01 by Fisher test) was detected in women of the IB subgroup. In patients with IB subgroups, arrhythmias of high gradations (51.4%) were more frequent (21.9% χ^2 = 4.56 p <0.05) compared with the IA subgroup.Using the method of calculating the odds ratio, it was found that the AHI ≥ 5 episodes per hour of sleep increases the chance of development of high-grade VA by 2.5 times, polymorphic pair VE by 7 times.
Conclusions: Sleep-disordered breathing (AHI ≥ 5 per hour of sleep) is associated with high-gradation VA and polymorphic paired VE.

Odds ratio of developing VA

Indicator	index of apnea / hypopnea		
OR	95%CI	P criteria χ^2	
High gradations ventricular arrhythmias	2,52	1,16 - 5,92	<0,05
Polymorphic pair ventricular extrasystole	7,0	1,75 - 28,22	<0,01

OR - odds ratio; CI - confidence interval

Effects of early vs. late initiated pressure unloading on myocardial reverse remodeling and recovery of cardiac dysfunction in a rat model of left ventricular hypertrophy induced by pressure overload

T Radovits[1]; M Ruppert[1]; S Korkmaz-Icoz[2]; S Loganathan[2]; A Olah[1]; AA Sayour[1]; BA Barta[1]; C Karime[1]; G Szabo[2]; B Merkely[1]
[1]Semmelweis University, Heart and Vascular Center, Budapest, Hungary; *[2]University Hospital of Heidelberg, Department of Cardiac Surgery, Heidelberg, Germany*

Funding Acknowledgements: NVKP-16-1-2016-0017, ÚNKP-18-3-I-SE-9 (MR), ÚNKP-18-3-III-DE-387 (BB)

Background: Left ventricular hypertrophy (LVH) induced by pressure overload (PO) regresses after pressure unloading. However, distinct structural alterations become irreversible during the progression of LVH, which might influence the recovery of cardiac function.
Purpose: Here, we investigated how an early- versus late initiated pressure unloading affects reverse remodeling and different aspects of LV function.
Methods: PO was induced by abdominal aortic banding (AB) of rats for 6, 12 and 18 weeks. Sham-operated animals served as controls. Pressure unloading was evoked by removing the aortic constriction at week 6 (early-debanded) and week 12 (late-debanded). Echocardiography and histology were carried out to detect structural alterations. Pressure-volume analysis was performed to assess LV function. Molecular alterations were analyzed by qRT-PCR and western blot.
Results: LV hypertrophy regressed to a similar degree in early- and late-debanded groups (similar regression regarding LV mass, cardiomyocyte diameter, heart weight - to - tibial length ratio and beta-to-alpha myosin heavy chain expression). In contrast, resorption of myocardial fibrosis was only detected in the early-debanded group (LV collagen fraction: 7.7±0.7 vs. 5.4±0.3% ABw12 vs. early-debanded; p<0.05, while it persisted in the late-debanded group (7.4±0.9 vs. 6.9±0.6% ABw18 vs. late-debanded; ns.). Debanding normalized ventriculo-arterial coupling and increased systolic performance in both groups. However, the residual dysfunction in active relaxation (Tau normalized to control: 18±5 vs. 38±8% early-debanded vs. late-debanded; p<0.05) and increased stiffness was more severe in the late- compared to the early-debanded group.
Conclusion: Early debanding led to complete structural reverse remodeling and full restoration of LV function. In contrast, late debanding resulted in partial regression of PO-induced structural alterations, which impeded the normalization of diastolic but not systolic function.

P634

Dapagliflozin improves diastolic performance in an animal model of heart failure with preserved ejection fraction

D Cappetta[1]; K Urbanek[1]; LP Ciuffreda[1]; A Cozzolino[1]; A Micciche'[1]; R Coppini[2]; L Berrino[1]; A De Angelis[1]
[1]University of Campania "Luigi Vanvitelli", Department of Experimental Medicine, Naples, Italy; [2]University of Florence, Department of Neuroscience, Drug Research and Child's Health (NeuroFarBa) - Division of Pharmacology, Florence, Italy

Background: Heart failure with preserved ejection fraction (HFpEF) that share co-morbidities like hypertension and diabetes, is a challenging clinical syndrome and represents yet unresolved pathophysiological continuum with a consequent perception of lack of effective treatments. In a non-diabetic, hypertensive model of HFpEF we tested the effects of SGLT2 inhibitor dapagliflozin on the progression of heart disease.
Methods: Dahl salt-sensitive rats were fed a high salt diet (8% NaCl) to induce hypertension. Then, rats continued with a high salt diet and were orally administered with either dapagliflozin (0.1 mg/kg/day) or vehicle for the following 6 weeks. Heart function were monitored by echocardiography.
Results: The animals progressively developed hypertension and after 5 weeks of high-salt diet, before initiation of pharmacotherapy. Diastolic function was compromised as documented by decrease of E/A ratio along with increase of E deceleration time and isovolumetric relaxation time. At treatment completion, hypertrophied LV had normal systolic parameters and diastolic parameters were partially recovered when compared to high-salt animals. These results define an improved ventricular relaxation. Interestingly, urine albumin-to-creatinine ratio (UACR), indicative of endothelial dysfunction, that was higher in animals on high-salt diet, was reduced by treatment with dapagliflozin. Decreased UACR was associated with the declined activation of NF-kB in coronary endothelium.
Conclusions: Dapagliflozin positively modulates diastolic compliance with the specific molecular mechanisms yet to be identified. Because of a non-diabetic nature of our model and unaltered blood glucose levels, the improvement of cardiovascular profile by dapagliflozin can depend on endothelium-related mechanisms rather than its anti-hyperglycaemic effect.

P635

Cholesterol-lowering gene therapy prevents HFpEF in obese type 2 diabetic mice

JP Aboumsallem[1]; I Muthuramu[1]; M Mishra[1]; B De Geest[1]
[1]KU Leuven, DEPARTMENT OF CARDIOVASCULAR SCIENCES, Leuven, Belgium

Funding Acknowledgements: Onderzoekstoelagen grant OT/13/090 kU Leuven an grant GOA3114N fonds voor wetenschappelijk Onderzoek-Vlanderen

Background: Hypercholesterolemia may be causally related to heart failure with preserved ejection fraction (HFpEF) even in the absence of coronary artery disease.
Purpose: The objectives of this study were to establish a model of HFpEF associated with hypercholesterolemia in obese diabetic mice and to evaluate the preventive effect of cholesterol lowering induced by adeno-associated viral serotype 8 (AAV8)-low-density lipoprotein receptor (LDLr) gene transfer in this model.
Methods: Gene transfer with 5 x 1010 genome copies of AAV8-LDLr or with the same dose of AAV8-null was performed in C57BL/6J LDLr-/- mice at the age of 11 weeks. The standard chow (SC) diet was continued in part of the mice whereas the high-sucrose high fat (HSHF) diet was initiated at the age of 12 weeks and continued for 16 weeks. All endpoint analyses were performed at the age of 28 weeks.
Results: Body weight in the AAV8-null HSHF diet mice progressively increased and was 1.49-fold ($p<0.001$) higher at 16 weeks after the start of the diet compared to AAV8-null SC diet mice (32.8 ± 1.0 g versus 22.1 ± 0.4 g). This weight gain was associated with hyperinsulinemia and type 2 diabetes mellitus. AAV8-LDLr gene transfer significantly ($p<0.001$) decreased plasma cholesterol in SC diet mice (66.8 ± 2.5 mg/dl versus 213 ± 12 mg/dl) and in HSHF mice (84.6 ± 4.4 mg/dl versus 464 ± 25 mg/dl. The HSHF diet induced cardiac hypertrophy (1.23-fold ($p<0.001$) increase of left ventricular weight) and resulted in pathological remodelling as evidenced by a 21.1% ($p<0.01$) decrease of myocardial capillary density and by increased interstitial ($p<0.001$) and perivascular fibrosis. AAV8-LDLr potently counteracted cardiac hypertrophy and pathological remodelling. Moreover, wet lung weight was 19.0% ($p<0.001$) higher in AAV8-null HSHF diet mice than in AAV8-null SC diet mice whereas no increase of lung weight was present in AAV8-LDLr HSHF diet mice. Pressure-volume loop analysis was consistent with HFpEF in AAV8-null HSHF diet mice as evidenced by a preserved ejection fraction (52.2 ± 2.5% versus 57.2 ± 2.1% in AAV8-null SC diet mice), a significant reduction of the end-diastolic volume (25.1 ± 1.4 µl versus 31.5 ± 1.5 µl; $p<0.01$), of cardiac output (7.76 ± 0.46 ml/min versus 10.9 ± 0.6 ml/min; $p<0.001$), and of the peak filling rate (509 ± 52 µl/min versus 712 ± 22 µl/min; $p<0.01$). The slope of the end-diastolic pressure to volume relationship ($p<0.01$), ventriculo-arterial coupling ratio ($p<0.05$), and the time constant of isovolumetric relaxation ($p<0.001$) were significantly higher in AAV8-null HSHF diet mice than in AAV8-null SC diet mice. AAV8-LDLr HSHF diet mice were characterized by a completely normal cardiac function. Treadmill exercise testing showed that the total distance covered was reduced by 62.0% ($p<0.001$) in AAV8-null HSHF diet mice compared to AAV8-null SC diet mice and was not reduced in AAV8-LDLr HSHF diet mice.
Conclusion: Cholesterol-lowering AAV8-LDLr gene therapy prevents HFpEF.

P636

Reconstituted HDL reverses pathological remodeling and cardiac dysfunction in a murine model of HFpEF associated with hypertension

M Mudit Mishra[1]; I Muthuramu[1]; J P Aboumsallem[1]; H Kempen[2]; B De Geest[1]
[1]KU Leuven, Department of Cardiovascular Sciences, Leuven, Belgium; [2]The Medicines Company (Schweiz) GmbH, Zürich, Switzerland

Funding Acknowledgements: Onderzoekstoelagen grant OT/13/090 KU Leuven and grant G0A3114N Fonds voor Wetenschappelijk Onderzoek-Vlaanderen

Background: Drug strategies with strong evidence in heart failure with reduced ejection fraction have proved unsuccessful in heart failure with preserved ejection fraction (HFpEF).
Purpose: The objectives of this study were to establish a murine model of HFpEF associated with hypertension and to evaluate the effect of reconstituted HDL Milano administration on established HFpEF in this model.
Methods: Subcutaneous infusion of angiotensin II (600 ng/kg/min) in combination with 1% NaCl in the drinking water was initiated at the age of 12 weeks to induce hypertension and HFpEF in male C57BL/6N mice. To evaluate the effect of reconstituted HDL Milano on HFpEF, five intraperitoneal injections of MDCO-216 (100 mg/kg protein concentration) or of an equivalent volume of control buffer were executed with a 48-hour interval starting at the age of 16 weeks. Endpoint analyses were performed at the age of 16 weeks in the reference control and reference hypertension groups and at the age of 16 weeks plus 9 days in the control buffer and the MDCO-216 groups.
Results: Peak systolic pressure was significantly ($p<0.01$) higher in reference hypertension mice (113 ± 3 mm Hg; n=12) than in reference control mice (99.6 ± 2.1 mm Hg; n=12). Left ventricular weight and cardiomyocyte-cross sectional area were 1.44-fold ($p<0.001$) and 1.48-fold ($p<0.001$) higher, respectively, in reference hypertension mice than in reference control mice. Pathological remodelling in reference hypertension mice was evidenced by increased interstitial (8.37 ± 0.71% versus 1.92 ± 0.11%; $p<0.001$) and perivascular (0.543 ± 0.068 versus 0.284 ± 0.013; $p<0.001$) fibrosis and a reduction of myocardial capillary density (3720 ± 140 mm-2 versus 4710 ± 190 mm-2; $p<0.001$). Pressure-volume loop analysis was consistent with HFpEF in reference hypertension mice as evidenced by a preserved ejection fraction (52.2 ± 1.4% versus 58.7 ± 2.7%), a significant reduction of the end-diastolic volume (24.2 ± 1.1 µl versus 28.4 ± 0.8 µl; $p<0.01$), of cardiac output (7.78 ± 0.56 ml/min versus 10.5 ± 0.7 ml/min; $p<0.01$), and of the peak filling rate ($p<0.01$). Arterial elastance ($p<0.001$), ventriculo-arterial coupling ratio ($p<0.001$), and the time constant of isovolumetric relaxation ($p<0.05$) were significantly increased in reference hypertension mice. Treatment with MDCO-216 (n=14) completely normalised all parameters of cardiac function whereas no effect was observed in control buffer mice (n=16). In addition, perivascular fibrosis and cardiomyocyte cross-sectional area were significantly lower and capillary density was significantly higher in MDCO-216 mice than in both reference hypertension and control buffer mice. Wet lung weight in the MDCO-216 group (152 ± 4 mg) was significantly ($p<0.01$) lower than in the control buffer group (182 ± 9 mg) and similar than in the reference control group (150 ± 4 mg).
Conclusion: Reconstituted HDL is an effective treatment for HFpEF associated with hypertension.

P637

Plasma proteome analysis of patients with heart failure identifies HFmrEF with unimproved EF as an intermediate state between HFpEF and HFrEF, HFmrEF with improved EF as a distinct biological state

L Luigi Adamo[1]; J Yu[1]; R Head[1]; DL Mann[1]
[1]Washington University School of Medicine, Cardiovascular Division, Department of Medicine, St. Louis, United States of America

Background : Patients with EF 40-49% have been identified as having Heart Failure with Mid-Range Ejection Fraction (HFmrEF). However, this group of patients is heterogeneous and it remains unclear whether they constitute a distinct entity.
Purpose : To investigate whether HFmrEF and its subgroups identified based on prior EF trajectory are characterized by the activation of specific biological pathways.
Methods: Within the Heart Failure Registry of our institution we identified 87 patients with a documented LVEF between 40–50% (HFmrEF) at the time of enrollment and sex/age matched patients with HFrEF (LVEF <40%, n=51) or HFpEF (LVEF>50%, n=43). HFmrEF patients were further sub-categorized based on the prior trajectory

of EF as either HFmrEF with improved EF (63) or HFmrEF with unimproved EF (24). Plasma samples collected from each patient at the time of enrollment were profiled using the SOMAscan protein array platform, a technology that renders quantitative measurements of over 1300 protein analytes.

Results: Analysis of the plasma proteome via Principal Component Analysis (PCA) centroid estimation suggested that HFmrEF is a state more similar to HFpEF than HFrEF (Fig1 A). However, when we sub-divided HFmrEF patients based on the prior trajectory of their EF, we found that HFmrEF with improved EF is a separate biological state that deviates markedly from the straight line connecting HFrEF and HFpEF while HFmrEF with unimproved EF is merely an intermediate state between HFpEF and HFrEF (Figure 1B). The spatial distance between patient subgroups on the PCA matched both the number of differentially expressed proteins and the number of differentially activated pathways identified through network analysis.

Conclusions: HFmrEF with unimproved EF is an intermedite state between HFpEF and HFrEF. HFmrEF with improved EF is a distinct biological state characterized by the activation of several specific biological pathways.

Heart preservation with the organ care system for mechanical circulatory support recipients

Z Zhuldyz Nurmykhametova[1]; R Kaliyev[1]; S Bekbossynov[2]; M Bekbossynova[2]; N Smagulov[2]; S Novikova[2]; L Faizov[1]; Z Ashirov[1]; Y Pya[2]
[1]National research center for cardiac surgery, OR, Astana, Kazakhstan; *[2]National research center for cardiac surgery, Astana, Kazakhstan*

Background: The Organ Care System (OCS) Heart is non-inferior compared to standard cold storage for preservation of donor hearts.
Purpose: We hypothesized that its properties for prolonged heart preservation might be especially beneficial for high-risk on Mechanical Circulatory Support Recipients.
Methods: Patients transplanted using the OCS Heart at our center between 10/2012 and 10/2018 were prospectively followed. All recipients were potentially considered eligible.
Results: During the study period among the 70 transplanted patients, 55 (78.5%) high-risk recipients (median age 39 years, 80% male) were transplanted using the OCS for donor (median age 41year, 74% male) heart preservation. Before transplantation, 24(43%) recipients (VAD, n=16; CARMAT, n=2; BiVAD, n=3; ECLS, n=2) had a median 2 previous cardiac operation. Among the 16 VAD patients, 6(37%) and 2(14%) had show VAD/driveline infections and VAD dysfunctions, respectively. All OCS hearts successfully transplanted. Median OCS perfusion and donor aortic cross-clamp to recipient aortic clamp opening times were 5 and 7 hours, respectively. In addition, due to geographical distant retrievals (more than 1000km) were only realized for their respective recipients without exceeding the maximum ischemic time because the OCS was available. Postoperatively 10(41%) and 12(50%) patients required re-sternotomy for bleeding and temporary dialysis, respectively. Six (37%) patients required postoperative ECLS due to right heart failure that completely recovered after median 6 days. One (4%) patient died in hospital due to sepsis. At discharge, all patients showed a left ventricular ejection fraction >55% in echocardiography. At follow up end survival was 96%.
Conclusion: OCS Heart allowed safe transplantation of recipients on Mechanical Circulatory Support. Despite preservation time was approaching 9 hours (maximum 16) enabling allocations otherwise not acceptable, patient and graft conditions were favorable.

639

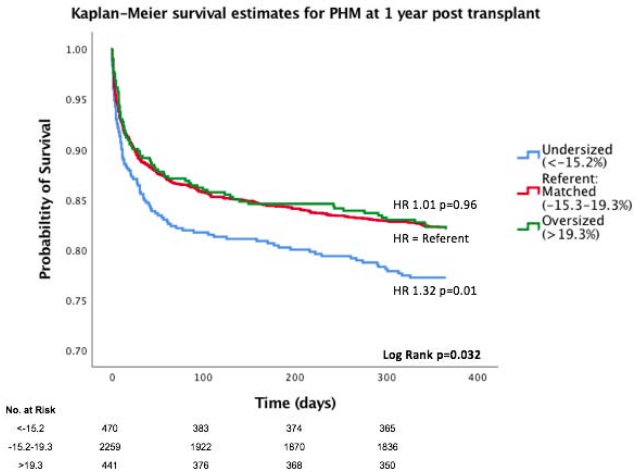
Donor-recipient size-mismatching by predicted heart mass and survival after heart transplantation.

C Cheshire[1]; N Nerlekar[2]; AC Kydd[1]; Y Abu-Omar[1]; P Catarino[1]; AJ Brown[2]; J Parameshwar[1]; S Pettit[1]
[1]Papworth Hospital NHS Trust, Cambridge, United Kingdom of Great Britain & Northern Ireland; *[2]Monash University, Monash Cardiovascular Research Centre , Melbourne, Australia*

Introduction: Current international (ISHLT) guidance for donor-recipient size matching in cardiac transplantation is based on body weight differences, yet recent studies have demonstrated that this approach has minimal association with survival post transplantation. The use of population-based, cardiac MRI derived equations for predicted left and right ventricular mass incorporating weight, height, age and gender have been recently proposed as a potential alternative to evaluate donor sizing. These equations can be applied retrospectively to classify discrepancies between donor and recipient predicted heart mass (PHM).
Purpose: To determine whether there is an association between clinical outcomes following cardiac transplantation and donor-recipient size mismatch, as defined using cardiac MRI-derived equations, in the UK.
Methods: The study cohort comprised of 3266 adut heart transplant recipients from the NHS UK transplant registry, who received their first, isolated heart transplant between 1995-2017. The data was normally distributed and the cohort was divided into 3 groups based on being above or below one standard deviation, with the central cohort used as reference. Kaplan-Meier plots and univariate Cox proportional regression modelling performed to evaluate the association with 1-year mortality.
Results: Ninety-six patients were excluded due to missing data, resulting in a total of 3170 patients in the analysis. Baseline demographics are demonstrated in Table 1. Undersizing (<-15.2%) by PHM was associated with increased mortality at one year (HR 1.32, 95%CI 1.01-1.50, p=0.01) compared to the reference cohort. In contrast, oversizing had no effect on mortality (HR 1.01, 95%CI 0.79-1.28, p= 0.96).
Conclusion: Receiving an undersized donor heart by PHM was associated with decreased survival in cardiac transplant recipients in the UK. Further studies are needed to explore the mechanisms that lead to deleterious outcomes in these patients and strategies to optimise size mismatching.

Table 1- Baseline demographics

	Undersized (<-15.2%) n=470	Referent: Matched (-15.2-19.3%) n=2259	Oversized (>19.3%) n=441	p Value
1 year mortality	22.8% (n=107)	17.7% (n=400)	17.9% (n=79)	
Donor Age (years)	39±12	36± 12	35 ± 12	<0.001
Donor Male	18.4%	73.9%	80.8%	<0.001
Recipient Age (years)	48±12	48±12	44 ±12	<0.001
Recipient Male	96.2%	81.1%	42.8%	<0.001
Ischaemic Time (hours)	3.3±1	3.3±1.1	3.2±1	0.22



640

Heart failure from cardiac ATTR-amyloidosis is a highly malignant disease

A Kaser[1]; F Kocher[2]; A Bair[1]; E Vikoler[1]; S Dengler[1]; R Bernardi[1]; M Klassnitz[1]; J Doerler[1]; MM Zaruba[1]; C Mussner-Seeber[1]; G Gerhard Poelzl[1]
[1]Department of Internal Medicine III - Cardiology, Innsbruck, Austria; *[2]Innsbruck Medical University, Department of Internal Medicine V - Hematology and Oncology, Innsbruck, Austria*

Background: Cardiac amyloidosis is an underappreciated cause of morbidity and mortality. Light chain (AL) and transthyretin (ATTR) amyloidosis have different disease trajectories. Recent evidence suggests that ATTR is probably much more

common than widely appreciated. ATTR was evident in patients with heart failure with preserved ejection fraction (HFpEF) and in elderly patients with aortic stenosis.
Purpose: No data are available on subtype-specific comparisons of prognosis with other heart failure etiologies.
Methods: In this single-centre registry 2181 patients treated for heart failure according to prevailing guidelines between 2000 and 2018 were analysed. Underlying CMPs were classified into eight groups: cardiac amyloidosis (6.6%) [ATTR 3.0%; AL 3.6%], ischemic (25.7%), idiopathic (25.4%), hypertensive (15.3%), inflammatory (14.5%), toxic (4.4%), HCM (4.4%), and valvular (3.6%). Primary endpoint was death of any cause. Kaplan-Meier estimator was used to calculate 5-year survival. A multivariate cox regression analysis was performed to compare survival between groups.
Results: Patients were followed for a median of 87 months (IQR 44–138). Five year overall survival in the whole cohort was 80.6% (ATTR-amyloidosis 51.3%, AL-amyloidosis 36%, ischemic 72.4%, toxic 77.7%, valvular 79.9%, hypertensive 81.1%, idiopathic 85.3%, HCM 92.8, inflammatory 93.1%).
In multivariate analysis adjusted for age, gender, LV-EF, and NYHA class, individuals with ATTR-amyloidosis were 2.6 time (95% CI 1.4 – 4.7; P=0.002) and AL-amyloidosis 7.1 time (95% CI 4.4 – 11.6; P<0.001) more likely to die of any reason than were individuals with inflammatory CMP. Differences in mortality between ATTR-amyloidosis and ischemic CMP were not significantly different (HR 1.5, 95%CI 0.9 – 2.5; P=0.096). In the multivariate model, mortality was significantly higher in AL (HR 2.9, 95%CI 1.5 – 5.6; P=0.001) compared with ATTR-amyloidosis.
Conclusion: Data from this single-centre registry study that compared cardiac amyloidosis with various reasons of cardiomyopathies indicate worst prognosis in patients with cardiac amyloidosis. Although outcome in ATTR is better than in AL, ATTR-amyloidosis is still associated with poor long-term survival. From this perspective, thorough etiologic evaluation and targeted therapy should be mandatory in patients with heart failure and suspected ATTR-amyloidosis.

Effect of SGLT2 inhibitor on cardiac function in diabetic patients with or without heart failure: an echocardiographic study

IC In-Chang Hwang[1]; GY Cho[1]; YE Yoon[1]; JJ Park[1]
[1]*Seoul National University Bundang Hospital, Seongnam, Korea (Republic of)*

Background: Recent trials showed that the use of sodium-glucose cotransporter 2 inhibitor (SGLT2i) reduces the occurrence of heart failure (HF). However, the effect of SGLT2i on cardiac function is not fully understood.
Purpose: We aimed to assess the changes in cardiac function assessed by echocardiography in diabetic patients with or without HF.
Methods: Diabetic patients who underwent repetitive echocardiographic examinations from 2014 to 2018 were retrospectively enrolled (n=1107). Among these patients, we identified 202 patients underwent echocardiography before and 1- or 2-year after the initiation of SGLT2i, and compared with 227 diabetic patients without SGLT2i who underwent repetitive echocardiography with same interval. Using propensity score matching, we categorized the study population into 4 groups: patients without HF nor SGLT2i (group 1; n=76), patients without HF and received SGLT2i (group 2; n=78), patients with HF but without SGLT2i (group 3; n=72), and patients with HF and received SGLT2i (group 4; n=74). The changes in echocardiographic parameters were compared between these 4 groups.
Results: After 1- or 2-year of SGLT2i treatment, the left ventricular end-diastolic dimension (LV-EDD) decreased and LV ejection fraction (LV-EF) increased in patients without HF (p=0.036 for LV-EDD, p<0.001 for LV-EF) as well as in those with HF (p<0.001 for both LV-EDD and LV-EF). A modest reduction in LV mass index (LV-MI) was also noted in patients with HF treated with SGLT2i (p=0.05). There were significant differences in changing patterns of LV-EDD, LV-EF, and LV-MI according to the use of SGLT2i in both patients without HF and with HF.
Conclusions: The use of SGLT2i reduced LV-EDD and improved LV-EF in diabetic patients regardless of the presence of HF. These hemodynamic effect of SGLT2i would contribute to the reduction in HF morbidity and mortality in diabetic patients.

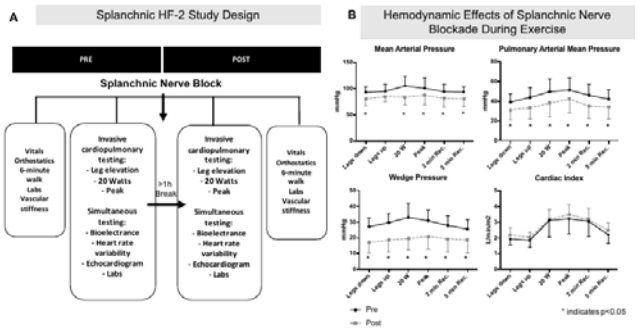
Funding Acknowledgements: Translating Duke Health and National Institute of Health

Background Chronic heart failure (HF) is characterized by limited exercise capacity driven by an excessive elevation of intra-cardiac pressure during exercise. In acute HF patients, splanchnic nerve blockade (SNB) decreased intra-cardiac pressures and improved cardiac output.
Purpose We hypothesized that SNB would attenuate exercise-induced cardiac filling pressures.
Methods Prospective, open-label, interventional study in chronic HF patients regardless of ejection fraction. Eligible patients were enrolled from May 2018 to January 2019 and had NYHA class II/III symptoms with elevated intra-cardiac filling pressures on baseline right heart catheterization. Patients underwent invasive cardiopulmonary exercise testing on a supine bike followed by a temporary percutaneous SNB with bupivacaine (Figure), followed by repeat exercise testing. Primary outcomes were changes in the pulmonary arterial mean, wedge and exercise capacity on repeat testing from before and after SNB. Additional testing parameters are presented in the Figure.
Results Of the 10 enrolled patients, 50% were male, 50% had ischemic cardiomyopathy, with an overall mean age of 56 ± 15 years and median left ventricular ejection fraction of 18%. No procedural complications were encountered. SNB significantly reduced resting and exercise-induced mean arterial pressure, pulmonary arterial and wedge pressure (Figure). SNB did not result in significant changes in resting (1.9 L/min/m2±0.5 vs 2.2 L/min/m2±0.7; p=0.83) or peak exercise (3.2 L/min/m2±1.3 vs 3.5 L/min/m2±1.0, p=0.84) cardiac index or peak VO2 (8.6 ml/kg/min ±2.5 vs 8.9ml/kg/min ±1.8, p=0.41). Post SBN patients had a lower degree of intra-thoracic fluid shifts as measured by bioelectrance technology (1.6 ±0.9 vs 1.0 ±0.5; p<0.05) and lower central vascular stiffness (pulse wave velocity: 7.04 m/s ±0.8 vs 6.47 m/s±0.5; p<0.05).



Study design and hemodynamic results

Conclusions In this preliminary analysis of the Splanchnic-HF2 study, SNB reduced resting and exercise-induced pulmonary arterial and wedge pressure without an effect on peak cardiac index in patients with chronic HF. SNB induced favorable changes in central and peripheral hemodynamics without significant effects on exercise function. Continued efforts to investigate short- and long-term effects of SNB in chronic HF are warranted.

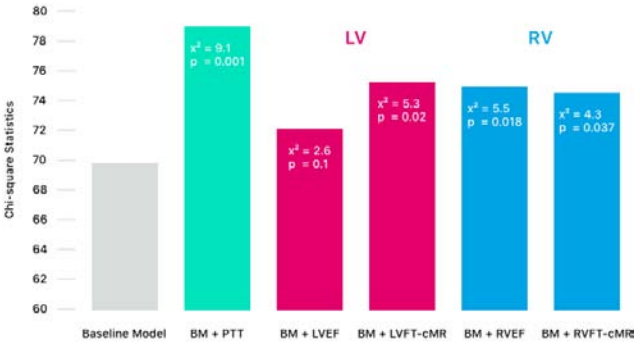
[1]Cliniques Saint-Luc UCL, Cardiology, Brussels, Belgium; *[2]Philips research, Paris, France*

Funding Acknowledgements: Fond national de recherche (FNRS)

Background: Right ventricular (RV) ejection fraction and hemodynamic congestion are known as powerful predictor of mortality in HF-rEF. Pulmonary transit time (PTT) assessed by cMR is a novel parameter, which reflects multiple indicators of cardiopulmonary status, including not only left ventricular(LV) and RV function but also hemodynamic congestion.
Purpose: We sought to explore the prognostic value of the PTT above well-known risk factor for predicting outcomes in HF-rEF in direct comparison with cardiac function assessed either by the conventional cMR-systolic parameters or by cMR-feature tracking (FT).
Methods: 410 patients in sinus rhythm with a LVEF <35% (age 61 ± 13 years; 25% female) underwent a cMR and an echocardiography. Patients were followed for a primary endpoint of overall mortalit.
Results: Average cMR-LVEF was 23% ± 7%, average cMR-RVEF was 43 ± 15%, average cMR-FT-RVGLS was -11.7±4.5%, average cMR-FT-LVGLS was-6.6±2.7% average estimated systolic pulmonary pressure (eSPAP) was 33 ± 12mmHg and PTT was 11± 6s. After a median follow-up of 6 years, 192 (47%) patients reached the primary endpoint. In univariate cox regression, age, female sex, ischemic cardiomyopathy, diabetes, NYHA class III-IV, eSPAP> 40mmHg, E/A ratio, e/e'ratio, cMR-RVEF, LVEF, LV scar, PTT, GFR, beta blockers and diuretics were associated with primary endpoint. For the multivariate analysis, a baseline model was created where age, female sex, ischemic etiology, diabetes, eSPAP>40mmHg, diuretics, beta blockers were found to be significantly associated with the endpoint. PTT (X2 to improve = 9.05, HR: 1.04; 95%CI: [1.02; 1.07]; P=0.001) showed a significantly higher additional prognostic value over the baseline model than cMR-LVEF (X2 to improve = 2.61, HR: 0.99; 95%CI: [0.98; 0.99]; P=0.11), cMR-RVEF (X2 to improve = 5.53, HR: 0.99; 95%CI: [0.98; 0.99]; P=0.018), LV-cMR-FT(X2 to improve =5.31, HR: 1.08; 95%CI: [1.01; 1.14]; P=0.023) and RV-cMR-FT (X2 to improve =4.34, HR: 1.04; 95%CI: [1.00; 1.08]; P=0.037).Conclusion:Pulmonary transit time provides higher prognostic information than cardiac function assessed by cMR or by cMR feature tracking over well-known risk factors with high power to stratify prognosis in HF-rEF and might be promising tools to identify patients at higher risk among HF patients



The additional value of the pulmonary transit time (PTT), left ventricular ejection fraction (LVEF), left ventricular feature tracking cardiac magnetic resonance (LVFT-cMR), right ventricular ejection fraction (RVEF) and right ventricular feature tracking (RVFT) in predicting overall mortality over a baseline model (BM) including age, female sex, ischemic etiology, diabetes, estimated systolic pulmonary pressure >40mmHg, diuretics and beta blockers. LV and RV indicate left ventricle and right ventricle respectively.

Clinical Case Corner 2 - A story of success. Recovering in heart failure

676

Recovery of heart failure due to severe malnutrition and marked electrolyte abnormalities.

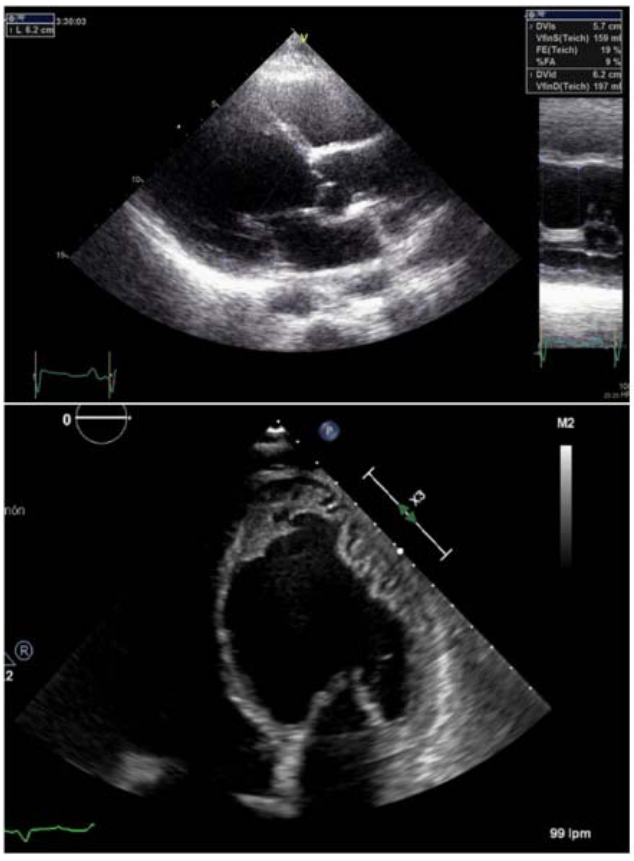
[1]*Hospital Arnau de Vilanova, Cardiology, Lleida, Spain*

We present a 55 year old male who was a heavy smoker and consumed 25-38 grams of alcohol per day (2-3 beers and 1 glass of wine). He had Diogenes syndrome and had no social support. He lived alone in a flat with deficient hygienic measures. He also had a poor diet, based in processed carbohydrates. He had no past medical history and had not visited foreign countries.

He presented with a history of 4 months of worsening heart failure symptoms, finally with dyspnea at rest. At presentation he was cachectic, tachycardic, normotensive but with clinical signs of hypoperfusion and venous congestion. An EKG showed sinus tachycardia, a narrow QRS complex and a Q wave in V1. A chest X-ray exhibited signs of emphysema, bilateral pleural effusion and cardiomegaly. Blood tests displayed signs of intravascular disseminated coagulation, ischemic hepatitis, rhabdomyolysis and hyperlacticaemia. A TTE revealed biventricular dilation and failure, with a LVEF of 19%, restrictive filling pattern, moderate pulmonary hypertension and a thrombus in the apex of the LV.



TTE showing DCM and apical thrombus.

He was admitted in the cardiac ICU and was managed with dobutamine and furosemide with a slow but favorable response, with progressive correction of organ failure. A diagnostic study was performed including a coronary angiogram that was normal. Infections including HIV, CMV, EBV, varicella, parvovirus, hepatitis B and C, syphilis and coxiella were all negative. A nutritional panel showed normal levels of selenium, vitamins B1 and B3; but signs of protein-energy malnutrition and low levels of sodium (126.8 NV 135-150), chloride (93 mmol/L NV 95-110), ionic calcium (0.88 mmol/L NV 1.05-1.35), magnesium (0.45 mmol/L NV 0.66-0.99), phosphorus (1.96 mg/dL NV 2.7-4.5) and vitamin D (4.6 ng/L NV >20). He was started on supplementation until correction. Due to persistent signs of hypervolemia, he received an infusion of levosimendan. Afterwards, euvolemia was achieved. He was discharged after 30 days of hospitalization with oral anticoagulation and low doses of ACEI, betablocker, MRA, ivabradine and 40 mg of furosemide per day.

His cardiomyopathy was attributed either to malnutrition with severe electrolyte abnormalities or to alcohol, although his intake was lower than what is usually associated with DCM (>80-90 g/day). He was followed up by social services, a nutritionist, his primary care center and the nurses and physicians of the heart failure clinic. He changed his diet and living, abstained from alcohol and during the first year of follow up remained in NYHA class I and did not have any hospitalizations. At the one-year follow up a TTE revealed normal biventricular size and function. A cardiac MRI corroborated the TTE and showed no regional fibrosis in LGE sequences.

In conclusion, we present a patient with severe malnutrition, dilated cardiomyopathy and cardiogenic shock that recovered after a multidisciplinary management and correction of the nutritional deficits and abstention from alcohol.

677

Carbon monoxide induced cardiomyopathy: a rare cause of Takotsubo symdrome

I Ioannis Michelis[1]; K Tsitlakidis[1]; C Tsakliadou[1]; A Angelopoulos[1]; P Papanikolaou[1]; N Kouvelas[1]

[1]*251 Air Force General Hospital, Athens, Greece*

Introduction: Carbon monoxide (CO) poisoning is known to cause cardiac toxicity. Although the exact pathophysiological mechanism is not completely understood, it is usually classified as a type of Takotsubo syndrome (TTS). Diagnosis can sometimes be challenging due to possible concomitant respiratory symptoms from CO exposure.

Case summary: A 75-year old female with a history of hypothyroidism was admitted to the emergency department of our hospital as one of the many victims of the tragic wildfire in Mati, Greece the past summer. She sought medical attention 24 hours after inhaling smoke from the fire, with symptoms of dyspnea, nausea, burning sensation in the chest, and dizziness. With no significant findings from the electrocardiogram, the patient's symptoms were initially misinterpreted as of respiratory origin. Upon admission, cardiac enzymes were found elevated and left ventricular function was significantly impaired, displaying mid-ventricular hypokinesia. A coronary angiogram was performed which ruled out coronary artery disease and cardiac magnetic resonance showed no signs of inflammation or scarring of the myocardium. At this point, Takotsubo cardiomyopathy induced by carbon monoxide inhalation seemed the most reasonable diagnosis. Heart failure therapy with zofenopril, carvedilol and eplerenone was initiated resulting in gradual improvement of the symptoms. The patient was discharged after eight days of hospitalization, only to return home to the devastating aftermath of the wildfire. At the follow-up after three weeks, she was completely asymptomatic. Her left ventricular function had returned to normal and medical treatment was adjusted accordingly.

Conclusion: Different triggers of Takotsubo syndrome have been increasingly recognized since its first initial report, both emotional and physical. Carbon monoxide exposure should alert the clinical doctor to the possible cardiac involvement. Victims of wildfires, who are exposed to CO in an uncommon way, should receive the appropriate attention, since cardiac manifestations can be easily misinterpreted as respiratory symptoms from smoke inhalation injury.

Bilateral pheochromocytoma presenting with inverted takotsubo cardiomyopathy and cardiogenic shock

B Bebiana Faria[1]; J Portugues[1]; R Roncon[2]; R Pimentel[2]; O Azevedo[1]; M Oliveira[1]; P Hafe[1]; G Dias[1]; F Cardoso[1]; S Ribeiro[1]; A Lourenco[1]
[1]*Hospital Guimaraes, Guimaraes, Portugal*; [2]*Sao Joao Hospital, Porto, Portugal*

Takotsubo cardiomyopathy show transient left ventricular dysfunction and rarely presents with cardiogenic shock. Basal or inverted takotsubo cardiomyopathy is a variant of this syndrome important to identify because it tends not to be recognized as readily as the typical presentation and is associated with the presence of Pheochromocytoma.

Pheochromocytoma is a rare, catecholamine-secreting neuroendocrine tumour arising from the adrenal medulla. Recent studies have focused on estimation of the prevalence of Takotsubo cardiomyopathy in patients with pheochromocytoma but very little is reported about the management of these complex cases. Here, we report the case of a 26-year-old woman who presented with an inverted Takotsubo cardiomyopathy (picture 1) secondary to a catecholamine crisis, caused by an occult bilateral pheochromocytoma. The initial presenting crisis manifested with symptoms of severe headache, palpitations and breathlessness triggered by surgery procedure and exogenous corticosteroid. In the emergency department, the patient clinical condition rapidly deteriorated, developing respiratory failure and cardiogenic shock and she was transferred to a VA-ECMO support center, which in this case was life-saving therapy, allowing myocardial recovery, and stabilization for tumors excision.

Pheochromocytoma should systematically be considered for patients with Takotsubo cardiomyopathy, and/or unexplained cardiogenic shock. Extracorporeal life support devices provide temporary mechanical circulatory support in patients on refractory cardiogenic shock who have an underlying potentially reversible heart condition, like Takotsubo cardiomyopathy.

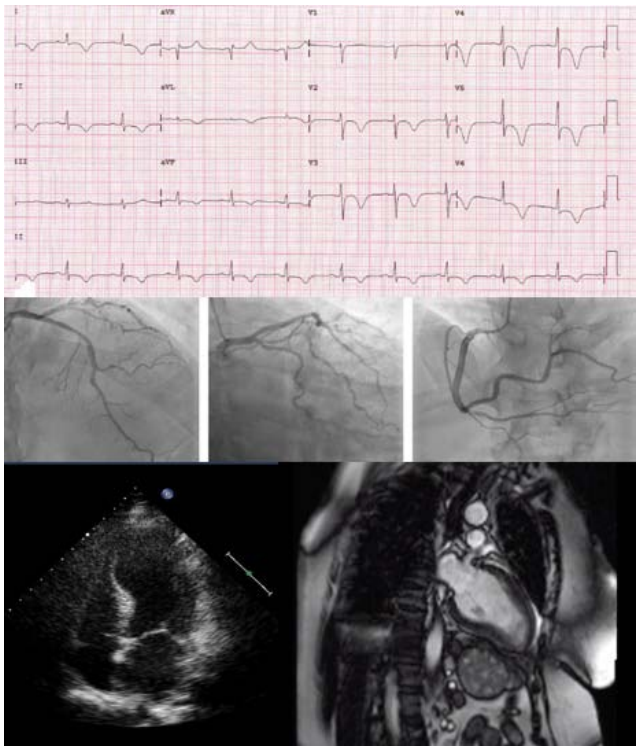
I am hurt, but I will be okay- An unusual case of reversible heart failure

K L Kin Leong Tan[1]; AA Nuruddin[1]
[1]*National Heart Institute, Cardiology, Kuala Lumpur, Malaysia*

Funding Acknowledgements: No

A 56-year-old lady with underlying mild coronary artery disease, diabetes mellitus and hypertension presented with typical angina radiating to the left arm. Upon arrival at the emergency department, she had stable hemodynamic with BP 140/80mmHg and HR of 80/min. Lungs were clear to auscultation and cardiovascular examination was unremarkable. Electrocardiogram revealed sinus rhythm without ST-T changes. Rapid troponin test was positive. Subsequent ECG in the ward showed dynamic T inversion from lead V1 through V6. Serum hs Trop T was elevated; 324pg/ml (NR <14pg/ml). A transthoracic echocardiogram demonstrated reduced left ventricular ejection fraction of 31% with akinesia at apical wall and hypokinesia at the anteroseptal wall. Her baseline echocardiogram in the year 2017 showed normal left ventricular function with no evidence of regional wall motion abnormalities. Diagnosis of Non-ST elevation MI was established.

Coronary angiogram showed non-obstructive coronary arteries. Standard medical therapies were started; dual antiplatelets, statin and S/C low molecular weight heparin were given. Electrocardiogram post catheterization revealed deepening of T inversion from lead V1-V6. She was observed in the ward and anti-failure therapies were initiated; beta blocker and renin-angiotensin-aldosterone blockade agents. Cardiac MRI was performed which showed apical hypokinesia with viable myocardium and normal left ventricular ejection fraction; 60% suggestive of Takotsubo Cardiomyopathy



Picture

Takostubo Cardiomyopathy or "Transient Apical Ballooning/ Stress Cardiomyopathy" is a rare cause of acute reversible heart failure presented with an entity called MINOCA; Myocardial Infarction in Non-Obstructive Coronary Arteries. It occurs predominantly in postmenopausal women soon after exposure to sudden, unexpected emotional or physical stress. The aetiology remains unclear and most patients attained full recovery within weeks.

A tricky case of rapid ejection fraction improvement in patient with preeclampsia and peripartum cardiomyopathy complicated by subsequent heart failure readmissions

S Bondari[1]; A Soloveva[1]; M Teterina[1]; L Babaeva[1]; I Meray[1]; A Safarova[1]; Z Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), Institute of Medicine, Department of Internal Medicine, Moscow, Russian Federation

Introduction: Acute heart failure (AHF) in late pregnancy is a rare and potentially life-threatening complication. As many conditions can lead to AHF in this setting, making an accurate diagnosis could be difficult.
Case report: A 28-year-old primigravida developed cardiogenic shock with need to mechanical ventilation after 3 days of normal vaginal delivery at 39 weeks of gestation. Her medical history was unremarkable. 3 weeks before delivery a progressing ankle swelling with shortness of breath and fatigue developed. 1 week before she had persistent proteinuria (PU) up to 5g/d, BP 135/95 mmHg, hypoalbuminemia to 23,7 g/L. Her weight gain during pregnancy was 30 kg. Laboratory tests showed increased NT-proBNP level (1944 pg/ml), normal GFR (90 ml/min/1,73m2). Low ejection fraction (EF) 32% without regional contractility impairment, severe mitral regurgitation (MR) were revealed. Causes of AHF were discussed. Myocardial infarction, myocarditis and autoimmune disorders were excluded given the normal values of troponin and autoimmune markers. Clinical probability of pulmonary embolism was low. BP tended to be normal or even hypotension was noted, so hypertensive disorders as a reason for AHF were ruled out. Further PU decreased to 1.9 g/l. Because of obvious criteria of preeclampsia and significant weight gain, AHF due to hypervolemia was considered. However, peripartum cardiomyopathy (PPCM) as a most serious cause of AHF during pregnancy was the main concept given the acute deterioration and low EF. Bromocriptine (2.5 mg b.i.d.) therapy was added to AHF treatment consisted of 24h infusion of levosimendan (12.5 mg), and IV furosemide (40 mg o.d.), enoxaparin (sc. 4000 IU), magnesium sulfate infusion. After extubation and hemodynamic stabilization therapy with metoprolol succinate (12.5 mg o.d.), enalapril (2.5 mg b.i.d.), spironolactone (25 mg o.d.) was started and fastly uptitrated. Notably, at 4th day of treatment patient's clinical status was stable and euvolemic, EF remarkably improved to 50% which questioned PPCM. At 5th day of hospital stay woman was discharged on her own. Enalapril (2.5 mg b.i.d.), metoprolol succinate (75 mg o.d.), bromocriptine (2.5 mg b.i.d.), enoxaparin (sc. 4000 IU) and non-breastfeeding were recommended. However, resulting from low adherence, 1 week after discharge patient was readmitted with severe AHF with EF 30%. Emergency heart transplantation was discussed but this was managed to avoid. After that there were 2 more readmissions with AHF and drug-induced hypotension. In 3 months of stable HF therapy EF was 45%, mild MR, kidney function was normal, PU regressed.
Conclusions: Diagnosis of PPCM as a cause of AHF in late pregnancy, especially in cause of concomitant preeclampsia and misleading fast EF improvement thought is challenging but should be kept in mind given high risk of complications. Patient education and depth counseling regarding the risks of non-adherence are the important parts of PPCM management.

681

Atypical HUS associated cardiomyopathy and its recovery on warfarin in a hemodyalisis patient

M Maria Poltavskaya[1]; N Kozlovskaya[2]; E Gilarova[2]
[1]Moscow Medical Academy, Moscow, Russian Federation; [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

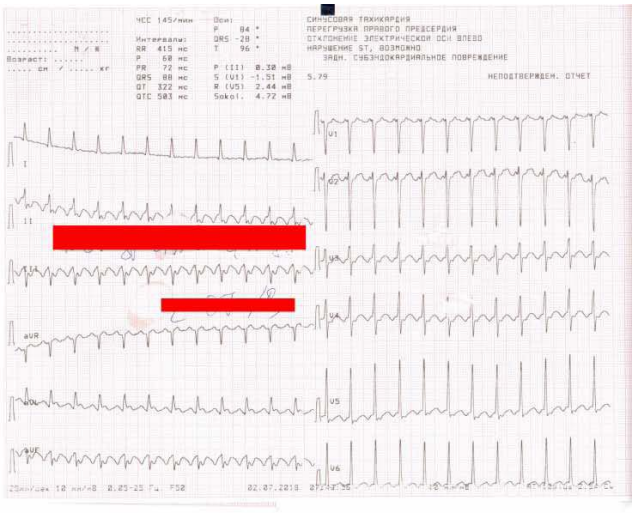
A 29 year old man was admitted to his local hospital after painting work with acute abdominal pain, vomiting, high fever, fatigue, high blood pressure, black urine, oliguria progressing to anuria, oedema, ascitis. His analyses showed leukocytosis, mild thrombocytopenia, anemia with Hb = 50g/l, creatinine = 919mcmol/l, proteinuria of 5-9g/l. The examination including laparotomy did not find any obvious cause. Patient was treated by hemodialysis, erythrocyte and plasma infusions. Renal failure did not recover and chronic dialysis was started. After several months the patient presented with biventricular heart failure, LVEF = 28% and LV dilation. Screening for systemic connective tissue diseases and antiphospholipid syndrome was negative. Treatment with bisoprolol, losartan, statin and digoxin was started. In 1,5 years the patient was admitted to our hospital with atrial fibrillation and decompensation of heart failure. CMR showed marked LV enlargement and noncompaction with EF of 11% and late gadolinium enhancement of non-ischemic type. Diagnosis and treatment. The onset with intravascular haemolysis, acute renal impairment and thrombocytopenia was characteristic of thrombotic microangiopathy. History and blood ADAMTS 13 level excluded STEC-HUS and thrombotic thrombocytopenic purpura. Atypical haemolytic uraemic syndrome (aHUS) was diagnosed. The importance of LV noncompaction was questionable. The patient was given beta-blocker. ACEi, amiodarone, enoxaparine. His sinus rhythm with grade 1 AV block was restored by electrical cardioversion. LVEF on echo at discharge was 27%. After discharge the patient continued ACEi, amiodarone and warfarin. He was also recommended eculizumab, but he failed to get it. During the 2-year follow up the condition of the patient markedly improved. He has sinus rhythm and there are no symptoms of heart failure and no AV block. He has normal platelet count. LV size normalized and LVEF has grown to 64%. Kidney transplant with eculizumab is being considered. Discussion. Atypical haemolytic uraemic syndrome (aHUS) is an extremely rare disorder attributed to defective alternative complement pathway regulation which leads to thrombotic microangiopathy with organ damage and poor prognosis. Data on cardiovascular complications come from scarce case reports and small series. In our patient the disease was not recognized on its onset though it presented with typical triade of hemolytic anemia, thrombocytopenia, and acute renal failure. Eculizumab - a monoclonal antibody to complement C5 is approved as a first line treatment of aHUS but the patient did not get it. The recovery of aHUS associated cardiomyopathy was achieved on anticoagulant treatment started due to atrial fibrillation. It must be noted that anticoagulation in afib hemodialysis patients is not mandatory. Conclusion: This is the first report on aHUS associated cardiomyopathy not on eculizumab treatment but on anticoagulation.

682

The clinical case of successful treatment of heart failure due to tachycardia-induced cardiomyopathy in a patient with paroxysmal atrial flutter.

MR Atabegashvili[1]; DU Shchekochikhin[1]; MU Gylarov[1]; KV Razumov[1]; GA Gromiko[2]; ES Pershina[1]
[1]Pirogov First City Clinical Hospital, Cardiology, Moscow, Russian Federation; [2]3 Central Military Clinical Hospital n.a. A.A. Vishnevsky Ministry of Defense of Russian Federatio, Cardiac Surgery, Moscow, Russian Federation

The patient, a 56-year-old Caucasian male, was admitted to the emergency room because of progressive dyspnea. He experienced shortness of breath, weakness, and recurrent palpitations for 6 months before this admission but did not seek medical help or take any medications.
Upon prior admission, the patient's condition was regarded as severe. His skin was cyanotic and cold. His legs were swollen. His RR was 35 per minute; SpO2 was 92%. His BP was 90/40 mmHg, and his HR was 78 beats per minute, the beats were correct. The abdomen was soft and increased in volume due to ascites. The liver was enlarged. No urine was in the urinary catheter.The ECG obtained upon admission revealed sinus rhythm. The CT scan revealed submassive pulmonary thromboembolism and, hydrothorax. TTE revealed dilatation of ventricles and atriums, global hypokinesia and reduced EF to 33%, and grade 2 mitral and tricuspid regurgitation. The sPAP was 56 mmHg. During ECG monitoring, the series of atrial flutter paroxysms were registered.
Laboratory tests revealed the following changes: 189 μmol/L of creatinine, 3165 U/L units of ALT, 4130 U/L units of AST, 78 μmol/L of total bilirubin 78 μmol/L, and 2.73 for the INR range.During the hospital stay, other causes of renal and hepatic dysfunction were excluded. The coronary angiograms did not show any significant stenosis. We performed active diuretic therapy and also initiated low-dose therapy of beta blockers and ACE inhibitors, which were satisfactory tolerated. We used amiodaron to stop the patient's arrhythmia, but it recurred repeatedly. The acute renal failure was resolved, allowing us to give the patient rivaroxaban as an anticoagulant agent.We suspected the tachycardia-induced cardiomyopathy due to atrial flutter to be the cause of a chronic heart failure decompensation with ischemic hepatitis and acute renal failure in a patient who had already suffered from pulmonary thromboembolism. An electrophysiology study with catheter ablation was proposed. We performed radiofrequency catheter ablation across the cavotricuspid isthmus; this resulted in the termination of the atrial flutter. The cardiac MRI after the procedure did not show any pathologic changes of the myocardium. The EF was 55% and the size of the atriums and ventricles was normal. The patient was discharged with directions to take the following medications: 200 mg daily of amiodarone, 20 mg daily of rivaroxaban, 10 mg daily of fosinopril (raised gradually), and 2.5 mg daily of bisoprolol. The diuretic therapy was gradually canceled after discharge. He has maintained sinus rhythm since the ablation. The patient has not had any signs of heart failure and is now back to his normal lifestyle.
Tachycardia-induced cardiomyopathy is a rare case of heart failure. In spite of being widely reported in literature nowadays the differential diagnosis between tachycardia-induced cardiomyopathy and other cardiomyopathies complicated with arrhythmias is challenging.



flutter paroxysm on ECG

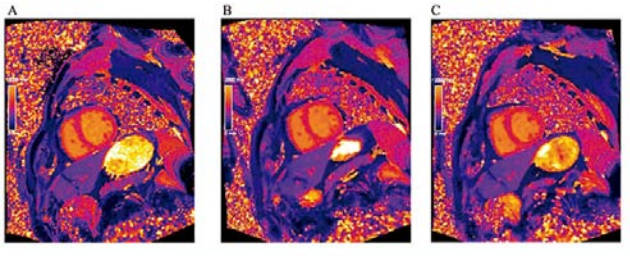
Myocardial iron repletion and changes in left ventricular function

M Soler Costa[1]; I Cardells[1]; G Minana[1]; M Amiguet[1]; J Gonzalez[1]; E Valero[1]; E Santas[1]; MP Lopez-Lereu[1]; JV Monmeneu[1]; R De La Espriella[1]; J Nunez[1]
[1]*University Hospital Clinic of Valencia, CARDIOLOGY, Valencia, Spain*

Introduction: In patients with chronic heart failure and reduced ejection fraction, iron deficiency has emerged as a common co-morbidity that affects up to 50% of these patients. It is associated with an impaired quality of life, exercise capacity and higher risk of adverse events. Importantly, treatment with intravenous ferric carboxymaltose has shown beneficial effects in patients with heart failure and reduced ejection fraction. However, the mechanisms behind these effects are not well established. Scarce evidence suggests myocardial iron repletion would improve myocardial energetic efficiency and left ventricular systolic function in heart failure and reduced ejection fraction.
Description of the case: We describe a case of a 63-year-old man with non-ischemic stable heart failure and reduced ejection fraction and iron deficiency in which cardiac magnetic resonance with evaluation of T1 mapping (as a surrogate of tissue iron) and 2D-echocardiography with global longitudinal strain were evaluated before, 7- and 30-days following administration of 1000 mg of ferric carboxymaltose. Myocardial iron repletion, ascertained by a reduction in T1-mapping cardiac magnetic resonance relaxation times at 7 and 30 days, was observed. Likewise, this change was in parallel with improvement in left ventricle ejection fraction, global longitudinal strain and surrogates of exercise capacity and quality of life.
Conclusions: This case suggests that myocardial iron repletion plays a role improving ventricular systolic function in heart failure and reduced ejection fraction. Therefore, treatment of iron deficiency might be considered a therapeutic target in patients with heart failure and reduced ejection fraction.

FIGURE 1



Images from T1 mapping cardiac magnetic resonance at A) Baseline (1082ms), B) 7 days after iron repletion (1045ms) and C) 30 days after iron repletion (1037ms). Reduction in T1 mapping values over time suggest myocardial iron repletion.

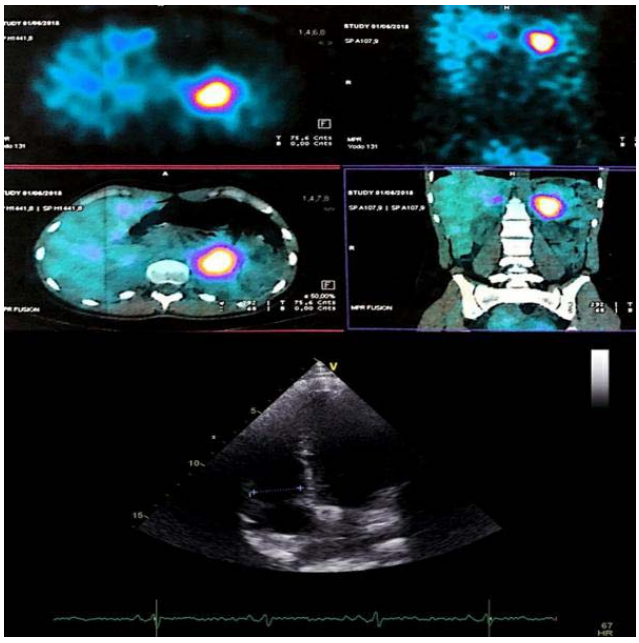
T1 mapping Cardiac Magnetic Resonance

685

Pheochromocytoma as cause of heart failure with recovered ejection fraction.

C Catalina Gallego[1]; CI Saldarriaga[1]; JD Uribe[1]; LA Fajardo[1]; LJ Tamayo[1]; JD Martinez[1]; A Agudelo[1]
[1]*Cardiovascular Clinic Santa Maria, Medellin, Colombia*

Case report: A 24-year-old woman with no significant medical history, NYHA I, consults due to the evolution of respiratory symptoms during the past six days worsening during the last 24 hours prior to consult with oppressive chest pain and palpitations. On admission, tachycardia and hypoperfusion are diagnosed and an electrocardiogram was performed showing sinus tachycardia, chest x-rays showed signs of acute pulmonary edema and a transthoracic echocardiogram reported a 20% left ventricle ejection fraction with diffuse hypokinesia, dilated left atrium, normal right atrium and a right ventricle with global hypokinesia and a 12 mm TAPSE; integral valves without pericardial effusion. The patient was admitted into the intensive care unit in cardiogenic shock while presenting cardiorespiratory arrest, which after 26 minutes of advanced resuscitation returned to spontaneous circulation. Extracorporeous membrane oxygenation (ECMO), vasopressors and inotropics were initiated, which were removed after 72 hours due to clinical improvement. A control transthoracic echocardiography was performed, in which, an ejection fraction of 44% was found, left ventricle with normal diameter, parietal thickness with concentric remodeling and myocardial contractility with diffuse hypokinesia. With the patient's clinical picture and evolution, viral myocarditis was considered as the first diagnostic option. Due to clinical improvement and recovery of echocardiographic parameters, the patient continued the treatment in an outpatient setting. Two weeks later, the patient checked into the emergency room with headache, arterial hypertension and palpitations. In this opportunity a tumor producing catecholamines was suspected, a metanephrines urine test was requested testing positive afterwards, a contrasted abdominal resonance was performed finding a lesion compatible with pheochromocytoma in the left adrenal gland. A cardiac resonance was carried out as well, in which produced no signs of acute myocarditis or its sequelae, no ischemia or infiltrative diseases. A normal valvular function was also evident, thus demonstrating that the origin of the patient's heart failure was pheochromocytoma. Patient underwent a left adrenalectomy and three months after the procedure an echocardiography was performed, reporting an ejection fraction of 60%, left ventricle of normal size and thickness with global and normal segmental myocardial contractility.
Discussion: Improved left ventricular function occurs in up to 40-50% of patients with heart failure due to acute myocarditis, peripartum cardiomyopathy, some forms of chemotherapeutic cardiac dysfunction, and tachycardia-induced cardiomyopathy. Although the presence of cardiogenic shock by pheochromocytoma, as occurred in our patient, is highly unusual with an incidence of 0.8% per 100,000 people per year in non-family pheochromocytomas. A high rate of suspicion must be at scene since it may be a reversible cause of heart failure.



Pheochromocytoma Image and Heart Failure

Moderated Poster Session - Chronic heart failure

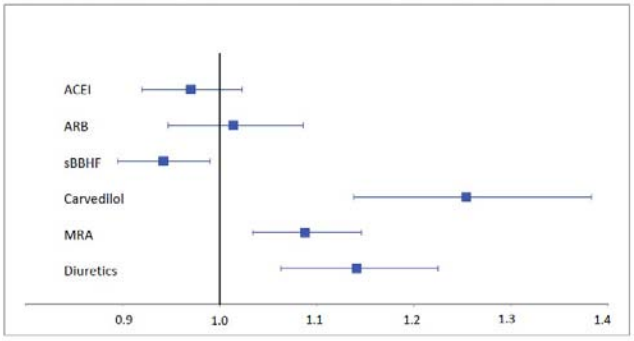
Association between heart failure medication at discharge and heart failure readmission

W J Willemien Kruik-Kolloffel[1]; J Van Der Palen[2]; CJM Doggen[2]; HJ Kruik[3]; EM Heintjes[4]; KLL Movig[5]; GCM Linssen[3]
[1]Röpcke-Zweers Hospital, Clinical Pharmacy, Hardenberg, Netherlands (The); *[2]University of Twente, Enschede, Netherlands (The)*; *[3]Hospital Group Twente, Cardiology, Hengelo, Netherlands (The)*; *[4]Pharmo Institute, Utrecht, Netherlands (The)*; *[5]Medical Spectrum Twente, Clinical Pharmacy, Enschede, Netherlands (The)*

Introduction and purpose: The aim of this large population-based cohort study is to compare hospital readmission rates of patients with heart failure (HF), prescribed core HF medications versus non-use in a real-world scenario. Angiotensin-converting-enzyme inhibitors (ACEI), angiotensin-receptor blockers (ARB), beta-blockers (BB) and mineralocorticoid-receptor antagonists (MRA) have demonstrated in randomized clinical trials in selected groups of HF patients to reduce the risk of readmission for HF. Diuretics, being indispensable for most patients with HF, are also investigated.
Methods and results: Medication at hospital discharge was determined on the basis of dispensing data from the Dutch PHARMO Database Network including 22,476 patients with a diagnosis of HF between 2001 and 2015. Median follow-up was 29.3 months. One third of all patients were readmitted for HF. Propensity scores were calculated as a proxy for comorbidities and hazard ratios were adjusted (HRadj) accordingly. ACEI and ARB were not associated with readmission. Only β1-selective BB (sBBHF; bisoprolol, metoprolol and nebivolol) decreased risk of readmission (HRadj 0.94; 95%CI 0.90-0.99). Carvedilol, a β- and partly α1-blocking agent, (HRadj 1.25; 95%CI 1.14-1.38), MRA (HRadj 1.09; 95%CI 1.03-1.15) and diuretics (HRadj 1.14; 95%CI 1.06-1.23) were associated with an increased risk of readmission.
Conclusion Based on our results, sBBHF should be preferred to the non-selective BB carvedilol, whereas they are considered equivalent in current guidelines. Further investigations are necessary to confirm our results in other real-world HF patients.

Figure 1 Forest plot for hazard ratios* associated with heart failure medication



*HR versus non-use adjusted for age, gender, number of drugs (excl particular medication), year of admission propensity score of particular medication (based on baseline covariates and co-medication)
ACEI: angiotensin-converting enzyme inhibitor
ARB: angiotensin receptor blocker
sBBHF: Selective beta1- receptor blocker with a market autorisation for heart failure
MRA: mineralocorticoid-receptor antagonist

Association of loop diuretics use and dose with outcomes in outpatients with heart failure: a systematic review and meta-analysis involving 48,628 patients

C Chris Kapelios[1]; M Bonou[1]; K Malliaras[1]; S Vakrou[1]; E Athanasiadi[1]; A Athanasiou[1]; C Masoura[1]; J Barbetseas[1]
[1]Laiko University General Hospital, Athens, Greece

Background: There is an ongoing controversy regarding association between loop diuretics (LD) receipt, especially in high doses, and adverse clinical outcomes in outpatients with heart failure (HF).
Purpose: We performed a systematic review of the evidence for LD in outpatients with HF.
Methods: We searched MEDLINE, EMBASE, clinicaltrials.gov and Cochrane Clinical Trial Collection to identify controlled studies, evaluating the association between LD and morbidity and mortality in outpatients with HF. Two reviewers independently identified citations and extracted data. Primary end-point was all-cause mortality and secondary measure HF hospitalizations. Quantitative analysis was performed by generating forest plots and calculating effect sizes by random-effect models. Between-study heterogeneity was assessed through Q and I2 statistics.
Results: Fifteen studies with a total of 48,628 patients were included. No randomized studies were identified. Use of LD was associated with increased all-cause mortality compared with non-use (30.7% vs 16.9% [pooled adjusted risk estimates: 1.30; 95% CI: 1.23-1.37, P<0.001]) and increased rates of hospital admissions for HF (30.7% vs 10.2% [pooled adjusted risk estimates: 1.89; 95% CI: 1.65-2.16, P<0.001]). High-dose LD (median dose 80 mg) were also associated with increased all-cause mortality (39.4% vs 24.6% [pooled adjusted risk estimates: 1.33; 95% CI: 1.21-1.46, P<0.001]) compared with low-dose LD.
Conclusions: The totality of evidence indicates that LD, especially in high doses, are associated with increased all-cause mortality in outpatients with HF. Use of LD are also associated with higher rates of HF hospitalizations. For this reason, and until prospective, randomized studies clarify whether this association indicates causality or is merely an epiphenomenon, LD should be administered at the lowest, possible dose in outpatients with HF.

Funding Acknowledgements: AS receives research grant support from CardioPath

Aims: Multiple hormone deficiencies (MHD) are common in heart failure (HF). Although preliminary studies have demonstrated effectiveness of single replacement

therapy for growth hormone deficiency (GHD) or testosterone deficiency (TD) in HF, no data are available regarding combined treatment with GH and T. Aim of the present study was to evaluate the effects of multiple hormonal replacement therapy in HF. Methods and results: Five stable GHD and TD patients affected with HF, after completing 1 year of GH replacement treatment, started simultaneous GH and T replacement therapies. After 1-year, a significant improvement in left ventricular ejection fraction ($p<0.01$), New York Heart Association class ($p<0.05$), and peak oxygen consumption (VO2 peak) ($p<0.01$) with a significant reduction in NT-proBNP levels ($p<0.01$) were observed. GH+T replacement therapies resulted in a further increase in VO2 peak, and in a significant improvement in muscular strength, as assessed by handgrip dynamometry ($p<0.01$) leading to an improvement of the overall clinical status. Of note, neither adverse effects nor cardiovascular events were reported.
Conclusions: Combined replacement therapy with GH and T is safe and therapeutic in HF patients with MHD. MHD syndrome can be considered as a novel and promising therapeutic target in HF.

[1]Waterford Regional Hospital, Waterford, Ireland; *[2]Beaumont Hospital, cardiology, Dublin, Ireland*; *[3]Connolly Hospital Blanchardstown, cardiology, Dublin, Ireland*; *[4]Cavan General Hospital, cardiology, Cavan, Ireland*; *[5]Mid-Western Regional Hospital Ennis, cardiology, Clare, Ireland*; *[6]University Hospital Limerick, Limerick, Ireland*; *[7]Nenagh General Hospital, cardiology, Nenagh, Ireland*; *[8]Letterkenny General Hospital, cardiology, Donegal, Ireland*; *[9]Mater Private Hospital, cardiology, Dublin, Ireland*; *[10]Mater Misericordiae University Hospital , cardiology, Dublin, Ireland*; *[11]Mallow General Hospital, cardiology, Cork, Ireland*; *[12]Monaghan General Hospital, cardiology, Monaghan, Ireland*; *[13]Wexford General Hospital, cardiology, Wexford, Ireland*; *[14]Tallaght University Hospital, cardiology, Dublin, Ireland*

On behalf of: Irish Heart Failure Nurses Group

Background: In Ireland seven percent of all inpatient bed days are heart failure (HF) related. Cardiomyocyte ferroportin is essential for intracellular iron homeostasis which affects cardiac function. Up to fifty percent of stable HF patients are frequently observed to be iron deficient (ID). Iron replacement improves HF outcomes. According to the current ESC guidelines the administration of intravenous iron for HFrEF patients is currently a class IIa level A recommendation. This first national collaborative clinical audit was undertaken to examine the extent to which this ESC guideline has been implemented for heart failure patients.
Purpose
1. Identify patients enrolled in a specialised heart failure clinic (HFC) who were ID.
2. Identify if iron deficiency screening occurred as an inpatient or in the HFC.
3. Assess if patients received iron replacement as per ESC guidelines.
4. Assess if average length of stay (LOS) in hospital differed between the groups reviewed.
Methods: Retrospective audit and cohort analysis was conducted by HF nurses at eleven hospital centres across Ireland. A total of 474 patient-level data was extracted from both electronic and written health records. Intravenous iron replacement to patients was identified as per ESC guidelines. Standard Bayesian statistics were employed to assess for associations within this cohort.
Results: 168 patients admitted with HF and had ID: 61(36.3%) were screened while an inpatient , 104 (61.9%) in HFC, 2 (1.2%) levels unknown, 1(0.6%) died. In this subgroup;31 (18.5%) were treated with intravenous iron while inpatient, 82 (48.8%) were treated in HFC, 53 (31.5%) not treated.
Conclusion: The prevalence of ID in heart failure patients included in this audit was 54 %. The group who had ID had a longer LOS compared to those who did not. The total number of inpatients screened for ID was 27%, of this group, 49% were not treated as per ESC guidelines. Heart Failures nurses play a significant role in the implementation of ESC guidelines for optimisation of treatment for patients with heart failure, as the majority of screening (61.9%) took place post discharge in the HFC. Further studies are needed to explore the barriers to screening for ID in heart failure inpatients/HFC and ways to improve implementation of this ESC guideline.

Effect of ferric carboxymaltose on LVEF as assessed by cardiac MRI in patients with chronic heart failure and iron deficiency: a randomized, double-blinded, placebo-controlled, dual-center trial

M Karakas[1]
[1]University Heart Center Hamburg, General and interventional Cardiology, Hamburg, Germany

On behalf of: iCHF study group
Funding Acknowledgements: Investigator initiated trial -funded in part by means of Vifor Pharma

Background: Iron deficiency is a common comorbidity in patients with heart failure (HF) and is associated with poor outcomes. Intravenous (i.v.) ferric carboxymaltose (FCM) has been shown to improve symptoms, quality of life and functional capacity.

Purpose
Whether correction of iron deficiency with intravenous ferric carboxymaltose affects the left-ventricular ejection fraction (LVEF) has not been examined to date using an objective and prognosis-relevant measure in HF.
Methods: We studied patients with systolic HF (LVEF ≤ 45%) and mild to moderate symptoms (NYHA 2 and NYHA 3) despite optimal HF medication. Patients were randomized 1:1 to treatment with FCM or placebo (saline). Treatment covered correction of iron deficiency during first 4 weeks. The primary endpoint, change in LVEF measured using cardiac MRI from baseline to 12 weeks, was assessed by an independent external core-lab. Secondary endpoints included further MRI-based parameters like stroke volume, six minute walking test (6MWT), renal function, cardiac biomarkers, quality of life, and safety.
Results: Due to poor recruitment of the study after departure of the principal investigator, only 18 subjects were randomized. Of the 18 subjects, 10 were randomized to FCM, and 8 to saline. At month 3 there was an increase of 2.1% in the LVEF within the FCM group, in contrast to a decrease of 3.5% in the saline group (mean difference between groups: 5.5% ± 3.8%; p = 0.009) during the same period. Moreover, systolic stroke volume increased by 6.0 mL in the verum group, while it decreased by 11.1 mL in the placebo group from baseline to end of study (mean difference between groups: 17.1 mL ± 13.5 mL; p = 0.008). Similarly, there was an increase of 55.0 meters (m) in the 6MWT in the i.v. iron group, while the placebo group experienced a mean decrease of 27.1 m during follow-up, although the difference did not meet statistical significance (mean difference between groups: 82.1 m ± 104.3 m; p = 0.121). Regarding safety, 1 out of 10 patients in the verum (FCM) group, and 2 out of 8 patients in the control group experienced a serious adverse event (SAE). In addition, 5 out of 10 patients in the verum group, and 5 out of 8 patients in the control group experienced an adverse event (AE). All events were judged as "not related" to application of verum/ placebo.
Conclusion: Correction of existing iron deficiency with intravenous FCM in patients with HF improves systolic heart function and further remodeling parameters as assessed by cardiac MRI. Current cardiovascular guidelines recommend screening of iron status in all newly diagnosed patients with systolic HF and consideration to administer FCM in symptomatic patients with iron deficiency. By using the gold standard cardiac MRI, our study clearly documents that even one-time correction of iron efficiency using FCM not only improves symptomatic endpoints and functional capacity, but also heart function itself.

692
Sacubitril/valsartan reduces ventricular arrhythmias in parallel with left ventricular reverse remodeling in HFrEF.

P Pieter Martens[1]; M Dupont[1]; W Mullens[1]
[1]*Hospital Oost-Limburg (ZOL), Cardiology, Genk, Belgium*

Background: Sacubitril/valsartan reduced the occurrence of sudden cardiac death in the PARADIGM-HF trial. However, no information is available about the mechanism.

Methods: Heart failure (HF)-patients receiving sacubitril/valsartan for a class-I indication equipped with an implantable cardioverter defibrillator (ICD) or cardiac resynchronization therapy (CRT) with remote tele-monitoring were retrospectively analyzed. Device registered arrhythmic-events were determined (ventricular tachycardia/fibrillation[VT/VF], appropriate therapy, non-sustained VT [NsVT;>4beats and <30seconds], hourly premature-ventricular-contraction [PVC]-burden), following sacubitril/valsartan initiation (incident-analysis) and over an equal time-period before initiation (antecedent-analysis). Reverse remodeling to sacubitril/valsartan was defined as an improvement of left ventricular ejection fraction (LVEF) of ≥5% between baseline and follow-up.
Results: A-total of 151 HF-patients with reduced LVEF (29±9%) were included. Patients were switched from ACE-I or ARB to equal doses of sacubitril/valsartan (expressed as %-target-dose; before=58±30% vs. after=56±27%). The mean follow-up of both the incident and antecedent-analysis was 364-days. Following the initiation, VT/VF-burden dropped (individual-patients with VT/VF pre_n=19 vs. post_n=10, total-episodes of VT/VF pre_n=51 vs. post_n=14, both p<0.001), resulting in reduced occurrence of appropriate therapy (pre_n=16 vs. post_n=6; p<0.001). NSVT-burden per patient also dropped (See table). There was no impact on atrial-fibrillation burden (see table). PVC-burden dropped significantly, which was associated with an improvement in BiV-pacing in patients with <90% BiV-pacing at baseline. A higher degree of reverse remodeling was associated with a lower burden of NsVT and PVCs (both p<0.05). Following initiation of sacubitril/valsartan 44% of patients exhibited beneficial reverse remodeling.
Conclusion: Initiation of sacubitril/valsartan for a class-I recommendation, is associated with a lower degree of VT/VF, resulting in less ICD-interventions. This beneficial effect on ventricular arrhythmias might be related to cardiac reverse remodeling.

Security of vacubitril-valsartan in Naive patients. Subanalysis of SAVE-RLife study

M Sanmamed Giron[1]; M Galvan Ruiz[1]; M Singh[1]; M Groba Marco[1]; M Lopez Perez[1]; J Medina Suarez[1]; D Rua-Figueroa Erausquin[1]; P Pena Ortega[1]; A Cardenes Leon[1]; V Quevedo Nelson[1]; H Mendoza Lemes[1]; JJ Garcia Salvador[1]; P Martin Lorenzo[1]; E Caballero Dorta[1]; A Antonio Garcia Quintana[1]
[1]*University Hospital of Gran Canaria Doctor Negrin, Las Palmas De Gran Canaria, Spain*

On behalf of: SAVE-RLife Group

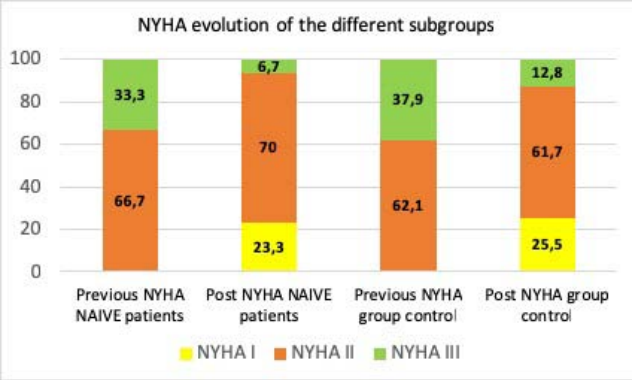
Background: In the PIONEER-HF and TRANSITION-HF studies, sacubitril-valsartan (SV) was used in naive hospitalized patients (52.7%) without increasing side effects. However, few data are known about the use of SV in naive patients in real life.
Objective: To analyze the safety of starting SV in patients with optimal medical treatment compared to naive patients.

Methods: A subanalysis of the SAVE-RLife (SAcubitril-Valsartan Evidence in Real Life) study was performed. This is an observational, ambispective study that included all patients with stable HFrEF who started SV between SEP2016 and DEC2018. The safety results of the naives patients were compared with the patients with ACE or ARB treatment prior to the start of SV.
Results: 31 out to 276 patients were naives (11.2%), with a follow-up of 204 (48;320) days and an average age of 66.9±9.4 years. The baseline characteristics are shown

Baseline Characteristic & Adverse events

	ACE/ARB baseline N = 245 (88.8%)	Naive Patients N = 31 (11.2%)	P value
HBP n (%) / DM n (%)	180 (73.5%) / 121 (49.4%)	21 (67.7%) / 14 (45.2%)	0.499 / 0.657
Dyslipidemia n (%) AF n (%)	138 (56.3%) / 90 (36.9%)	19 (61.3%) / 9 (29%)	0.599 / 0.391
SBP pre/post (mmHg)	128.8±20.4 / 119.7±20.5	119.5±20.9 / 110.1±17.7	0.233 / 0.027
GFR pre/post (mmHg)	69.66±27.2 / 63.29±19.5	68.96±24.1 / 68.06±19.5	0.681 / 0.554
Potassium pre/post (mEq/L)	4.55±0.44 / 4.77±0.52	4.71±0.78 / 4.66±0.63	0.968 / 0.578
Δ N-BNP (pg/mL)	-1332	-2110	0.702
Acute Kidney failure n(%)	42 (17.2%)	3 (9.7%)	0.285
Symptomatic hypotension	23 (9.4%)	1 (3.2%)	0.249
Asympt. hypotension n(%)	23(9.4%)	4(12.9%)	0.540
Hiperkalemia n(%)	38 (15.6%)	4 (12.9%)	0.697

in Table 1. There is no significant worsening of renal function in both subgroups and a similar trend to a greater reduction in N-BNP levels. Naive patients had less visits to the emergency room compared to the control group (p=0.009) at follow up. There were no differences in the side effects between the control group and the naive group, 3 patients (9,7%) suffered an acute renal failure, 4 (12,9%) episodes of asymptomatic hypotension and 4 (12,9%) hyperkalemia. There were no major adverse effect, including angioedema in the naive group, and none of the naive patients died during the follow-up. Evolution of NYHA class is shown in Figure 1.
Conclusions: Despite the limitations of our SV naive sample, it seems to be a safe and effective drug in naives patients, without increasing side effects and with the same efficacy in our population, in concordance with the results of recent clinical trials.



NYHA evolution of naive vs control group

694

In-hospital initiation of sacubitril/valsartan in stabilized patients with heart failure and reduced ejection fraction naive to renin-angiotensin system blocker: An analysis of the TRANSITION study

Background: In-hospital initiation of sacubitril/valsartan (S/V) in patients with reduced ejection fraction (HFrEF), after an acute episode (ADHF), was associated with superior than enalapril reduction in NT-proBNP in PIONEER-HF study, that was not different in patients naïve to angiotensin converting-enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB).
Methods: TRANSITION (NCT02661217) randomized 1002 patients with HFrEF, admitted for ADHF. After stabilization, patients were randomized to start open-label S/V either pre-discharge or during days 1–14 post-discharge, stratified by ACEI/ARB use status. Primary endpoint was the proportion of patients achieving the target dose of 97/103 mg S/V bid at 10 weeks. Endpoints, adverse events (AE), study treatment discontinuations were compared by ACEI/ARB status in the combined pre- and post-discharge arms.
Results: 326 patients (32.9%) were ACEI/ARB naïve and 665 (67.1%) were not. At baseline, ACEI/ARB naïve patients had lower systolic blood pressure, serum creatinine, and fewer comorbidities but had higher heart rate and more often non-ischemic HF etiology. Similar proportions of ACEI/ARB naïve patients achieved the target dose of S/V compared to subjects with prior ACEI/ARB use (48.3% vs. 47.9%, RRR 1.008, 95% CI 0.878, 1.156) and 88% of subjects in both groups were maintained on any S/V dose at week 10. The rate of permanent discontinuation of S/V due to AEs was low and comparable. (Figure 1). Overall incidence of AEs and SAEs were similar in both groups. Hyperkalemia as an AE occurred in fewer naïve patients (Table 1).
Conclusion: In hospitalized patients with HFrEF who are naïve to ACEI or ARB, S/V can be safely initiated pre-discharge or shortly after discharge, and up-titration is well tolerated.

Table 1

Event	Naive to ACEI/ARB (N=326) n (%)	Not naive to ACEI/ARB (N=665) n (%)	P-value

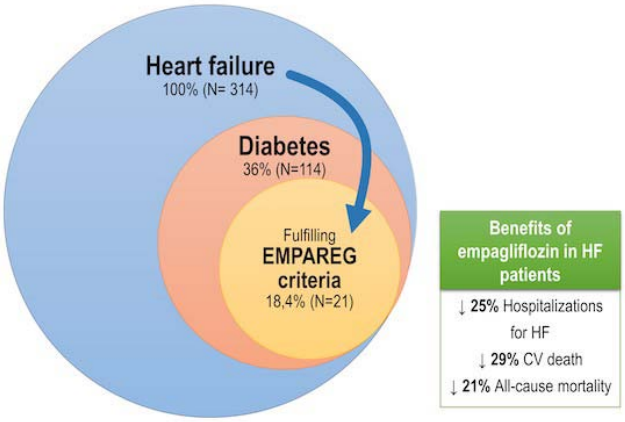
Empaglifozin in real-world chronic heart failure

B Rocha[1]; G Cunha[1]; R Ventura Gomes[2]; R Morais[3]; L Fernandes[3]; L Campos[4]; I Araujo[3]; C Fonseca[3]
[1]Hospital de Santa Cruz, Cardiology, Lisbon, Portugal; *[2]Hospital de Vila Franca de Xira, Cardiology, Vila Franca de Xira, Portugal*; *[3]Hospital São Francisco Xavier, CHLO, Clínica de Insuficiência Cardíaca, Lisbon, Portugal*; *[4]Hospital de Sao Francisco Xavier, Medicine, Lisbon, Portugal*

Introduction: Heart Failure (HF) is a burdensome syndrome with significant mortality, morbidity and costs. Its prognosis is further aggravated by diabetes mellitus (DM). The EMPA-REG OUTCOME trial suggested that empagliflozin significantly reduced HF hospitalizations compared to placebo in patients with DM.
Purpose: We aimed to investigate which patients with chronic HF and DM in an outpatient setting could have been enrolled in the EMPA-REG OUTCOME trial.
Methods: This analysis is based on a retrospective cohort enrolling consecutive chronic HF patients who attended the HF appointment between January and July 2018. Of these, those with concomitant DM were selected and further analysed. The key EMPA-REG OUTCOME trial inclusion criteria [(i.e., hemoglobin A1c 7-10%, high cardiovascular (CV) risk and glomerular filtration rate [GFR] ≥30mL/min/1,73m2) were considered. Further, the European Medicine Agency (EMA) restriction (GFR>60mL/min/1,73m2) was also considered in an additional analysis.
Results: Of 316 patients with HF, 114 (36%) concomitantly had DM. Mean age was 74 ± 10 years, 63% were male and most (54%) had HF with preserved left ventricular ejection fraction. Ischemic (51%) and hypertensive (27%) HF were the most often observed etiologies. According to the inclusion criteria, 21 (18.4%) (or 5.3% when further considering the EMA restriction) HF patients could have been potentially enrolled in the main trial and derive a HF hospitalization reduction benefit from starting empagliflozin. The remainder would be excluded due to GFR<30mL/min/1.73m2 (2.6%), absence of "high CV risk" as per trial's definition (7%), HbA1c off target (18,4%) or a combination of the above criteria (53.6%).

Conclusions: Roughly 1 in every 5 patients with HF and DM could have been enrolled in the main empagliflozin trial, as per key inclusion criteria, and potentially derive CV benefit from it. Thus, only a minority of our cohort shared the features for EMPA-REG OUTCOME trial inclusion, limiting the extrapolation of the trial's observed CV benefits to our HF cohort. Indeed, whether these benefits also expand to overall HF cohort is eagerly awaited by ongoing trials.



HF and DM enrolled in EMPA-REG trial

Development and feasibility testing of an avatar-based education application for improving heart failure patients' knowledge and self-care behaviours

P Parichat Wonggom[1]; H Du[1]; C Burdeniuk[2]; S Kelman[3]; P Nolan[1]; T Barry[1]; RA Clark[1]
[1]Flinders University, College of Nursing and Health Sciences, Adelaide, Australia; *[2]Flinders Medical Centre, Southern Adelaide Local Health Network, Cardiac Services, Adelaide, Australia*; *[3]Flinders Medical Centre, Southern Adelaide Local Health Network, Community Heart Failure Service, Adelaide, Australia*

Funding Acknowledgements: A Heart Foundation Future Leader Fellowship, Establishment Grant, a Tom Simpson Trust Fund, and the Faculty of Nursing, Khon Kaen University, Thailand

Background: Self-care is an essential part of heart failure (HF) management. Interactive patient education using technology has the potential to improve self-care particularly in people with low literacy.
Purpose: Develop and evaluate an interactive avatar-based application for improving HF knowledge and self-care.
Methods: Participatory action research and feasibility testing using pre-post methods.
Results: An avatar-based application was developed by 6 HF patients, 2 HF family members, and 15 cardiovascular and information technology experts through two cycles of development and critical reflection. Based on feedback, the application was updated to improve user experience including avatar characteristics, illustration, concepts and random quizzes.
Feasibility testing was conducted on 11 HF participants to assess improvements in HF knowledge (Dutch HF Knowledge Scale), self-care behaviours (The Self-Care of HF Index), and satisfaction. Mean age was 67.7 $\pm$ 13.9 years, 72.7% male. After using the app there was a significant improvement in HF knowledge (11.6 $\pm$ 2.2 to 12.6 $\pm$ 2.2, p = 0.004), self-care maintenance (30.3 $\pm$ 3.1 to 34.2 $\pm$ 5.2, p = 0.045) and self-care confidence (19.1 $\pm$ 2.7 to 23.3 $\pm$ 1.3, p < 0.0005). Self-care management did not significantly improve (14.3 $\pm$ 5.2 to 15.7 $\pm$ 6.7, p = 0.245). Overall satisfaction with the revised avatar application was high at 88.2%.
Conclusion: The final version of the app had improved navigation, was shorter in time to completion in order to enhance technology confidence and enjoyment. The avatar-based technology demonstrated positive improvements in enhancing HF knowledge and self-care behaviours.

704

Unexpected loss in advanced heart failure

L Kitko[1]; JE Hupcey[1]; JG Gilchrist[2]
[1]The Pennsylvania State University, University Park, United States of America; *[2]Duke University Medical Center, Durham, United States of America*

Funding Acknowledgements: NIH/NINR R01 NR013419

Background: Over 6 million Americans have been diagnosed with heart failure (HF) with half of newly diagnosed predicted to die within 5 years. HF has an unpredictable trajectory and death is often unexpected. Palliative care has been recommended to meet the needs of persons living with advanced HF and their family members. Palliative care services/consultations often do not occur or occur too late to benefit the person living with HF and their family caregiver.
Purpose: To investigate how caregivers' perceptions and understanding of the terminality
of advanced HF impacted their expectations of death and subsequent bereavement.
Methods: Descriptive qualitative study of bereavement interviews of family caregivers (n=39) of persons with advanced HF. The caregivers were individually interviewed after the death of their family member living with advanced HF. Interviews were analyzed to determine whether caregivers perceived the patient's death as expected, expected but not at the time of death, or unexpected. Interviews were analyzed using qualitative content analysis. A review of the electronic medical record was conducted to determine palliative care service utilization.
Results: Thirty-nine family caregivers were interviewed. Of the 39 caregivers who participated in this study, 90% (35/39) of the caregivers were female with a mean age of 65 years of age. The majority of the caregivers (64%; 25/39) were the spouse of the person living with advanced HF. The majority (61%; 24/39) of caregivers were completely surprised or did not expect the patient's death. Few caregivers (15/39) acknowledged the patients' decline and subsequent death. Twenty-six percent of the caregivers (10/39) described difficulty coping in the bereavement period. Palliative care consultations or services were not initiated in the majority (65%) of the patients whose death was perceived as unexpected by the caregiver. The majority of the palliative care consults were received during the terminal admission within a few days or hours prior to death. Some exemplar quotes from the caregivers who participated in the study:
"I never thought when he went to the hospital with a bloody nose that would be the time that
he wouldn't come home."
"The grief nurse came in prior to him dying to make sure we were in agreement with everything,
but then it all hit me, I said, are you telling me he is dying?'"
Conclusions and Implications: Most caregivers were surprised by the patient's death despite the advanced HF diagnosis. The lack of palliative care services in the advanced HF illness trajectory may contribute to the poor perceptions by family caregivers of the seriousness of HF. Caregivers may experience complicated bereavement due to a lack of anticipatory grieving. Palliative care consultation and end-of-life discussions may help caregivers perceive disease terminality. Healthcare providers need to initiate more end-of-life conversations and timely palliative care consultations.

705

Motivations and barriers towards physical activities in heart failure patients with focus on age differences

L Klompstra[1]; T Jaarsma[1]; A Stromberg[2]; MHL Van Der Wal[3]
[1]Linkoping University, Department of Social and Welfare studies, Linkoping, Sweden; *[2]Linkoping University, Department of Medical and Health Science, Linkoping, Sweden*; *[3]University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands (The)*

Background: Physical activity is important for all heart failure (HF) patients in order to improve prognosis. Since adherence is low, it is essential to explore motivations and barriers of patients. Since elderly persons in general are less active, it is important to explore if there are differences in motivations and barriers related to age.
Purpose: To examine motivations and barriers to physical activity in HF patients with special focus on differences between patients older and younger than 65 years.
Methods: A cross-sectional study, including baseline data of HF patients participating in the HF-Wii trial. Motivations were measured with the Exercise Motivation Index, including 15 motivations with answers ranging from 0 (not important) to 4 (extremely important), with 3 subscales (physical, psychological and social motivations). Self-efficacy was measured with the Exercise Self-Efficacy Scale, including 6 possible barriers, with answers ranging from 1 (not confident to overcome the barrier) to 10 (very confident to overcome the barrier).
Results: In total 605 HF patients participated (mean age 67$\pm$12; 60% NYHA I/II; 71% men). Mean motivation per item was 2.3$\pm$0.9 and physical and psychological motivations were rated as the most important (2.7$\pm$0.9 and 2.5$\pm$0.9). The most important physical motivation was 'I want to be healthier and perhaps live longer' (80% rated important/very important) and most important psychological motivation was 'exercise increases my overall sense of wellbeing' (63% rated important/very important). Although social motivations were seen as the least important (mean 1.6$\pm$1.1), 39% of the patients found it important 'to be as active as their family and friends'. Most difficult barrier to overcome was 'physical fatigue' (64% rated little/no confidence to overcome), with a mean confidence to overcome barriers of 5.0$\pm$2.0. Elderly HF patients (65 years, n=393) were more motivated to be physically active than patients younger than 65 years (n=212; 2.4$\pm$0.9 vs. 2.1$\pm$0.9, p-value<0.01), with a higher social (1.9$\pm$1.1 vs 1.5$\pm$1.1) and psychological motivation (2.6$\pm$0.9 vs 2.4$\pm$0.9 p-value=0.03). The largest difference was found in the item 'I want to belong to groups with people in good shape' (with 43% of the elderly rated as important/very important vs. 26% of younger patients, p-value<0.01) and the psychological item 'I feel I have more control over my life when I exercise' (with 58% of the elderly rated as important/very important compared to 47% of younger patients, p-value<0.01).

Conclusions: Since younger and elderly patients experience different motivations towards physical activity, physical activity programs may need to use different strategies in elderly and younger patients and focus on the individual motivation. Physical activity programs should include tools to increase patients' self-efficacy, in able to be confident to exercise when barriers occur.

706

The effect of multiple interventions by a specialist nurse on the heart failure patients knowledge in self-care management

A Protopapas[1]; F Kalogirou[2]; N Vouri[3]; A Malaktou[4]; L Paikousis[1]; V Barberis[5]; E Lambrinou[1]

[1]Nursing Department, Cyprus University of Technology, Limassol, Cyprus; *[2]NHS Foundation Trust, Cambridge University Hospital, Cambridge, United Kingdom of Great Britain & Northern Ireland*; *[3]General Hospital of Famagusta, Surgical Ward, Famagusta, Cyprus*; *[4]General Hospital of Larnaca, emergency room, Larnaca, Cyprus*; *[5]American Medical Center, American Heart Institute, Nicosia, Cyprus*

Funding Acknowledgements: Cyprus University of Technology's state funded budget [Startup Fund EX2007 (04)]

Background: In order to improve knowledge and self-care management of heart failure (HF) patients, different disease management programs have been developed at the discharged and follow-up phase.
Purpose: To determine the effectiveness of a three-month telephone follow-up, a telephone follow-up with education before discharge, or education only before discharge, on the development of knowledge and the improvement of self-care in patients with HF by a nurse specialist.
Method: This is a multicenter randomized clinical trial with three different intervention groups (IGs) and one control group (CG). The first intervention group included patients' education (E) before discharged from the hospital and a telephone follow-up (T) for three months. The second intervention group included only the telephone follow-up after discharge for three months (T) and the third intervention included only a patient's education before discharge (E). The Greek versions of the Dutch Heart Failure Scale (Gr- DHFS) and the European Heart Failure Self-Care Behavior Scale (Gr9-EHFScBS) were used. The statistical analysis of the impact of the intervention was done using the analysis of covariance (ANCOVA). The magnitude of the effect of the intervention was studied by the Cohen's d(rm) coefficient for repeated measurements
Results: The study included 334 patients. The complete case analysis (N=239) demonstrated that the study group differentiates the level of Knowledge and Self-Care behavior in the post-intervention measurement ($F = 3.06$, $p = 0.029$; $F = 5.38$, $p<0.001$) while adjusting for the pre-intervention measurements. The adjusted mean level of Knowledge in the control group was found: 8.6 (SE=0.3) while the IGs were found to be improved (Higher Average Score) [E: 9.6 (0.3), E and T: 9.8 (0.3), T: 9.5 (0.3)]. The adjusted mean level of Total Gr9-EHFScBS in the CG was found: 27.3 (SE=0.7) while the IGs were found to be improved (Lower Average Score) [E: 246(0.8), E and T: 23.3(0.8), T: 24.6(0.8)]. Total Gr9-EHFScBS score was found to have a low negative correlation with Knowledge (r = -0.30). Knowledge had a moderate correlation with Fluid and sodium Management (r = -0.341) and a low correlation with Adhering to Recommendations (r = -0.235), and with Physical activity and recognition of deteriorating symptoms (r = -0.198). A separate ANCOVA showed that the three intervention groups do not significantly differentiate the patients' total Gr9-EHFScBS or Knowledge scores. However, with respect to the Fluid and sodium Management dimension, E&T (drm = 0.73) and T (drm = 0.75) IGs exhibit significantly higher adherence compared to the CG (drm = 0.53) and the E (drm = 0.55) intervention group.
Conclusion: Telephone has been found to be very important on the controlled intake of fluid and sodium. Continuing follow-up even via telephone seems to be very important for the management one of the most common reasons of HF decompensation which is not adherence to fluid/salt intake.

707

Diuretic adjustment algorithm and nonpharmacologic management in patients with heart failure reduce readmission: a randomized clinical trial

E R Rabelo-Silva[1]; MKEF Feijo[2]; EB Ferro[3]; KB Ruschel[2]; GB Aliti[3]; A Biolo[2]; LEP Rohde[2]

Funding Acknowledgements: Fundo de Incentivo à Pesquisa do Hospital de Clinicas de Porto Alegre

Background: Approaches such as self-monitoring and the use of telemonitoring technologies are strategies that have been effective in reducing clinical outcomes in patients with heart failure by identifying early signs and symptoms of decompensation in North American and European countries. The use of validated diuretic adjustment protocols is poorly explored in developing countries. Aiming to fill this gap this study proposed to test a diuretic adjustment protocol combined with non-pharmacological management.
Purpose: To compare the effectiveness of a Diuretic Adjustment Algorithm (DAA) on clinical outcomes (reduction of hospital admissions and maintenance of clinical stability) within 90 days. Methods: Randomized Clinical Trial. Patients with indication for furosemide adjustment during routine outpatient visits were randomized. The intervention group (IG) had the diuretic dose adjusted with the DDA and received four phone calls (one per week) for 30 days to reinforce the guidance on non-pharmacological management. Participants in the control group (CG) had the diuretic dose adjusted by a physician at the time of study inclusion and they did not receive the phone calls. Patients from both groups returned for clinical evaluation in one month. Primary outcomes (admissions for HF and all causes) and the combined outcome (admissions and modification in the Clinical Congestion Score - ECC in two points) were analyzed.
Results: A total of 206 patients, mean age 62 ± 13 years, predominantly male 119 (58) and white 174 (84) were included. The hospital admission rate at 90 days for HF was 5% in IG and 14% in CG, Odds Ratio (OR) = 0.36, p = 0.03. For the combined outcome, IG had 19 (9.2) events and CG 23 (11.2), OR = 0.89, p = 0.73. When the Kaplan-Meier survival curve was evaluated for the occurrence of HF admission, the longrank value was 5.26, p = 0.02. That is, CG patients presented 3x the number of hospitalizations of IG patients. Conclusion: The use of DDA added to non-pharmacological guidelines reduced admissions by HF. In the evaluation of the combined outcome, there was no difference. The result was favorable and significant for the use of DDA, reducing admissions for HF in outpatients.

708

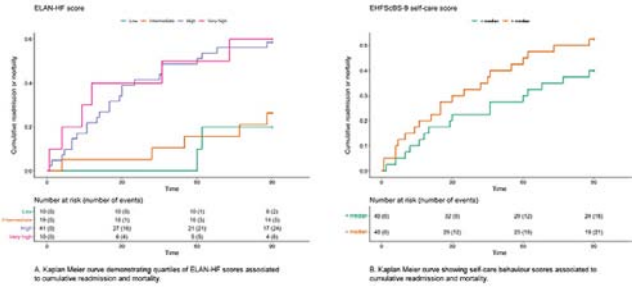
Validation of the ELAN HF model and selfcare behaviour in patients with acute decompensated heartfailure. A single centre cohort study in the Netherlands.

TAM Vinck[1]; R Deneer[2]; CCAG Verstappen[1]; WE Kok[3]; K Salah[4]; V Scharnhorst[2]; LC Otterspoor[1]

[1]Catharina Hospital, Cardiology, Eindhoven, Netherlands (The); *[2]Catharina Hospital, clinical laboratory, Eindhoven, Netherlands (The)*; *[3]University of Amsterdam, Heart Center; department of Clinical and Experimental Cardiology, Amsterdam Cardiovascular Sciences,, Amsterdam, Netherlands (The)*; *[4]Radboud University Medical Centre, Department of Radiology and Nuclear Medicine, Nijmegen, Netherlands (The)*

On behalf of: SMASH study group

Introduction The European collaboration on acute decompensated heart failure (ELAN-HF) score is a validated prognostic model used at discharge for patients admitted for acute decompensated heart failure (ADHF). It predicts readmission and mortality at 6 months can therefore be used for risk stratification on a nurse-based heart failure out-patient clinic. Previous studies demonstrated that improving self-care may lead to fewer readmissions for HF.
Purpose: To validate the predictive value of the ELAN-HF score on readmission and/or mortality, and to assess the effect of self-care behaviour on readmission and mortality inpatients after admission with ADHF in our hospital.
Methods: In a prospective, single centre cohort study, 88 patients (all-comers) hospitalized for ADHF were included. N-terminal pro–B-type natriuretic peptide (NT-proBNP) levelswere measured directly at admission as well as at discharge, and were used along with other clinical and laboratory parameters to calculate the ELAN-HF Score. Patients were divided in four groups (low, intermediate, high, very high) according tot their risk score. The scaling response of the European Heart Failure Self-care Behaviour Scale (EHFScBS-9) was analysed (a score of > 0.5 is regarded as optimal). Cox regression analysis was used to demonstrate the



KM

association between both scores and re-admission for heart failure and all-cause mortality within 90 days, in order to validate and assess their respective prognostic predictive values within the study population.Kaplan-Meier survival analysis was used to assess survival among the risk groups.

Results: The median age of the study population was 75 years (IQR 69-83), 43% woman. NYHA III/IV functional class was present at discharge in 68 patients (85%). A left ventricular ejection fraction below 40% was present in 27 patients (34%). Complete data and follow up was available in 80 patients, and the endpoint of mortality and rehospitalisation was reached in 46 % of patients. The median NT-pro BNP level at discharge was 3505 pg./ml. (IQR 1912 - 7861). There was a significant association between the ELAN-HF score and re-admission and/or mortality <90 days (HR = 1.25, 95% CI 1.08 - 1.45,P = 0.003). The median EHFScBS-9 score was 68.1(IQR 58.3 - 77.8) with 19% patients having a low value of < 50. There was a non-significant association between the EHFScBS-9 score and re-admission and/or mortality <90 days (HR = 1.02,95% CI 1.00 - 1.04, P = 0.111).

Conclusions: This study reinforces the potential of the ELAN-HF score to triage patients with ADHF after discharge, possibly adding in optimizing the nurse-based follow-up treatment in order to prevent readmission or death. Self-care behaviour was non-significantly associated with readmission and/or mortality in our study population.

GRK2 regulates the endothelial responsiveness to bradykinin: role in human angioedema

J Gambardella[1]; D Sorriento[1]; A Fiordelisi[1]; M Bova[2]; S Loffredo[2]; L Carucci[2]; I Mormile[2]; B Trimarco[1]; G Iaccarino[1]; M Ciccarelli[3]
[1]Federico II University of Naples, Naples, Italy; *[2]Federico II University Hospital, Department of Translational Medical Sciences and Center of Basic and Clinical Immunology Research (C, Naples, Italy*; *[3]University of Salerno, Medicine and Surgery, Salerno, Italy*

Background: Bradykinin (BK) regulates vascular homeostasis through the endothelial Gq protein coupled receptors (B1-B2), using Ca2+ as second messenger. Several kinases are involved in the regulation of BK signaling, such as CamKII; also GRK2 could be involved as it is able to phosphorylate BK receptors but with unknown biological effects. Purpose: to verify the role of GRK2 in regulation of BK signaling in physiological and pathological conditions. Methods: We used Bovine Aortic Endothelial cells (BAEC) for in vitro study where we determined GRK2 modulation by western blot and ubiquitination test, Ca2+ release and Nitric Oxide (NO) production using probes based techniques, and cell permeability through a vascular permeability assay. In mice with endothelial GRK2 Knock out (Tie2-CRE/GRK2fl+/fl-) we performed a Miles assay to test vascular permeability. In PBMCs from patients with ACE-inhibitor-related Angioedema (ACEi-A) and C1- deficit related Angioedema (C1-inh-HA) we evaluated GRK2 levels by western blot analysis. Results: At 5min, BAEC stimulation with BK(100nM) induced an increase of GRK2, which reverberates in all cellular compartments returning to baseline levels at 15min. BK induced-GRK2 accumulation is proteasome dependent, since GRK2 ubiquitination was significantly reduced post BK stimulation and the interaction between GRK2 and E3 ligase mdm2, decreased. We hypothesized that CamKII activated upon BK stimulation, can regulate GRK2 accumulation. Indeed, GRK2 and CamKII interaction increased in response to BK and the accumulation of GRK2 does not occur after CamKII inhibition (C17) supporting the involvement of the Kinase in GRK2 recruitment. Ca2+cytosolic accumulation induced by BK was sensitive to GRK2 activity, as it was enhanced by inhibition of the kinase with KRXC7. Accordingly, permeabilization and NO induced vasodilation, typically endothelial responses to BK, were enhanced when GRK2 was inhibited. To test in vivo the involvement of GRK2 in the regulation of BK-dependent endothelial responses we evaluated BK-induced vascular permeability in Tie2-CRE/GRK2fl+/fl- mice. Interestingly, these mice showed an increased vascular permeability already in basal condition and an increased response to BK respect to wt mice. Since GRK2 regulates the sensitivity of endothelium to BK, we speculated that GRK2 could have a role in BK- mediated Human Angioedema. We evaluated GRK2 levels in ACEi-A and C1inh-HA patients. Interestingly, we evidenced that in both populations, patients with reduced GRK2 levels showed a more severe phenotype of Angioedema.
Conclusions: Through CamKII, BK is able to activate GRK2 which in turn inhibits BK signalling; indeed, in vitro end in vivo results evidenced GRK2 as endogenous inhibitor of BK signalling. Consistently, patients with severe Angioedema have reduced levels of GRK2, suggesting that GRK2 can contribute to BK-dependent pathological response of endothelium during Angioedema

788

Empaglifozin has cardioprotective and anti-inflammatory effects in mice during doxorubicin treatment

V Vincenzo Quagliariello[1]; C Coppola[1]; D Rea[2]; A Barbieri[2]; C Arra[2]; G Botti[3]; N Maurea[1]
[1]National Cancer Institute G.Pascale Foundation IRCCS, Division of Cardiology, Naples, Italy; *[2]National Cancer Institute G.Pascale Foundation IRCCS, SSD Sperimentazione Animale, Naples, Italy*; *[3]National Cancer Institute G.Pascale Foundation IRCCS, Scientific Direction, Naples, Italy*

Funding Acknowledgements: This work was funded by the "Ricerca Corrente" grant from the Italian Ministry of Health.

Background: Empagliflozin (EMPA), a selective inhibitor of the sodium glucose co-transporter 2 (SGLT2), reduces the risk of hospitalization for heart failure or cardiovascular death in type 2 diabetic patients.

Purpose: We hypothesize that EMPA could have cardioprotective and anti-inflammatory effects in Doxorubicin-Induced cardiotoxicity.
Methods: For this purpose, we tested the effects of EMPA (at 100 or 500 nM) alone or in combination with DOXO (20 μM) in HL-1 adult cardiomyocytes evaluating: mitochondrial viability (at 24h of incubation), lipid peroxidation (quantifying cellular Malondialdehyde [MDA] and 4-hydroxynonenal [4-HNA]), Leukotriene-B4 expression, p65-NF-κB activation and Interleukin 1β, 8 and 6 secretion. To evaluate cardiac function in vivo, Global Longitudinal Strain (GLS) were measured using 2D speckle tracking echocardiography in C57BL6 mice, 24 months old , pretreated with EMPA (dose: 10 mg/kg/day) orally for 3 days. EMPA was then administered for additional 7 days, alone and in combination with DOXO (2,25 mg/kg/day ip), according to our well established protocol; cardiac lysates were processed for analysis of pro-inflammatory Interleukins.
Results: We demonstrated that EMPA, co-incubated with DOXO, is able to increase cardiomyocyte viability of 33,6 and 82,3 % at 100 and 500 nM, respectively (compared to only DOXO treated cells). EMPA is able to inhibit lipid peroxidation by decreasing MDA and 4-HNA production of around 23,6 and 28,7 %, at 100 nM and of 47,8 and 52,1 % at 500 nM , respectively, compared to untreated cells ($p<0,01$ for all). Moreover, EMPA has anti-inflammatory activity in a concentration dependent manner with a reduction of Leukotriene B4 expression and p65-NFkb activation of 37,4 % and 31,6 % at 100 nM and of 58,4 and 64,3 % at 500 nM , respectively (all compared to only DOXO treated cells). EMPA also decreased the expression of Interleukin 1β (of 28,5 and 68,8 %), Interleukin-8 (of 21,2 and 57,3 %) and Interleukin-6 (of 28,1 and 49,8 %) at 100 and 500 nM, respectively, compared to only DOXO exposed cells ($p<0,05$ for all). In our in vivo studies, after 7 days with DOXO, GLS decreased. Interestingly, in mice treated with EMPA+DOXO, EMPA prevents the GLS's reduction : GLS was 19.24 ± 1.5 ($p < 0,01$) vs DOXO alone. In DOXO-EMPA groups heart IL-1β, IL-6 and IL-8 tissue extract were reduced of 48, 54,4 and 58,2 % compared to only DOXO group ($p<0,001$ for all).
Conclusion: EMPA has strong anti-inflammatory and cardioprotective effects in Doxorubicin-Induced cardiotoxicity and these effects are mainly mediated by a reduction of the lipid peroxidation, Leukotriene-B4 and NF-κB activation bringing to a strong inhibition of the Interleukin 1β, 8 and 6 production in cardiomyocytes. Preclinical studies demonstrate that EMPA has cardioprotective and anti-inflammatory effects during DOXO treatments, proposing as possible cardioprotective drug in cancer patients.

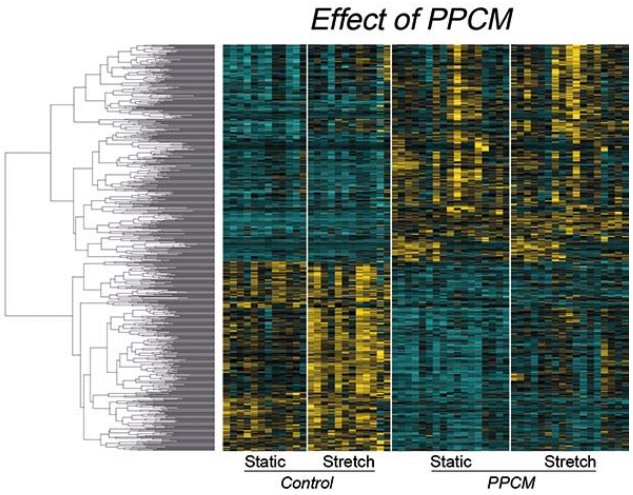
Sterol metabolism is differentially regulated in human induced pluripotent stem cell-derived cardiomyocytes of peripartum cardiomyopathy patients

M F Hoes[1]; N Bomer[1]; TV De Jong[2]; M Ricke-Hoch[3]; V Guryev[2]; D Hilfiker-Kleiner[3]; P Van Der Meer[1]
[1]University Medical Center Groningen, Department of Cardiology, Groningen, Netherlands (The); *[2]University of Groningen, European Research Institute for the Biology of Ageing, Groningen, Netherlands (The)*; *[3]Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany*

Funding Acknowledgements: This research was supported by the Dutch Heart Foundation, ZonMW Clinical Fellow and by the European Research Council.

Background: Peripartum cardiomyopathy (PPCM) is a rare form of heart failure that occurs at the end of the pregnancy or in the first months after delivery. PPCM diagnosis is based on exclusion and is therefore difficult to diagnose and characterize.
Objective: This study aims to determine which pathways are differentially regulated in PPCM patients compared to familial controls.
Methods: Cardiomyocytes were generated from three PPCM patient-derived induced pluripotent stem cell (iPSC) clones, and from two iPSC clones derived from her healthy sister. Pregnancy-associated wall stress was simulated by the application of equiaxial mechanical stretch for 48 hours on these cardiomyocytes. RNA sequencing was performed on cardiomyocytes derived from a PPCM patient and a healthy sister after mechanical stretch compared to static conditions. Sequencing results have been replicated in stem cell-derived cardiomyocytes from a second patient and a familial control using real time qPCR. Pathway and transcription factor enrichment analyses have been performed to identify affected pathways.

Results: Pathway analysis of differentially expressed genes in patient-derived cardiomyocytes widely indicated that major sterol and lipid metabolic pathways were reduced in PPCM, regardless of mechanical stretch. Additionally, pathways related to adaptive immune response, regulation of multicellular organismal process, and cofactor metabolism were significantly affected in PPCM. Further analysis revealed that SP1 and NF-Y were central transcription factors involved in nearly all identified pathways related to lipid metabolism. Moreover, PPCM-specific cardiomyocytes released significantly more troponin T than control cardiomyocytes. Strikingly, these results could be reproduced in iPSC-derived cardiomyocytes from a second patient, as well as in an established mouse model harboring a cardiac specific deletion of the STAT3 gene.
Conclusions: The present study mainly identified pathways related to sterol and lipid metabolism to be aberrantly regulated in PPCM. These data provide new insights into cell autonomous mechanisms and are indicative for novel pathways associated with PPCM.



Differentially expressed genes in PPCM

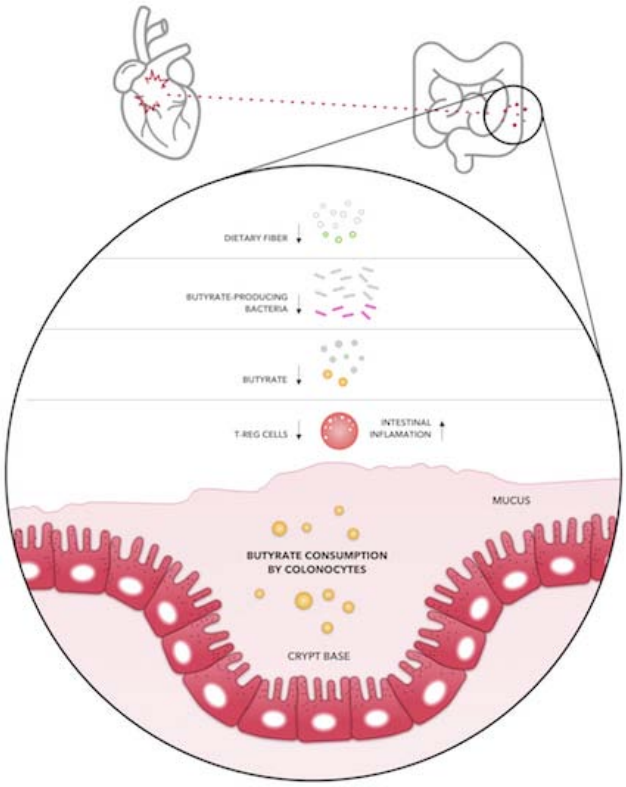
Gut microbiota composition and interactions with diet: dysbiosis in heart failure is partly related to lower fiber intake

26/05/2019 15:00C Mayerhofer[1]; M Kummen[2]; K Holm[2]; K Broch[1]; A Awoyemi[3]; B Vestad[2]; C Storm-Larsen[2]; I Seljeflot[3]; T Ueland[2]; P Bohov[4]; RK Berge[4]; A Svardal[4]; L Gullestad[1]; JR Hov[2]; M Troseid[5]
[1]Oslo University Hospital, Department of Cardiology Rikshospitalet, Oslo, Norway; *[2]Oslo University Hospital, Research Institute of Internal Medicine, Oslo, Norway*; *[3]Oslo University Hospital, Department of Cardiology Ullevål, Oslo, Norway*; *[4]University of Bergen, Bergen, Norway*; *[5]Oslo University Hospital, Section of Clinical Immunology and Infectious diseases, Oslo, Norway*

Funding Acknowledgements: This work was supported by the Norwegian Health Association [6782 to CCKM]

Objectives: To explore differences in the gut microbiota between patients with heart failure (HF) and healthy controls with a particular focus on associations with diet, etiology and disease severity.
Background: Recent reports have suggested alterations in the gut microbiota of patients with HF. Associations with diet remain largely uninvestigated.
Methods: The microbiota composition of two independent, cross-sectional cohorts (discovery, n=40 and validation, n=44) of patients with systolic HF and healthy controls (n=266) were characterized by sequencing of the bacterial 16S rRNA gene. Dietary and metabolite data were available for the validation cohort and follow-up data were available for the discovery cohort.
Results: The overall microbial community (beta diversity) differed between patients with HF and healthy controls in both cohorts (P<0.05). Patients with HF had a lower Firmicutes/Bacteroidetes (F/B)-ratio than controls (P=0.005), with a decreasing trend going from healthy controls via ischemic HF to non-ischemic HF (p for trend <0.05). Patients reaching a clinical endpoint (heart transplant or death) showed lower alpha diversity and lower F/B-ratio compared to healthy controls (P<0.01). Meat intake was associated with levels of trimethylamine-N-oxide (P=0.016). Finally, bacterial richness and abundance of several genera in the Firmicutes phylum were positively associated with fiber intake.
Conclusions: The gut microbiota composition in chronic HF was characterized by a decreased F/B ratio, which was associated with etiology and clinical outcome. The dysbiosis in patients with HF was related to low fiber intake, thus dietary patterns should be included in future studies, both as covariates and potential treatment targets.



Diet and butyrate-producing bacteria

Diastolic function modulation via protein kinase G-dependent Ca2(+)/calmodulin-dependent protein kinase-II phosphorylation and oxidation

M Herwig[1]; S Pabel[2]; A Kovacs[1]; S Ghaderi[1]; D Kolijn[1]; D Cimiotti[3]; E Robinson[4]; V Nikolaev[5]; S Van Linthout[6]; C Tschoepe[6]; K Jaquet[3]; S Heymans[4]; S Sossalla[2]; N Hamdani[1]
[1]Ruhr University Bochum (RUB), Department of Systems Physiology, Bochum, Germany; *[2]University Hospital Regensburg, Clinic and Polyclinic for Internal Medicine II, Regensburg, Germany*; *[3]Ruhr University Bochum (RUB), Institute for Molecular Cardiology, Bochum, Germany*; *[4]Maastricht University, Centre for Heart Failure Research, Department of Cardiology, Maastricht, Netherlands (The)*; *[5]University Medical Center Hamburg Eppendorf, Institute of Experimental Cardiovascular Research, Hamburg, Germany*; *[6]CharitÇ- UniversitÇÏtsmedizin Berlin, Department of Internal Medicine and Cardiology, Berlin, Germany*

Background: Myocardial diastolic stiffness is dependent, in part, on signaling pathways and phosphorylation. Ca(2+)/calmodulin-dependent protein kinase-II (CaMKII) δ and protein kinase G (PKG) are known to target titin, but it is unknown so far if PKG phosphorylates CaMKIIδ.
Purpose: Our purpose was to reveal PKG and CaMKIIδ interaction and the functional effect of this interaction on cardiomyocyte and cardiac function in heart failure with preserved ejection fraction (HFpEF)
Methods: Left ventricular (LV) endomyocardial biopsies were procured in 15 HFpEF patients and 13 controls. Quantitative mass spectrometry (MS), recombinant human CaMKIIδ for in vitro studies, and biochemical analyses were performed to confirm CaMKIIδ-dependent PKG phosphorylation. Acute sGC stimulation was studied on HFpEF (with diastolic dysfunction) and control rats.
Results: All HFpEF patients had high diastolic stiffness, increased fibrosis and cardiomyocytes passive stiffness. They showed unchanged CaMKIIδ expression and increased phosphorylation and oxidation compared to controls. The in vitro CaMKIIδ phosphorylation by PKG and MS analysis revealed several phosphosites on CaMKIIδ. The most highly phosphorylated sites were located in the regulatory domain and the linker region of CaMKII. The luminescense signal was decreased

in HEK293 cells after acute sGC treatment, indicating association and dissociation of PKG from CaMKII. CNP resulted in a significant change in FCFP/FYFP of CaMKII compared to baseline. PKG inhibitor inhibits completely CaMKII activity. Significant correlations between PKG loss of each individual (patient) and increased CaMKII activity and oxidative stress were observed. Acute sGC stimulation, significantly improved LV diastolic dysfunction in HFpEF rats evident from improved ratio of peak velocity blood flow from gravity in early diastole to peak velocity flow in late diastole caused by atrial contraction, isovolumic relaxation time and time constant of isovolumetric pressure decline, in addition to improved LV end-diastolic pressure and stiffness in HFpEF rats. sGC stimulation improved cGMP-PKG pathway via increased cGMP level and PKG activity. Also, we found reduced CaMKIIδ auto-phosphorylation and oxidation, reduced oxidative stress and inflammation via reducing the pro-inflammatory cytokines. Cellular sGC stimulation caused a significant increase in Ca2+ transient amplitude in wild type (WT) mice but not in CaMKIIδc knock-out mice suggesting that the effects of sGC on calcium transient amplitude might be CaMKII dependent. In addition, sGC treatment in WT cardiomyocytes showed significant higher calcium transient amplitude compared to sGC treated cells from CaMKIIδc, suggesting the important role of PKG mediated-CaMKII phosphorylation in regulating calcium handling.

Conclusion: Our study shows that PKG plays a central role in regulating and maintaining the balance of CaMKIIδ activity and oxidative stress and thereby improving diastolic function.

Background: Doxorubicin is an anthracycline used as a chemotherapeutic drug for the treatment of a wide range of adult and pediatric cancers. Doxorubicin use is limited do to its association with an increased risk of cardiomyopathy and heart failure. It is estimated that up to 10% of patients treated with doxorubicin will develop cardiac complications. The cardiotoxic effect of doxorubicin is dose-dependent with an increased percentage of patients developing heart failure at cumulative doses higher than 300-400mg/m2. A GWAS conducted of 1,191 patients from the N9831 clinical trial identified that cardiac gene expression and genetic variants of TRPC6 were associated with a decline in left ventricular ejection fraction (LVEF) (p=0.005 and p=1.62x10-6 respectively). TRPC6 is a non-selective cation channel expressed in heart and vascular tissue. TRPC6 participates in the pathogenesis of cardiac hypertrophy as a pathological response to chronic mechanical stress. Chronic activation has been found to promote cardiac fibrosis leading to heart failure. Overall these data suggest that TRPC6 variants could be associated with increased risk of doxorubicin-induced cardiotoxicity.

Purpose: Tests to determine which patients may progress to cardiomyopathy and heart failure are currently lacking and there are no targeted treatments to prevent cardiomyopathy in these patients.

Methods: In preliminary in vivo data, B6.129 wild-type mice (10 females, 10 males) were treated with either 6x intraperitoneal saline or 4mg/kg doxorubicin injections (cumulative dose of 24mg/kg).

Results: Our in vitro preliminary data show that inhibition of TRPC6 using the TRPC6 inhibitor GsMTx-4 in human iPSC-derived cardiomyocytes significantly reduced doxorubicin-induced apoptosis ($p<0.0001$). In vivo we found doxorubicin decreased HW/BW (p=0.008) and HW/TL (p=0.0004) ratios and increased cardiac vacuolation (p=<0.001) in male mice treated with doxorubicin compared to controls. Higher HW/BW ratio were also observed in TRPC6 knock out mice treated with doxorubicin compared to wild-type mice (p=0.005). Additionally, we found that doxorubicin-induced injury was significantly reduced in TRPC6 knock-out mice compared to wild-type mice based on reduced vacuolation (p=0.0004 males, p=0.03 females). Furthermore, a significant decrease in stroke volume (p=0.007), diastolic volume (p=0.01) and cardiac output (p=0.004) were found at day 21 post treatment in wild-type male mice treated with doxorubicin in comparison to control and TRPC6 knock-out mice.

Conclusions: Our results suggest that TRPC6 could be a novel therapeutic target in the prevention of chemotherapy-induced cardiomyopathy and heart failure. Genetic mapping of TRCP6 functional variants may provide a new screening tool to determine which cancer patients are at increased risk of developing heart failure and may benefit from increased cardiac monitoring and TRPC6-specific therapies.

Clinical Case Corner 3 - The many faces of valve disease

An interesting case of right middle and lower zone pneumonia vs infective endocarditis secondary to aortic root abscess presenting as unresolving fever

P Parin Sangoi[1]; S Narayanan[1]; S Ramkumar[1]; A Mullasari[1]
[1]Madras Medical Mission, CARDIOLOGY, Chennai, India

54 years old gentleman was admitted with complaints of fever and cough with expectoration for the past 3 weeks. His CXR showed right middle and lower zone homogenous opacity and ECHO showed dilated left atrium and ventricle, global hypokinesia of left ventricle, moderate left ventricular systolic dysfunction, adequate right ventricular systolic function, thickened aortic valve and RCC prolapse, dilated aortic root (40 mm), AML tip prolapse, type II diastolic dysfunction, severe eccentric AR, moderate MR, grade II TR, severe PAH (RVSP 75), HYPERECHOIC MASS (8 X 13) seen attached to RCC protruding into the LVOT. TEE confirmed HYPERECHOIC MASS (OLD HEALED VEGETATION) seen attached to RCC of aortic valve protruding into the LVOT with RCC prolapse with severe AR and also showed small aortic abscess (10 x 15) posterior to LCC of aortic valve towards LA. Whole body PET-CT revealed areas of consolidation in the right lung showing increased metabolic activity. No focal mass is seen. Enlarged metabolically active right hilar and mediastinal lymph nodes.

DISCUSSION Eventhough ECHO showed a vegetation, PET SCAN proved it metabolically inactive and thus the source of infection in this patient was right lung pneumonic consolidation which was treated with appropriate IV antibiotics and patient improved symptomatically.

TAKE HOME MESSAGE

Thus for a patient with unresolving fever of long duration even though echocardiogram showed a vegetation attached to aortic valve and trans esophageal ECHO confirmed the mass on RCC with a small aortic abscess inferior to LCC and severe eccentric AR, the WHOLE BODY PET SCAN was the need of the hour to pick up the metabolically active lesion which was the right lung pneumonic consolidation in this patient. The appropriate antibiotic for the correct duration can alone save the patient's life. Hence the right diagnosis / the source of infection was found with the help of PET SCAN.

821

Acute papillary muscle rupture: multi-specialty team approach ensuring good clinical outcome

K Katherine Mccreary[1]; A Farooqui[1]; B Mcclements[1]; R Jegenathan[1]
[1]Royal Victoria Hospital, Cardiology , Belfast, United Kingdom of Great Britain & Northern Ireland

A 48 year old male presented to a district general hospital with acute shortness of breath, with chest pain in the preceding 12 hours. Physical examination revealed a pan-systolic murmer at the apex with bilateral lung crepetations. Initial ECG appeared relatively unremarkable and pulmonary oedema was demonstrated on chest radiograph. Within 2 hours his condition deteriorated with type II respiratory failure and academia. Transthoracic echocardiogram confirmed suspicion of acute posterior papillary muscle rupture with severe mitral regurgitation. Left atrial size appeared normal and hyperdynamic left ventricular systolic function.

The patient was transferred to the nearest cardiac centre with catheterization laboratory. The cardiothoracic surgery team and cardiac anaesthetics responded immediately and the patient was intubated and ventilated. Simultaneously, interventional cardiology performed emergency cardiac catheterization revealing an occluded RCA, severe proximal LAD and left circumflex disease and an intra-aortic balloon pump was placed. There was marked haemodynamic instability with significant adrenaline requirements and a short cycle of CPR. There was no facility for VA ECMO in this centre. Repeat arterial blood gas sampling was consistent with cardiogenic shock. pH 7.08, lactate 5.6, PCO2 10.9, PO2 34.7. A multi-specialty decision was made to proceed to emergency surgery despite high mortality likelihood. pH was recorded at 6.9 at the beginning of the case.

Emergency mitral valve replacement was performed with concomitant coronary artery bypass grafting to the left anterior descending, right and obtuse marginal coronary arteries. There was haemodynamic instability in the immediate post operative period and recovery thereafter was complicated by renal failure and academia. Total ICU stay was 22 days before discharge at day 33 to make an excellent recovery with persevered left ventricular systolic function with a normally functioning prosthetic mitral valve.

This case is particularly poignant due to the patients' excellent clinic outcome despite severe acidaemia (pH 6.9). Internal audit on emergency cases performed in this regional centre demonstrated no survival in patients with pH less than 7.1. Problem Acute papillary muscle rupture often results in marked and rapid clinical deterioration. Without emergency surgery, there is 90% mortality within one week and therefore early involvement of the cardiac surgical team is paramount to survival. Discussion In instances of acute heart failure secondary to mechanical complication there is a narrow time window in which prompt diagnosis, percutaneous intervention and surgery are crucial. This was achieved in this case by an effective multi-specialty team approach. Trauma centers are perhaps the original example of this, finding a mortality reduction of 15% in trauma cases by utilizing this method. As a result of this case, formation of a 'cardiac shock' team should be considered.

Mitral Valve & Ruptured papillary muscle

The importance of Heart Team in acute heart failure

I Ines Almeida[1]; D Faria[2]; M Santos[2]; L Brizida[2]; R Teles[3]; L Raposo[3]; J Brito[3]; M Almeida[3]; H Gabriel[3]; C Morais[2]
[1]*Hospital N.S. Rosario, Barreiro, Portugal*; [2]*Hospital Prof. Doutor Fernando da Fonseca , Lisbon, Portugal*; [3]*Hospital de Santa Cruz, Lisbon, Portugal*

Introduction: Acute heart failure is a life-threatening medical condition that could result from many cardiac ad extracardiac conditions. Concerning to severe aortic stenosis (AS), TAVI widened the spectrum of patients susceptible of treatment, although its utilization in context of cardiogenic shock is exceptional.
Clinical case: 83-years old male patient with previous history of arterial hypertension, diabetes, dyslipidaemia and ferropenic anaemia. The patient was admitted at emergency room due to acute pulmonary oedema (APO) refractory to medical therapy, with necessity of intubation and invasive mechanical ventilation (IMV). Electrocardiogram at admission revealed complete left bundle branch block. It was hypothesized to be an acute coronary syndrome so a coronarography was performed, with no angiographically relevant lesions. Maximum hs troponin was 13 pg/ml. The patient was hospitalized at cardiac intensive care unit due to a clinical scenario of de novo acute heart failure, of unknown aetiology, with presentation on B profile and progression to C. Transthoracic echocardiogram (TTE) revealed a left ventricle with hypertrophied walls, severe global systolic dysfunction with an estimated ejection fraction (EF) of 25%, diffuse hypokinesis and akinesis of medio and apical segments of anterior wall and anterior septum; aortic valve with extensive calcification, not being possible to define tricuspidia and conditioning restriction of its opening (medium gradient 31mmHg, maximum gradient 61mmHg, maximum velocity 3.5m/s). During hospitalization, the patient evolved with cardiogenic shock with multiorgan failure, persistent necessity of vasopressor support with noradrenalin, two failed attempts of extubation due to recurrent APO with respiratory exhaustion and reintubation necessity. Considering the AS the principal determinant of the clinical scenario, a proposal for percutaneous aortic valvuloplasty and TAVI implantation was made, performed with success. Posterior favourable clinical evolution allowing extubation two days after the procedure and clinical discharge at NYHA class I. TTE at revealing EF 43%, biologic valvular prothesis in aortic position with normal function and with slight transprothesic regurgitation.
Conclusion: In selected cases where AS seems to be the defiant and perpetuator factor of patient condition and his principal limitation to leave IMV, the discussion in heart team for TAVI implantation or balloon valvuloplasty with TAVI in backup seems to be a good solution.

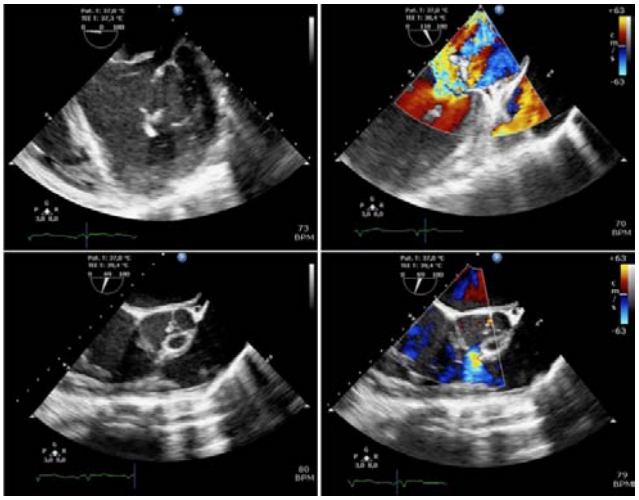
A life-threatening cause of acute heart failure at a young age

AR Ana Rita Pereira[1]; AR Almeida[1]; I Cruz[1]; A Marques[1]; S Alegria[1]; A Briosa[1]; JG Santos[1]; D Sebaiti[1]; MJ Loureiro[1]; H Pereira[1]
[1]*Hospital Garcia de Orta, Cardiology, Almada, Portugal*

We present a case of a 33-year-old man, with clinical history of a non-specified cardiac murmur since childhood. He was admitted to our Emergency Department with complaints of progressive worsening exertional dyspnea (occurring in rest at admission), orthopnea, paroxysmal nocturnal dyspnea and lower limb oedema with 2 weeks of evolution. He also reported symptoms of consumption in the last month. At hospital admission, his medical examination revealed hypotension, tachycardia, polypnea and signs of decreased peripheral perfusion. A grade IV/VI, systolic heart murmur with axillary radiation was heard at cardiac auscultation.
A 12-lead electrocardiogram showed sinus tachycardia. Additional work-up revealed mixed acidemia, elevated systemic inflammatory parameters and microcytic, hypochromic anemia. Bedside transthoracic echocardiogram showed a mitral valve with thickened leaflets and severe, posterolateral directed mitral valve regurgitation caused by the prolapse of the anterior leaflet; preserved biventricular function and a dilated inferior vena cava without respiratory size variation.
The diagnosis of cardiac and septic shock was assumed, and the patient had to be transferred to the Intensive Care Unit in need of invasive mechanical ventilation.
To better clarify the clinical case, a transesophageal echocardiogram was performed revealing: 1) hyperechogenic thickening of the ventricular face of non-coronary and right coronary cusps of aortic valve, suggesting small vegetations and a diastolic flow, suggesting perforation of the non-coronary cusp; 2) severe, posterolateral directed mitral valve regurgitation caused by the prolapse of the anterior leaflet and destruction of the posterior leaflet with pulmonary venous flow reversal; 3) a serpiginous image of erratic movement attached to the head of the postero-medial papillary muscle, suggesting vegetation or part of the destructed posterior leaflet. A restrictive perimembranous ventricular septal defect (VSD) and a patent foramen ovale were also observed.
The diagnosis of native mitral and aortic valve infective endocarditis (IE) resulting in mitral valve destruction with acute major regurgitation and acute heart failure (HF) was established. Blood cultures were collected, empirical antibiotic therapy was initiated, and the patient was emergently transferred for a cardiac surgical center. He was submitted to mitral valve replacement with mechanical prostheses, aortic valve plasty and SVD closure. Blood cultures isolated a penicillin-sensitive Streptococcus viridans. After 6 weeks of guided therapy, the patient was hospital discharged. Currently, he is asymptomatic.
Acute HF is rare at a young age. IE is among the most common causes of this clinical syndrome in youth, especially in those patients with previous structural heart disease. The present case report is an illustrative example of this aetiology, whose urgent recognition and treatment were crucial for patient's survival.



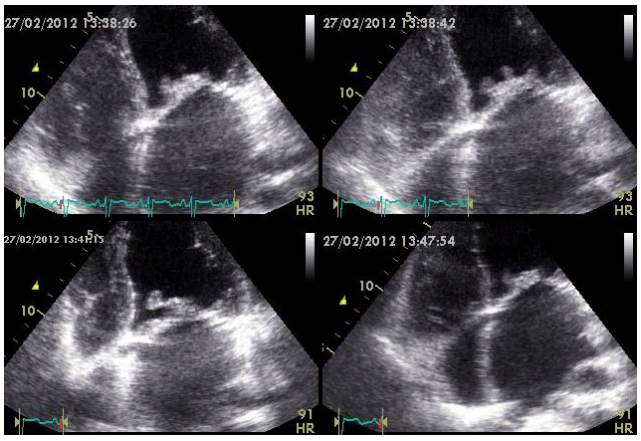
Transesophageal Echocardiogram

824

A long history of recurrent prosthetic mitral valve thrombosis due to hypereosinophilic syndrome

S Antit[1]; S Bellakhal[2]; I Boussabeh[1]; M Thameur[1]; L Zakhama[1]; S Benyoussef[1]
[1]*Interior Security Forces Hospital, Department of Cardiology, Marsa, Tunisia*;
[2]*Interior Security Forces Hospital, Department of medicine interne, Marsa, Tunisia*

Background: Hypereosinophilic syndrome (HES) is a rare disorder defined as a persistent, unexplained peripheral marked eosinophilia. Although the exact mechanism of eosinophil-related tissue damage is not well known, endocardial fibrosis and thrombus formation are common occurrences. Cardio embolism is acknowledged as the most common etiology for stroke and transient ischemic attack (TIA).
Case report: We report the case of a 42-year-old woman suffering from idiopathic HES with recurrent stroke and TIA, due to native mitral valve thrombosis followed by mechanical prosthetic mitral valve thrombosis one month postoperatively, concomitant with severe eosinophilia and despite adequate anticoagulation. A bioprosthetic mitral valve replacement was performed and oral anticoagulation was



TTE: native mitral valve thrombosis

maintained associated with 100mg of aspirin. Four years postoperatively, the patient presented with dyspnea and recently diagnosed atrial fibrillation. Transesophageal echocardiography (TEE) was performed prior to cardioversion, showed leaflet thrombosis in the bioprosthetic mitral valve concomitant with severe eosinophilia despite corticosteroid therapy and adequate anticoagulation. Patient was putted on heparin therapy and high dose of corticosteroid. TEE performed at 04 weeks follow up showed the disappearance of thrombi. Electric cardioversion was successfully done. Oral anticoagulation associated with aspirin was maintained and no recurrent thromboembolic event was recorded at 03 months clinical follow-up.
Conclusion: Other than cardiac emboli and direct eosinophil toxicity, there is a hypercoagulable state in eosinophilia which can contribute to strokes. Our patient had recurrent heart embolism and strokes due to native, mechanical prosthetic and bioprosthetic mitral valve thrombosis induced by eosinophilia. Reduction of eosinophils with corticosteroid therapy and simultaneous anticoagulation had contributed in the resolution of thrombus and complete clinical recovery of the patient in our case.

825

The prevention of heart failure in case of severe mitral regurgitation. The clinical case of the patient with mitral valve dysplasia.

Y Yuliya Martyanova[1]
[1]*Federal Center of Cardiovascular Surgery, Astrakhan, Russian Federation*

Background. The mitral valve dysplasia is most common cause of the severe non-ischemic mitral regurgitation. Medical treatment of these patients is not effective. Only surgery of mitral valve dysplasia is the method that prevents development of heart failure in patients with severe mitral insufficiency (MR). This is achieved by performing different kind of mitral surgery, such as mitral valve repair, mitral valve replacement (by biological or mechanical prosthesis).
The goal of the study. To assess the results of surgical treatment of patients with severe mitral regurgitation in case of mitral valve dysplasia.
Materials and methods. We analyzed case studies of 250 pts with mitral valve dysplasia, who were operated in the period 2009-2016.
The mean age of patients was 53,8 ± 8.7 years. The studies population included 130 males (52 %) and 120 females (48%). Pts had preserved LV EF (59 ± 5%), NYHA III, IV (148 pts, 61%), atrial fibrillation (88 pts, 35%), anterior leaflet prolapse (54 pts, 19 %), posterior leaflet prolapse (124 pts, 52%), dual leaflet prolapse (75 pts, 29%). Performed surgical treatment consisted of mitral repair (78 %), mitral valve replacement (22 %), and 44 % of them had got a biological prosthesis, tricuspid interventions 26%, RFA 7%.
Results. The restoration of mitral valve function, regress of heart failure and improving of life quality indiscriminate after mitral surgery in case of mitral valve dysplasia. At discharge from hospital 98 % males and 93 % females had mitral regurgitation 0-1, most of them are freedom from anticoagulants in the three months after surgery.
Conclusions. The surgery of mitral valve in case of mitral valve dysplasia with severe MR is effective prevention of heart failure. Obviously the priority of mitral valve repair has good restoration of mitral valve function.

826

The crucial role of the heart valve team in the management of a complex case of multivalvular disease and heart failure.

F Francesco Cannata[1]; M Chiarito[1]; C Panico[1]; B Pagliaro[1]; L Ardino[1]; L Torracca[1]; M Gasparini[1]; P Pagnotta[1]; E Corrada[1]; B Reimers[1]; G Condorelli[1]; D Pini[1]
[1]*Clinical Institute Humanitas IRCCS, Rozzano, Italy*

Multivalvular disease is a common condition with a complex pathophysiology and management. The Heart Valve Team (HVT) has a crucial role in defining the most appropriate timing and type of treatment.
A 60-y-old woman, with a history of bicuspid aortic valve in regular echocardiographic follow-up, referred to our heart failure unit due to worsening functional capacity (NYHA class III) in the previous 6 months. She had undergone a surgical suture of patent ductus arteriosus at the age of 18 and had a history of CKD and asthma.The EKG revealed a sinus rhythm with a complete LBBB (QRS 168 ms).The TTE showed a severely stenotic aortic bicuspid valve (type 1, NC - RC) with a concomitant moderate aortic regurgitation, a severe functional mitral regurgitation (MR), a severely dilated left ventricle (VTD 210 ml) with a severely depressed systolic function (EF 27%)(Fig.A-B-C).The dobutamine stress echo established the diagnosis of low-flow low-gradient aortic stenosis while the coronary angiography excluded the presence of CAD.A chest CT revealed an ascending aorta aneurysm (50 mm).
The case was evaluated by the local HVT which excluded the surgical solution (SAVR + MV repair + ascending aorta replacement) due to the high operative and in-hospital mortality (STS score for isolated SAVR 4% and a severely depressed EF) and chose a trans-catheter treatment. TAVR is a winning therapy for low-flow low-gradient aortic stenosis, provided that there is not any residual regurgitation.New-generation devices are associated with low rates of paravalvular leak post-TAVR in bicuspid valves.Moreover, the likeliness of MR improvement after TAVR was high in this patient due to many imaging and baseline predictors (anatomy of mitral valve, functional MR, no AF, low EF, severely dilated left ventricle).However, the LBBB represented a limiting factor of MR response to TAVR.
Thus, the patient underwent a CRT-D implantation and then a TAVR procedure with a CoreValve Evolut R 34 mm device (Fig.D). The LBBB and the associated systolic asynchrony were solved, the aortic device was correctly positioned without residual paravalvular leaks and the MR was immediately reduced to mild degree(Fig.F).The hospital course was uneventful and the patient was discharged with an optimized medical therapy. 3 months later, the patient referred an improvement of functional capacity (NYHA class II). The TTE showed an almost totally recovered EF (51%), no residual paravalvular leaks, low trans-aortic gradients, mild MR. The chest computed tomography excluded the ascending aorta size increase(Fig.E)so an elective ascending aorta replacement surgery was planned.
The evaluation and treatment of patients with multivalvular disease and heart failure is complex and requires the expertise of a multidisciplinary HVT, of which this case is a brilliant example. In these complex patients, transcatheter therapies are appealing options, when used according to evidences and with correct indications.

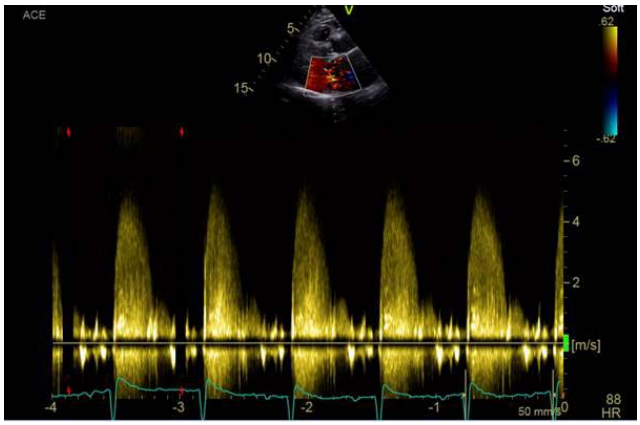
A case of an acute mitral regurgitation: differential echocardiographic diagnosis with the chronic form.

F Nicoli[1]; S Mushtaq[1]; E Conte[1]; D Andreini[1]; F Celeste[1]
[1]*Cardiology Center Monzino IRCCS, Milan, Italy*

A 63 years old man came to Emergency Department because of breathlessness after fifteen days of worsening dyspnea. At medical visit, he had cardiac systolic heart murmur (IV/VI), rales at left inferior thoracic field and tachycardia. The arterial blood gas analysis demonstrated an initial compensated respiratory acidosis, while the chest x-Ray showed interstitial pulmonary congestion and lower left pleural effusion. An echocardiogram showed severe mitral regurgitation (MR) due to chordal rupture with P2 flail causing an eccentric jet directed towards the interatrial septum. The flow was easily detectable with continuous Doppler and graded as severe by quantitative methods. Interestingly the echocardiography findings were suggestive for acute MR. Indeed at continuous wave Doppler we founded an early peak and low-velocity triangle shaped MR , due to low left ventricular-atrium gradient and reduced atrial compliance. Moreover a very high (78%) left ventricle (LV) ejection fraction and hyperdynamic ventricle was visualized associated with tachycardia and hypotension In accordance with severe increase of LV diastolic pressures a restrictive pattern of the diastolic mitral flow and low cardiac output were also recorded.
The patients was then treated with non invasive ventilation, diuretics. After stabilization a coronary angiography and an early surgical intervention were performed with triangular resection of P2, annuloplasty (Physio Ring n.30) and aorto-coronary bypass (LIMA-LAD) because of significant stenosis of left anterior descending artery. The result was a trivial mitral regurgitation with a mild reduction of left ventricle systolic function.
This case shows an unusual presentation of acute MR with severe decompensation, hypotension and severe pulmonary hypertension. These findings were clinical

findings were associated with severe MR due to P2 flail with very small LV, high LV filling pressures and very low LV- left atrium gradient. This atypical clinical and Echo-Doppler presentation of MR with acute chordal rupture differs from the well-known Echo-Doppler patterns of chronic condition characterized by LV and LA adaptation to volume overload.



Eccentric acute MR flow

Moderated Poster Session - Devices for structural heart disease

On behalf of: CLASP Investigators

Background: Severe mitral regurgitation may lead to an impaired prognosis if left untreated. Transcatheter treatment options have emerged as an alternative to surgery and an adjunct to medical therapy. We report the six-month results of the PASCAL transcatheter valve repair system in treating patients with mitral regurgitation enrolled in the multicenter, prospective, single arm CLASP study.
Methods: The PASCAL implant is comprised of two broad and curved paddles, two clasps capable of independent leaflet capture, and a Nitinol woven spacer which enable optimized leaflet capture, intended to reduce mitral regurgitation while minimizing concentrated stress on the leaflets. Eligible patients had clinically significant MR despite optimal medical therapy and were deemed candidates for transcatheter mitral repair by the local Heart Team. Safety, performance, and clinical outcomes were prospectively assessed at baseline, discharge, 30 days, and 6 months post-procedure. All major adverse events (MAE) were adjudicated by an independent clinical events committee and echocardiographic images were assessed by a core lab. The MAE rate was the primary safety endpoint, defined as the composite of cardiovascular mortality, stroke, MI, new need for renal replacement therapy, severe bleeding, and re-intervention for study device-related complications.
Results: Between June 2017 and September 2018, 62 patients were enrolled at 14 sites worldwide for transcatheter mitral valve reconstruction using the PASCAL system. The mean age was 76.5 years (62.9% male). All patients had MR grade ≥3+, with 59% functional, 34% degenerative, and 7% mixed etiology. The average STS Score for MV repair was 4.4%, EuroSCORE II was 5.2%, and 51.6% of patients were in NYHA Class III/IV. Successful implantation of the PASCAL device was achieved in 95% of patients. At discharge, 95% of patients had MR grade ≤2+ with 81% grade ≤1+. The MAE rate was 4.8%. At 30-day follow-up, paired analyses shows that 98% of patients had MR grade ≤2+ with 81% grade ≤1+ and 88% were in NYHA Class I/II ($p<0.0001$). The 6MWD improved by 38.9 m ($p=0.0015$) and was accompanied by average improvements in KCCQ and EQ5D scores by 14.1 points ($p<0.0001$) and 8.3 points ($p=0.0028$), respectively. The six-month data will be available for presentation.
Conclusions: In this early device experience, the Edwards PASCAL transcatheter valve repair system showed an acceptable safety profile and performed as intended in treating patients with mitral regurgitation. The PASCAL device resulted in significant MR grade reduction, which was associated with clinically and statistically significant improvements in functional status, exercise capacity, and quality of life. Continued follow-up is warranted to validate these initial promising results.

829

One-year outcomes of the TRI-REPAIR study assessing cardioband tricuspid valve reconstruction system for patients with severe tricuspid regurgitation

RS Von Bardeleben[1]; J Hausleiter[2]; U Schaefer[3]; KH Kuck[4]; A Vahanian[5]; JM Juliard[5]; A Latib[6]; S Baldus[7]; F Maisano[8]; G Nickenig[9]
[1]University Medical Center of Mainz, Mainz, Germany; *[2]Ludwig-Maximilians University, Munich, Germany*; *[3]Internistische Intensivmedizin, Hamburg, Germany*; *[4]St. George Hospital, Hamburg, Germany*; *[5]Hospital Bichat-Claude Bernard, Paris, France*; *[6]San Raffaele Institute, Milan, Italy*; *[7]University Hospital , Cologne, Germany*; *[8]University Hospital Zurich, Zurich, Switzerland*; *[9]University Hospital Bonn, Bonn, Germany*

On behalf of: The TRI-REPAIR Investigators
Funding Acknowledgements: Edwards Lifesciences

Background: Severe tricuspid regurgitation (TR) is associated with high morbidity and mortality rates with limited treatment options.
Objectives: We report the one-year outcomes of the Cardioband™ Tricuspid Valve Reconstruction System in the treatment of severe functional TR in 30 patients enrolled in the TRI-REPAIR study.
Methods: Between October 2016 and July 2017, 30 patients were enrolled in this single-arm, multicenter, prospective study. Patients were diagnosed with severe, symptomatic TR in the absence of untreated left-heart disease and deemed inoperable because of unacceptable risk for open-heart surgery by the local heart team. Clinical, functional, and echocardiographic data were prospectively collected before and up to one year post-procedure. An independent core lab assessed all echocardiographic data and an independent clinical event committee adjudicated the safety events.
Results: Mean patient age was 75 years, 73% were females, 23% had ischemic heart disease, and 93% had atrial fibrillation. At baseline, 83% were in NYHA Class III-IV, 63% had edema, and LVEF was 58%. Technical success was 100%. Through one year, one patient had a reintervention and exited the study. Five patients died of which one was device-related. Between baseline and one year (paired analyses), echocardiography showed average reductions of annular septolateral diameter of 16% (44mm vs. 37mm; $p<0.01$), PISA EROA of 49% (0.73cm2 vs. 0.37cm2, $p<0.01$), and mean vena contracta of 30% (1.2cm vs. 0.9cm, $p<0.01$). Clinical assessment showed that at one year 78% of patients were in NYHA Class I-II ($p<0.01$). Six minute walk distance improved by 42m ($p<0.01$). Kansas City Cardiomyopathy Questionnaire score improved by 19 points ($p<0.01$). Edema was absent in 70% of the patients.
Conclusions: These results show that the Cardioband tricuspid system performs as intended and appears to be safe in patients with symptomatic and severe functional TR. At one year significant reduction of TR through a sustained decrease of annular dimensions, improvements in heart failure symptoms, quality of life, and exercise capacity were observed. Further studies are warranted to validate these initial promising results.

830

Clinical scenarios predict procedural outcomes and indices of right heart function in transcatheter repair of valvular right heart failure

F Schlotter[1]; KP Rommel[1]; M Orban[2]; C Besler[1]; M Von Roeder[1]; D Braun[2]; M Unterhuber[1]; M Borger[3]; M Nabauer[2]; S Massberg[2]; H Thiele[1]; J Hausleiter[2]; P Lurz[1]
[1]Heart Center Leipzig, Internal Medicine/Cardiology, Leipzig, Germany; *[2]Klinikum der Universität München, Medizinische Klinik und Poliklinik I, Munich, Germany*; *[3]Heart Center Leipzig, Cardiac Surgery, Leipzig, Germany*

Background: Transcatheter tricuspid valve repair (TTVR) is an emerging technique to treat tricuspid valve regurgitation (TR). Predictors of adverse events are scarce, and stratification by TR etiologies is lacking.
Methods: We report the procedural outcomes of 164 patients undergoing TTVR for TR from a bi-center registry classified into four etiology-based clinical scenarios (CS; lone atrial fibrillation TR (Afib-TR), pulmonary hypertension TR (PHT-TR), mitral regurgitation TR (MR-TR), and TR in dialysis (Dialysis-TR)). TR procedural success was defined as a TR reduction by ≥ one grade. Clinical characteristics, procedural outcomes and the co-primary endpoints mortality and a combined endpoint (mortality, re-hospitalization and tricuspid valve (TV) re-intervention) at mid-term follow-up at one year were evaluated.
Results: In total, 164 patients were assessed. Fourtyfour (26.8%) patients were categorized as AfibTR; 30 (18.3%) as PHT-TR; 74 (45.1%) as MR-TR; and 11 (6.7%) as Dialysis-TR. We applied a stepwise categorization approach that classified patients on chronic hemodialysis into Dialysis-TR; patients not undergoing dialysis with MR ≥ grade 3 into MR-TR; patients not meeting the inclusion into Dialysis-TR or MR-TR with an invasively-determined systolic pulmonary artery pressure >50mmHg into PHT-TR; and the remaining patients into Afib-TR in case a history of atrial

fibrillation/flutter existed. Five patients (3.0%) did not meet pre-specified inclusion criteria and were excluded from the analysis. Procedural success was > 80% in all CS and did not differ between groups (p=0.38). The Dialysis-TR CS had the highest STS-scores (14.60 [12.93; 30.03]; p<0.01), largest coaptation gap (6mm [3.61; 7.17]; p=0.03), and rate of NYHA class ≥ 3 (n=11/11 (100%); p<0.01). Patients categorized into the Afib-TR CS had the lowest STS-scores (3.09 [2.99; 4.28]; p<0.01), lowest rate of NYHA class ≥ 3 (n=35/44 (79.5%); p<0.01), and highest functional capacity (6MWT; 316m [264; 341]; p<0.01). Concomitant MR clipping was highest in MR-TR CS (69/74 (93%); p<0.01). Within the group of patients that had procedural success, CS predicted the combined primary endpoint (Afib-TR CS (n=5/37 (13.5%), PHT-TR CS (n=15/26 (57.7%)), MR-TR CS (n=25/69 (36.2%), and Dialysis-TR CS (n=4/9 (44.4)); p<0.01). One-year mortality was highest in the PHT-TR CS when compared to the other CSs (p=0.03). One-year heart failure hospitalization was highest in the PHT-TR CS (12/26 (46.2%); p=0.02)). The rate of re-intervention was not significantly different among CSs.

Conclusions: Stratification of TTVR into etiology-based clinical scenarios may add value to the risk prediction in the heterogeneous patient population of TR patients, overcoming some of the limitations of regression-based risk prediction models and may better guide decision-making in the TTVR patient population.

831

Impact of pulmonary hypertension on procedural and clinical outcomes in patients with right heart failure and tricuspid tegurgitation undergoing transcatheter edge-to-edge repair

P Lurz[1]; KP Rommel[1]; M Orban[2]; C Besler[1]; D Braun[2]; F Schlotter[1]; C Hagl[3]; M Borger[4]; M Nabauer[1]; S Mssberg[2]; J Hausleiter[2]; H Thiele[1]
[1]University of Leipzig, Heart Center, Department of Internal Medicine and Cardiology, Leipzig, Germany; *[2]Ludwig-Maximilians University, Medizinische Klinik und Poliklinik I, Munich, Germany*; *[3]Ludwig-Maximilians University, Herzchirurgische Klinik und Poliklinik, Munich, Germany*; *[4]Heart Center of Leipzig, Cardiac Surgery, Leipzig, Germany*

Aims: Transcatheter tricuspid valve leaflet edge-to-edge repair is a novel treatment option for symptomatic tricuspid regurgitation (TR) in patients with right heart failure. The aim of the present study was to investigate the prognostic significance of baseline pulmonary hypertension and its impact on procedural outcomes.

Methods and results: The analysis was carried out in 164 consecutive patients at increased risk for surgery (median age 78 (IQR 74-82) years) and symptomatic TR treated by interventional tricuspid valve edge-to-edge repair at two centers in Germany.

Seventy patients (43%) were found to exhibit a systolic PAP (sPAP) ≥ 50mmHg and were classified as PHT+ group and compared to the remainder of patients (PHT- group).

When compared to PHT- patients, the PHT+ group demonstrated a higher pre-opprative risk (EuroSCORE II 8 vs. 5%, p<0.01), more frequent prior heart failure hospitalizations (86 vs. 70%, p=0.02), more severe symptoms (NYHA class IV in 43 vs. 19%, p=0.01; 6-minute walking distance 197 vs. 261m, p<0.01) and higher NT-pro-BNP levels (p<0.01).

PHT+ patients had more impaired left and right ventricular function (LVEF 46 vs. 51%,p=0.03; TAPSE 17 vs. 15mm,p=0.02) and higher estimated sPAP (56±17 vs. 45±12, p<0.01) with comparable quantitative and semi-quantitative measures of mitral and tricuspid regurgitation severities on baseline echocardiography.

Procedural success (defined as successful clip implantation and residual TR ≤2) was achieved in 86% vs. 82% in PHT+ and PHT- patients respectively (p=0.52). None of the invasive PHT measures was predictive of procedural success on logistic regression analysis.

After a median follow-up of 245 days, 69 patients (39%) reached the combined endpoint of death (22% of patients,), rehospitalization for heart failure (29% of patients) or reintervention (4% of patients).

Both invasive and echocardiographic assessment of systolic PAP ≥ 50mmHg predicted the combined endpoint on univariate analyses. However, this criterion conveyed risk when assessed invasively (HR 1.73 (1.06 - 2.83), p=0.03), while it paradoxically conveyed protection when assessed non-invasively (HR 0.61 (0.36-0.98), p=0.04). This discrepancy was elicited by patients with a false negative echocardiographic assessment of PH (invasive systolic PAP ≥50mmHg, Echo systolic PAP < 50mmHg, n=28). In fact, this group demonstrated the worst right ventricular function (TAPSE 14±4mm), the most severe tricuspid regurgitation (TR grade IV in 57%) and the worst clinical outcomes (combined endpoint in 64% of patients).

Conclusions: Among patients with symptomatic TR undergoing transcatheter tricuspid valve leaflet edge-to-edge repair, invasively measured PH is associated with worse clinical status and advanced HF, but is not associated with procedural failure. Importantly, Echocardiographic estimation of pulmonary artery pressure seems to be unreliable.

832

Echocardiographic L-Wave as a prognostic indicator in TAVI patients

B Ben Sadeh[1]; I Merdler[1]; A Finkelstein[1]; G Keren[1]; S Banai[1]; Y Topilsky[1]
[1]Tel Aviv Sourasky Medical Center, cardiology, Tel Aviv, Israel

Introduction: The L wave represents mid-diastolic trans-mitral flow. Its clinical and prognostic value is not completely understood. It is assumed that this wave represents decreased relaxation of the left ventricle and thus diastolic dysfunction. Patients with severe aortic stenosis are prone to left ventricular hypertrophy and diastolic dysfunction. It has been previously shown in this group of patients that Trans-catheter aortic valve replacement (TAVR) induces reverse remodeling and improves diastolic function and prognosis. Our aim was to examine the change in L wave after TAVR and its clinical importance.

Methods: We examined the clinical and echocardiographic data of 535 patients (mean age 82.58±5.9) undergoing TAVR. The presence and velocity of L-Wave was recorded at baseline and 1 and 6 months post procedure. The impact of the procedure on L-Wave and clinical outcomes were analyzed.

Results: Patients with L-wave on baseline echocardiography (n=64, 12%) had a smaller stroke volume index by 5.7±2.3ml/m2 (p=0.01) and a lower systolic blood pressure by 17.2±6.6mmHg (p=0.01) compared to patients without L wave at baseline echocardiography. In patients with L-wave at baseline, in 31% the L-wave disappeared at 1 month and in 70% at 6 months follow up. In addition, baseline L wave velocity was 34.8±11.5 (cm/s) and decreased significantly at follow up. Patients with L-wave at baseline had higher 3 year mortality post procedure (HR 1.93, 95% CI 1.46-2.54, p<0.001). This was also true for patients with L-wave after 1 month (HR 5.03, CI 3.12-8.08, p<0.001). Multivariate analysis of survival was also statistically significant (p<0.001).

Conclusion: Post TAVR velocity of L wave decreases significantly and often disappears completely. The presence of L wave before TAVR is an independent risk factor for mortality.

833

Long term outcomes in asymptomatic patients with severe aortic stenosis

A B Kvaslerud[1]; K Santic[1]; A Fiane[2]; H Skulstad[3]; L Aaberge[3]; L Gullestad[4]; K Broch[3]
[1]University of Oslo, Faculty of Medicine, Oslo, Norway; *[2]Oslo University Hospital, Dept of Cardiothoracic Surgery and Faculty of Medicine, University of Oslo, Oslo, Norway*; *[3]Oslo University Hospital, Department of Cardiology, Oslo, Norway*; *[4]Oslo University Hospital, Department of Cardiology, Rikshospitalet and Faculty of Medicine, University of Oslo, Oslo, Norway*

Objective: Patients with asymptomatic, severe aortic stenosis (AS) are presumed to have a benign prognosis. Current guidelines therefore do not recommend aortic valve replacement (AVR) for isolated, asymptomatic, severe AS. The aim of this study was to explore the natural history of patients with severe AS advised against surgery due to lack of symptoms.

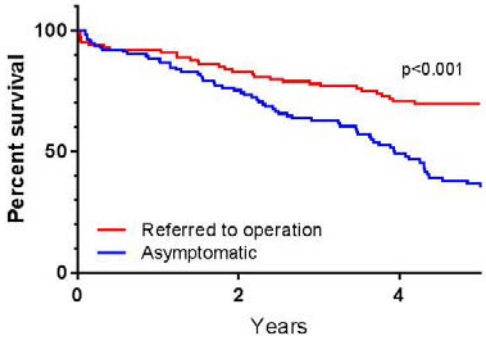
Methods: Patients who were referred for diagnostic evaluation for severe AS were identified through a search in the hospital database. We reviewed the medical records of every patient with the ICD-10-code for AS (I35) between Dec 1st, 2002 and Dec 31st, 2016. Clinical data, biochemistry and imaging data were procured for the patients categorised as asymptomatic and 100 age- and gender matched patients referred to AVR. By March 2017, mortality data were obtained from the national Norwegian Cause of Death Registry. This study was approved by the Regional Ethical Committee, which waived the need for patient consent because of the retrospective nature of the study.

Results: Among the 3454 patients with the code for AS, 2341 patients were evaluated by the heart team for possible AVR due to severe AS during the period in question. 1953 patients were referred to AVR. 388 patients received conservative treatment due to either a lack of symptoms (n=114), patient refusal (n=49) or a high risk-benefit ratio or because they had comorbidities presumed to reduce life expectancy significantly (n=225). The asymptomatic patients had a median age of 83.4 (IQR: 76.5-87.0). 42 % were male. The peak aortic jet velocity was 4.4±0.8 m/s, and the aortic valve opening area was 0.68±0.16 cm2. During a mean duration of follow up of 4.0±2.5 years (median 4.1 years, IQR: 2.10-5.4), 72 of the 114 patients died (63%). Survival at 1, 2 and 3 years for the asymptomatic patients was 88%, 75% and 63% respectively, compared with 91%, 82% and 77% in those who were referred to AVR (p<0.001) (Figure 1). 28 patients received AVR at a median 1.6 (IQR:1,1,-2.8) years after they were initially advised against surgery. When censoring the asymptomatic patients at the time of AVR, 1, 2 and 3 years survival was 88%, 72% and 57%. Cox regression analysis identified Troponin T as an independent predictor of mortality in patients with asymptomatic severe AS, p= 0.029. Age, valvular disease severity, NT-ProBNP, diabetes and coronary artery disease were not predictors of mortality.

Conclusions: Patients with severe AS who were advised against surgery due to lack of symptoms, had significantly higher mortality than patients referred for AVR.

Troponin T was an independent predictor of mortality. Our results suggest that in patients with severe AS, AVR should be considered even in "asymptomatic" patients, particularly if Troponin T is elevated.

Figure 1. Survival analysis. Kaplan-Meier curve reflecting survival in asymptomatic patients with severe aortic stenosis compared to 100 age- and gender matched patients referred to operation.



834

Utilization of machine learning to identify gender-specific patterns in short- and long-term mortality after Cardiac Resynchronization Therapy

A Annamaria Kosztin[1]; M Tokodi[1]; Z Toser[1]; W Schwertner[1]; AM Boros[1]; A Kovacs[1]; P Perge[1]; G Szeplaki[1]; L Geller[1]; B Merkely[1]
[1]*Semmelweis University, Heart Center, Budapest, Hungary*

Background: Cardiac Resynchronization Therapy (CRT) is a standard treatment for chronic heart failure with decreased ejection fraction and wide QRS complex. However, not every patient benefits from the treatment, moreover, some studies reported difference in the outcomes between male and female patients.
Purpose: In the current study we utilized machine learning (ML) to explore gender-specific patterns among the predictors of 1- and 5-year mortality in patients undergoing CRT implantation.
Methods: We created six separate random forest models to predict 1- and 5-year all-cause mortality (3 for both follow-up duration: entire cohort, males and females). A registry of 2269 patients (66±10 years, 1700 [75%] males) was used as the training set for the 1-year mortality prediction models, whereas 5-year mortality prediction models were trained on the subset of patients who completed 5 year follow-up (n=1650, 66±10 years, 1258 [76%] males). 47 pre-implant parameters including cardiovascular risk factors and clinical variables were utilized to train our models. For each clinical parameter, we calculated the mean decrease in Gini impurity. Based on the extent of decline, the 10 most important features were selected, we took the union of these features and plotted the results on radar charts.
Results: There were 267 (12%) deaths during the 1-year and 879 (53%) deaths during the 5-year follow-up period. For the entire population the most important predictor of 1-year mortality was age followed by serum creatinine and urea levels (mean decrease in Gini impurity [dG]: 0.086, 0.058 and 0.057, respectively). To predict 5-year mortality, age, serum urea and left ventricular ejection fraction (LVEF) were of paramount importance (dG: 0.093, 0.049 and 0.048 respectively). We observed several gender-specific differences, the most important predictors of 1-year mortality were age, serum urea and creatinine for males (dG: 0.089, 0.066 and 0.055, respectively); age, body mass index (BMI) and serum urea for females (dG: 0.077, 0.062 and 0.059 respectively). In males the strongest predictors of 5-year mortality were age, serum urea and LVEF (dG: 0.108, 0.048 and 0.0.47, respectively), whereas in females these were age, LVEF and NYHA class (dG: 0.096, 0.055 and 0.047, respectively).
Conclusions: As explored by ML, there are marked differences between males and females regarding the predictors of mortality following CRT implantation. The most relevant predictors are age, renal function parameters, LVEF, BMI and NYHA class, however, their importance changes over time, which should be taken into consideration.

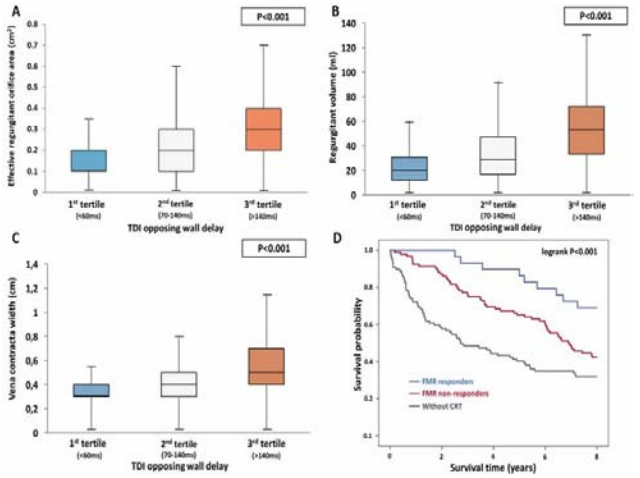
Papillary muscle dyssynchrony-mediated functional mitral regurgitation: mechanistic insights and modulation by cardiac resynchronization

G Georg Spinka[1]; P Bartko[1]; H Arfsten[1]; G Heitzinger[1]; N Pavo[1]; G Strunk[2]; M Gwechenberger[1]; C Hengstenberg[1]; T Binder[1]; M Huelsmann[1]; G Goliasch[1]
[1]*Medical University of Vienna, Internal Medicine II, Cardiology, Vienna, Austria*; [2]*Research Institute for Complex Systems - Complexity-Research, Vienna, Austria*

Background: Mechanistic features of functional mitral regurgitation (FMR) include papillary muscle displacement due to left ventricular remodeling. Intraventricular conduction delay might further augment this condition by introducing interpapillary muscle dyssynchrony.



Dyssynchrony-FMR

Objectives: To define this mechanism as a major contributing factor in FMR and prove the reversibility of FMR by interpapillary muscle resynchronization.
Methods: We enrolled 269 chronic HFrEF patients with conduction delay and comprehensively assessed dyssynchrony by complementary echocardiographic techniques. Opposing wall delay, calculated by speckle tracking, was determined as the time difference between peak longitudinal strain of the mid-anterior and inferior wall from a 2-chamber view. Furthermore, opposing wall delay was assessed as the time difference between peak strain values from tissue Doppler velocity-coded data of the mid-inferior septal and mid-lateral wall segments.
Results: Patients with severe FMR had markedly increased interpapillary longitudinal dyssynchrony (160ms[IQR120-200]) compared to those with moderate (70ms[IQR40-110]), no, or mild FMR (60ms[IQR30-100]; P<0.001). Increased interpapillary muscle dyssynchrony was correlated with effective regurgitant orifice area (P<0.001; Figure A), regurgitant volume (P<0.001, Figure B) and vena contracta

width (P<0.001, Figure C). Restoration of longitudinal papillary muscle synchronicity by cardiac resynchronization therapy (CRT) was correlated with FMR regression, as reflected by the reduction in regurgitant volume (P<0.001) and vena contracta width (P<0.001). Conversely, the improvement of FMR was associated with improved interpapillary radial (P=0.006) and longitudinal (P<0.001) dyssynchrony. The improvement of dyssynchrony-mediated FMR signified a better prognosis compared to no improvement in FMR during the 8-year follow-up period even after comprehensive adjustment by a bootstrap-selected confounder model (adj. HR of 0.41; 95% CI 0.18-0.91; P=0.028; Figure D). The results remained virtually unchanged after adjustment for left bundle branch block.

Conclusion: Intraventricular dyssynchrony introduces unequal contraction by papillary muscle bearing walls, which has an adverse effect on FMR. CRT can effectively restore interpapillary balance and thus create a less tented leaflet configuration, resulting in a clinically meaningful reduction of FMR. The restoration of papillary muscle synchronicity in dyssynchrony-mediated FMR translates into a significantly better prognosis.

Clinical Case - Advanced interventions from Alpha to Omega

Venovenous ECMO as a rescue tool in acute respiratory failure during LVAD implantation in a patient with Cardiogenic Shock

G Guirgis Gabra[1]; F Bader[1]; M Elbanna[1]; I Hamour[1]; M Soliman[1]
[1]*Cleveland Clinic Abu Dhabi, Abu Dhabi, United Arab Emirates*

Funding Acknowledgements: Cleveland Clinic Abu Dhabi

We report a case of a 48 year-old gentleman with past history of non-ischemic severely dilated CMP, persistent AF, S/P CRT-D and both alcohol and tobacco abuser who was transferred to us for possible advanced heart failure therapy after being admitted with acute decompensated heart failure and rapidly progressed to cardiogenic shock with multi-organs dysfunction including renal failure, hepatic failure and cerebral hypo-perfusion. Upon arrival, he was started on dialysis and placed on VA ECMO to provide full hemodynamic support as a bridge to decision. . His RV function was mildly to moderately impaired. LVAD was inserted one week after admission due to failure to wean VA ECMO despite significant inotropic support. During surgery for LVAD, VA ECMO was shifted to VV ECMO; as a rescue procedure for intraoperative pulmonary edema and severe resistant hypoxia. Intraoperative TEE showed no worsening RV systolic dysfunction but worsening of pulmonary HTN. Insertion of the VV ECMO occurred via the left femoral vein (LFV) cannula and right internal jug IJ cannula under TEE. Over the next 4 days, there were many challenges which were total atelectasis of left lung twice (resolved through bronchoscopic lavage with clot removal) and transient renal shutdown required continuous renal replacement therapy. Bedside echo was frequently the corner stone to evaluate the pulmonary artery pressure and RV dimensions and systolic function especially after resolution of lung issue to decide removal of VV ECMO. VV ECMO has been successfully removed successfully in the 5th day.There is no prior reported case of using VV ECMO for acute respiratory failure during VAD surgery. In our patient: VV ECMO was helpful to pass the acute respiratory failure phase but unfortunately because of Left lung's atelectasis caused by blood clot, its removal was postponed until day 4 postoperatively otherwise it should be removed as soon as possible to avoid vascular complications and infection.
Learning objectives: (1) VV ECMO could be a rescue procedure in case of acute respiratory failure during VAD surgery, (2) Right side invasive monitoring and bedside echo evaluation are helpful tool to decide removal of the VV ECMO, (3) LVAD can be used as a bridge to decision

839

The combined use of left ventricular assist device and extracorporeal membrane oxygenation in a patient with severe heart failure due to myocardial infarction after stent thrombosis

AH Aylin Hatice Yamac[1]; B Schieffer[2]
[1]*Hannover Medical School, Department of Cardiology and Angiology, Hannover, Germany*; [2]*University Hospital Giessen and Marburg, Cardiology, Marburg, Germany*

A 56-year-old male patient was transferred to our hospital with severe heart failure due to acute myocardial infarction after stent thrombosis of the left anterior descending artery. He progressed to multi-organ failure requiring intubation and maximal doses of multiple inotropic agents. Invasive cardiac output monitoring was implemented using the Swan Ganz pulmonalis catheter system. Circulatory support was first provided by an extracorporeal membrane oxygenator (ECMO) due to low-output related right ventricular (RV) failure with enhanced pulmonary artery pressures (pulmonary mean pressure 50 mmHg and pulmonary wedge pressure 40 mmHg) demonstrating poor LV unloading. The hemodynamic worsening was also triggered by concomitant development of pneumonia yielding septic shock caused by an Acinetobacter baumannii infection. Five days after ECMO implantation the patient was partially weaned from the ventilator, being completely awake and speaking with the help of a tracheostomy tube.
The first weaning attempt from the ECMO system, one week after implantation, failed. Cardiac index parameters, determined by the Fick principle, were very low between a rate of 1.4 to 1.6 L/min/m2. Echocardiographic findings revealed a severely reduced systolic cardiac function with a LV ejection fraction of 15%. Besides, the patient developed heparin induced thrombocytopenia with several hemoglobin relevant bleedings from the ECMO puncture sites. Thus heparin was replaced by argatroban with no longer major bleeding events at follow-up. At day 8, the patient developed pulmonary edema due to fluid overload yielding RV decompensation and subsequent LV compression after required enhancement of the ECMO flow. Facing this massive LV failure on ECMO, we decided to perform LV decompression with a percutaneous cardiac assist device. Immediately after Impella positioning, right-sided pressures, left-sided volumes, and pulmonary edema rapidly decreased (Impella outflow 2,0 L/min, pulmonary mean pressure 20 mmHg, and pulmonary wedge pressure 14 mmHg), paralleled by an average systemic arterial mean pressure of 70 mmHg under low-dose dobutamin and an ECMO flow of 2l/min. However, the second ECMO weaning attempt under Impella support also failed, indicating the poor cardiac function, verified by echocardiographic parameters. Therefore we decided a biventricular unloading until admission to a heart center, where a Levitronix CentriMag system was implanted. Unfortunately the patient died 5 days after implantation due to diffuse haemorrhage related to hyperfibrinolysis.
To conclude the implantation of ventricular assist devices is a logistical and ethical challenge and needs to be evaluated very carefully with a clearly defined 'exit strategy' for the patient.

840

Oversizing amplatzer device for aortic valve closure in patient with L-VAD, aortic regurgitation and dilated aortic annulus

F Nicolo[1]; A Andrea Montalto[1]; M Comisso[1]; A Lio[1]; F Musumeci[1]
[1]*San Camillo Hospital, Cardiac Surgery and Heart Transplantation, Rome, Italy*

Objective: Development of aortic regurgitation (AR) is a significant complication in patients with long-term LVAD support, leading to recurrent clinical heart failure symptoms and significantly increased mortality. Recently, percutaneous interventions, such as transcatheter aortic valve replacement (TAVR) and percutaneous occluder devices, have emerged. TAVR is a challenging procedure in these patients, because of the subsequent difficulty in anchoring the prosthesis in a non-calcified aortic annulus, especially in the presence of a dilated aortic annulus. Pre-stenting strategy with an uncovered stent to prepare an easy landing-zone for TAVR has been described; anyway it's not always feasible in very dilated aortic annulus. We report the case of a percutaneous transcatheter aortic valve closure with oversizing of the prosthesis, in order to treat AR in a dilated aortic annulus.
Methods: A 68-year old man was admitted to our Hospital with rapidly progressive symptoms of fatigue and shortness of breath 3 years after continuous-flow L-VAD implantation. Severe AR and severe pulmonary hypertension were detected at echocardiography, while a CT-scan showed a virtual basal ring perimeter of 9,3 cm. Because of high surgical risk and contraindication to heart valve transplantation for severe comorbidities, the patient underwent right transfemoral positioning of an Amplatzer PFO MF 30 mm Device. At the end of the procedure, a severe paravalvular leak was observed. In order to prevent device migration and hemolysis, an oversizing Amplatzer MF 35 mm was implanted.
Results. Cardiac hemodynamic improved with RPM reduction from 11.400 to 10.600, the post-procedural wedge of 6 mmHg, reduction in Pulsatility Index (PI) from 6 to 3 and a MAP of 70 mmHg. the Absence of paravalvular leaks was detected at TE-echocardiography.
Conclusions: We consider this technique a useful novel approach to treat AR in patients with aortic annulus dilatation and L-VAD that are poor candidates for repeat operation. Further data are needed to assess long-term results.

841

Fulminant lymphocytic myocarditis with cardiogenic shock and multiorgan failure with complete recovery after percutaneous mechanical support and immunosuppression.

I Ivana Jurcova[1]; V Melenovsky[1]; M Pindak[2]; H Riha[2]; I Netuka[3]; J Maly[3]; O Szarszoi[3]; J Maluskova[4]; E Honsova[4]; W Bracamonte-Baran[5]; D Cihakova[5]; M Kubanek[1]; J Kautzner[1]
[1]*Institute for Clinical and Experimental Medicine (IKEM), Cardiology, Prague, Czechia*; [2]*Institute for Clinical and Experimental Medicine (IKEM), Anaesthesiology and Resuscitation Department, Prague, Czechia*; [3]*Institute for Clinical and Experimental Medicine (IKEM), Cardiovascular Surgery, Prague, Czechia*; [4]*Institute for Clinical and Experimental Medicine (IKEM), Department of Pathology, Prague, Czechia*; [5]*Johns Hopkins University of Baltimore, Department of Pathology, Baltimore, United States of America*

Fulminant myocarditis is rare but serious myocardial inflammatory disease that presents with acute heart failure, cardiogenic shock and/or life-threatening arrhythmias. The management often requires intensive care, inotropes and mechanical circulatory support. Immunosuppressive therapy may result in a complete recovery. We report a case of previously healthy 19- year-old female that presented to regional hospital after two days of gastrointestinal symptoms with 3rd degree AV block, left ventricular (LV) systolic dysfunction (LVEF 40 %), significantly elevated cardiac biomarkers (hsTnT 13850 ng/l, NTproBNP 19686 ng/l) and cardiogenic shock requiring inotropes, temporary pacing and endotracheal intubation. Coronary angiography showed patent coronary arteries. Within next 24 hours, her status deteriorated with development of severe biventricular dysfunction (without wall thinning), widening of QRS complex and multiple organ failure. She was transferred to our center for further management and peripheral VA-ECMO was introduced. However, LVEF dropped to less than 10% with further QRS widening. An endomyocardial biopsy (EMB) revealed diffuse lymphocytic myocarditis (LM), resembling severe cellular allograft rejection with diffuse interstitial edema, but relatively sparse myocyte necrosis. FACS analysis of EMB showed CD4/CD8 ratio shifts to 1/3, normal ratio is 3/1. Both CD4 and CD8 Tcells were activated, rather than in a naïve status. Activated cells were predominantly Th1 cells. There was a significant expansion of CD14+CD16low cells (inflammatory, classical monocytes). PCR for panel of possible viral pathogens in the EMB specimen was negative. Therefore, immunosuppression with 1g/day (in 3 days) of methylprednisolone and intravenous IgG (0,5 g/kg, once) was instituted. Because of development of long runs of incessant VT (rate 220/min.) and LV dilatation, Impella 2.5 was introduced to achieve LV venting and to improve myocardial edema drainage. Immediately after addition of Impella to VA-ECMO, VTs ceased and QRS complex narrowed. Due to continuing LV dysfunction, Impella 2.5 was exchanged for Impella 5.0. On the day 10, echocardiogram showed significant recovery of LVEF. Therefore, VA-ECMO was discontinued on the day 11 and Impella was explanted on the day 13. Further recovery was uneventful and the patient was discharged after 44 days. Clinical status was stabilized with normal cardiac function by echocardiography and normal BNP and troponin levels. She is currently being tapered off of low dose of prednisone 2,5mg/day.

Conclusions: Our case illustrates that if acute viral infection is ruled out, immunosuppressive protocol can be successfully used in management of fulminant LM together with temporary mechanical circulatory support consisting of VA-ECMO + Impella. Rapid resolution of QRS prolongation and LV dysfunction with LV unloading by Impella suggest possible role of myocardial edema in development of severe mechanical ventricular dysfunction.

842

A case of cardiac sarcoidosis diagnosed after heart transplantation

M Stratinaki[1]; I Iakovos Armenis[1]; N Kogerakis[1]; E Leontiadis[1]; MJ Bonios[1]; A Gkouziouta[1]; A Platania[1]; L Kaklamanis[1]; S Adamopoulos[1]
[1]*Onassis Cardiac Surgery Center, Athens, Greece*

A 53-year old female Caucasian was admitted to our hospital due to presyncope and shocks delivered from her defibrillator. She had been diagnosed with non-ischemic cardiomyopathy two years ago in a tertiary hospital, where she was admitted because of worsening exertional dyspnea. In that hospitalization, reduced left ventricular ejection fraction (LVEF) and new onset conduction abnormalities [1st degree atrioventricular block (AVB) -left bundle branch block with intermittent complete AVB] were documented. A Magnetic Resonance Imaging (MRI)-scan had revealed LVEF 26%, akinetic interventricular septum (IVS) and hypokinetic anterior (AW) and inferior (IW) walls and diffuse late gadolinium enhancement mainly located at the IVS and AW and to a lesser extent to IW and anterolateral wall (with transmural /midwall distribution), a pattern indicative of old myocarditis or atypical non-ischemic cardiomyopathy. The patient had been implanted CRT-D 18 months before, but this was the first time it delivered shocks. In our hospital, she received intravenously amiodarone and esmolol and ventricular tachycardia was successfully terminated. However, the patient rapidly deteriorated. Dobutamine was initiated and the patient was transferred to the Cardiac Care Unit where an intra-aortic balloon pump (IABP) was placed. Under IABP and intravenous inotropes the patient's haemodynamic status improved and no further arrhythmias occurred. However, the patient was unable to wean off IABP and intravenous inotropes. As a result, the patient became candidate for heart transplantation and an extensive pre-transplant evaluation, including total body Computerized Tomography (CT) was performed. Chest CT revealed few sub-pleural nodules mainly in upper lobes compatible with small granulomas. Successful heart transplantation was performed after three months. Post-transplantation histology of the patient's native heart revealed diffuse inflammatory reaction with noncaseating granulomas and few giant cells, findings consistent with cardiac sarcoidosis.

This case highlights the need for high clinical suspicion of rare, potentially reversible causes of heart failure, especially in patients with clinical/paraclinical findings suggestive of specific causes (conduction abnormalities and MRI findings in our patient). Diagnosis of cardiac sarcoidosis in the absence of previously documented systemic sarcoidosis remains intriguing and requires high clinical suspicion. Endomyocardial biopsy, a procedure that might be diagnostic, especially if guided, was not performed in our patient, due to the relatively insidious onset of heart failure symptoms and her end-stage heart failure status. Conclusively, endomyocardial biopsy, although invasive, potentially dangerous and not always conclusive, may be considered in selected, relatively young patients with unexplained dilated cardiomyopathy and clinical features suggestive of infiltrative disease.

843

Successful transplantation of heart from a donor with Takotsubo syndrome

E Elmir Omerovic[1]; J Oras[1]; B Redfors[1]; C Pirazzi[1]; R Doueh[1]; G Dellgren[1]
[1]*Sahlgrenska University Hospital, Gothenburg, Sweden*

One reason for the shortage of donor hearts is the fact that current guidelines recommend against the use of donor hearts with regional wall motion abnormalities or left ventricular ejection fraction <40%. Fully reversible acute stress-induced cardiac dysfunction (Takotsubo syndrome) can occur in the setting of severe somatic stress and catecholamine excess. Here we present a donor heart with left ventricular dysfunction due to Takotsubo syndrome that was successfully transplanted.

The donor was a previously healthy, 59-years old female, with rapid onset of headache and neurological deterioration. In the ambulance, she became suddenly unconscious with seizures, respiratory arrest and hypoxia. She was successfully resuscitated after a brief period of CPR. Upon arrival to the hospital, her Glasgow Coma Scale was 3 and CT-scan showed a massive subarachnoid hemorrhage originating from a basilar aneurysm. The neurosurgeon was consulted but further measures were considered futile. She was transferred to the ICU where brain dead was diagnosed a couple of hours later. Echocardiography twelve hours after onset of symptoms revealed a left ventricle with apical akinesia in the apical and EF 35%. Troponin levels were modestly increased at 888 ng/l. Coronary angiography was performed 24 hours after onset of symptoms and showed normal coronary arteries. Ventriculography confirmed apical akinesia and basal hypercontractility typical for Takotsubo syndrome. End-diastolic pressure was 10 mmHg.

The recipient was a 57-year-old man on waiting list for heart transplantation for three months due to dilated cardiomyopathy diagnosed 12 years earlier. He was on guideline-recommended therapy, including synchronized biventricular pacing. Despite optimal therapy, cardiac function had deteriorated substantially during the last months. At the time he was accepted for heart transplantation he had biventricular heart failure with a dilated left ventricle and EF <20%, a moderate mitral insufficiency and a right ventricular systolic pressure of 70 mmHg. The peri-operative period was uneventful and the heart was successfully transplanted. Peri-operative transesophageal echocardiography showed good bi-ventricular function after ECC. Post-operatively, he had severe vasoplegia and required vasopressor support the first postoperative days. He had pulmonary hypertension that was treated with inhaled vasoprost and later per-oral sildenafil. He also developed acute renal failure with need of renal replacement therapy. However, left ventricular function was good with a hyperdynamic left ventricle and an ejection fraction >65% two days postoperatively (Video 3). Right ventricular function was initially compromised but was normalized within two weeks. He was discharged from the ICU after 14 days.

The electrocardiographic markers of sudden cardiac death (SCD) and left ventricular global longitudinal strain in recovery peripartum cardiomyopathy patients : do they really recover?

H S Prameswari[1]; M Hasan[1]; M Iqbal[1]; T I Dewi[1]; T A Sabrawi[1]; N S Liem[1]
[1]*Hasan Sadikin Hospital, Cardiovascular Medicine, Bandung, Indonesia*

Background: The risk of arrhythmia and sudden cardiac death was prevalently high in Peripartum Cardiomyopathy (PPCM) patients, regardless of complete left ventricular ejection fraction (LVEF) recovery. The previous study has shown that residual myocardial injury might be a potential risk of arrhythmia in recovered PPCM patients. Global longitudinal strain (GLS) with speckle tracking analysis is more sensitive than LVEF to identify subclinical LV dysfunction in cardiomyopathies. This study was conducted to assess the association between ECG markers of SCD and LV GLS in recovery PPCM patients. To date, study related to ECG markers of SCD and their association with LV GLS in this population has not been reported.
Methods: Data were obtained from registry of PPCM in our Hospital, Faculty of Medicine, Indonesia. The data comprised of 12-lead ECGs and 2-D Echocardiography from recovered PPCM patients (n=35 women). The QRS duration, QTc interval using Bazett's formula, T peak to T end interval, and spatial QRS-T angle were measured from the 12-lead ECG prior to and unrelated to the SCD event. LV GLS was measured from the apical 2-, 3-, and 4-chamber views using speckle-tracking analysis. The bivariate analysis was analyzed using Pearson correlation and the linear regression multivariate analysis was analyzed using alternative models.
Result: Thirty-five recovery PPCM patients (mean age 31 ± 6 years) were enrolled in this study. Bivariate analysis showed there was a significant strong negative correlation between QTc and GLS (r=-0.645 ; p-value <0.001). A significant negative correlation was found between T peak to T end interval and GLS (r=-0.430; p-value=0.005) and between spatial QRS-T angle and GLS (r=-0.345; p-value=0.021). There were no correlation between QRS duration with GLS (p-value >0.05). Statistical analysis results showed that among studied markers, the strongest association for single marker was found between QTc and GLS value (R2=0.451). Further analyses utilizing alternative model also resulted a strong association between GLS value with combination of QTc and other ECG markers. Among all combinations of ECG markers, however, combination between QTC and T peak to T end interval with GLS value (R2=0.500) produced even stronger association.
Conclusions: From 12-lead ECG markers for SCD, QTc alone had demonstrated the strongest association with low GLS compared to QRS duration, T peak to T end interval, and spatial QRS-T angle. Utilizing a combination of ECG markers, QTc and T peak to T end interval gave a better association with GLS value compared to other markers.

P875

The characteristics of electrocardiographic markers of sudden cardiac death (SCD) in recovery peripartum cardiomyopathy patients : a novel study

T A Sabrawi[1]; H S Prameswari[1]; M Iqbal[1]; N S Liem[1]; T I Dewi[1]; M Hasan[1]
[1]*Hasan Sadikin Hospital, Cardiovascular Medicine, Bandung, Indonesia*

Objective: This study was conducted to asses the characteristics of electrocardiographic markers of sudden cardiac death (SCD) from the 12-lead electrocardiogram (ECG) in recovery peripartum cardiomyopathy (PPCM) patients.
Background: A Patient with PPCM has a risk of ventricular arrhytmia or sudden cardiac death (SCD). The risk of SCD persist even after complete recovery of left ventricular function. This study was conducted to asses known ECG markers for SCD in recovery PPCM patients. The study of ECG markers of SCD in this population has not been reported.
Methods: Data was obtained from registry of PPCM in our Faculty of Medicine, Indonesia, 12-lead ECGs were taken from recovery PPCM patients (29 women) compared to post labor women without PPCM in control group (29 patients). The QRS duration, QTc, T Peak to T end, spatial QRS-T angle, delayed QRS transition zone, and electrocardiographic LVH were measured from the 12-lead ECG prior to and unrelated to the SCD event in both groups. The QRS duration, QTc, T Peak to T end, QRS-T angle, delayed QRS transition zone, and electrocardiographic LVH were analyzed using Mann-Whitney test, Independent Samples T-Test, and Chi-Square test. Continuous variable were expressed as mean ± standard deviations if normally distributed and as median (minimum-maximum) if abnormally distributed.
Result: Twenty-nine PPCM patients in PPCM group (mean age 31 ± 6.2 years) and 29 healthy post labor women without PPCM in control group (mean age 31 ± 4.6 years) were enrolled in this study. The QRS duration were significantly higher in PPCM group compared to the QRS duration in control group (median 100 (80-110) ms vs 80 (74-96) ms; p-value <0.001). The QTc were significantly higher in PPCM group compared to the control group (median 443 (359-491) ms vs 410 (353-468) ms; p-value <0.001). The T peak to T end were significantly higher in PPCM group compared to the control group (mean 85.8 ± 17 ms vs 70 ± 9.6 ms; p-value <0.001). The spatial QRS-T angle (median 28 (2-170) ms vs median 21 (6-113) ms ; p-value = 0.312) and delayed QRS transition zone (27.6% (n=8) vs 17.2% (n=5) ; p-value = 0.345) were not statistically significant difference between two groups.
Conclusions: The characteristics of electrocardiographic markers of sudden cardiac death (SCD) from the 12-lead electrocardiogram were significantly higher in the PPCM patients compared to the control group, particularly the QRS duration, QTc, and T peak to T end. Their potential clinical significances for predicting SCD is needed to be investigated in larger sample and prospective studies.

P876

Impact of sustained cardiac tachyarrhythmias recorded in coronary intensive care unit (cicu) on short and long-term mortality and duration of cicu hospitalization.

P Panteleimon Papakonstantinou[1]; A Malliou[1]; G Chlouverakis[2]; F Parthenakis[1]; E Simantirakis[1]
[1]*University Hospital of Heraklion, Cardiology Departmnet, Heraklion, Greece*;
[2]*University of Crete, Biostatistics Lab, School of Medicine, Heraklion, Greece*

Introduction: Several studies conducted in Coronary Intensive Care Units (CICU) have demonstrated that ventricular arrhythmias (VAs) are associated with increased short and long-term mortality after acute coronary syndromes. However, the data for arrhythmias occurred in CICUs due to other cardiac disorders is limited. PurposeWe aimed to show the impact of VAs and supraventricular tachycardias (SVTs) recorded in CICU hospitalized patients on short and long-term mortality and duration of CICU hospitalization.
Methods: We conducted a prospective single-center observational study, which included consecutive patients (>18 years old) who was admitted to the CICU of the Cardiology department of our University Hospital for any cardiac disorder, from 1st January 2014 until 31st May 2017.ResultsNine hundred forty-three (943) consecutive CICU patients [age 66.35±15.52; 667 male (70.7%)] were included in our analysis (Table 1). The most common causes of CICU admissions were acute coronary syndromes (68.7%), followed by acute heart failure (17%). Patients who presented an arrhythmia had a higher all-cause mortality (12.9% vs 6.1%; p=0.003); a higher in-CICU mortality (8.1% vs 4%; p=0.002) and higher mortality after

Table 1.

	All*v*=943 (100%)	No arrhythmia *v*=757 (100%)	Arrhythmia 186 (100%)	Supraventricular tachyarrhythmia *v*=63 (100%)	Ventricular tachyarrhythmia *v*=123 (100%)
Death	70 (7.4%)	46 (6.1%)	24 (12.9%)	4 (6.4%)	20 (16.2%)
In-CICU death	45 (4.8%)	30 (4%)	15 (8.1%)	2 (3.2%)	13 (10.6%)
Death during 6-month follow-up period	25 (2.6%)	16 (2.1%)	9 (4.8%)	2 (3.2%)	7 (5.7%)

Arrhythmias occurrence, in-CICU mortality and 6-month outcomes.

discharge (4.8% vs 2.1%; p= 0.006). The occurrence of VA was associated with higher all-cause mortality compared to no arrhythmia (16.2% vs 6.1%; p= 0.003) and to SVT (16.2% vs 6.4%; P=0.003). In-CICU mortality was greater in patients with VAs than in patients with no arrhythmia (10.6% vs 4%; p= 0.02) or with SVT (10.6% vs 3.2%; p=0.02). VAs were also associated with greater 6-month all-cause mortality than SVTs (5.7% vs 3.2%; p<0.05) or no arrhythmia (5.7% vs 2.1%; p<0.05). No significant correlation between the occurrence of SVTs and all-cause mortality was observed. The mean duration of CICU hospitalization for the patients who presented arrhythmias was 3.90±4.91 days, while for the patients who did not present was 2.79±3.31 days (p=0.004).ConclusionsThe occurrence of arrhythmias prolonged the CICU hospitalization in our patients, while patients suffered from VA had a significantly higher short (in-CICU) and long-term (6-month follow-up) mortality. Our results confirm the poor prognosis of VA not only in ACS patients but also in all CICU hospitalized patients and show that early onset VA is associated with prolongation of CICU stay and poor outcome.

P877

Survival of patients with ischemic cardiomyopathy and ventricular tachyarrhythmias: Effect of catheter treatment

R Roman Tatarsky[1]; RB Tatarskiy[2]; SV Garkina[2]; DS Lebedev[2]
[1]Almazov centre of heart, blood and endocrinology , Saint-Petersburg, Russian Federation; *[2]Federal Almazov Medical Research Centre, Saint Petersburg, Russian Federation*

Background: Ventricular arrhythmias contribute to significant increase of mortality rate in patients with ischemic cardiomyopathy (ICM). Risk of sudden cardiac death (SCD) could be reduced after implantation of a cardioverter-defibrillator (ICD), yet at the same time more frequent shock episodes are associated with poor life quality and higher hospitalization rate. Radiofrequency (RF) ablation of triggering ventricular premature beats or substrate-based catheter treatment are considered to be effective in patients with ICM but prognosis remains controversial.
The purpose of the study was to evaluate role of catheter treatment of ventricular tachyarrhythmias (VTA) and its effect on survival in patients with ischemic cardiomyopathy.
Materials and methods: We enrolled 72 consecutive patients (mean age 64±13 years, 63 male) with prior myocardial infarction (more than 40 days ago) and documented ventricular tachycardia (VT) episodes, including 12 patients which underwent emergency electrical storm ablation. Considering number of VT recurrence episodes after catheter treatment all patients were divided into two groups. First group consisted of 27 patients (37%) with recurrent sustained VT (mean age 62 ± 10 years) while second group included 45 patients (63 %) without VT recurrence (mean age 63± 12 years). During follow up most of VT episodes were registered in 13±9 years after acute myocardial infarction. Catheter treatment included mapping during hemodynamically tolerated clinically relevant VT and then ablation of VT triggers with subsequent homogenization of the scar. Patients with "fast" VT underwent primary scar homogenization.
Results: Effectiveness of RFA in patients with ICM and clinically relevant VT was 63%. During follow-up period all patients were alive and remained relatively stable. Long-term effectiveness of ES elimination was 100% while freedom from clinically significant VTA was up to 79% due to repeated ablation procedures. We also observed improvement of NYHA functional class in 80% of patients.
Conclusion: Catheter ablation of VTA may be effective treatment both in acute period and long term follow up. It also may be effective in improvement of heart failure NYHA functional class in some patients and contributes to better survival in patients with ICM.

Chronic Heart Failure - Pathophysiology and Mechanisms

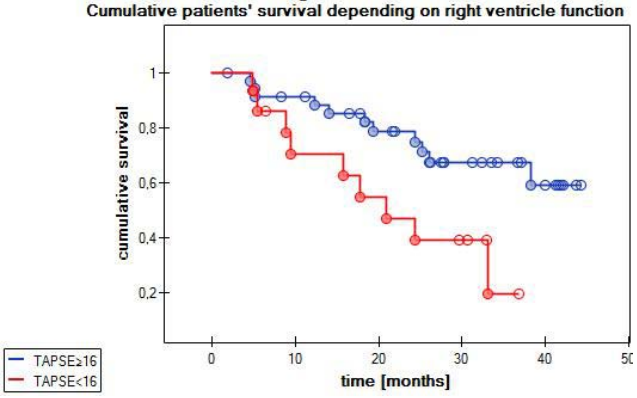
P878

Right ventricle function as a predictor of worse prognosis in patients with advanced heart failure with reduced ejection fraction

A Anna Drohomirecka[1]; M Lipczynska[1]; T Rywik[1]; K Kozuch[1]; K Zukowska[1]; K Kodziszewska[1]; K Komuda[1]; T Zielinski[1]
[1]Institute of Cardiology, Warsaw, Poland

Background: Left heart failure may contribute to occurrence and progression of a secondary right ventricle dysfunction. It was previously demonstrated that parameters defining right ventricle function, like a tricuspid annular plane systolic excursion (TAPSE), correlate with indicators of exercise capacity.
Purpose: The aim of the present study was to evaluate whether right ventricle function can predict prognosis in patients with reduced left ventricle ejection fraction.
Material and Methods: Fifty one patients (aged 55.6±7.5 years) – 43 men (84%) and 8 women (16%) with advanced heart failure (LVEF≤35%, mean 21.7±5.4) were referred to a transplant center to be assessed for their suitability for heart transplantation. Patient demographics and clinical characteristics, including results of cardiopulmonary exercise test, echocardiographic examination and right heart catheterization, were recorded. The following parameters were used to evaluate right ventricle size (RVOT, RVIT) and function (TAPSE, S', FAC, global longitudinal strain and free wall strain). Patients were followed up for up to 3.7 years (1.96±1.05 years on average). The composite endpoint defined as death of any cause, urgent heart transplantation or urgent LVAD implantation occurred in 20 patients (39%).
Results: TAPSE positively correlated with peak VO2 (R=0.35, p=0.01). There was no relationship between TAPSE and age, sex, heart failure etiology, NYHA class, NT-pro-BNP, co-morbidities, left ventricle function or size, pulmonary systolic or pulmonary capillary wedge pressure. Cox proportional hazards regression analysis showed TAPSE<16mm as a significant predictor of composite endpoint (HR 2.86, 95% CI: 1.16-7.08, p=0.02), which was consistent with logrank test result (Chi2=5.7, p=0.02; Figure 1 shows Kaplan Meier curves). The remaining parameters measuring right ventricle function and size were not related to patient prognosis.
Conclusion: Right ventricle dysfunction assessed with TAPSE may predict worse physical capacity and poorer prognosis in patients with left heart failure.

Figure 1.
Cumulative patients' survival depending on right ventricle function



P880

Cardiodepression and subepicardial obesity: is there a connection?

A Andrey Vorobev[1]; VI Ruzov[1]; SM Akberova[1]; EA Gurbanova[1]; R Khayrullin[1]
[1]Ulyanovsk State University, Ulyanovsk, Russian Federation

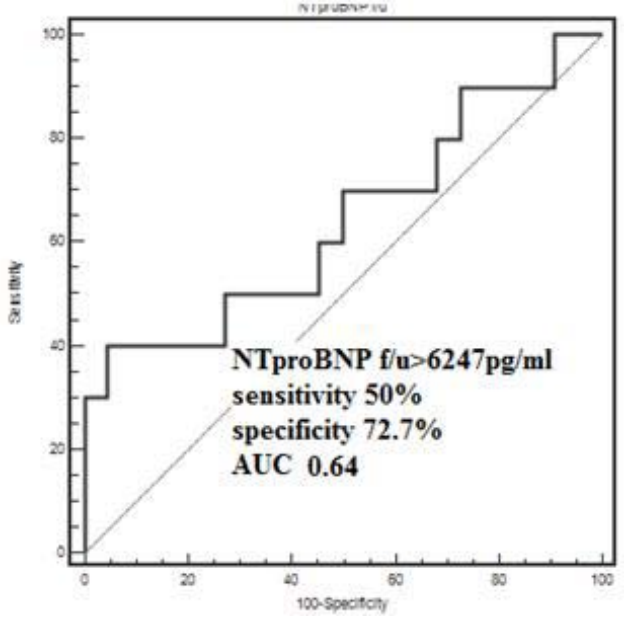
Introduction . The left ventricular ejection fraction (LVEF) is an integral indicator of systolic function, and the most frequent cause of a decrease in the ejection fraction is coronary heart disease, especially its acute forms. The pathogenetic significance of subepicardial obesity (SEO) in the pathogenesis of cardiac pathology is not fully understood, and the data in the literature are contradictory.
Purpose. To study the severity of subepicardial obesity and its relationship with LVEF in patients with primary stenting for AMI.
Methods. 22 patients were examined, the average age was 56.2 ± 9.6 years (6 women, 16 men), 6 weeks after AMI with stenting of coronary arteries ad hoc. The control group - 20 healthy volunteers, average age 51.4 ± 11.4 years (10 women, 10 men). LVEF was estimated by the Simpson method. Epicardial fat was defined as the echo-negative space between the myocardial wall and the pericardial visceral leaf, visualized behind the free wall of the right ventricle in B-mode using the parasternal position along the long axis of the left ventricle at the end of systole. The significance and strength of the correlation relationship were determined using the non-parametric Spearman test.
Results. The study established the average thickness of epicardial fat in patients - 4.24 ± 1.34 mm, in healthy volunteers - 3.62 ± 1.40 mm (the differences are not statistically significant). The mean value of LVEF in patients was 54.1 ± 5.15% and 65.1 ± 3.6% in healthy individuals (p <0.0001). As a result of the study, a negative significant correlation relationship r = −0.51 (p <0.05) was found between LVEF and thickness of subepicardial fat in patients. The control group did not find a significant relationship between the systolic function of the left ventricle and the thickness of epicardial fat (r = -0.17, p> 0.05).
Conclusion. The presence of an inverse relationship between LVEF and thickness of epicardial fat only in patients with primary stenting for AMI indicates the significance of SEO in the pathogenesis of heart failure, the mechanism of which requires further study.

P881

Markers of cardiac adverse events in patients with reactive fixed pulmonary hypertension secondary to systolic heart failure treated with sildenafil

A Duszanska[1]; M Gierlotka[2]; M Zakliczynski[1]
[1]*Medical University of Silesia, Silesian Centre for Heart Diseases, Zabrze, Poland*; [2]*University Hospital Opole, Cardiology, Opole, Poland*

Objective: Reactive fixed pulmonary hypertension (RFPH) in patients with advanced systolic heart failure (HF) is a contraindication do heart transplantation (HTx) and is associated with increased morbidity and mortality. Oral sildenafil has been used in selected heart failure patients to reduce pulmonary hypertension and to restore heart transplant candidacy. We sought to determine predictors of cardiac adverse events (CAE) such as death or HF decompensation in patients with systolic HF and RFPH treated with sildenafil.
Methods and results: Between 2007 and 2018, 1136 patients were evaluated at our department as candidates for HTx. 35 of them, who presented with systolic HF and were ineligible for HTx due to RFPH [pulmonary vascular resistance (PVR)>2,5 Wood units (WU), transpulmonary gradient (TPG)>12 mmHg or ≤2,5 WU with systolic arterial pressure ≤85 mmHg during vasoreactivity test] were included in the study [31 men aged 55.1±7.4 years]. In all patients sildenafil was introduced and up-titrated to a maximal tolerated dose in addition to optimal medical therapy. Patients were reassessed at 3-6 months intervals. 22 (63%) had restored HTx candidacy following sildenafil therapy within median 5 [IQR 4-6] months. In the whole cohort, during oral sildenafil therapy we observed improvement of NYHA class [from 2.9±0.2 to 2.7±0.5, p=0.05]. 19 patients (54%) reported reduction of HF symptoms. Pulmonary hemodynamic parameters had reduced as follows: pulmonary artery systolic pressure [67±14 to 54±15 mmHg, p<0.001], mean pulmonary artery pressure [42±8 to 34±11 mmHg, p<0.001], TPG [19±6 to 14±7 mmHg, p<0.001] and PVR [5.0±1.7 to 3.4±1.7, p<0.001]. In 10 (29%) patients CAE such as death (5 pts) and heart failure decompensation (5 pts) were noted during median 16 months [IQR 9-30].
Baseline GGTP [OR 1.01; 95% CI (1.0-1.03) p=0.04], and follow-up (f/u): GGTP [OR 1.0; 95% CI (1.0-1.01) p=0.05], NTproBNP [OR 1.0002; 95% CI (1.0000- 1.0004 p=0.002], left ventricular (LV) end-diastolic volume [OR 1.02; 95% CI (1.00-1.04) p=0.03], LV ejection fraction [OR 0.57; 95% CI (0.33-0.97) p=0.03] were defined as markers of CAE in patients with systolic HF and RFPH treated with sildenafil. f/u NTproBNP was identified as an independent but moderate predictor of CAE at level of more than 6247 pg/ml, with sensitivity 50%, specificity 72.7% (AUC 0.64, p=0.03).
Conclusion: Higher follow-up NTproBNP levels are associated with cardiac adverse events in patients with reactive fixed pulmonary hypertension secondary to systolic heart failure treated with sildenafil.



NTproBNP as predictor of adverse events

P882

Incidence and predictors of pacemaker induced cardiomyopathy: a single-center experience

A Amr Abdin[1]; K Yalin[2]; M Gramlich[1]; M Zink[1]; N Marx[1]; K Schuett[1]
[1]*RWTH University Hospital Aachen, Aachen, Germany*; [2]*Usak State Hospital, Usak, Turkey*

Background: Pacemaker induced Cardiomyopathy (PICM) is an important cause of heart failure with reduced ejection fraction in patients exposed to frequent right ventricular (RV) pacing. Data regarding this complication are sparse. Therefore, the aim of this study was to identify the incidence and predictors of PICM.
Methods: Between 2011 and 2017, 857 consecutive patients undergoing pacemaker (PM) implantation, were reviewed, and according to our inclusion criteria 173 individuals were enrolled in this retrospective single center study. All patients included had normal left ventricular ejection fraction (LVEF) before implantation and underwent single-chamber ventricular or dual-chamber PM implantation. Frequent RV pacing was present (≥ 20%), and repeated echocardiogram was available ≥1 year after implantation. PICM was defined as deterioration LVEF ≥10%, resulting in LVEF <50%, which cannot be explained by other cardiac causes.
Results: During a mean follow-up of 39.9 ± 21.0 months, PICM occurred in 26 patients (16%) with post-Implantation LVEF being 38.6± 2.5% in patients with PICM vs 55.4 ± 7.4% in patients without PICM (p <0.001). RV pacing percentage did not differ significantly between the both groups (76.5 vs 76.2 %, p= 0.65). The PICM group patients were likely to be men (23/26 vs 82/147, p=0.002) and had a lower rate of arterial hypertension (HTN) (16/26 vs 121/147, p=0.016). Multivariable analysis revealed male gender (HR 8.4, 95% CI 2.16-32.58, p =0.002), lower prevalence of HTN (HR 4.9, 95% CI 1.71-14.09, p =0.003) and wider paced QRS complex (HR 1.04, 95% CI 1.02-1.07, p <0.001) as predictors of PICM.
Conclusions In patients with frequent RV pacing, the prevalence of PICM is not uncommon. Male sex and wider paced QRS complex are independent predictors of PICM and these patients may require closer follow-up.

P883

Logistic regression model to predict left ventricular ejection fraction recovery in a heart failure unit

CR Carlos Ruben Lopez Perales[1]; M Lasala Alastuey[1]; I Caballero Jambrina[1]; A Ruiz Aranjuelo[1]; V Alonso Ventura[1]; G Hurtado Rodriguez[1]; A Portoles Ocampo[1]; M Sanz Julve[1]; T Blasco Peiro[1]; A Perez Guerrero[1]; E Gambo Ruberte[1]; J Jimeno Sanchez[1]; B Peiro Aventin[1]; D De Las Cuevas Leon[1]; MR Ortas Nadal[1]
[1]*University Hospital Miguel Servet, Zaragoza, Spain*

Background/Introduction: Heart failure with improved ejection fraction is a novel phenotype defined as improvement in left ventricular ejection fraction (LVEF) to>40% in patients with previous reduced ejection fraction (HFrEF).
Purpose To assess predictors of LVEF recovery in patients with HFrEF.
Methods We randomly selected a sample of 216 HFrEF patients from a heart failure unit diagnosed between January 1st of 2000 and September 23th of 2018. Univariate and multivariate logistic regression analysis were undertaken to select appropriate variables to predict LVEF recovery.
Results 56% patients showed improvement of LVEF. Female gender, antecedents of alcoholism, left bundle branch block and the etiology were significant predictors of LVEF recovery in the univariate analysis. Multivariate logistic analysis selected four parameters: female gender (coefficient - 0.99, CI:-1.83,-0.15, p=0.021), alcoholism (coefficient: 1.31, CI 0.23,2.38, p=0.017), idiopathic etiology (coefficient: 0.98, CI: 0.2, 1.76 p= 0.014), and tachycardiomyopathy (coefficient: 2.27, CI: 0.08,4.45, p=0.042). This model showed a good fit with a Homer-Lemeshow value of 0.41. The area under the ROC curve was 0.76, indicating a good discrimination power.
Conclusion: This multivariate model may be used in day-to-day practice to estimate patient-specific potential of LVEF recovery.

Dynamics of left ventricular ejection fraction in patients with stable coronary artery disease after coronary artery bypass grafting

O Olga Yepanchintseva[1]; O Zharinov[2]; K Mikhaliev[3]; B Todurov[1]

[1]Heart Institute of the Ministry of Healthcare of Ukraine, Kiev, Ukraine; *[2]National Medical Academy of Postgraduate Education, Kiev, Ukraine*; *[3]State Scientific Institution "Scientific and Practical Center of Preventive and Clinical Medicine", Kiev, Ukraine*

Purpose: to study clinical characteristics of patients with stable coronary artery disease (CAD) in groups with different dynamics of left ventricular (LV) ejection fraction (EF) after coronary artery bypass grafting (CABG); to assess LV EF dynamics after CABG in groups with different baseline value (grade) of LV EF.

Methods: We conducted a prospective single-center study and enrolled 384 patients with stable CAD, selected for CABG (328 (85,4%) males and 56 (14,6%) females, age 39-92; average age (61±8) years. We analyzed demographic, clinical, laboratory, echocardiographic, coronary angiographic, intra- and postoperative data. The changes of LV EF were evaluated at period 1 (between 6 and 12 months after CABG) and period 2 (24 months after CABG). The total sample of enrolled patients were subdivided retrospectively into three groups according to the LV EF change: 1) 1st – LV EF relative change of ≥10% towards its improvement (n=110 [28,7%]); 2) 2nd – "without change" (LV EF relative change up to 10% in both directions; n=207 (53,9%); 3) 3rd – LV EF relative change of ≥10% towards its decline (n=67 [17,4%]). LV EF at both follow-up periods was assessed in 128 (33,3%) patients. The sample of 128 patients was used for LV EF change evaluation depending on baseline LV EF grade: LV EF ≥50% (n=35; 27,3%); LV EF 40-49% (n=27; 21,1%) and LV EF <40% (n=66; 51,6%). Numeric data were presented as median with interquartile range.

Results: Group 3, compared to the pooled group 1 and 2, was characterized by the higher frequency of patients with HF stage C2 (modified AHA/ACC classification, 2007): 20/67 (18,2%) vs. 10/274 (3,6%), respectively (0,001). The baseline LV EF in group 1 was significantly lower compared to that in groups 2 and 3: 37% (32-47%), 55% (45-62%) and 52% (38-59%), respectively (0,001 for both comparisons). The frequency of patients with preserved LV EF (≥50%) was lower in group 2, as opposed to groups 2 and 3. Group 3, in contrast to groups 1 and 2, was characterized by the higher value of end-systolic LV volume (and its index), as well as the higher frequency of patients with mitral and tricuspidal regurgitation. At period 1, the structure of the sample of 128 patients by LV EF grades was as follows: LV EF ≥50%, 40-49% and <40%, respectively, 54 (42,2%) patients, 38 (29,7%) and 36 (28,1%). At period 2 we observed the shift towards increased frequency of patients with LV EF <40% (55 (43,0%) patients).

Conclusions: The LV EF improvement at different follow-up periods was associated with worse baseline LV EF and more prevalent HF stage C2 cases. The LV EF dynamics in patients with baseline LV EF <50% was "biphasic": the initial LV EF improvement or recovery was subsequently shifted to its decline in part of the patients. The determination of predictors of different LV EF dynamics patterns is crucially important for individualized management of post-CABG patients.

P885

Predictors of left ventricular systolic recovery may depend on patients' age

J Pereira[1]; I Albuquerque[1]; V Guiomar[1]; A Monteiro[1]; C Gomes[1]; I Ferreira[1]; S Tavares[1]; V Chaves[1]; P Lourenco[1]; P Bettencourt[2]

[1]Sao Joao Hospital, Department of Internal Medicine, Porto, Portugal; *[2]Faculty of Medicine University of Porto, ;Internal Medicine Department,Hospital da CUF; Internal Medicine Department,Centro Hospitalar S.João, Porto, Portugal*

Background: The prognostic impact of left ventricular functional recovery(LVF-Rec)is unclear and its predictors are still understudied.PURPOSE:to evaluate predictors of LVF-Rec in a cohort of ambulatory Heart Failure(HF)patients and to study the influence of age on those predictors.

Methods: We analyzed patients followed in our HF clinic from 2002 to 2015 who had at least 2 echocardiograms performed during the follow-up period.A total of 304 patients with left ventricular ejection fraction(LVEF)<50% and an echocardiographic re-evaluation with no intervention(revascularization or surgical valve correction)between images were included.Systolic dysfunction was categorized:severe(LVEF <30%),moderate(LVEF 30-39%),mild(LVEF 40-49%).Recovery(HF-rec)was considered when systolic dysfunction improved at least one category even when no full recovery(LVEF >49%)was attained.HF-rec and non-recovered patients were compared.Multivariate logistic regression models were built to determine independent predictors of recovery.The analysis was then stratified according to patient's age(cut-off 70 years).

Results: Most patients were male(71.1%),mean age 66(±14),71.7% had severe systolic dysfunction at first evaluation.Between echocardiogram re-evaluation(median time:34 months),150 patients(49.3%)showed no LVEF recovery or even worsening and 154(50.7%) recovered.HF-rec patients were less often male(61.7%vs80.7%, p<0.001),more often had history of arterial hypertension(61.7%vs50.0%, p=0.04)and less often had ischemic aetiology(25.3%vs46.0%, p<0.001).HF-rec patients had smaller end-diastolic left ventricular diameter(EDLVD) (59±8vs65±9mm, p<0.001),lower serum creatinine(median 1.00vs1.13mg/dL, p=0.003)and lower loop diuretic dose(median 60vs80mg/day, p=0.04).Independent predictors of LVF-Rec(model 1 included:gender,ischemic aetiology,EDLVD≥60mm,age,arterial hypertension history,severe initial systolic dysfunction,serum creatinine ≥1.5mg/dL and B-type natriuretic peptide)were female gender(OR: 2.17, 95% CI 1.11-4.35, p=0.02),non-ischemic aetiology(OR: 2.78, 95% CI 1.35-5.56, p=0.005),and EDLVD<60mm (OR: 3.12, 95% CI 1.56-6.25, p=0.001).If prognostic modifying therapy and diuretic dose were included in the model(model 2)results would be similar.When the analysis was stratified according to patients' age(cut-off 70):in the younger group of patients,gender,ischemic aetiology and EDLVD were still independently associated with recovery;however in patients ≥70 years only a smaller EDLVD remained an independent predictor of LVF-Rec.

Conclusions: Females,patients with non-ischemic HF and those with EDLVD<60mm have higher probability of LVF-Rec.Age appears to influence

the predictors of recovery.In elder patients only a smaller EDLVD predicts recovery while gender and aetiology appear to be less important.Our results highlight the relevance of ventricular remodeling in systolic function recovery-patients with less severe remodeling have more 3-fold higher probability of functional recovery.

P886

Mitral annular plane systolic excursion and peak systolic shift are simple echocardiographic parameters to detect left ventricle systolic dysfunction in heart failure

D Dina Shorikova[1]; A Gabrielyan[2]; E Shorikov[1]
[1]*Bucovinian State Medical University, Chernivtsy, Ukraine*; [2]*National Institute of Surgery and Transplantology n. a. O. O. Shalimov, Kyiv, Ukraine*

The most important method for left ventricular state determination in patients with coronary heart disease is regional contractility assessment. However, evaluation of local contractile capacity by echocardiography is rather subjective method. Strain Rate imaging gives more possibilities because consists of multiple analysis for each segment of myocardium.
Materials and methods. We have learnt the regional contractility of 145 patients with ischemic heart disease. Tissue doppler imaging, strain rate imaging and angioventriculography were performed for all people. For strain rate imaging wall motion tracking (WMT) with 4Ch Tracking option was used.
Results. Graphes of longitudinal (Sl) and transmural (St) shift for each segment were obtained. The correlation coefficient (Pearson) r between mitral annulus excursion (MAE) and ejection fraction (EF) of left ventricle was 0,88. The linear regression model is presented as EF=5,0145*MAE+0,8946.
The results of sensitivity, specificity, positive and negative prognostic value for peak systolic shift, mitral annulus excursion and ejection fraction in predicting left ventricle contractility in compare with angioventriculography data are presented in the table. The highest diagnostic level was established for longitudinal peak systolic shift in basal segments (Sl) for the value 6,9 mm with sensitivity 83,7%, specificity 96,8%, diagnostic value 85,4%, and mitral annulus excursion for the value 11 mm with sensitivity of 74,4%, specificity of 100%, diagnostic accuracy of 81,2%.
Conclusion: the parameters of peak systolic shift in basal segments and mitral annulus excursion have high sensitivity, specificity and diagnostic value for assessment of left ventricle contractility at patients with coronary heart disease.

Diagnostic value				
	Sl	St	Mitral annulus excursion	EF
Prognostic value	7,0 mm	6,9 mm	11 mm	**55%**
Sensitivity, %	**83,7**	**54**	**74,4**	**66,3**
Specificity, %	**96,8**	**90**	**100**	**100**
Positive prognostic value	**98,6**	**91,9**	**100**	**100**
Negative prognostic value	**65,2**	**48,3**	**58,5**	**51,7**
Diagnostic value, %	**85,4**	**65,6**	**81,2**	**75,2**

P887

Left ventricular myocardial non-compaction associated with hypertrophic cardiomyopathy: mutation range, life-threatening complications and outcomes

N Nadiia Rineiska[1]; S Komissarova[1]; N Chakova[2]; C Niyazova[2]; V Prybylskaya[3]
[1]*Republican Scientific and Practical Centre of Cardiology, Minsk, Belarus*; [2]*Institute of Genetics and Cytology of the National Academy of sciences of Belarus, Minsk, Belarus*; [3]*Minsk Consulting and Diagnostic Center, Minsk, Belarus*

Purpose: to assess the range of mutations, life-threatening complications and outcomes in patients with phenotype of hypertrophic cardiomyopathy (HCM) associated with left ventricular myocardial non-compaction (LVNC).
Methods: the research included 280 patients with HCM (184 men and 96 women, median age 44.6±16.0 years). Eleven (3.9%) of them underwent echocardiography and cardiovascular magnetic resonance (CMR) presented with phenotype of HCM/LVNC associated (6 men and 5 women, median age 43±11 years). Mutation search was carried out by the next generation sequencing (NGS) in 8 patients.
Results: presence of LVNC in patients with HCM was followed by the heavier clinical manifestations: functional class (FC) of heart failure (HF) NYHA 2.8±0.01 against 2.2±0.02, p<0.05, lower LV EF of 43.5±2.4% against 67.5±5.6%, p<0.001, higher frequency of ventricular arrhythmias (80% against 45.8%, p<0.001). For the observation period (median of observation - 6.7 years) implantable cardioverter defibrillator (ICD) was implanted in 4 patients with unstable ventricular tachycardia (UVT), in two of them were noted numerous operations of ICD. Life-threatening arrhythmias were registered in 2 patients against the background of the manifesting WPW syndrome; radiofrequency ablation (RFA) of additional connection was executed. Within a period of observation adverse patient outcomes were registered in 3 cases: 1 patient was diagnosed with sudden cardiac death (SCD) against the background of operation of ICD, lethal outcome occurred due to HF progression to III FC NYHA and development of thromboembolic events in 2 patients.
All the patients with phenotype of HCM/LVNC associated underwent genetic analyses. There was revealed pathogenic mutation p.Gln1233 * and options with the uncertain clinical importance of p.Arg346His, p.Ala1255Thr in MYBPC3 gene; pathogenic mutations of p.Arg663His and Glu930del in MYH7 gene and also a combination of two mutations: p.Arg502Gln in a gene of MYBPC3 and p.Arg1712Trp in MYH7 gene. It should be noted that the registered options in sarcomere genes are associated with development of HCM, at the same time mutations of p.Arg663His and Gln1233 * in a gene of MYBPC3 were detected by us earlier in patients with HCM and without signs of LVNC. Also the mutation with the uncertain clinical importance c.298+1G> C (rs780476936), leading to the disturbance of splicing, in NEXN gene coding nexilin F-actin binding protein was revealed. There were no mutations in analyzed genes in 1 (12.5%) out of 8 patients.
Conclusion: phenotype of HCM/LVNC associated is characterized by the high risk of life-threatening arrhythmias development, SCD and HF progression. The mutations identified in patients with such phenotype are associated with HCM. However, these mutations are not unique markers of the combined genotype because they were detected in patients with HCM and without LVNC.

P888

Left ventricular diastolic dysfunction in patients with paroxysmal atrial fibrillation

AR Aida Babaeva[1]; EA Slepukhina[1]; SI Davidov[1]; NS Kondruchaya[1]; YV Zaharov[1]
[1]*Volgograd State Medical University, Volgograd, Russian Federation*

Background: Heart failure (HF) and atrial fibrillation (AF) are very common clinical conditions linked by similar risk factors and pathogenic mechanisms preferably structural cardiac remodeling and rate-related left ventricular function impairment. The strict diagnosis of HF with preserved ejection fraction (HF-PEF) in pts with concomitant AF still remains a clinical challenge due to symptoms similarity and raised natriuretic peptide levels in both conditions. Evaluation of HF on the basis of diastolic dysfunction in AF is crucial in term to prevent HF deterioration and to improve outcome.
The purpose of our clinical study was to evaluate LV diastolic dysfunction in pts with paroxysmal AF (PAF) presenting or not with LVHF.
Methods: 196 patients, 111 women and 85 men aged from 47 to 75 years with PAF were enrolled in the study. Patients were divided into two demographically comparable groups, depending on the presence or absence of typical HF symptoms and signs in the setting of AF and when PAF was stopped. There were 120 pts in the 1st group: 70 women and 60 men aged from 48 to 71 years. The 2ndgroup included 76 pts: 41 female and 25 male, aged from 47 to 75 years. All subjects underwent echocardiographic examination after PAF stopping. The diagnosis of LVHF and its severity was proved on the basis of respiratory rate (RR), clinical and radiologic signs of the pulmonary congestion, and the brain natriuretic peptide (BNP) levels. The DD was diagnosed according to the recommendations of the American Society of Echocardiography in conjunction with the European Association for Cardiovascular Imaging (2016).
Results: In the 1st group LVHF manifested as pulmonary edema in 5 pts (4.16%), in 18 pts (15%) there were clinical and radiologic signs of pulmonary bed congestion. The mean levels of BNP was 74.84±6.28 pg/ml in the 1stgroup and 56.27±7.19 pg/ml (p>0.05) in the 2nd group. All patients from the 1st group were diagnosed having DD of different degrees 7.5% of pts had grade 3, 57.88% had grade 2 and 41.66% had grade 1 DD. In the 2nd group 13.16% of pts had not evidence of LVDD, 1-2 degree LVDD was found in 72.37% and 14.47% of cases respectively. The frequency of 2-3 degree DD recording in two groups differed significantly by the χ^2-test. Significant differences in the mean DD values between groups were obtained: the mean maximal tricuspid regurgitation velocity was 4.42±0.76m/s vs 2.73±0.64m/s, the mean E/e' ratio was 19.5±1.89 vs 10.29±2.01 (p<0.05), the mean PAP accounted for 62.38±3.55 mm Hg vs 41.86±3.94 (p<0.05).
Conclusion: PAF even in the absence of clinical futures of HF is associated with LVDD. The degree of LVDD reflects the manifestation and severity of LVHF in observed cohort.

P889

Left ventricle diastolic dysfunction in ambulatory patients with atrial hypertension

VV Kirillova[1]
[1]*Ural State Medical Academy, Ekaterinburg, Russian Federation*

Three or four from four criterias (septal e' < 7 cm/sec, lateral e' < 10 cm/sec), average E/e' ratio > 14, left atrial volume index (LAVI) > 34 mL/m2, and peak TR velocity > 2.8 m/sec) need for diagnosis diastolic dysfunction in the presence of normal left ventricle ejection fraction.

Purpose: Investigating the frequency of diastolic dysfunction in the presence of normal left ventricle ejection fraction in ambulatory patients with arterial hypertension.

Materials and methods. The study included 129 ambulatory patients with arterial hypertension aged 66,92±0,97. The control group included 55 people without cardiovascular disease (aged 37.1±1.3). The left ventricular diastolic dysfunction patterns was detected by E/A and e'/a' ratios. The left ventricular diastolic dusfunction was assessed using septal and lateral e', average E/e' ratio, LAVI and systolic pressure of pulmonary artery (SPAP).

Results: The studied patients had a pattern of left ventricular diastolic dysfunction type 1 in 102 cases (E/A-0.72±0.01; e'/a' septal - 0.61±0.01; e'/a' lateral - 0.63±0.02), a pattern of diastolic dysfunction type 2-in 27 cases (E/A-1.26±0.04; e'/a' septal -0.75±0.05; e'/a' lateral-0.77±0.07) compared with the control (E/A – 1.69±0.05; e'/a' septal – 1.54±0.05; e'/a' lateral – 1.84±0.08). Diastolic dysfunction was diagnosed in 23 patients (18%): 6 of them had four criteria (E/e' – 22,97±2,38; e' septal – 4,7±0,41; e' lateral – of 7.02±0,59; LAVI -81,67±5,64; SPAP 43,83±3,24); 17 patients had three criteria (E/e' – 9.23±0.78; e' septal – 5.71±0.30; e' lateral – 8.16±0.42; LAVI - 81.9±6.87; SPAP 32.92±1.96). 83 patients (64%) had two criteria of four: (E/e' – 10,25±0,46; e' septal – 6,69±0,21; e' lateral – 8,82±0,23; LAVI - 38,97±0,68; SPAP 20,48±0,60), that is diastolic dysfunction indeterminated. The remaining 23 patients (18%) had one or no signs (E/e' – 8,7±0,49; e' septal – 7,64±0,28; e' lateral – 9,82±0,3; LAVI -22,73±0,21; SPAP 19,25±1,33), that is, had normal diastolic function.

Conclusions. Thus, in only 18% of cases ambulatory patients with arterial hypertension with left ventricular diastolic dysfunction patterns have criteria of diastolic dysfunction; in 64% of cases diastolic dysfunction indeterminated.

P890

Tissue doppler E/E ratio, a predictor of in-hospital complications in acute myocardial infarction

J Joao Santos[1]; H Antunes[1]; L Abreu[1]; I Pires[1]; L Goncalves[1]; I Almeida[1]; E Correia[1]; G Pereira[1]
[1]*Hospital Sao Teotonio, Viseu, Portugal*

Introduction: Diastolic dysfunction is an early finding in patients presenting with acute myocardial infarction (AMI), often heralded by an increase in E/E' ratio. The purpose of this study was to assess the relationship between the E/E' ratio and in-hospital complications (IHC) in AMI.

Methods: A retrospective analysis of 250 patients admitted to a Cardiology ward diagnosed with AMI was performed. The primary endpoint was defined as the composite of re-infarction, stroke, mechanical complications (MC), heart failure (HF), acute kidney injury (AKI) and/or arrythmia. Mann-Whitney U test was used for mean comparison between variables. Two different multivariable logistic regression (MRlog) models were applied, one evaluating the effect of other echocardiographic variables besides E/E' ratio (left ventricular ejection fraction – LVEF, pulmonary artery systolic pressure – PASP, telediastolic diameter of left ventricle and left atria diameter) and the other one evaluating the effect of clinical variables (age, obesity, history of hypertension and diabetes mellitus) on IHC. A Pearson analysis was performed to evaluate correlation between variables.

Results: IHC occurred in 158 patients (63%). 73% of patients in the population were male, and the mean age was 69 (±13) years. HF occurred in 51% of patients, arrythmias in 22%, AKI in 11% and MC in 1%. No re-infarction/stroke was noticed. Mann-Whitney U test revealed a statistically significant association between E/E' ratio and IHC (p<0.001). The MRlog using the echocardiographic variables above mentioned demonstrated a statistically significant result for E/E' ratio (p=0.016 – Exp(B): 0.847) and for PASP (p=0.009 – Exp(B): 0.906). The MRlog model that included clinical variables demonstrated that E/E' ratio retained predictive value for IHC (p=0.022 – Exp(B): 0.922). For each unit increase in E/E' ratio, the probability of not having an IHC decreases by 8-15%, according to the model used. The effect of E/E' ratio on IHC was mainly driven by the risk of developing HF (p=0.03, Exp(B):0.88). Pearson correlation test between variables did not achieve statistical significance, therefore an independent variation between them was admitted.

Conclusion: The increase in E/E' ratio is associated with a higher risk of IHC. E/E' ratio has predictive value in IHC risk, particularly HF, which is independent from the effect of other clinical and echocardiographic variables.

P891

Lack of consensus on the non-invasive diagnosis of diastolic dysfunction in individuals referred for cardiovascular screening

G B Gideon Bastien Valstar[1]; SH Bots[1]; FH Rutten[2]; MJ Cramer[3]; AJ Teske[3]; FW Asselbergs[3]; L Hofstra[4]; R Menken[5]; ML Bots[2]; HM Den Ruijter[1]
[1]*University Medical Center Utrecht, Laboratory of Experimental Cardiology, Utrecht, Netherlands (The)*; [2]*Julius Health Center - Julius Gezondheidscentra, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands (The)*; [3]*University Medical Center Utrecht, Dept. of Cardiology, Division of Heart and Lungs, Utrecht, Netherlands (The)*; [4]*VU University Medical Center, Dept of Cardiology, Amsterdam, Netherlands (The)*; [5]*Cardiology Center Netherlands, Location Utrecht, Utrecht, Netherlands (The)*

On behalf of: University Medical Center Utrecht, Utrecht University
Funding Acknowledgements: Supported by the Dutch Heart Foundation 2013T084 (Queen of Hearts) and Dutch Heart Foundation Grant CVON2014-11 RECONNECT.

Introduction: Left ventricular diastolic dysfunction (LVDD) is common and can progress to heart failure, notably with preserved ejection fraction (HFpEF). International consensus on diagnostic criteria for LVDD is crucial, however, multiple different criteria and cut-points exist.

Purpose: To assess the impact of three recent diagnostic recommendations on the prevalence and classification of LVDD.

Methods: The study population comprised 574 consecutive participants of an ongoing case-cohort study (HELPFul) enrolling patients (>45 years) referred to a cardiology clinic for cardiac evaluation. We evaluated the criteria in the 2018 Heart Failure Association (HFA) recommendations with the 2016 guidelines of the European Society of Cardiology (ESC) and the 2016 American Society of Echocardiography (ASE)/European Association of Cardiovascular Imaging (EACVI) guidelines. Patients with history of cardiac disease were excluded. Cardiac evaluation included natriuretic peptides and echocardiography.

Results: All LVDD criteria could be applied to 432 subjects, mean age 62.6 years (SD=9.3), 67% women. The prevalence of LVDD was 6.0% with 'HFA 2018', 24.3% with 'ESC 2016', and 2.1% with 'ASE/EACVI 2016'. Concordance of 'HFA 2018' with 'ESC 2016' and 'ASE/EACVI 2016' was 21.5%, and 28.2%, respectively. Upward classification with 'HFA 2018' occurred in 254 (58.8%) compared with 'ESC 2016' and in 305 (70.6%) compared with 'ASE/EACVI 2016'. Downward classification with 'HFA 2018' occurred in 85 (19.7%) compared with 'ESC 2016' and in 5 (1.2%) when compared to 'ASE/EACVI 2016'. The 'HFA 2018' classified 330 (76.3%) in an intermediate group. There were no substantial sex differences.

Conclusions: The prevalence of LVDD in our cohort varied considerably with prevailing international recommendations, making the impact of LVDD and HFpEF difficult to quantify. This hampers comparisons between different studies and in meta-analyses. Moreover, the 'HFA 2018' recommendations result in a large intermediate group requiring additional (invasive) imaging.

P892

Molecular and genetic markers a renin-angiotensin-aldosteron systems as predictors of development of a diastolic heart failure in patients with an obesity

T Tatiana Zaletova[1]; SA Derbeneva[1]; AR Bogdanov[1]; YG Panova[1]
[1]*Research Institute of Nutrition of Russian Academy of Medical Sciences, Moscow, Russian Federation*

Research objective: Searching of the molecular and genetic markers which are presumably involved in a pathogenesis of a secondary diastolic heart failure (DHF) at patients with an obesity.

Materials and methods: PCR-diagnostics of biomaterials (whole blood) of 104 patients with an obesity which were divided into 2 groups, depending on existence or lack of a diastolic heart failure was carried out. The following candidate genes were analyzed: gene of an angiotensinogen AGT (C521T and T704C), gene of an angiotensin II first type receptor AGTR1 (A1166C), gene of an angiotensin II second type receptor AGTR2 (G1675A), aldosteronsintaza gene CYP11B2 (C (-344)T). The maintenance of aldosteronum, renin, angiotensin II in patients' blood plasma was estimated.

Results: It is shown that development of secondary DHF in persons with an obesity of both sexes is associated with CYP11B2 aldosteronsintaza gene mutation, namely with replacement allele of C in the provision-344 on an allele of T and existence of a genotype of T/T. The relative risk of development of a disease at a genotype of T/T is increased by 5,93 times at men (=0,008) and by 4,57 times at women (=0,014).

For men AGT angiotensinogen gene mutation, namely replacement allele C in the provision 521 on T allele matters. At the same time, the relative risk of development of DHF at a genotype of T/T is increased by 4,26 times (=0,039). Mutations of genes of a angiotensin II first type receptor AGTR1 (A1166C) and angiotensin II second type receptor of an AGTR2 (G1675A) are not associated with development of DHF in patients with an obesity. It is established that patients with an obesity of the III degree and DSN, are characterized by authentically more high average level of plasma Aldosteronum (for 25,9%, <0,05) in comparison with patients without DHF; what is followed by the normal maintenance of a renin and angiotensin of II.
Conclusion: The submitted data can be used at stratification of risk of development of a secondary heart failure in persons with an obesity.

P893

Role of endothelin-1 in HFpEF-related ventricular and atrial remodeling

D David Bode[1]; P Deissler[1]; S Reimers[1]; F Schoenrath[2]; S Soltani[2]; C Stamm[2]; V Duesterhoeft[2]; C Knosalla[2]; V Falk[2]; BM Pieske[1]; FR Heinzel[1]; F Hohendanner[1]
[1]Charite - Campus Virchow-Klinikum (CVK), Innere Klinik m.S. Kardiologie, Berlin, Germany; *[2]German Heart Institute of Berlin, Department of Surgery, Berlin, Germany*

Introduction: Atrial remodeling is common in patients with heart failure and associated comorbidities (e.g. diabetes, metabolic syndrome) and has been shown to independently increase mortality. Endothelin-1 is a pro-fibrotic cytokine which is thought to be involved in the progression of cardiac remodeling. In contrast, ET-1 has also been shown to be a potent inotropic agent. We investigated the interplay between tissue ET-1 concentrations and cardiac function in patients with and without diabetes/obesity.
Methods: Right atrial appendages were collected from 9 patients undergoing cardiac surgery. Right atrial and ventricular contractile function were assessed using transthoracic echocardiography. Myocardial ET-1 of atrial appendages was quantified with an ELISA.
Results: Mean age of patients included was 63.3 ± 1.6 years. 44 % of patients were female and 78 % of patients were on ß-blockers and/or ACE inhibitors. The study cohort presented with a mean LVEF of 51.7 ± 0.8 % and a mean LAVI of 35.6 ± 1.8 %. In addition, mean right atrial and ventricular function were preserved (mean RVFAC 44 ± 1 %, RAEF 34.5 ± 1.6 %). Tissue ET-1 concentration was not significant different between control and diabetic patients (8.5 ± 1 vs. 9.8 ± 2.7 pg/ml; n.s.). Moreover, ET-1 was not related to body mass index, left atrial volume index or left ventricular function ($R^2 < 0.03$; $p < 0.05$). However, even though myocardial right atrial ET-1 was not related to right atrial ejection fraction ($R^2 = 0.2258$; n.s.), high concentrations of myocardial ET-1 significantly correlated with reduced right ventricular function (i.e. right ventricular fractional area change ($R^2 = 0.8692$; $p < 0.05$)). This indicates an important link between ventricular function and atrial hormonal activity.
Summary: Myocardial ET-1 was associated with ventricular contractile function. Atrial neurohumoral activation might represent the culprit for the vicious circle of ventricular dysfunction and atrial myocardial ET-1 release.

P894

Renal function in patients with different types of left ventricular remodeling after acute myocardial infarction

V Valentin Oleinikov[1]; L Salyamova[1]; O Kvasova[1]; T Aryasova[1]
[1]Penza State University, Penza, Russian Federation

Purpose: to study the functional capacity of the kidneys in patients with rapidly progressive remodeling of the left ventricle after acute myocardial infarction with ST segment elevation (STEMI).
Methods: The study included 86 patients with STEMI. Inclusion criteria was the presence of significant stenosis of only one coronary artery according to the coronary angiography results. The treatment in the framework of the study was carried out without a washout period with preservation of the prescribed pharmacotherapy for STEMI. The follow-up period was 48 weeks. At baseline and after 24, 48 weeks of follow-up, the creatinine level was determined on the analyzer Olympus AU400, the GFR was calculated using the CKD-EPI formula. In addition, patients underwent echocardiography with MyLab scanner (Esaote, Italy) with the determination of the end diastolic volume index (EDVi). Then the patients were divided into two groups. The first group included 51 people without echocardiographic signs of LV remodeling: the dynamics of EDVi after STEMI was <20%. Group 2 consisted of 35 patients with rapidly progressive LV remodeling (increase in EDVi by > 20%). The compared groups were matched by age, sex, anthropometric data, and treatment.
Results: In group 1, creatinine initially amounted to 91 [95% CI 86.9; 95.2], after 24 weeks - 90.5 [95% CI, 86.9; 94.1] (p = 0.83), 48 weeks - 93.6 [95% CI 88.3; 98.9] μmol / l (p = 0.25). GFR in this group was 82.3 [95% CI 78; 86.6], 82.9 [95% CI 98.8; 87] (p = 0.76), 80.2 [95% CI 75.7; 84.7] ml / min (p = 0.34). In group 2, the following creatinine values were identified: baseline - 86.2 [95% CI 79.7; 92.7], after 24 weeks - 90.1 [95% CI 84.8; 95.5] (p = 0.2), after 48 weeks - 93.9 [95% CI 87.7; 100.1] μmol / l (p = 0.02). GFR at hospital admission was 91.6 [95% CI 83.1; 100], after 24 weeks - 85.1 [95% CI 79.4; 90.8] (p = 0.08), 48 weeks - 83 [95% CI 77.5; 88.5] ml / min (p = 0.04).
Conclusions: a deterioration in renal function, manifested by an increase in creatinine and a decrease in GFR level has been revealed in STEMI patients with rapidly progressive left ventricular remodeling.

P895

Biomarkers of hemodynamics stress and development of adverse left ventricular remodeling in patients with acute primary myocardial infarction with ST segment elevation

M Kercheva[1]; T Ryabova[1]; A Gusakova[1]; T Suslova[1]; V Ryabov[1]
[1]Cardiology Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation

On behalf of: MASTARD

Background: To evaluate changes in serum levels of soluble ST2 (sST2) and N-terminal- probrain natriuretic peptide (NT-proBNP) and their association with the development of adverse left ventricular remodeling (LVR) during the six months after primary ST-segment elevation myocardial infarction (STEMI). Methods: Subjects were 31 patients with STEMI (median age, 59 yr), who underwent percutaneous coronary intervention (PCI) during the first 24 h of the onset of myocardial infarction (MI). Blood samples and parameters of echocardiography were assessed at days 1, 3, 7, and 14, and six months after STEMI. Results: Serum levels of sST2 decreased by 48% from admission to day 7. Serum levels of NT-proBNP decreased by 40% from day 7 to six months after STEMI. High sST2 serum levels were associated with the development of early LVR at timepoints T1-T3 (r=0.8; r=0.6, r=0.9, p<0.05, respectively) in the group with development of adverse LVR by six months after STEMI. The absence of decrease in NT-proBNP serum levels to 125 pg/mL by day 7 (r=0.69, p=0.04) was associated with the development of the adverse LVR by six months after STEMI.
Conclusions: Serum levels of sST2 and NT-proBNP decreased in the six months after STEMI. Significant decrease of the serum levels of sST2 occurred in the first 7 days; serum levels of NT-proBNP decreased after day 7. Elevated levels of both these markers on day 7 were associated with development of adverse LVR by 6 months after STEMI.

P897

Features emotional status at patient with ischemic heart disease and chronic heart failure and different types of left ventricle remodeling

A Alexey Ibatov[1]
[1]Sechenov Moscow medical academy , Moscow, Russian Federation

Purpose: to study emotional status at patients with ischemic heart disease (IHD) and chronic heart failure (CHF) and different types of left ventricle remodeling (LVR). Materials and methods: 91 men with IHD and CHF (II - IV function class on NYHA, and left ventricular ejection fraction < 45%) in the age from 42 till 65 years (average age 56.5+0.5 years) were examined. 51 patients with disadaptive left ventricle remodeling (DLVR) (end diastolic size index > 3.3 and relative wall thickness of LV < 30) were included in the first group. 40 patients with adaptive left ventricle remodeling (ALVR) (end diastolic size index > 3.3 and relative wall thickness of LV < 45, but > 30) were included in the second group. A level of anxiety and the depression were examined by the Hospital Anxiety and Depression Scale (HADS), personality characteristics - by the MMPI questionnaire. Results: The groups did not differ on age, duration IHD, function class of heart failure (NYHA). The patients with CHF and DLVR had 4.8±0.7 and 8.5±0.9 scores of anxiety and depression level accordingly. The patients with CHF with ALVR had accordingly 4.7±0.4 (p > 0.05) scores of anxiety level and 5.2±0,5 (p < 0.05) scores of depression level. The patients with CHF and DLVR had the such MMPI test parameters accordingly: on scale of Hypochondriasis – 62.3±2.1 scores; on scale of Depression – 51.4±3.9 scores; on scale of Hysteria – 54.7±2.8 scores; on scale of Psychopathic Deviate – 46.7±3.6 scores; on scale of Paranoia – 46.4±1.9 scores; on scale of Psychasthenia – 53.3±1.7 scores; on scale of Schizophrenia – 47.1±1.9 scores; on scale of Hypomania – 43.8±3.3 scores. The patients with CHF with ALVR had the such MMPI test parameters accordingly: on scale of Hypochondriasis – 55.7±1,4 scores (p < 0.05); on scale of Depression – 51.1±1.4 scores (p > 0.05); on scale of Hysterias – 49.9±1.1 scores (p > 0.05); on scale of Psychopathia Deviate – 44.5±0.9 scores (p > 0.05); on scale of Paranoia – 50.6±1.4 scores (p > 0.05); on scale of Psychasthenia – 46.8±1.6 scores (p < 0.05); on scale of Schizophrenia – 45.9±1.0 scores (p > 0.05); on scale of Hypomania – 42.1±1.4 scores (p > 0.05). Conclusion: the patients with ischemic heart with disease and chronic heart failure and disadaptive left ventricle remodeling had more high expressed accentuated personality characteristics and level of depression, in comparison with the patients

with a chronic heart failure with adaptive left ventricle remodeling, these data may negatively affect the prognosis of these patients and also these data must be considered when prescribing treatment.

P899

Interrelation of the clinical-functional state and parameters of myocardial remodeling with the functional state of the kidneys in patients with chronic heart failure

Z D Zulfya Rasulova[1]; UK Kamilova[1]; DR Tagaeva[1]; DR Masharipova[1]
[1]Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan

Purpose: To study the relationship between the clinical-functional condition and parameters of the myocardial remodelation and functional state of the kidneys in patients with chronic heart failure (CHF).
Methods: A total of 223 patients with I-III functional class (FC) of CHF were examined (patients were randomized to FC functional group CHF according to the six-minute walking test (SMWT) and the scale of assessing the clinical state of patients (SACS)). The mean age of patients was 62,3±5,6 years. Patients were divided into 2 groups depending on the estimated calculated the rate of glomerular filtration (cGFR) according to the formula MDRD: cGFR≤60 ml/min/1.73m2 - 67 patients and cGFR≥60 ml/min/1.73m2 - 156 patients. All patients, along with general clinical methods of evaluation, were evaluated: SACS, SMWT, quality of life (QOL), echocardiography (EchoCG) with determination of structural and geometric parameters, systolic and diastolic LV function, serum creatinine (Cr).
Results: In patients with CHF, as the disease progresses, there is a significant impairment of the functional state of the kidneys, characterized by a decrease in cGFR≤60 ml/min/1,73m2, which are early biochemical predictors of dysfunction of the kidneys (DK) in patients with CHF. There was a decrease in cGFR≤60ml/min/1,73m2 in 30% of patients with CHF. Patients with CHF with progression of the disease have worsened kidney function, clinical course of the disease, accompanied by a decrease in exercise tolerance for SMWT and deterioration in the QOL, which was most pronounced in patients with DK. The inverse high correlation dependence of SMWT with the SACS indexes (r=-0,91) and the total index (TI) of the QL (r=-0,86) was revealed; there was an average positive correlation between the rates of cGFR and SMWT in patients with cGFR≤60 and cGFR≥60 ml/min/1,73 m2 (r=0,41, r=0,48); in patients with cGFR≤60 ml/min/1,73 m2, the SMWT values were reliably lower by 14,1% (p<0,005), and the SACS was 16% higher (p<0,005) compared to those in patients with cGFR≥60 ml/min/1,73 m2. The relationship between diastolic and systolic function and cGFR parameters was established: the early filling rate of the LV - E in patients with cGFR≤60 ml/min/1,73m2 by 6,7% (p<0,05), LVEF by 8,3% (p<0,05) is lower, and the final systolic volume is 9,8% (p<0,05) higher in comparison with these parameters in patients with cGFR≥60 ml/min/1,73m2. The mean positive correlation between cGFR and the rate E (r=0,38, r=0,46) and between cGFR and LVEF (r=0,40, r=0,38) was noted in the groups of patients with cGFR≤60 and cGFR≥60 ml/min/1,73 m2.
Conclusions: In patients with CHF Interrelation of the clinical-functional state and parameters of myocardial remodeling with the functional state of the kidneys was established.

P900

LV global longitudinal strain as a predictor for LV reverse remodeling in dilated cardiomyopathy

IH Jung[1]
[1]Inje University, Gimhae-si, Korea (Republic of)

Background The prognosis of dilated cardiomyopathy (DCM) has significantly improved in the past few years, mostly as the result of successful therapy-induced reverse remodeling. The aim of this study is to investigate the predictors of left ventricular reverse remodeling (LVRR) in DCM patients with normal sinus rhythm.
Method We reviewed medical records and analyzed echocardiographic data of 143 DCM patients who had been first diagnosed, evaluated, and followed at our institute between Mar. 2013 and Aub. 2017. We defined LVRR as improvement of LVEF ≥10% point and decrease in LVEDV ≥10% as suggested in previous studies.
Results The mean age was 64.6 years. During the median follow-up period of 40.0 months, LVRR developed in 37 patients (25.9%). Mean LVEF was 27.4 ± 7.6% at entry and 35.2 ± 12.5% at last follow up (mean increase 7.8 ± 13.6%, p<0.001). By multivariate regression analysis, only LVGLS independently predicted the LVRR (hazard ratio= 1.340, 95% CI; 1.060-1.693, p=0.014). Receiver-operating characteristic curve analysis showed that the optimal LVGLS cut-off value to identify the patients with LVRR was -11.5% (AUC=0.770, 95% CI; 0.674-0.865, p<0.001)
Conclusion GLS was an independent predictive factor for LVRR in DCM patients with sinus rhythm.

Evolution of LV remodeling geometry and insulin resistance indices under conventional active medication on RAS: ramipril and eprosartan

N Nadejda Sapojnic[1]; AP Caraush[1]; CD Roibu[2]; MP Caraush[3]; V Moscalu[1]
[1]Institute of Cardiology , Hypertension, Chisinau, Moldova (Republic of); *[2]Institute of Neurology and Neurosurgery, Stroke, Chisinau, Moldova (Republic of)*; *[3]Rehabilitation Hospital, Cardiovascular Recovery, Iasi, Romania*

Funding Acknowledgements: Academy of Sciences of Moldova

In hypertensive patients, LVH and insulin resistance (IR) often coexist, amplifying development of TOD and HF. Therapeutic strategies should aim BP values, LVH , IR and RAS inhibitors would be "drug of choice" for such combinations.
Objective: To compare the effects of an ARB-based regimen with eprosartan and ACEI ramipril on LVH and IR in hypertensives with preserved EF.
Methods: 101 hypertensives (48,51% of men; 51,1±0,71 yrs) with LVH and IR were randomly assigned to ramipril (R-gr; n=56, mean dose=15,3mg±1,2 mg/d) or eprosartan (E-gr; n=45, mean dose=850±12,4 mg/d). ABPM, TTE, and HOMAIR were performed (baseline, 6, 12- months). LVMI> 95 g/m2 in women and >115 g/m2 in men identified LVH. Relative wall thickness (RWT >0.42) categorize geometry of

Fig.1 Baseline characteristics of groups

LV remodeling. To define IR was used HOMAIR levels > 2.5. Results: LV remodeling indices have a beneficial evolution in both study groups, but more significant (p<0.05) in the E-gr. After 12 months, number of patients in E-gr, who expressed normal pattern of LV geometry, appears to be almost twice higher compared to R-gr. Both therapeutic regimens have gradually improved HOMAIR values (p<0.001), but with greater reduction in Egr (p<0.001) (Tab.1)

Conclusion: Both drug-regiment progressively improve hypertensive LV geometry and IR indices, but with greater efficiency in the Eprosartan-medicated arm, probably due to additional sympatholytic effect of its moiety

P902

Impact of sacubitril/valsartan on reverse cardiac remodeling in Taiwan population

CT Liao[1]; MC Lee[2]; FH Kuo[1]; HS Toh[3]; WT Chang[1]; ZC Chen[1]

[1]Chi-Mei Medical Center, Cardiology, Tainan, Taiwan, Province of China; *[2]Chi-Mei Medical Center, Department of pharmacology , Tainan, Taiwan, Province of China*; *[3]Chi-Mei Medical Center, Department of intensive care unit, Tainan, Taiwan, Province of China*

Background: Sacubitril/valsartan is an angiotensin receptor and neprilysin inhibitor (ARNI), which benefits the patients with heart failure and reduced ejection fraction (HFrEF). The literature of ARNI impact on cardiac remodelling for Asian is sparse.

Purpose: The objective of this study is to use echocardiography to evaluate the effect of ARNI on the cardiac remodelling of the HFrEF patients using echocardiography in Taiwan population.

Methods: We performed a retrospective study of 136 HFrEF patients using ARNI during the period from 1 November 2016 to 30 November 2017. Data including clinical characteristic, comorbidity, medications, renal function, NT-pro B-type Natriuretic Peptide (NT-BNP) and New York Heart Association (NYHA) functional class of the patients were collected. Besides, we analysed the relevant echocardiography parameters of left ventricle (LV) and right ventricle (RV), which indicating cardiac remodelling before and six months after using ARNI.

Results: A total of 136 patients with HFrEF were analysed in the given period. The study population mean age was 69.6 ± 11.6 years and men made up 82% of them. NYHA class II, III and IV constituted 21.3%, 67.6%, and 11.1%, respectively.LV ejection fraction (LVEF) significantly increased (34.7% vs 41.8%, p<0.001) and LV mass index (LVMI) reduced obviously (100.7g/m2vs 74.3g/m2, p<0.001) after six months of ARNI therapy. Parameters indicated the systolic function of LV also showed noticeable improvement, including LV internal diameter end-systole (LVIDs, 5.37cm vs 4.99cm, p<0.001), LV end-systolic diameter (LVESD, 5.31cm vs 4.98cm, p<0.001), LV end-systolic volume (LVESV, 157.7ml vs 122.7ml, p=0.011). The size of left atrium was also found to have reduced (4.43cm vs 4.23cm, p=0.014). However, LV end-diastolic volume (LVEDV), LV end-diastolic diameter (LVEDD), E/A ratio and RV S' have no statistical difference after six months. Conclusions: TheHFrEF population treated with ARNI have statistically significant improvement in LA size, LVEF, LVMI, LVIDS, LVESD, and LVESV after six months. This result emphasised the effectiveness of ARNI on LV reverse remodelling process in the Asian population. However, larger cohort studies are needed to confirm the results and to ensure the role of ARNI in the management of patients with heart failure.

Right ventricular outflow tract hypertrophy assessment as a diagnostic stratification tool in patients with pulmonary hypertension

I Aguiar Ricardo[1]; R Placido[1]; J Agostinho[1]; T Guimaraes[1]; J Rigueira[1]; R Santos[1]; A Nunes-Ferreira[1]; N Cunha[1]; T Rodrigues[1]; S Pereira[1]; P Silverio-Antonio[1]; AG Almeida[1]; S Martins[1]; N Lousada[1]; FJ Pinto[1]

[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology, Lisbon, Portugal

Introduction: The right ventricle (RV) is a complex structure whose geometry changes in the presence of pulmonary hypertension (PH). The impact of chronic RV pressure overload on its remodeling process and the relationship with the hemodynamic phenotype and clinical group of PH is not stablished.

Purpose: To evaluate the relationship between the RV outflow tract (RVOT) thickness and the hemodynamic phenotype and clinical characteristics of PH patients.

Methods: Longitudinal observational study of consecutive patients with diagnosis of PH, based on hemodynamic criteria, and submitted to a high-resolution CT pulmonary angiography. PH was defined as pre-capillary [pulmonary arterial wedge pressure (PAWP) of 15 mmHg or lower], isolated pos-capillary [PAWP higher than 15 mmHg and diastolic pressure gradient (DPG) less than 7 mmHg] or combined pos-capillary (PAWP higher than 15 mmHg and DPG of 7 or more). The thickness, in millimeters, of the RVOT was measured in sagittal planes. The values obtained were compared with patient's hemodynamic profile, clinical classification (Nice 2013), WHO functional class and the presence of signs of heart failure (HF) at presentation.

Results: 78 patients were included, 69.2% females, with mean age 67 years old (IQR:26). 76% had pre-capillary PH, 21% combined post-capillary PH and 4% isolated post-capillary PH. Based on the clinical classification, 50% of the patients belonged to group 4, 28% to group 1, 11% to group 3 and 6% to group 2. The RVOT thickness did not differ significantly according to the WHO functional class, presence of right-sided HF signs at presentation or with hemodynamic classification. However, considering the clinical classification, the RVOT thickness varied significantly between groups (group 1: 6,1±1,7mm; group 4: 5,6±1,2mm; group 3: 5,2±1,2mm; group 2: 3,5±0,3mm, p=0,002). By analysis of variance, it was verified that this variation was due to the lower thickness of the RVOT in group 2 when compared with the other groups (versus group 1, 3 and 4; respectively p<0,001, p=0,004 and p<0,001).

Conclusion: The thickness of RVOT varies between clinical groups of PH, being significantly lower in patients from the group 2 patients. Based on this result we concluded that this parameter is useful in the diagnostic and etiological evaluation of patients with PH.

P904

The blood levels of apelin and angiotensin-(1-7) and their interrelations with parameters of left ventricular remodeling in patients with hypertension and type 2 diabetes

K Iushko[1]; S Koval[1]; I Snihurska[1]; T Starchenko[1]; D Miloslavskiy[1]

[1]L.T.Malaya Therapy National Institute of the National Academy of Medical Science of Ukraine, Department of Hypertension, Kharkiv, Ukraine

Introduction: The left ventricular (LV) remodeling and LV hypertrophy (LVH) are the initial stages of the development of the heart failure in patients with hypertension. The apelin and angiotensin-(1-7) are the functional antagonists of renin-angiotensin-aldosterone system and the important protective cardiovascular peptides, but their role in the development of LV remodeling in such comorbidities pathology as hypertension and type 2 diabetes (T2D) is not clear enough.
Purpose. The aim of the study was to determine the blood levels of apelin and angiotensin-(1-7) in patients with hypertension and T2D and to investigate their interrelations with parameters of LV remodeling.
Methods: The study involved 76 patients with hypertension of 2-3 degrees with concomitant T2D (37 men and 39 women) aged 40 to 70 years. The investigation complex included general clinical examination methods, the echocardiography with determination of the LV internal dimension at end diastole (LVIDed), septal wall thickness at end diastole, posterior wall thickness at end-diastole and calculation of the relative wall thickness, the LV mass (LVM) and LVM index. The LVH we determined according 2018 ESH/ESC Guidelines. Control group consisted of 21 healthy volunteers. The blood levels of the apelin and angiotensin-(1-7) determined using ELISA.
Results: Both the apelin and angiotensin-(1-7) levels in patients with hypertension and T2D were significantly lower than in control group (0,874(0,840;0,926) ng/ml versus 1,097(0,963;1,179) ng/ml, p<0,001 and 105,51(89,13;121,17) ng/l versus 132,75(125,06;142,87) ng/l, p<0,05, respectively). In patients with LVH the levels of apelin and angiotensin-(1-7) were significantly lower than in patients without LVH (0,866(0,788;0,924) ng/ml versus 0,917(0,892;0,984) ng/ml, p<0,05 and 129,3(117,5;136,8) ng/l versus 101,9(88,2;117,7) ng/l, p<0,01, respectively). The correlation analysis revealed significant negative relationships of the apelin levels with SWTd (r=-0,50, p<0,001), PWTd (r=-0,46, p<0,001), RWT (r=-0,29, p<0,05), LVM (r=-0,39, p<0,01) and LVM index (r=-0,42, p<0,001) and significant negative relationships of the angiotensin-(1-7) levels with LVIDed (r=-0,37, p<0,01), LVM (r=-0,40, p<0,001) and LVM index (r=-0,41, p<0,001).
Conclusion. The study showed, that in patients with hypertension and T2D observed decreasing of the blood levels of apelin and angiotensin-(1-7), particularly in the presents of LVH and their negative correlations with main parameters of LV remodeling, that indicating the patogenetic role of these peptides in progression of heart lesion.

P905

Bone morphogenetic protein and adverse left ventricular remodeling in patients with acute primary STEMI

M Kercheva[1]; T Ryabova[1]; T Suslova[1]; A Gusakova[1]; V Ryabov[1]
[1]Cardiology Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences, Tomsk, Russian Federation

On behalf of: MASTARD

Purpose: to study the dynamics of serum levels of bone morphogenetic proteins (BMP)-2 and BMP-4 and its association with a development of adverse left ventricular remodeling (LVR) in patients with acute primary anterior myocardial infarction with ST segment elevation (STEMI).
Methods: 21 patients with STEMI (mean age 60.4±7.4) were enrolled. All patients underwent percutaneous coronary intervention during 24 hours from onset, in 34% of patients it was during the first 3 hours. Blood samples and echocardiography data were performed on the days 1 (T1), 3 (T2), 7 (T3), 14 (T4) and through 6 months after STEMI (T5). The serum levels of BMP-2 and BMP-4 were determined by the immunoassay. In addition we assessed levels of troponin I, creatine phosphokinase-MB (CPK-MB), matrix metalloproteinases (MMP)-2, 9, high-sensitivity C-reactive protein (hCRP), soluble suppression of tumorigenicity-2 (sST2), N-terminal pro brain natriuretic peptide (NTproBNP) in the same terms. End-diastolic (EDV) and end-systolic (ESV) volume, ejection fraction (EF) of LV were determined by a Simpson method. Adverse LVR was established when values of EDV or/and ESV LV increased in 20% from admission to 6 months period.
Results: Serum levels of BMP-2 decreased on 50% from hospital period to 6 months after MI (p<0.05): 38 (T1)→28 (T2)→32 (T3)→36 (T4)→11 pg/ml (T5). The dynamics of BMP-2 in hospital period was not revealed. Level of BMP-2 in the group without adverse LVR decreased from the first 7 days after MI to 6 months period: from 41 to 21 pg/ml (p<0.05).
High level of BMP-2 in this group at 14th day was associated with a large values of EDV LV (r=0.7, p<0.05). The level of BMP-2 at the admission was associated with reperfusion time (r=-0.8, p<0.05), with levels of MMP-9 and hCRP at time-point T3 (r=0.5, p<0.05). Serum levels of BMP-4 increased from 325 (T2) to 395 pg/ml (T3) (p<0.05), however to the 6 months after MI its level decreased to 298 pg/ml (T5) (p<0.05). The level of BMP-4 was associated with MMP-9 and hCRP (T2) and sST2 (T4) in negative power (r=-0.6, p<0.05), but with MMP-2 (T4) (r=0.6, p<0.05).However in group without adverse LVR the level of BMP-4 decreased from 360 (T2) to 528 pg/ml (T4) (p<0.05).
Conclusion: Serum levels of BMP-2 and BMP-4 decreased to 6 months after MI. In hospital period only serum levels of BMP-4 increased, but the level of BMP-2 was without dynamics. High levels of hCRP, MMP-9 were associated with high levels of BMP-2 in hospital period. Reverse association was revealed for BMP-4 with sST2 and hCRP. Adverse LVR was associated with the absence of BMP-4 increase to time point T4 and BMP-2 decrease to time-point T5.

P906

Heart rate variability and left ventricle volumetric indices in patients after the acute Q-wave myocardial infarction

N Zakirov[1]; Y Kevorkova[1]; G Mullabaeva[1]; A Kevorkov[1]
[1]Republican Specialized Center of Cardiology, Tashkent, Uzbekistan

Purpose: to estimate interrelations between heart rate variability (HRV) and left ventricle volumetric indices in patients after the acute Q-wave myocardial infarction (Q-AMI).
Materials and methods: 213 male patients in the average age of 52.0±9.1 y.o. survived after the primary Q-AMI were included into the study. All patients underwent Holter ECG monitoring (HMECG) with the estimation of HRV and transthoracic echocardiography. HMECG in all cases were performed in normal conditions, on standard therapy without any specific restrictions on 10-14 day of the Q-AMI. Standard therapy included antiplatelet agents, beta-blockers, ACE inhibitors or ARB, statins in individually matched doses, nitrates (if necessary) and amiodarone (if necessary). Interpretation of HRV parameters was made in accordance with the recommendations of the ESC working group and the NASPE (1996) with estimation of SDNN, SDANN, RMSSD and pNN50. As a decrease in the total HRV, a reduction of SDNN≤100 ms was assumed. Statistical analysis was performed using nonparametric Spearman R correlation test. Differences were considered significant for p<0.05.
Results: Analysis of the features of the baseline level of HRV and its correlation with left ventricle volumetric indices was carried out. It was revealed negative correlation between level of SDNN and LVEDD (R=-0.197; p=0.005); LVESD (R=-0.244; 0.001); LVEDV (R=-0.172; p=0.014); LVESV (R=-0.280; p=0.001); level of SDANN and LVEDD (R= -0.236; p=0.001); LVESD (R=-0.251; 0.001); LVEDV (R=-0.211; p=0.003); LVESV (R=-0.299; p=0.001); level of RMSSD and LVESD (R=-0.251; 0.001); and level of pNN50 and LVEDD (R=-0.167; p=0,018); LVESD (R=-0.239; 0.001); LVESV (R=-0.207; p=0.003). All four analyzed HRV parameters also show the positive correlation with LVEF: SDNN (R=0.287; p=0.001); SDANN (R=0.283 p=0.001); RMSSD (R=0.161; p=0.022) and pNN50 (R=0.229; p=0.001).
Conclusions: Obtained results show the unity of pathologic processes of myocardial remodeling in patients after Q-AMI and presence of interrelation between the increases in the size of left ventricle and decreasing of its contractility and parameters of heart rate variability.

HRV parameters and LV volumetric indices

Parameter	Mean±St.Dev.	Parameter	Mean±St.Dev.
LVEDD, cm	5.73±0.70	SDNN, ms	101.41±35.83
LVESD, cm	3.92±0.82	SDANN, ms	87.99±31.69
LVEDV, ml	156.06±51.73	RMSSD, ms	27.19±21.17
LVESV, ml	82.15±40.84	pNN50, %	6.11±9.85
LVEF, %	48.67±11.54

The PARTHENON study: PAtient RegisTry assessing effectiveness and safety of HEart failure treatmeNt with Sac/Val acrOss CaNada

M Mcdonald[1]; A Ducharme[2]; J Ezekowitz[3]; J Howlett[4]; J Udell[5]; N Bastien[6]
[1]Toronto General Hospital, Division of Cardiology, Toronto, Canada; *[2]Montreal Heart Institute, Montreal, Canada*; *[3]Mazankowski Alberta Heart Institute, Edmonton, Canada*; *[4]University of Calgary Foothills Hospital, Calgary, Canada*; *[5]Toronto General Hospital, Toronto, Canada*; *[6]Novartis Pharmaceuticals inc, Montreal, Canada*

Background: Sacubitril/valsartan (sac/val) was introduced into clinical practice in Canada in 2015 for patients with Heart Failure with a reduced Ejection Fraction (HFrEF). The PARTHENON registry was initiated simultaneously to evaluate the effectiveness and safety of sac/val followed in routine clinical practice for up to 3 years. We present the interim results of PARTHENON at a median follow-up time of 6.6 months.
Methods: This observational, multicenter Canadian registry enrolled patients who initiated sac/val as per guideline recommendations within a prior 3 month period. Patients were actively recruited at 32 community and academic centers between May/2016 and October/2017. The primary endpoint is the association between

baseline natriuretic peptide levels and the composite endpoint of all-cause hospitalization or all-cause mortality. Safety endpoints included physician- reported clinically relevant symptomatic hypotension (Systolic Blood Pressure <100 mmHg), hyperkalemia (Serum Potassium > 5.5 mmol/L) and renal impairment (Decrease in eGFR>=40 % Compared to Baseline). All treatment decisions were made as per the treating physician.

Results: This interim analysis included 998 patients (80% male), with a mean age of 67 years, with predominantly NYHA Class II (83%) symptoms. The mean baseline BP was 119/70 mmHg, LV ejection fraction was 29.5± 7.6% and the median NT-proBNP and BNP levels were 992 pg/mL and 226 pg/mL respectively. Following sac/val initiation, 137 patients (13.7%) had a hospitalization, and 33 patients (3.3%) died. Clinically relevant symptomatic hypotension occurred in 126 patients (12.6%) and hyperkalemia and renal impairment were reported in 26 (2.6%) and72 (7.2%) patients, respectively. Eighty-two patients (8.2%) discontinued sac/val, either due to adverse events (n=35, 43%), investigator decision (n=27, 33%) or other reasons (n=20, 24%).

Conclusion: The PARTHENON registry describes the HFrEF patient population receiving Sac/Val in Canadian practice which is characterized by a high proportion of HFrEF patients with NYHA class II, normal BP and a low rate of adverse events when compared to the Canadian product monograph.

P908

Prediction of pharmacological reverse remodeling in non-ischemic dilated cardiomyopathy with wide QRS-complex.

K Kenji Maemura[1]; Y Ikeda[1]; M Yazaki[1]; T Ooki[1]; T Fujita[1]; T Nabeta[1]; E Maekawa[1]; T Naruke[1]; T Koitabashi[1]; T Inomata[2]; J Ako[1]
[1]Kitasato University School of Medicine, Department of Cardiovascular Medicine, Kanagawa, Japan; *[2]Kitasato University School of Medicine, Department of Cardiovascular Medicine, Kitasato University Kitasato Institute Hospital, Kanagawa, Japan*

Background: No data is yet available to help decide introduction of device treatment, such as cardiac resynchronization therapy, in heart failure patients with a wide QRS-complex. Therefore, we attempted to identify the clinical indicators of left ventricular reverse remodeling (LVRR) after pharmacotherapy in non-ischemic dilated cardiomyopathy (NIDCM) patients with a wide QRS-complex.

Methods and Results: We evaluated 38 patients diagnosed with NIDCM and a wide QRS-complex (≥120 ms) who were treated by medical treatment including beta-blockers. Of the total patients evaluated, 19 (50%), 6 (16%), and 13 (34%) patients had left bundle branch block (LBBB), right bundle branch block (RBBB), and nonspecific intraventricular conduction delay (NICD), respectively. Electrocardiograms and echocardiograms taken at baseline (BSL) and at 6 (6M) and 12 months (12M) after initiation of the standard medical treatments were analyzed. LVRR (ΔLV ejection fraction [EF] ≥ +10% and ΔLV end-diastolic diameter ≤ −10% at 12M) was detected in 19 (50%) patients. Although BSL-LVEF was not significantly different between patients with LVRR and those without it (29 [IQR: 22.37]% vs. 31 [20.42]%, p = 0.74), 12M-LVEF was higher in patients with LVRR than in those without it (52 [47.60]% vs. 42 [24.50]%, p = 0.0019). Among the BSL-parameters, only the presence of LBBB was strongly associated with the prediction of LVRR. In the LBBB group, the presence of severe mitral valve regurgitation at 6M and higher systolic blood pressure at 6M were predictors of LVRR. No significant predictor of LVRR was noted in the RBBB group. In the NICD group, New York Heart Association class ≤ II at 6M, longer PQ interval at 6M, longer QT interval at 6M, and normal QRS-complex duration at 6M were found to be predictors of LVRR.

Conclusions: Combined assessment using BSL- and 6M-parameters provided supportive data that helps in the decision regarding the introduction of device treatment in patients with NIDCM with a wide QRS-complex. The predictors of LVRR may differ according to different morphology types of the QRS-complex.

Neurohormonal antagonist therapies, renal function and kalaemia: a trade-off to consider when treating heart failure patients

J Rigueira[1]; JR Agostinho[1]; T Rodrigues[1]; R Santos[1]; A Nunes-Ferreira[1]; I Aguiar-Ricardo[1]; N Cunha[1]; T Guimaraes[1]; M Mendes Pedro[1]; F Veiga[1]; M Almeida Ribeiro[1]; S Longo[2]; N Lousada[2]; FJ Pinto[1]; D Brito[1]
[1]Santa Maria University Hospital/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal; *[2]Hospital Pulido Valente/CHULN, CAML, CCUL, Lisbon School of Medicine, Universidade de Lisboa, Cardiology Department, Lisbon, Portugal*

Introduction: The heart failure (HF) with reduced ejection fraction (rEF) therapeutic algorithm encompasses three pharmacological classes that interact with homeostatic renal mechanisms and with potassium (K) excretion. The known effects of sacubitril/valsartan (S/V) on renal function and K levels accrue form the PARADIGM-HF Trial results but there is a lack of every-day clinical practice derived evidence.

Objectives: To evaluate the impact of S/V initiation therapy on renal function, serum K levels and concomitant K-retaining drugs in patients (pts) with HFrEF.

Methods: Single-centre, prospective study of pts medicated with S/V. Estimated glomerular filtration rate (eGFR) calculated by the CKD-EPI formula, serum creatinine (sCr) and K were recorded before S/V initiation and after the up-titration (to maximal individualized tolerated doses) period. Concomitant therapy with mineralocorticoid receptor antagonists (MRAs) and their respective doses was recorded. The effect of S/V introduction on laboratorial data and changes in MRA doses were evaluated by Wilcoxon test.

Results: S/V was prescribed to 102 pts. The mean sCr value was 1.24±0.5 mg/dL, corresponding to an average eGFR of 67.5±23.4 ml/min/1.73. There was no significant change in mean sCr (1.26±0.46, P=NS) or eGFR (62.6±22.5 ml/min/1.73; P=NS) after S/V initiation. Eleven pts (10.8%) had an increase of sCr >0.3mg/dL, which, however, did not led to the interruption or reduction of S/V dose. In 8 pts (7.8%) the drug was started off-label in pts with eGFR < 30ml/min/1.73 but >20ml/ min/1.73: in 7 of these pts, a sCr reduction was observed after S/V initiation (this reduction was >0.3 mg/dL in 3 pts).The mean baseline K value was 4.5±0.6 mmol/L and there was seen a statistically but not clinically significant increase (4.66±0.5mmol/L; P= 0.034) after S/V introduction. Hyperkalaemia with K >5.5mmol/L was observed in 6 pts (5.9%).

In 18 pts (17.6%) S/V was started in the presence of K between 5 and 5.5mmol/L. In this sub-population, 10 pts (9.8%) had K reduction after starting the drug, 1 pt maintained the exact same level of K, and 4 pts (3.9%) had a rise of 0.1 to 0.2mmol/L. Only 1 pt required S/V dose reduction (basal K: 5.5mmol/L, maximum K: 6.2mmol/L). There was a need for MRA dose reduction in 5 pts (4.9%), and even interruption in 3 pts (2.9%) in order to reduce K levels. It is also worth noting that in 35 pts (34%) S/V was started without prior MRA prescription.

Conclusion: In this study population the initiation of S/V did not affect negatively renal function and its introduction in pts with eGFR between 20 and 30ml/min/1.73 was found to be safe. Hyperkalaemia was a frequent problem, but did not led to S/V discontinuation. It was observed that sometimes physicians choose to reduce MRA dose in order to maintain S/V therapy and consequently take the possible clinical benefit from both drugs.

P910

Does PSV in ICA independently predict plasma levels of NT-proBNP in patients with HFrEF diabetic cardiomyopathy and ipsilateral carotid artery disease?

S-M Spyridon-Michail Papazoglou[1]; U Jaffer[2]; M Aslam[2]; D Richter[3]; A Trikas[1]; C Pantos[4]; K Toutouzas[5]; P Nihoyannopoulos[2]; NJ Standfield[2]; D Tousoulis[5]
[1]Elpis General Hospital, Athens, Greece; *[2]Imperial College Healthcare NHS Trust, London, United Kingdom of Great Britain & Northern Ireland*; *[3]Euroclinic of Athens, Cardiology, Athens, Greece*; *[4]University of Athens Medical School, Clinical Pharmacology, Cardiology Dept, Athens, Greece*; *[5]Hippokration Hospital, Cardiology Clinic, Athens, Greece*

Background/Introduction: Diabetes Mellitus is a systemic disease that clinically is presented with various forms of cardiovascular abnormalities. MACE and Cardiovascular Death among diabetics is mostly common. Carotid artery disease and Diabetic Cardiomyopathy is one of many common comorbidities in DM patients.

Purpose: The aim of this study was to evaluate the possible clinical correlation of ipsilateral Carotid Artery Disease in patients with HFrEF Diabetic Cardiomyopathy. Can PSVs of stenotic ICAs ipsilaterally, independently predict plasma levels of NT-proBNP in patients with HFrEF diabetic cardiomyopathy?

Material/Methods: 422 patients (234 male, 188 female) Diabetics betweeen 46 to 77 years of age with HFrEF DCMP and ipsilateral CAD were recruited for this study. All patients had an EF ≥25-40≤ % and ipsilateral carotid artery disease, diagnosed with U/S Echo. Internal Carotid Artery stenosis was considered to be significant when PSV≥230 cm/sec. NT-proBNP plasma levels were evaluated for Diabetic Cardiomyopathy assessment and considered to be significant when ≥400pg/ml. All data were analyzed using ANOVA and logistic regression and ICA PSV as an independent variable. Data are presented as mean ± standard deviation and level of significance was accepted when p<0. 05.

Results: Date were analyzed in 422 Diabetics (234 male, 188 female) betweeen 46 to 77 years of age with HFrEF DCMP and ipsilateral CarotidArteryDisease. 104 (24.6%) patients had ICA PSV 217 ± 34 cm/sec and NT-proBNP of 709 ± 124 pg/ml. 99 (23.4%) patients had ICA PSV 241 ± 41 cm/sec and NT-proBNP of 886 ± 96 pg/ml. 121 (28.7%) patients had ICA PSV 256 ± 38 cm/sec and NT-proBNP of 913 ± 119 pg/ml. 98 (23.3%) patients had ICA PSV 294 ± 37 cm/sec and NT-proBNP of 1136 ± 121 pg/ml. Ipsilateral ICA PSVs are markedly increased (p=0.019) and can independently predict augmented circulating NT-proBNP palsma levels (p<0.0001).

Conclusion: Increased ICA PSVs is an independent predictor of markedly NT-proBNP levels in DM patients with ipsialteral carotid artery disease and HFrEF DCMP.

P911

Ten-year differences in indications for cardiac resynchronization therapy in international guidelines - insights from the Heart Failure Pilot and Long-Term Registries of the ESC

K Krzysztof Ozieranski[1]; M Grabowski[1]; P Balsam[1]; A Kaplon-Cieslicka[1]; A Tyminska[1]; L Januszkiewicz[1]; M Michalak[1]; M Peller[1]; M Marchel[1]; MG Crespo-Leiro[1]; AP Maggioni[1]; J Drozdz[1]; KJ Filipiak[1]; G Opolski[1]
[1]*Medical University of Warsaw, 1st Department of Cardiology, Warsaw, Poland*

Background: Cardiac resynchronization therapy (CRT) applied to properly selected patients (pts) with heart failure (HF) improves quality of life and symptoms, as well as reduces HF rehospitalizations and mortality. In recent years, both the eligibility criteria (severity of symptoms in New York Heart Association (NYHA) class, left ventricle ejection fraction (LVEF), QRS complexes duration, presence of left bundle branch block (LBBB) or presence of atrial fibrillation (AF)), as well as the strength of scientific evidence attributed to them have been regularly changed.Purpose This study aimed to investigate the changes in eligibility of real-life HF pts for CRT according to differences in the last ten-years international guidelines.
Methods: We reviewed 7 international guidelines (5 European (2007, 2010, 2013, 2015, 2016), 1 North American (2012) and 1 Canadian (2017)) published from 2007 to 2017. Out of 2019 Polish HF ptsrecruited into the HF Pilot (years 2009-2010) and Long-Term (years 2012-2013) Registries of the ESC, 1456pts were included into the final analysis (563 pts with lacking data on CRT eligibility criteria, with paced rhythm or died during index hospitalization were excluded from the study). Patients with AF were assessed separately. Patients were clinically stable.Results Class I (indicated/recommended) of CRT implantation recommendations received from 44 pts (3%) in 2012 to 134 pts (9.2%) in 2010 (p-value for differences between groups <0.0001). There were 25 pts (1.7%) who would be eligible in the class I of recommendations across all of the guidelines (the common criteria in those pts were: sinus rhythm, LVEF ≤35%, LBBB, QRS ≥ 150 ms, NYHA class III or ambulatory class IV). Class IIa (should be considered) of recommendations received from 15 (1%) to 75 pts (5.2%) in 2015 and 2012 (p-value for differences between groups <0.0001), respectively. Class IIb (may be considered) of recommendations received from 28 (1.9%) to 80 pts (5.5%) in 2015 and 2013 (p-value for differences between groups <0.0001), respectively. Within pts with AF indication for CRT had from 16 (1.1%) to 53 pts (3.6%) in 2015 and 2012 (p-value for differences between groups <0.0001), respectively. In overall (including all classes of recommendations and patients with AF and sinus rhythm), the most patients would have been qualified for CRT in 2013 (261 pts, 17.9%), while the least in 2015 (111 pts, 7.6%; p-value for differences between groups <0.0001).
Conclusions: The results of our study suggest that there is an accumulation of recommendations for CRT implantation which may cause some confusion among clinicians. A high variability of the percentage of patients meeting the CRT eligibility criteria was observed. Across the ten years, the criteria overlappedonly in a small percentage of cases.

P912

Hypertrophic cardiomyopathy unmasked after treatment of heart failure

O Sheyin[1]; B Al-Sabeq[1]; N Tzemos[1]; R Davey[1]; S Smith[1]; R Mckelvie[1]; S De[1]
[1]*University of Western Ontario, Division of Cardiology, Department of Medicine, London, Canada*

Introduction: We report a case of heart failure with reduced ejection fraction (HFrEF) in whom hypertrophic cardiomyopathy (HCM) was unmasked following recovery of LV systolic function.
Clinical Case: A 61-year-old man presented with a six-month history of progressively worsening dyspnea and orthopnea. Physical examination revealed features of biventricular failure. Electrocardiogram revealed normal sinus rhythm and left ventricular hypertrophy (LVH). Chest X-ray revealed cardiomegaly and bilateral pleural effusions. He was treated for acute decompensated heart failure. Transthoracic echocardiography (TTE) demonstrated left ventricular dilation (LVIDd 6.0 cm) and moderate concentric LVH with septal and posterior wall thickness of 15 mm each. Left ventricular ejection fraction (LVEF) was 25-30% with akinesis of the mid septum and apex (Figure 1 a, b). He was started on perindopril and bisoprolol with outpatient titration. His repeat echocardiogram after three months on optimal medical therapy revealed a reduction in LVEF to 20%. His perindopril was switched to sacubitril-valsartan, titrated to the maximum dose. Coronary angiography demonstrated a chronically occluded left anterior descending artery not requiring intervention.
Repeat TTE performed three months later for primary prevention implantable cardioverter defibrillator candidacy determination revealed significant reduction in LV size (LVIDd 4.8 cm) and dramatic improvement in LVEF to 50-55%. Notably, the pattern of hypertrophy had changed from concentric to asymmetric septal hypertrophy, with the interventricular septum measuring 22 mm, consistent with HCM (Figure 1 c, d). Cardiac magnetic resonance (CMR) imaging confirmed these findings, with concomitant delayed gadolinium enhancement (Figure 1e) suggestive of HCM.
Discussion: In 5% of patients with HCM, there is progression to end stage or "burned out" phase characterized by systolic impairment. This stage of disease is associated with adverse LV remodeling, cavity dilation, and wall thinning due to a process of extensive myocardial fibrosis. Further clinical deterioration is rapid, often necessitating consideration for cardiac transplantation. We did not find any previously reported case of "burned out" HCM with full recovery of LV systolic function on medical therapy in the literature. Angiotensin receptor-neprilysin inhibitor (ARNI) use has been associated with significant improvements in the mortality and morbidity of patients with HFrEF although the remodeling benefits are still unknown.
Conclusion: This case serves as a possible example of reversal of adverse remodeling from two possible pathologic entities with normalization of LV function only 3 months after use of an ARNI. Proper diagnosis of the cardiomyopathy occurred after LV remodeling occurred. Ongoing studies may provide more robust data on the effects of sacubitril-valsartan on left ventricular remodeling.

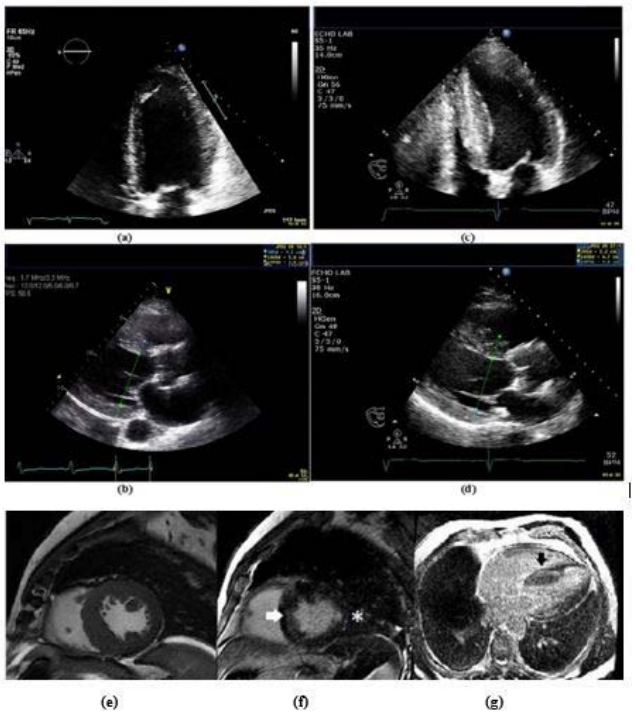

Figure 1.

Introduction: and objectives. A significant number of patients with heart failure (HF) and reduced left ventricular ejection fraction (LVEF) experience ventricular function recovery during follow-up. We studied the variables associated with LVEF recovery in patients treated with sacubitril/valsartan (SV) in clinical practice.
Methods: Prospective and multicenter registry including 427 outpatients with HF and reduced LVEF who started SV between October 2016 and March 2017. We selected patients with LVEF≤35% at the beginning and classified them into two groups according to LVEF at the end of follow-up (>35%, group R, or ≤35%, group NR).
Results: 249 patients (58.3%) had LVEF≤35%; after a mean follow-up of 7±0.1 months, 62 (24.8%) had LVEF>35%. They were older (71.3±10.8 vs. 67.5±12.1 years, p=0.025), and had more often hypertension (83.9% vs. 73.8%, p=0.096), higher blood pressure before and after SV (both, p<0.01). They took more often high doses of beta-blockers, with lower proportion of cardiac resynchronization and ICD (all, p<0.05), the latter being the only predictive variable of NR in multivariate analysis (OR 0.26, IC 95% [0.13–0.47], p<0.0001). At the end of follow-up they had a mean LVEF of 41.9±8.1% (vs. 26.3±4.7%, p<0.001), with a difference compared to the initial LVEF of 14.6±10.8% (vs. 0.8±4.5%, p<0.0001), Functional class improved in both groups, mainly in group R (p=0.035), with fewer consultations in the emergency department (p=0.07).
Conclusions. In patients with LVEF≤35% treated with SV, not being a carrier of ICD was independently associated with LVEF recovery, which was related to greater improvement in functional class.

P914
Real-world experience with angiotensin ii receptor blocker neprilysin inhibitor: reverse remodelling is the norm

A Ana Sofia Martinho[1]; J Almeida[1]; F Franco[1]; S Costa[1]; R Baptista[1]; M Robalo[2]; A Pinho[2]; L Goncalves[1]
[1]University Hospitals of Coimbra, Coimbra, Portugal; *[2]Hospital de Braga, Braga, Portugal*

Backgroung: The randomized clinical trial PARADIGM-HF proved that compared with enalapril, Angiotensin II Receptor Blocker Neprilysin Inhibitor (ARNI), sacubitril-valsartan, reduced the risk of hospitalization for heart failure (HF) by 21%, decreased cardiovascular (CV) and all cause of death and reduced the symptoms and physical limitations of heart failure, in patients with reduced left ventricular ejection fraction (LVEF).
Purpose: In our country reality, this drug has only 1-year approval. We considered that analysing the application and performance of this drug in our population was fundamental, through a real-word study.
Methods: We conducted a retrospective, observational study of 200 patients with HF treated with sacubitril-valsartan, in a single-centre. Patients were selected whether they were at 97/103mg dose, twice a day (b.i.d) (n=100). Then primary co-endpoints were: improvement of LVEF, New YorK Heart Association functional class (NYHA) and N-terminal pro B-type natriuretic peptide (NT-proBNP) from baseline (start ARNI) until 3 months after initiating 97/103mg (b.i.d) dose. We also analysed events after tolerating the studied dose: CV Death, HF first hospitalization, emergency visits for Acute HF (AHF), de novo atrial fibrillation (AF) and appropriate defibrillator shocks. Baseline clinical and demographic characteristics were evaluated, as well as the time until maximum dose was reached.
Results: In our cohort, mean age was 59 ±12.6, and 86% were male. 51.5% of patients had HF of non-ischemic etiology. Median time between initiation of the drug and reaching the 97/103mg dose was 11 weeks. Regarding our primary endpoints: LVEF improved on average 3.7% ±8.9, with statistical significance (95% IC 1.641 to 5.924; p=0.001). This was verified in 46% (n=32) of the subpopulation studied and in 16.7% of these, LVEF increased to >35%. NT-proBNP had a mild mean decrease of 15.7pg/mL, but without statistical significance; NYHA functional class had a significant improvement (IC 95% 0.008-0.012; p=0.005), 47% of patients with baseline NYHA II changed to I; 81% III to II and 66% IV to II. After 3 months on the 97/103mg b.i.d dose, CV Death occurred in 1%, de novo AF in 1%, first HF hospitalization in 2%, appropriate ICD shock in 3% and emergency visits for AHF in 9%.
Conclusions: as we expect there was a significant improvement in LVEF and symptoms of HF with this drug. Similarly to previous studies, 16.7% improve LVEF above 35%, and no longer have guideline-derived indication for prophylactic implantable cardioverter defibrillator.

P915
Alteration of left ventricular structure and function after treatment with angiotensin receptor-neprilysin inhibitor in patients with heart failure with reduced ejection fraction (ALLEVIATE-HF)

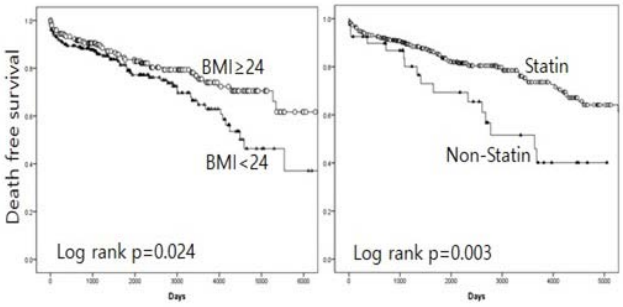
C Jirathiyut[1]; S Yamwong[1]; M Chandavimol[1]; P Vathesatogkit[1]; T Ngernsritrakul[1]; T Yingchoncharoen[1]
[1]Ramathibodi Hospital of Mahidol University, Cardiology division, internal medicine department, Bangkok, Thailand

Background: There is robust evidence that Angiotensin receptor-neprilysin inhibitor (ARNI) can reduce death and heart failure hospitalization in patients with heart failure with reduced ejection fraction (HFrEF). However, the improvement of function and reverse remodeling of the left ventricle after ARNI have not been established.
Method: In this single-center retrospective cohort study of 47 patients with HFrEF, we reviewed the clinical and echocardiographic data collected prior to the initiation of ARNI treatment compared to the one collected after maximal tolerated ARNI dose. Paired sample T-test was used for normally distributed data, while Wilcoxon Signed Rank test for non-normally distributed data.
Results: The mean left ventricular ejection fraction (LVEF) significantly improved from 30.23% to 42.15% (mean difference 11.92 ± 1.84, p < 0.001), left ventricular end diastolic diameter decreased by 5.02 mm (p = 0.001), left ventricular end systolic diameter decreased by 8.23 mm (p < 0.001), and LV mass index decreased by 20.45 g/m2 (p = 0.01) The mean duration from maximal tolerated ARNI dose to echocardiographic follow up was 17.98 ± 14.04 weeks. There were 30 patients (64.83%) whose LVEF improved ≥ 5% from baseline. Although the prognostic factor of improved LVEF was not identified, there were positive trend in those who had been up-titrated the ARNI dose and negative trend in those with left ventricular end diastolic diameter at baseline of more than 60 mm.
Conclusion: There were significant improvement of LVEF and other parameters of reverse remodeling of the left ventricle after treatment with ARNI.

P918
Prognostic impacts of body mass index and statin therapy on long term mortality in patients with ischemic cardiomyopahty

HJ Hyun Ju Yoon[1]; KH Kim[1]; HY Kim[1]; JY Cho[1]; HJ Park[1]; JC Park[1]
[1]The Heart center of Chonnam National University Hospital, Gwangju, Korea (Republic of)

Background and objectives: Uncontrolled ischemia is a frequent cause of heart failure exacerbation after myocardial infarction in the case of progressive remodeled heart. We investigated the prognostic factors of long term outcome in patients with ischemic cardiomyopathy (ICMP).
Methods: A total of 1,214 patients were found to have left ventricular (LV) ejection fraction (EF) <45% and LV end diastolic dimension >55mm with regional wall motion abnormality. After exclusions including acute myocardial infarction and absent acceptable invasive coronary imaging, 475 patients (73±10 years, 274 female) were included for analysis.
Results: During 6.0±4.7 year follow up, 111 patients (23.4%) were died. There were no significant differences on long term mortality between sex. Old age, diabetes, hypertension and low body mass index were poor prognostic factors of mortality in ICMP. Echocardiographic measured low EF less than 35%, elevated left ventricular filling pressure (e/e'>15) and presence of pulmonary hypertension (right ventricular systolic pressure>35mmHg) were significant poor prognostic factors in ICMP. In coronary angiography, left circumferential artery and right coronary artery lesion showed bad outcome rather than left anterior descending artery. Repeated percutaneous coronary intervention was not related with long term outcome. Mortality was significantly lower in patients taken statin medication. In Kaplan Meier survival analysis, mortality was significantly higher in lower BMI rather than higher BMI group (log rank p=0.024). Long term outcome was better in statin treated group than non-statin treated group (log rank p=0.003) (Fig)
Conclusion: Besides conventional risk factors, higher body mass and statin therapy significantly attenuated long term mortality in patients with ICMP. Therefore, optimal nutritional support and medication was helpful to improved outcome in patients with remodeled heart due to ischemia.

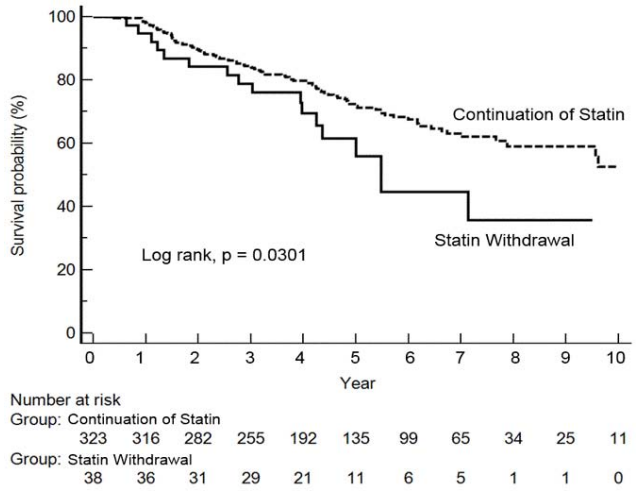


P919

Impact of post-discharge statin withdrawal on long-term clinical outcome in patients with ischemic heart failure with reduced ejection fraction

EE Kim[1]; BH Hwang[1]; K Chang[1]; Y Ahn[2]; JJ Kim[1]
[1]Catholic University Hospital, Seoul, Korea (Republic of); *[2]Chonnam National University Hospital, Gwangju, Korea (Republic of)*

Background: Statin therapy is necessary for secondary prevention in patients with acute myocardial infarction (AMI). However, among patients with ischemic heart failure (HF) with reduced ejection fraction (EF) who suffered from AMI before 1 year, limited data are available describing the clinical impact of statin withdrawal within 1 year after AMI.
Methods: Patients in the Korean multi-center registry who survived for 1 year after AMI were consecutively enrolled. After excluded patients with preserved EF, patients with ischemic HF with reduced EF who prescribed statin at discharge were divided into 2 groups on the basis of statin withdrawal history. A total of 449 patients were compared in all-cause mortality within a follow-up period.
Results: Median follow-up duration was 52 months (interquartile range 31 to 78 months). Age, sex, presence of diabetes, hypertension, and dyslipidemia, as well as status of smoking were not different between the groups. Patients with statin withdrawal history had greater all-cause mortality (31.3% vs. 47.5%). Withdrawal of statin within 1 year after AMI was an independent predictor of all-cause mortality after adjusting confounding risk factors (hazard ratio: 2.096, confidence interval: 1.238-3.548, p=0.006).
Conclusion: In patients with ischemic HF with reduced EF, post-discharge withdrawal of statin within 1 year after AMI is associated with increased risk of poor outcome independently of coexisting risk factors.



P920

Possibilities of clinical application of the new biomarker ST2 in heart failure patients: an exercise test

EV Grakova[1]; KV Kopeva[1]; AT Teplyakov[1]; MV Soldatenko[1]; ON Ogurkova[1]; AA Garganeeva[1]
[1]Cardiology Research Institute, Tomsk National Research Medical Centre of Russian Academy of Science, Tomsk, Russian Federation

Objective: The objective of this study was to evaluate prognostic value of sST2 biomarker at rest and after exercises in the development of adverse cardiac events in heart failure (HF) patients during the 12-month follow-up period. Methods. A total of 35 patients (91.4% men, median age of 62 [57; 67] years) with stable coronary artery disease and baseline LVEF of 44% [35; 52]% were enrolled in the study. At baseline evaluation, heart failure patients were of New York Heart Association (NYHA) class I-III. Serum levels of sST2 and NT-proBNP were measured using an enzyme immunoassay. Serum sST2 levels were measured prior to (at rest) and immediately after the 6-minute walk test (6MWT). Results. Depending on the course of HF, the patients were divided into 2 groups: group 1 comprised patients (n=15) with adverse cardiac events; group 2 comprised patients (n = 20) without it. The median values of baseline sST2 were 39.68 [32.28; 52.32] ng/mL in group 1 and 29.29 [26.34; 33.78] ng/mL (p=0.007) in group 2. The cut-off values predicting adverse cardiac events in ischemic heart failure patients were determined based on receiver operating characteristic curve analysis. Baseline sST2 concentration at rest of 33.14 ng/mL was identified as a cut-off value with the sensitivity of 73.3%, specificity of 75.0%, and AUC of 0.77 (95% CI 0.59-0.89, p=0.002). After 6MWT in patients with the unfavorable course of HF, there was a tendency (p = 0.211) to increase in sST2 level by 9.3% from 39.68 [32.28; 33.78] ng/mL to 43.75 [36.85; 54.80] ng/mL. In patients without adverse cardiac events, the level of sST2 did not change (29.29 [26.34; 33.78] ng/mL at rest and 29.43 [23.79; 34.79] ng/ml after 6MWT, respectively). Baseline sST2 concentration after 6MWT of 34.58 ng/mL was identified as a cut-off value with higher levels of specificity and sensitivity of 86.7 and 85.0%, respectively (AU - 0 86, p <0.0001) for prediction of adverse cardiac events during the 12-month follow-up period. Conclusion. Our data suggest that ST2 may be considered a non-invasive biomarker for prediction of adverse cardiac events during the 12-month follow-up period in ischemic heart failure patients. Baseline sST2 concentration after 6MWT demonstrated higher diagnostic sensitivity and specificity for prediction of adverse outcomes.

P921

Cerebral oximetry and haemodynamic parameters during controlled orthostatic challenge in heart failure and normal subjects

H Holm[1]; E Bachus[2]; V Hamrefors[2]; P Wollmer[1]; O Melander[2]; A Fedorowski[1]; M Magnusson[3]
[1]Skane University Hospital, Department of Clinical Physiology, Malmo, Sweden; *[2]Skane University Hospital, Department of Clinical Sciences, Lund University, Malmo, Sweden*; *[3]Skane University Hospital, Department of Cardiology, Skåne University Hospital, Malmö , Malmo, Sweden*

On behalf of: HARVEST

Background: Changes in cerebral oxygenation and hemodynamic parameters during orthostatic stress are poorly investigated in patients with congestive heart failure (CHF).Introduction / purpose
We aimed to investigate whether the presence of CHF affects cerebral tissue oxygenation relative to changes in haemodynamic parameters during controlled orthostatic stress.
Methods: Near infrared spectroscopy (NIRS) was applied to measure absolute frontal cerebral tissue oxygen saturation (SctO2) during 700head-up tilt (HUT) in 61 patients with CHF (mean-age: 71±11 years, 82% male,NYHA class I–III), in stable condition and in 60 non-CHF control individuals (mean age: 60±12 years, 42% male). Synchronized non-invasive beat-to-beat hemodynamic monitoring, cerebral oximetry and ECG were applied during rest and head-up-tilt test (HUT). Group differences in continuous variables between CHF- positive and -negative individuals were compared using Student's t-test.The associations between CHF and SctO2 levels in supine position and after 10 minutes of HUT were studied using multivariable-adjusted linear regression models including age, gender, systolic blood pressure (SBP) in supine position and after 10 min of HUT, heart rate (HR) in supine position and after 10 min of HUT.
Result: In patients with CHF, the SctO2 decreased from 67±5% in supine to 64±5% after 10 minutes in standing position while both systolic (SBP), diastolic blood pressure (DBP) and heart rate (HR) increased upon HUT (SBP from 123±27mmHg to 125±24mmHg, DBP from 67±13mmHg to 69±14mmHg; HR from 70±13bpm to 73±14bpm). In controls, SctO2 decreased from 71±3% (p<0.001 compared to HF patients) in supine to 69±3% (p<0.001 compared to HF patients), whereas SBP, DBP and HR increased (SBP from 142±19mmHg to 142±20mmHg, DBP from 79±12mmHg to 85±14mmHg; HR 71±12bpm to 78±13bpm). A diagnosis of CHF (beta = -3.3 %; p<0.001) and higher resting HR (beta = -0.09 % per bpm; p = 0.008) was associated with lower supine SctO2 levels. Lower SctO2 after 10 min HUT was independently associated with CHF (beta -2.9 %; p =0.001), age (beta -0.1 % per year; p = 0.001), resting HR (beta -0.073 % per bpm; p=0.010) and 10 min HUT SBP (beta 0.053 % per mmHg; p = 0.001). Ejection fraction (EF%) showed no significant correlation with SctO2 and its changes during HUT.
Conclusion: Patients with CHF in stable condition experience reduced levels of cerebral oxygenation in rest and in standing position as compared to controls without CHF. Age and higher resting heart rate are associated with reduced cerebral oxygenation whereas increased orthostatic systolic blood pressure is associated with increased cerebral oxygenation during orthostasis. These findings might indicate subclinical impaired posture-dependent cerebral perfusion oxygenation in heart failure.

P922

Diastolic heart failure in patients with chronic obstructive pulmonary disease in combination with hypertension

A Anastasiya Melenevych[1]
[1]Kharkiv National Medical University, Kharkiv, Ukraine

Purpose: to evaluate left ventricular (LV) and right ventricular (RV) diastolic function in patients with chronic obstructive pulmonary disease (COPD) in combination with hypertension (HT)

Methods: In total, 100 COPD patients (GOLD 2, group B) in remission (79 males and 21 females) 54,42±6,23 years old were monitored. The COPD group in combination with HT stage II included 69 patients, the isolated COPD group - 31 patients. All patients underwent 6-min walk test (6MWT), pulse oximetry, spirometry, electrocardiography, echocardiography (ultrasound device RADMIR Ultima) and chest x-ray.
Results: The 6MWT distance was significantly lower in comorbid group compared to isolated COPD group (383,41±14,85 m vs. 395,68±18,99 m, p < 0,05). Desaturation during the 6MWT was significantly higher (4,14±1,44 % vs. 3,39±1,31 %, respectively, p<0,05). LV mass index was significantly higher (130,77±23,12 g/m2 vs. 96,53±13,72 g/m2, respectively, p<0,05). RV wall thickness was higher (5,42±0,61 mm vs. 5,11±0,80 mm, respectively =0,0545). Analysis of the distribution of patients according to type of LV diastolic dysfunction showed probable (χ2=34,13, <0,0001) differences. According to type of RV diastolic dysfunction between the groups also revealed probable (χ2=12,83, =0,0016) differences.
Conclusions: Reduced exercise tolerance, exercise-induced desaturation, signs of heart remodeling and more pronounced diastolic dysfunction both ventricles are revealed in patients with COPD combined with HT.

P923
Laboratory and clinical indicators of chronic heart failure in patients with rapidly progressive left ventricular remodeling

V Valentin Oleinikov[1]; L Salyamova[1]; T Aryasova[1]; N Burko[1]
[1]*Penza State University, Penza, Russian Federation*

Purpose: to study the dynamics of laboratory and clinical parameters of chronic heart failure in patients with different types of left ventricular remodeling after acute myocardial infarction with ST segment elevation (STEMI) at 48-week of follow-up.
Methods: the study included 86 patients with STEMI. Inclusion criteria was the presence of significant stenosis of only one coronary artery according to the coronary angiography. The treatment in the framework of the study was carried out at the background of prescribed pharmacotherapy for STEMI. Initially at 7-9th days and after 24, 48 weeks of follow-up, the brain natriuretic peptide (BNP) was determined using immunochemical analysis, the patient's clinical condition scale (CCS) was analyzed. A 6-minute walk test was performed after 12 and 48 weeks. In addition, all patients underwent echocardiography using the device MyLab ("Esaote", Italy) with the evaluation of the end diastolic volume index (EDVi). Then the patients were divided into two groups. The first group included 51 people without echocardiographic signs of LV remodeling: the dynamics of EDVi after STEMI was <20%. Group 2 included 35 patients with rapidly progressive LV remodeling (increase in EDVi index was >20%). The compared groups were matched by age, sex, anthropometric data, and treatment.
Results: initially compared individuals did not differ in the BNP level: in group 1 - 117.2 [95% CI 80.6; 153.8] pg/ml, in group 2 - 146.2 [95% CI 79.5; 213] pg/ml (p=0.34). After 24 weeks, patients with no pathological increase in the EDVi index showed a decrease in BNP to 64.9 [95% CI 37.3; 92.6] pg/ml (p=0.009), after 48 weeks - 71.9 [95% CI 31.9; 111.9] pg/ml (p=0.01). In patients with rapidly progressive LV remodeling, the BNP values did not change significantly: after 24 weeks - 102.9 [95% CI 23.5; 182.2] pg/ml (p=0.11), after 48 weeks - 91.4 [95% CI 43.1; 139.7] pg/ml (p=0.11). According to the 6-minute walk test in group 1 after 12 weeks of follow-up, the average distance traveled was 487.9 [95% CI 459.3; 516.5] m, after 24 weeks - 506.8 [95% CI 481.6; 531.9] m (p=0.15), after 48 weeks - 520.6 [95% CI 496.5; 544.8] m (p=0.04). In group 2 the average distance after 12 weeks of follow-up was 499 [95% CI 460.3; 537.7] m, after 24 weeks - 515.6 [95% CI 463.7; 567.6] m (p=0.57), 48 weeks - 500.9 [95% CI 455.7; 546.3] m (p=0.91). According to CCS, group 1 had no dynamics: baseline - 1.1 [95% CI 0.9; 1.3] after 24 weeks - 1 [95% CI 0.8; 1.1], 48 weeks - 0.8 [95% CI 0.7; 1] points. In group 2, the initial CCS value was 1 [95% CI 0.7; 1.4], after 24 weeks, 0.8 [95% CI 0.4; 1.2] (p=0.01), 48 weeks — 1.09 [95% CI 0.8; 1.4] points (p=0.001).
Conclusions: in STEMI patients without pathological myocardial remodeling, a favorable decrease in the BNP level and an improvement in exercise tolerance were found. While in the group with rapidly progressive left ventricular remodeling, there was a worsening of clinical condition and without normalization of BNP.

P924
RecovHF - predictive markers of one year recovery

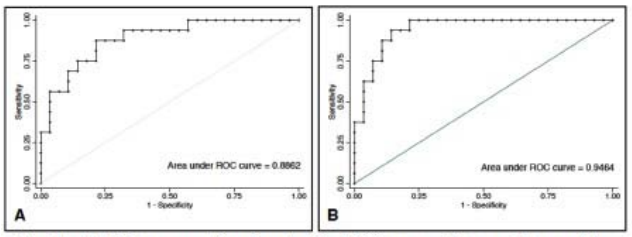
RITA R Carvalho[1]; C Ruivo[1]; F Montenegro Sa[1]; S Fernandes[1]; M Carvalho[1]; J Guardado[1]; J Correia[1]; F Soares[1]; J Morais[1]
[1]*Hospital Santo Andre, Cardiology, Leiria, Portugal*

Introduction: Left ventricular ejection fraction (LVEF) recovery in Heart Failure (HF) is associated with better overall prognosis, with different characteristics when compared to the other subgroups ofHF patients. Few data exists about its predictors in de novo HF, and its knowledge would be of great importance to better stratify, follow and treat this specific type of patients.
Methods: A single centered retrospective open cohort study. Data from the advanced HF consult database, including all newly diagnosed HF patients with LVEF<40%. LVEF recovery was defined as LVEF≥50% or an absolute increase of 15%. Clinical, biochemical, electrocardiographic and echocardiographic data were collected. Using logistic regression, predictors of LVEF recovery during follow-up and at 1year, were determined.
Results: 90 patients were analysed during a follow-up of 281.1py, with a significant improvement of LVEF (mean diff 14.4%, p<0.001) and an incidence rate of 1.6 cases/10py. 35.6% of those who recovered, did it in the 1st year. Hypertension (OR 0.40, p=0.048), diabetes (OR 0.36, p=0.028), previous treatment with neurohormonal antagonists drugs (OR 0.36, p=0.030), ischemic aetiology (OR 0.24, p=0.003), iron deficiency (OR 0.14, p=0.025) were significantly associated with no LVEF recovery during follow-up. Only QRS duration (OR 0.96, p=0.004), LBBB (OR 0.15, p=0.011) and eGFR (1.04, p=0.021) were significantly associated to LVEF recovery at the 1st year. A model including these data, age and gender performed highly predictive of LVEF in 1 year (AUC 0.95).
Conclusion: Different characteristics at HF diagnosis are associated with LVEF recovery within one year or later on, allowing to better identify, stratify an follow those patients. More studies are needed to corroborate these results.

Table 3. Variables significantly associated with LVEF recovery with the first year of follow-up.

Characteristic	OR	*p-value*
QRS duration	0.96	**0.004**
QRS ≥ 130ms	0.16	**0.015**
Left bundle branch block	0.15	**0.011**
Biochemical parameters		
eGFR [a]	1.04	0.021

[a] Assessed by CKD-EPI formula
eGFR - Estimate of glomerular filtration rate; LVEDV – Left ventricular end-diastolic diameter; LVEF – Left ventricular ejection fraction



Graphic 2. Reciever operating characteristic (ROC) curves of two models, predicting LVEF recovery within 1 year of follw-up. A) Including quadratic age, male gender, QRS duration, QRS≥130ms, the presence of LBBB and eGFR (using CKD-EPI formula) with an AUC of 0.09. B) Same as A, but including the variable LVEF and ischemic etiology.
AUC – area under the curve.

Predictive model for LVEF recovery at 1y

Chronic Heart Failure - Epidemiology, Prognosis, Outcome

P925
Prognostic value of NT-proBNP added to clinical parameters to predict two-year prognosis of chronic heart failure patients with mid-range and reduced ejection fraction, a report from FAR NHL registry

J Jindrich Spinar[1]; JS Spinar[2]; LS Spinarova[3]; PJ Parenica[2]; SM Spinarova[3]; LK Labr[3]; JJ Jarkovsky[3]; LO Ludka[3]; KJ Krejci[3]; MF Malek[4]; OP Ostadal[4]
[1]*University hospital, Brno, Czechia*; [2]*University hospital Brno and Masaryk university, Brno, Czechia*; [3]*Masaryk University, Brno, Czechia*; [4]*University Hospital, Prague, Czechia*

On behalf of: FAR NHL

Background: The guidelines recommend to determine natriuretic peptides, the NYHA classification and comorbidities in order to predict the patient's prognosis. The aim our work was to develop a prognostic score in chronic heart failure patients that would take account of patients' comorbidities, NYHA and NT-proBNP.
Methods and Results: Consecutive 1088 patients with chronic heart failure with reduced ejection fraction (HFrEF) (LVEF<40%) and mid-range EF (HFmrEF) (LVEF 40-49%) were enrolled. Two-year all-cause mortality, heart transplantation and/or LVAD implantation were defined as the primary endpoint (EP). The occurrence

of EP was 14.9% and grew with higher NYHA, namely 4.9% (NYHA I), 11.4% (NYHA II) and 27.8% (NYHA III-IV) (p<0.001). The occurrence of EP was 3%, about 10% and 15–37% in patients with NT-proBNP levels ≤125pg/ml, 126-1000pg/ml and >1000pg/ml respectively. Discrimination abilities of NYHA and NT-proBNP were (AUC 0.670; p<0.001 and AUC 0.722; p<0.001). The predictive value of the developed clinical model, which took account of older age, advanced heart failure (NYHA III+IV), anaemia, hyponatraemia, hyperuricaemia and taking a higher dose of furosemide (>40 mg daily) (AUC 0.773; p0.001) was increased by adding the NT-proBNP level (AUC 0.790). Conclusion: The use of prediction models in patients with chronic heart failure, namely those taking account of natriuretic peptides, should become a standard in routine clinical practice. It might contribute to a better identification of a high-risk group of patients in which more intense treatment needs to be considered, such as heart transplantation or LVAD implantation.

Prospective observational study on heart failure: one-year follow-up results of NATURE-HF (NAtional Tunisian REgistry of Heart Failure) outcome registry

L Leila Abid[1]; I Kammoun[2]; M Mechri[3]; C Yousfi[1]; A Korchani[4]; K Sammoud[3]; O Abid[5]; O Laabidi[6]; M Ben Hlima[3]; W Sdiri[7]; K Mzoughi[8]; L Bezdah[5]; S Milouchi[4]; MS Mourali[3]; F Addad[2]

[1]Hedi Chaker University Hospital, Sfax, Tunisia; *[2]Abderrahmen Mami Hospital, Ariana, Tunisia*; *[3]La Rabta Hospital, Tunis, Tunisia*; *[4]Habib Bourguiba, cardiology, medenine, Tunisia*; *[5]Hospital Charles Nicolle, cardiology departement , Tunis, Tunisia*; *[6]Sahloul University Hospital, cardiology departement , Sousse, Tunisia*; *[7]Habib boughatfa, cardiology, Bizerte, Tunisia*; *[8]Habib Thameur Hospital, cardiology departement , Tunis, Tunisia*

Background: The First clinical observational studies on heart failure (HF) in Tunisia.
Objective: NATURE-HF (NAtional Tunisian REgistry of Heart Failure) outcome registry.
Methods: This is a nationwide, multicenter, prospective observational trial on a population of 2040 patients followed up for 1 year..
Results: 268 patients were hospitalized for Heart Failure. 1772 were outpatients. The mean age was 63.6 ans ± 12.6. 70.9% were male. Hypertension and diabetes were noted in 42% and 38% respectively. Coronary artery disease was the most common etiology. 52% of patients was pauci-symptomatic (NYHA II). % 57.7 % of the patient presented HFrEF. 33.4% had LVEF ≤35 %. The cumulative total mortality rate at 12 months was 13 %. 7% of patient were hospitalized at 12 months. Average length of stay in hospital for hospitalized patients was around 1.9 (59.0% with 1 previous hospitalization; 32.9% with 2 to 3 previous hospitalizations and 8.1% with 4 or more previous hospitalizations).
Average length of hospital stay (public or private) was about for 8.7 days (64.0% were hospitalized for 1 week, 25.2% for
2 weeks and 10.8% for more than 2 weeks). 22% of patients were under optimized treatment.
Conclusions: Our results are concordant with the literature. but there are deficiencies concerning the therapeutic management and especially the optimization of the treatment.

P927

Sex-related differences in inflammation-associated biomarkers and their predictive utility for new-onset heart failure

LMG Meems[1]; N Suthahar[1]; RT Gansevoort[2]; WH Van Gilst[1]; P Van Der Harst[1]; SJL Bakker[2]; RA De Boer[1]

[1]University Medical Center Groningen, Experimental Cardiology, Groningen, Netherlands (The); *[2]University Medical Center Groningen, Nephrology, Groningen, Netherlands (The)*

Background: There are known sex-differences in heart failure (HF) pathophysiology, and chronic inflammation has been suggested to be more prominent in males. We evaluated whether baseline levels of inflammation-associated biomarkers differ among men and women from the general population, and investigated whether these differences translate to a sex-specific predictive utility for new-onset HF.
Methodology: We included 8569 HF-free participants (50% women) from the Prevention of Renal and Vascular End-stage Disease (PREVEND) cohort. Associations of sex with plasma concentrations of inflammatory biomarkers – copeptin (CP), procalcitonin (PCT), plasminogen activator inhibitor-1 (PAI-1), galectin (Gal)-3 and C-reactive protein (CRP) were evaluated using linear regression models. In longitudinal analyses, primary endpoint was new-onset HF. Sex-specific predictive value of these biomarkers for both endpoints was determined by Cox regression analysis and evaluated along with the gold standard HF biomarker – N-terminal pro-B-type natriuretic peptide (NT-proBNP).
Results: Males displayed significantly higher levels of PAI-1, CP, PCT (reflecting thrombosis and endothelial activation), whereas females demonstrated higher levels of Gal-3 and CRP (reflecting macrophage and T-cell activation); Pdifference-for-all<0.001. However, none of the inflammation-associated biomarkers displayed a sex-specific predictive utility for HF; Pmen vs women=ns. NT-proBNP levels were higher in women than in men (P<0.001) and strongly predicted incident HF (P<0.001), but did not display a sex-specific predictive utility; Pmen vs women=ns. Nevertheless, for HFrEF, and not HFpEF, but not HFpEF,, a doubling in NT-proBNP was associated with a greater risk of new-onset HFrEF (men vs women: 1.54 (1.35 – 1.76); p<0.001 vs 1.86 (1.49 – 2.32); p<0.001).
Conclusions: Sex-differences in plasma levels of inflammation-associated biomarkers need not translate to a differential predictive utility for new-onset HF in men and women. Sex should be considered as an independent factor in HF pathophysiology rather than a confounding factor.

P928

The patient journey of heart failure patients in Belgian hospitals

C Verhestraeten[1]; L Ghys[1]; S Kerckhofs[1]; J Todoroff[1]; S Wattel[1]; L Gabriel[2]; W Heggermont[3]; A Heyse[4]; P Martens[5]; P Troisfontaines[6]; M Michael Maris[1]

[1]Novartis Pharma, CardioMetabolic, Vilvoorde, Belgium; *[2]University of Namur, Namur, Belgium*; *[3]Olv Hospital Aalst, Aalst, Belgium*; *[4]AZ Glorieux, Ronse, Belgium*; *[5]Hospital Oost-Limburg (ZOL), Genk, Belgium*; *[6]Citadelle Regional Hospital, Liege, Belgium*

Introduction: Regional discrepancies in heart failure (HF) care are common. A better understanding of diagnosis, treatment and follow up (FUP) of HF patients, as well as of the organizational structure of medical centers, could lead to a better care trajectory for HF patients in Belgium.
Purpose: This project aims to map the in- and out-patient flow of HF care in Belgian hospitals to gain insights in HF management allowing the development of recommendations to optimize Belgian HF care specifically.
Methods: A survey of 44 multiple-choice questions related to HF disease management is currently carried out during face-to-face interviews with one cardiologist responsible for HF in all Belgian hospitals. The current interim analysis is based on interviews held between September and November 2018 and covers a representative sample in terms of regional center distribution and center size.
Results: Currently, 41 hospitals have completed the survey of which 22%, 27% and 51% were large (>600 beds), medium (400-600 beds) and small hospitals (<400 beds) respectively. Of these hospitals, 71% have a dedicated HF specialist and 66% a HF nurse. 85% of the respondents indicate to use NT-pro-BNP over BNP or pro-BNP mainly because of the hospital laboratory preferences and data from the literature. These markers are used by 71% of the hospitals in an emergency setting, by 61% for diagnosis and 51% for patient FUP. ACEi/ARB, BB and MRA are seen as standard of care (SoC) for HFrEF by 100% of the respondents, whereas ARNI, diuretics, devices and rehabilitation are only regarded as SoC by 78%, 73%, 61% and 56% of the respondents, respectively. Importantly, dedicated HF specialists more often regarded diuretics, devices and rehabilitation as SoC as compared to non-dedicated HF specialists, with no difference for ARNI. In line, dedicated HF specialists indicate that a much higher percentage of HFrEF patients reach the target dose of ACEi/ARB, BB, MRA and ARNI versus non-dedicated HF cardiologists. The most important causes why target doses cannot be reached are mainly related to hypotension and worsening of renal function for ACEi/ARB (68% and 63% respectively), brady/tachycardia for BB (80%), hyperkalemia for MRA (83%) and hypotension for ARNI (83%). Regarding the role of a HF nurse, hospitals indicate patient information at discharge and patient education during FUP as the most important tasks, followed by the point of contact for patients and FUP of the patient when hospitalized.
Conclusion: Despite well-defined guidelines for HF treatment, these interim results demonstrate an underuse and underdosing of guidelines-directed treatment. As the presence of a dedicated HF specialist and HF nurse might be associated with improved HF care, more attention should be directed towards the creation of well-established HF clinics. Additionally, reimbursement of NT-pro-BNP to screen and diagnose HF patients in an early stage, even at the GP's office seems desirable.

Frequency of cardiac and non cardiac monocomorbidity in heart failure outpatients stratified by ejection fraction phenotype: a single tertiary university center experience

G Gregory Giamouzis[1]; A Xanthopoulos[2]; N A Chroub-Papavaiou[1]; G Karagiannis[3]; A Pantziou[1]; A Douras[4]; A Simou[1]; J Skoularigis[1]; F Triposkiadis[1]

[1]University General Hospital of Larissa, Larissa, Greece; *[2]Cleveland Clinic Foundation, Cleveland, United States of America*; *[3]Harefield Hospital, London, United Kingdom of Great Britain & Northern Ireland*; *[4]General Hospital Volos, Volos, Greece*

Purpose: To assess the prevalence of major cardiac and noncardiac single comorbidity (mono-comorbidity) in a contemporary, unselected chronic heart failure (HF) population visiting the HF Clinic of a tertiary University Hospital, and its association with LVEF.
Methods: This is a prospective, observational study collecting epidemiological information in ambulatory HF patients from January 2016 to December 2018. Patients were classified according to baseline LVEF into HF with reduced EF [EF <40% (HFrEF)], mid-range EF [EF 40-50% (HFmrEF)] and preserved EF [EF >50% (HFpEF)]. Major cardiac and non cardiac comorbidities were recorded at baseline.
Results: Overall, 1064 patients (mean age 73.4 years, 57.7% men, mean LVEF=43.6%, 38.9% ischemic etiology) were recruited in this study [n = 361 (33.9%) HFrEF, n = 247 (23.2%) HFmrEF, and n = 456 (42.9%) HFpEF]. The frequency of mono-comorbidities in the total population as well as stratified by LVEF phenotype is presented in Table 1. In comparison with HFmrEF and HFpEF subjects, patients with HFrEF were more like to have a prior myocardial infarction (25.0% vs. 21.4% vs. 0%), atrial fibrillation (25.0% vs. 28.6% vs. 9.1%), diabetes (6.3% vs. 0% vs. 0%), and chronic kidney disease (12.5% vs. 0% vs. 0%), but less likely to have hypertension (12.5% vs. 35.7% vs. 81.8%) or obesity (0% vs. 14.3% vs. 4.5%).
Conclusion: The findings of the present study verify the theory that the presence of myocardial infarction favours the development of HFrEF whereas the presence of hypertension favours the development of HFpEF, with HFmrEF most probably representing a transition stage.

Table 1. Frequency of single comorbidity (monocomorbidity) by EF phenotype

Comorbidity	Total n=52/1064 (4.9%)	HFpEF n=22/456 (4.8%)	HFmrEF n=14/247 (5.7%)	HFrEF n=16/361 (4.4%)
Obesity, n (%)	3 (5.8)	1 (4.5)	2 (14.3)	0 (0)
Hypertension, n (%)	25 (48.1)	18 (81.8)	5 (35.7)	2 (12.5)
Myocardial infarction, n (%)	7 (13.5)	0 (0)	3 (21.4)	4 (25.0)
COPD, n (%)	0 (0)	0 (0)	0 (0)	0 (0)
Diabetes mellitus, n (%)	1 (1.9)	0 (0)	0 (0)	1 (6.3)
Atrial fibrillation, n (%)	10 (19.2)	2 (9.1)	4 (28.6)	4 (25.0)
Dyslipidaemia, n (%)	0 (0)	0 (0)	0 (0)	0 (0)
Smoking, n (%)	4 (7.7)	1 (4.5)	0 (0)	3 (18.8)
Anaemia, n (%)	0 (0)	0 (0)	0 (0)	0 (0)
Chronic kidney disease, n (%)	2 (3.8)	0 (0)	0 (0)	2 (12.5)

COPD, chronic obstructive pulmonary disease; EF, ejection fraction; HFmrEF, heart failure with mid-region ejection fraction; HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction

P931
Which results of the cardiopulmonary exercise test deserve greatest attention to establish the prognosis in heart failure?

F Francisco Gama[1]; P Freitas[1]; A Ferreira[1]; A Durazzo[1]; C Aguiar[1]; A Tralhao[1]; A Ventosa[1]; J Ferreira[1]; M Mendes[1]
[1]*Hospital de Santa Cruz, Lisbon, Portugal*

Background and aim: Limitation of exercise tolerance is one of the cardinal manifestations of heart failure (HF). Cardiopulmonary exercise testing (CPET) provides a thorough assessment of exercise integrative physiology involving the pulmonary, muscular, and oxidative cellular systems. We aimed to identify which data collected during a CPET shows the best prognostic performance with respect to predicting mortality or the need for heart transplantation (HT).
Methods: Single-centre retrospective cohort study of consecutive HF patients performing a CPET for functional and prognostic HF evaluation from October 1996 till May 2018. Left ventricular ejection fraction was not an exclusion criterion. A Cox model was fit with time to death or heart transplantation (whichever recorded first within 5 years) as the dependent variable and CPET parameters as the independent variables. Both unadjusted and adjusted covariate Cox regressions were performed. ROC curve analysis was used to determine whether the significant variables, as a model, could reliably predict the study endpoint.
Results: The study population consisted of 513 patients, median age 58 (IQ 16) years, and 74.9% male. The majority had reduced ejection fraction (75.4%), and the most common HF aetiology was ischemic heart disease (55.8%). During the 5-years follow up, 126 patients died and 60 underwent heart transplantation. In unadjusted Cox regression, nearly all CPET variables were significantly associated with the study endpoint. After covariate adjustment, with prior exclusion of redundant variables, three measures remained associated with the study endpoint: peak VO2 consumption (hazard ratio [HR] 0.85; 95% confidence interval [CI], 0.81-0.90); VE/VCO2 slope (HR 1.02; 95% CI, 1.00-1.02); presence of oscillatory ventilatory pattern (HR 3.73; 95% CI, 2.43-5.72). As a model, these 3 variables showed a strong discriminatory ability (c-statistic 0.87; 95% CI, 0.83-0.90) (see figure) for the study endpoint.
Conclusion: When using the CPET for prognostic stratification of HF patients, the presence of an oscillatory ventilatory pattern, the peak VO2 and the VE/VCO2 slope are the most important tools on which clinicians should focus.

P932
The long-term prognosis of patients with different types of heart failure admitted with decompensation in Russia

Y Yury Mareev[1]; V Mareev[2]; DS Polyakov[3]; IV Fomin[3]
[1]*National Research Center for Preventive Medicine, Moscow, Russian Federation*;
[2]*M.V. Lomonosov Moscow State University, Moscow, Russian Federation*;
[3]*Privolzhsky Research Medical University, , Nizhny Novgorod, Russian Federation*

Background: There is a lack of data about the long-term prognosis of patients with HFpEF and HFmrEF. Moreover, there is a debate about whether the diagnosis of these conditions is always correct in stable patients in countries where BNP/NT-proBNP is not checked routinely like Russia.
Purpose: To investigate the prognosis of patients who were admitted to a Russian hospital with proven decompensation of heart failure.
Methods: We investigate medical data of patients who were admitted to one hospital and whose LVEF were known. We investigated patients baseline characteristics and reviewed their prognosis for three years. We divided the patients into three subgroups regarding their LVEF.
Results: 494 patients were enrolled in the study: 100 HFrEF, 110 HFmrEF and 284 HFpEF. The median age of patients was 75 years, and there was no difference between groups regarding age. The highest rate of infarction and cardiomyopathy were in HFrEF (58% and 34%), followed HFmrEF (38% and 18%) and then HFpEF (25% and 9%). The percent of women was 42% in HFrEF, 50% in HFmrEF and 70% in HFpEF. At the admission, systolic blood pressure in HFrEF and HFmrEF were lower than in HFpEF (130 vs 145 mm Hg). Heart rate was the highest in HFrEF following HFmrEF and HFpEF (97 vs 91 vs 86 bpm). The one-year

mortality where 28%, 25.5% and 24.3% in HFrEF, HFmrEF and HFpEF respectively. (graph 1)

Conclusion: All three groups of patients had a bad prognosis. The mortality rate of these severely ill patients is similar to results from other studies with the same population which showed that mortality of patients with confirmed heart failure in Russia is not lower than in other countries opposite the results of subanalysis of patients from Russia in TOPCAT study.

Gender differences in plasma levels and prognostic value of NT-proBNP in chronic heart failure

A Aimo[1]; JL Januzzi[2]; G Vergaro[3]; R Latini[4]; IS Anand[5]; JN Cohn[5]; J Gravning[6]; HP Brunner-La Rocca[7]; A Bayes-Genis[8]; RA De Boer[9]; Y Takeishi[10]; M Egstrup[11]; HK Gaggin[2]; K Huber[12]; M Emdin[13]

[1]Azienda Ospedaliero-Universitaria Pisana, Scuola di Specializzazione Malattie dell'Apparato Cardiovascolare, Pisa, Italy; *[2]Massachusetts General Hospital, Boston, United States of America*; *[3]Gabriele Monasterio Foundation, Pisa, Italy*; *[4]IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Milan, Italy*; *[5]University of Minnesota, Minneapolis, United States of America*; *[6]Oslo University Hospital, Oslo, Norway*; *[7]Maastricht University Medical Centre (MUMC), Maastricht, Netherlands (The)*; *[8]Germans Trias i Pujol University Hospital, Badalona, Spain*; *[9]University Medical Center Groningen, Groningen, Netherlands (The)*; *[10]Fukushima Medical University, Fukushima, Japan*; *[11]Rigshospitalet - Copenhagen University Hospital, Copenhagen, Denmark*; *[12]Medical University of Vienna, Vienna, Austria*; *[13]Sant'Anna School of Advanced Studies, Pisa, Italy*

Background: Natriuretic peptides are established biomarkers of heart failure (HF). The existence of gender-related differences in circulating levels and prognostic value are still controversial.

Methods: Individual patient data from studies assessing cardiac biomarkers (N-terminal fraction of pro-B-type natriuretic peptide - NT-proBNP - and high-sensitivity troponin T) for risk prediction in stable chronic HF were analysed.

Results: Women (n=1964, 23%) had higher median [interquartile interval] NT-proBNP concentrations than men (1678 [659-4215] vs. 1294 [522-2973] ng/L, p<0.001). Female gender predicted higher NT-proBNP independently from age, body mass index, glomerular filtration rate, left ventricular ejection fraction (LVEF), and atrial fibrillation.

Over a 2.4-year follow-up (1.6-3.2), 2351 patients (27%) died, and cardiovascular death occurred in 1558/8271 (19%). HF hospitalization was recorded in 2088/7944 (26%) over 2.0 years (1.3-2.6). Women and men had similar areas under the curve for the 3 endpoints, with higher cut-offs among women: all-cause death, 2328 ng/L vs. 1319 ng/L; cardiovascular death, 2328 ng/L vs. 1413 ng/L; HF hospitalization, 1265 ng/L vs. 907 ng/L. In the prognostic model above, the risk of the three endpoints increased by 32%, 35%, and 17%, respectively, per doubling of NT-proBNP in women, and by 41%, 45%, and 30% in men.

Conclusions: Women with chronic HF display higher NT-proBNP levels than men in the whole population as well as across many patient subgroups. This difference is not entirely explained by heterogeneity in age, BMI, or renal function. NT-proBNP holds independent prognostic significance in both genders, although alternative prognostic cut-offs might be considered for women.

P934

RDW is an important marker in a one-year prediction of survival with stable systolic heart failure

LV Prokopova[1]; MYU Sitnikova[1]; EV Shlyakhto[1]

[1]Almazov National Medical Research Centre, Department for Heart Failure, Saint Petersburg, Russian Federation

Prediction of patient survival for one year is the stage of determining indications for high-tech methods of care. The forecasting process is hampered by a wide variety of markers of poor prognosis and variability in the course of the disease.

Purpose: Evaluate the contribution of the width of the distribution of red blood cells by volume (RDW) to the prediction of heart failure in a stabilized patient with systolic heart failure.

Materials and methods: A prospective study of 212 patients with "non-valvular etiology" of HF with an LV ejection fraction (Simpson) ≤ 35% at the age of 18-70 years. Of these, 176 men (83%) and 36 women (17%). Design work: hospitalization of patients in the treatment of heart failure; selection of therapy and stabilization of patients; assessment of status, performance of laboratory and instrumental studies; observation, telephone contacts, correction of therapy and hospitalization during decompensation; filling the database of 200 indicators. After 12 months, the endpoints were recorded. Results: Within 12 months, 64% of patients (135 people) survived, 2% (5 people) had an implant system EXCOR, 10% (21 people) had cardiac transplantation, 24% of cases (51 people) were lethal. The end points reached 77 people. In patients who reached the end point, the RDW level was significantly higher: Me 17.5% (min-max 12.3 - 28%). In patients who did not reach the end point, the RDW level was lower: 14.1% (min-max 11.0-13.0%). After a multifactor regression analysis procedure, RDW entered the method for predicting heart failure for 1 year. This method is as follows. The patient in the stable phase of the disease on the background of optimal drug therapy is determined by the frequency of respiratory movements, the level of systolic blood pressure measured at 3-5 minutes of orthostasis, the content of lymphocytes and RDW in the serum and the age of the patient in which the clinic of heart failure debuted. Calculate Z using the original formula. With Z> -1.7, survival is predicted to be less than 1 year, with Z≤-1.7 - more than 1 year.

Discussions: The increase in % RDW reflects the main pathological processes leading to the progression of HF — inflammatory stress and an iron metabolism disorder. In heart failure, a so-called "reticuloendothelial block" develops, mediated by overexpression of hepcidin, a peptide-hormone that is secreted in the liver and is a regulator of iron metabolism. Hepsidin is activated during hypoxia and inflammation, reduces the absorption of iron from the intestine and the reticuloendothelial depot. In addition, inflammatory cytokines can directly inhibit erythropoietin-induced maturation of erythrocytes, which is reflected in an increase in RDW.

P935

The Charlson comorbidity index: A significant predictor of increased mortality and cardiac related hospitalizations in patients with heart failure

I Israel Gotsman[1]; O Ezra[1]; DR Zwas[1]; C Lotan[1]; A Keren[1]

[1]Hadassah University Hospital, Jerusalem, Israel

Background: Comorbidities are highly prevalent in patients with heart failure (HF) and are suggested to have an impact on clinical outcome. The Charlson comorbidity index is a validated score to estimate mortality in patients with multiple comorbidities.

Purpose: To evaluated the predictive value of the Charlson comorbidity score on clinical outcome in patients with HF.

Methods: All patients with a diagnosis of chronic HF and the Charlson comorbidity index at a health maintenance organization were evaluated. Patients were followed for cardiac related hospitalizations and death.

Results: The cohort included 6,404 HF patients. Mean follow-up was 576 days; the median Charlson score was 6 (interquartile range 5-7); age-adjusted Charlson score was 9 (8-10). The Charlson score and the age-adjusted Charlson score were discriminative and significant predictors of survival as well predictive of the combined end point of death and cardiovascular hospitalization (Figure 1). After adjustment for other significant predictors, increasing Charlson score and age-adjusted Charlson score were independently predictive of survival and the combined end point of death and cardiovascular hospitalization by Cox regression analysis. Area under the curve (AUC) by receiver operating curve (ROC) demonstrated that the AUC for the Charlson, age-adjusted Charlson and the HF adjusted model were 0.62; 0.65 and 0.715 respectively (P<0.0001 for all models).

Conclusions: Comorbidities as evident by the Charlson comorbidity index have a significant impact on outcome in HF patients.

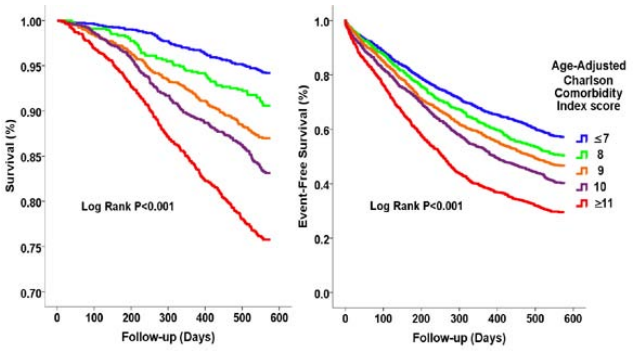

Figure 1. KM Survival Analysis

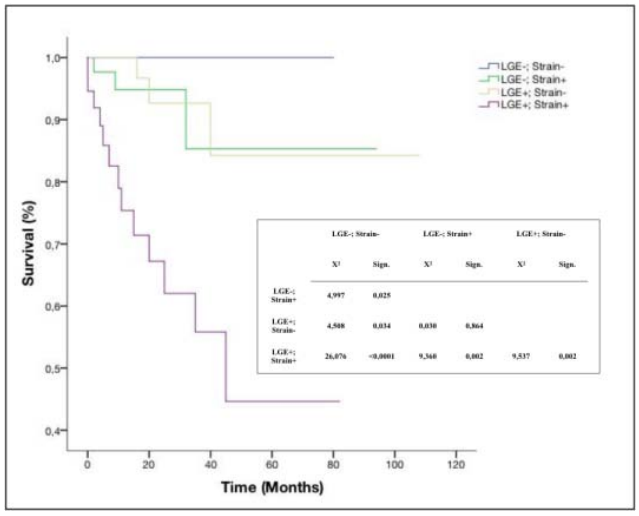
P936

Prognostic role of right ventricular global longitudinal strain in dilated cardiomyopathy

M Marco Cittar[1]; M Merlo[1]; G Vitrella[1]; M Mase'[1]; G Barbati[2]; M Belgrano[3]; L Pagnan[3]; M Gobbo[1]; L Crosera[1]; M Della Paolera[1]; MA Cova[3]; D Stolfo[1]; G Sinagra[1]
[1]University Hospital Riuniti, Cardiovascular Department, Trieste, Italy; *[2]University of Trieste, Biostatistic Unit, Trieste, Italy*; *[3]University Hospital Riuniti, Radiology Department, Trieste, Italy*

Introduction: The prognostic stratification in dilated cardiomyopathy (DCM) remains a demanding issue in clinical practice. In addition to left ventricular (LV) function evaluation, the presence of fibrosis and right ventricular (RV) dysfunction are considered among the most promising prognostic tools in DCM. In this field, cardiac magnetic resonance (CMR) has emerged as the gold standard technique for both ventricle dysfunction and tissue characterization (i.e. late gadolinium enhancement (LGE) distribution) assessment. Recently, speckle tracking echocardiography (STE) has emerged as a method to study the intrinsic performance of the myocardial wall, making it possible to identify subtle RV dysfunction in DCM patients. Other recent studies successfully demonstrated that LV feature tracking analysis (FTA) is able to give additional prognostic power when combined with the above-mentioned classical parameters.
Purpose: Evaluation of left ventricular strain at FTA has shown an incremental prognostic value compared to classical parameters, but nothing is known about the possible prognostic role of Right Ventricular (RV) strain. The aim of the study was to evaluate the prognostic impact of FTA focusing on Right Ventricular Global Longitudinal Strain (RV-GLS) in a large population of DCM.
Methods: 183 DCM patients were examined with a comprehensive morpho-functional CMR study including FTA. The study endpoint was defined as a composite of (i) cardiovascular death, (ii) cardiac transplant (iii) implantable cardiac defibrillator appropriate intervention.RESULTS During a median follow-up period of 23 months, 20 patients (11%) experienced the study endpoint. At the univariate analysis, LGE and RV-GLS were the most powerful predictors of events and they remained independent even at multivariate level (LGE Hazard Ratio [HR]: 4.86; p=0.006; RV-GLS HR: 1.17 per %; p=0.001). By Receiver Operating Characteristics (ROC) analysis, -19% emerged as the most accurate RV-GLS cut-off able to identify the risk of presenting the end-point. By Kaplan-Meier analysis, patients with a RV-GLS value >-19% showed a reduced survival (log-rank p<0.0001) even if the right ventricle ejection fraction (RVEF) was preserved (log-rank p=0.016). RV-GLS >-19% and LGE presence equally impacted on the end-point development and their compresence showed an additive effect (see Picture).
Conclusions: RV-GLS is an independent short-term predictor of major cardiovascular events in DCM and showed an incremental value, better than parameters such as LV and RV ejection fraction.



Picture

P937

Impact of nutritional scores in patients with stable heart failure with reduced ejection fraction

J Novak[1]; A Cho[1]; H Arfsten[1]; G Goliasch[1]; P E Bartko[1]; G Strunk[2]; M Huelsmann[1]; N Pavo[1]
[1]Medical University of Vienna, AKH – Vienna, Cardiology Clinic, Cardiology, Vienna, Austria; *[2]Research Institute for Complex Systems - Complexity-Research, Vienna, Austria*

Background: Malnutrition is a common condition associated with worse outcome in patients with heart failure with reduced ejection fraction (HFrEF). Inflammation is closely linked to nutritional depletion and advanced HF. We aimed to investigate the relationship of well-established nutritional indices with inflammation and the impact of on survival of stable patients with stable HFrEF.
Methods: Patients with stable HFrEF undergoing routine ambulatory care between January 2011 and November 2017 have been identified from a prospective registry. Comorbidities and laboratory data at baseline were assessed. All-cause mortality was defined as the primary study endpoint. The Nutritional Risk Index (NRI) [(1.519 × serum albumin, g/dL) + (41.7 × present weight (kg)/ideal body weight(kg))] and the Prognostic Nutritional Index (PNI) [(=albumin (g l−1) × total lymphocyte count × 109 l−1)] as well as the Neutrophil-to-Lymphocyte ratio (NLR), the Monocyte-to-Lymphocyte ratio (MLR) and the Platelet-to-Lymphocyte ratio (PLR) were calculated. The association of the scores with heart failure severity and impact on overall survival were determined.
Results: Data was complete and analyzed for a total of 443 patients. The median age of the study population was 64 years (IQR 53-72) and 73% of the patients were male. The median body mass index (BMI) was 26.6kg/m2 (IQR 23.8-30.2). Median NT-proBNP levels were 2053pg/ml (IQR 842-4345) with most patients presenting in the NYHA classes II (178, 40%) and III (173, 39%). The nutritional scores correlated well with heart failure severity reflected by NT-proBNP [r=-0.32, p<0.001 for NRI and r=-0.48, p<0.001 for PNI] and NYHA class [p<0.001 for NRI and PNI] as well as with progressing inflammation reflected by the inflammatory scores [NRI: r=-0.11, p=0.032 for NLR, r=-0.18, p<0.001 for PLR and r=-0.08, p=0.101 for MLR and PNI: r=-0.76, p<0.001 for NLR, r=-0.075, p<0.001 for PLR and r=-0.71, p<0.001 for MLR] and C-reactive protein [r=-0.25, p<0.001 for NRI and r=-0.24, p<0.001 for PNI]. Both nutritional scores were associated with all-cause mortality in the univariate analysis, and after adjustment for age, gender and kidney function [adj. HR 0.60 (0.41-0.89), p=0.011 for NRI and 0.48 (0.31-7.34), p<0.001 for PNI]. The ROC was 0.597 for NRI and 0.674 for PNI. The PNI, but not NRI, remained significantly associated with mortality when NT-proBNP was included in the multivariate model [adj. HR 0.62 (95%CI 0.40-0.96), p=0.032]. Kaplan Meier analysis confirmed the discriminatory power of PNI (Figure 1).
Conclusions: Nutritional depletion and enhanced inflammation is more common in advanced disease. The nutritional score PNI is associated with survival in HFrEF patients independently of NT-proBNP highlighting the importance of nutritional state on prognosis.The easily available score may help clinicians to identify HFrEF patients with worse prognosis with urgent need for intensified therapy and/or alternate treatment options.

P938

Relationship of genetic determination of peripartum cardiomyopathy to its clinical outcome

T Schimerova[1]; M Kubanek[1]; A Krebsova[1]; L Piherova[2]; V Stranecky[2]; V Melenovsky[1]; J Kautzner[1]
[1]Institute for Clinical and Experimental Medicine (IKEM), Prague, Czechia; [2]First Faculty of Medicine and General Teaching Hospital, Institute of inherited metabolic diseases, Prague, Czechia

Funding Acknowledgements: Supported by the research grants [MZ 15-27682A] and No 00023001 (IKEM, Prague, Czech Republic).

Background: Peripartum cardiomyopathy (PPCM) is an idiopathic form of cardiomyopathy characterized by manifestation of heart failure within the last month before or 5 months after the labour. PPCM reflects genetic predisposition and/or can be triggered by pathologic processes associated with pregnancy, such as preeclampsia or by oxidative stress due to prolactin hypersecretion.
We aimed to assess the genetic background of PPCM and to correlate it with the clinical outcome.
Methods: We performed whole-exome sequencing in 15 females with PPCM and analysed the data using bioinformatics. We evaluated the family history of dilated cardiomyopathy (DCM), clinical characteristics and results of echocardiographic follow-up, mainly of left ventricular ejection fraction (LVEF). Left ventricular reverse remodelling was defined by an increase of LVEF more than 10 % and a decrease of end-diastolic diameter (LVEDD) more than 10 % at 1 year of follow-up. Mean age of disease manifestation was 30.5±6.4 years, mean baseline LVEDD was 64±7 mm and mean baseline LVEF was 23±5 %.
Results: Family history of DCM was found in 7 patients (47 %). Suspected pathogenic mutation of one of the cardiomyopathic genes (TTN, DMD, MYH7, FLNC, TMEM43, OBSCN) was found in 9 patients (60 %). Early implantation of a mechanical assist device followed by heart transplantation was necessary in 1 case. Left ventricular reverse remodelling at 1 year of follow-up occurred in 6 patients (40 %). The mean LVEF at the last follow-up was 40 % (median of follow-up 5 years). At the last follow-up, genotype-positive patients were less likely to have LVEF >40 % than genotype-negative patients (33 % vs 100 %, p=0.010). The value of LVEF at the end of follow-up was not associated with family history of DCM (p=0.205).
Conclusion: A substantial proportion of patients with PPCM had a positive genetic background (family history of DCM or pathogenic mutation of cardiomyopathic genes). The genotype-positive patients with PPCM were more likely to have systolic dysfunction during the follow-up than genotype-negative patients.

P939

A TNM-like staging system for risk stratification in heart failure patients: comparison with others nosologies

P Severino[1]; R Scarpati[1]; M Mariateresa Pucci[1]; M Alfarano[1]; A D'amato[1]; L Netti[1]; F Infusino[1]; D Alunni Fegatelli[1]; A Vestri[1]; V Maestrini[1]; M Mancone[1]; F Fedele[1]
[1]Sapienza University of Rome, Rome, Italy

Background: To better classify patients with heart failure (HF), we proposed a new staging system named HLM, analogous to TNM classification used in oncology, which refers to heart damage (H), lung involvement (L), and malfunction (M) of peripheral organs (JACC 2014;20;63(19):1959-60). The aim of this study was a comparison between HLM and NYHA, ACC/AHA, ESC and MAGGIC score to assess the most accurate prognosis of HF patients in terms of rehospitalization for major adverse cardiac and cerebrovascular events (MACCE) and cardiac death.
Methods: We performed an observational registry of 1380 consecutive HF patients. All parameters for heart, lungs and peripheral organs function were examined. Each patient was classified according to HLM, NYHA, ACC/AHA, ESC and MAGGIC score at the entrance and at the discharge. Rehospitalization for MACCE and cardiac death were checked at 12 months follow up.
Results: Among 1380 patients: 68.5% males, 31.3% females, mean age 70.18 ± 7.48 years. Overall survival curves regarding rehospitalization for MACCE and cardiac death at 12 months, show that HLM classification is as valid as the others (p<0.001). In particular, the area under the ROC curve (AUC) is greater for HLM than NYHA, ACC/AHA, ESC and MAGGIC score in terms of MACCE (HLM=0.691; NYHA=0.625; ACC/AHA=0.593; ESC= 0.547; MAGGIC=0.624) and cardiac death (HLM=0.792; NYHA=0.711; ACC/AHA=0.637; ESC=0.562; MAGGIC=0.729). All the variables of each nosology are significantly correlated with rehospitalization for MACCE and cardiac death (p<0.001), except NYHA II, HFmrEF and all the ACC/AHA stages (p>0.05).
Conclusions: According to these results, HLM classification has greater prognostic power compared to the other nosologies in terms of MACCE and cardiac death in HF patients, thanks to the evaluation of heart, lung and peripheral organs involvement. A wider and systemic approach should be used in HF patients, in order to improve clinical management and costs.

P940

Vegetative nervous system imbalance as the factor of development and progression of chronic kidney disease in patients with heart failure associated with metabolic syndrome

GM Dussekeyeva[1]; RR Rekvava[1]; AK Abdymomunov[1]; ZN Ligay[2]; AI Isakhanova[1]; MV Khomyakova[2]
[1]Scientific Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan; [2]Kazakh-Russian Medical Univercity, General practioners, Almaty, Kazakhstan

Introduction: Metabolic Syndrome (MS) is a very common condition among patients with heart failure (HF).MS is associated with subclinical defeat of vitals and has a great contribution for the development of HF, which can be complicated with Chronic Kidney Disease (CKD). CKD quite often defines quality of life,the forecast in patients with HF.Early identification of markers of CKD at patients with HF and MS can prevent CKD progression.
Objective: To estimate presence of an imbalance of the vegetative nervous system (VNS) patients with HF and MS and its influence on development of CKD.
Methods: Retrospective analysis of clinical records of 350 patients corresponding to the diagnosis of HF (according HFA recomendatios,2016) and MS (according to criteria of consensus of the International federation of diabetes) being on hospitalization in one of the hospitals of Almaty,Kazakhstan from 2015 to 2018 was carried out. In all patients was calculated the standardized glomerular filtration rate (GFR),ml/min./ 1,732, and the analysis of urine on a microalbuminuria (MAU) was made.Twenty- four hours monitoring of an electrocardiogram by Holter was carried out to all patients.
Results: 78% of patients had HF with preserved ejection fraction (EF), other 22% had HF with mildly reduced EF. All of them had elevated levels of proBNP. According kidneys function, all patients were divided into 4 groups: 1) patients with norm filtration (NF) without MAU (average GFR 90)- 79 patients entered 2) patients with NF with MAU (average GFR 84) and MAU (average value 47,5)-75 patients entered 3) patients with hyperfiltration (HRF) -115 patients (average GFR - 120) 4) patients with a hypofiltration (HPF) (average GFR 57) - 81 patients. The analysis of a condition of VNS in these groups according to twenty-hours long monitoring of an electrocardiogram by Holter has been carried out. The following indicators were analyzed: the circadian index (CI);SDNN, milliseconds(ms)(a standard deviation of all normal R-R of intervals); SDANN, ms (the standard deviation of average NN calculated for short (5 minutes) periods). Data of the temporary analysis of VSR in group with HRF are characterized by the prevalence of sympathetic activity (SA) of VNS over parasympathetic (PA). In group with NF the tendention to decrease in SA with some increase in PA was noted. In group with a hypofiltration -hyper activation of SA with strengthening of PA. The group with HRF and HPF, in the analysis of a daily rhythm variability (DRV) was characterized by his expressed decrease, in group without markers of CKD DRV is close to norm.
Conclusions: We showed the presence of VNS imbalance among the patients with HF and MS and impaired kidneys function. The degree of VNS imbalance correlate with the stage of CKD. For the prevention of CKD development greater attention for the blocking of sympathetic nervous system must be paid.

Value of lung ultrasound in chronic stable ambulatory heart failure patients

M Domingo[1]; L Conangla[1]; J Josep Lupon[1]; M De Antonio[1]; P Moliner[1]; E Santiago-Vacas[1]; E Zamora[1]; B Gonzalez[1]; V Diaz[1]; C Rivas[1]; P Velayos[1]; J Santesmases[1]; S Altimir[1]; M Boldo[1]; A Bayes-Genis[1]
[1]Germans Trias i Pujol University Hospital, Badalona, Spain

Background: The role of lung ultrasound (LUS) in diagnosis and response to diuretic treatment of patients with acute HF has been widely studied, but less is known about its value in chronic HF.
Purpose: To assess the prognostic value of LUS in a cohort of chronic HF stable ambulatory patients and to explore the relationship of LUS findings with clinical data, such as NYHA functional class, left ventricular ejection fraction (LVEF) and NTproBNP.
Methods: Consecutive stable ambulatory patients who attended a scheduled follow-up visit in a HF clinic were included. LUS were performed with a pocket device and examined 4 chest areas per side (two anterior and two lateral). Scans were analysed offline by two investigators blinded to clinical data, who evaluated the number of B-lines of each area. The addition number of B-lines of each area and the quartiles of such addition were used for the analyses. The primary outcome end-point was the composite of all-cause death or hospitalization due to HF at one year. Linear regression and Cox regression analyses were performed.
Results: Five-hundred seventy-seven patients were included between July 2016 and July 2017 (age 69 ± 12 years, 72% men). The main HF aetiology was ischemic heart disease (43%) followed by dilated cardiomyopathy (20%). Median HF duration was 79 months (Q1-Q3 38-144). Mean LVEF was 45%±13 (mean LVEF when admitted at the Unit 34%±13). Most patients were in NYHA functional class II (70%), 13% were in class I and 17% in class III. Median NTproBNP was 722 ng/L (Q1-Q3 262-1760). Mean number of B-lines was 5 ± 6 (Q1, 0; Q2, 1-3; Q3, 4-7; Q4, ≥8). The number of B-lines was associated with age (beta-coefficient 0.11, p<0.001), NYHA functional class (beta-coefficient 1.75, p<0.001), and logNTproBNP (beta-coefficient 1.40, p<0.001). Mean number of B-lines according to NYHA functional class was: class I, 3.5 ± 6; class II, 4.9 ± 6; and class III, 7.1 ± 7. During the one year follow-up 47 patients suffered the primary end-point. In total there were 24 HF related hospitalizations and 26 deaths. In Cox regression analysis, Q4 of B-lines showed a double risk of suffering the primary end-point (HR 2.13 [95%CI 1.18-3.84], p=0.01). However, statistically significance was not maintained for LUS results in the multivariable analysis when age, NYHA functional class and logNTproBNP were included in the model, although a 38% increase in the risk of suffering the primary end-point for Q4 was observed (HR 1.38 [95%CI 0.75-2.54], p=0.31).
Conclusion: In outpatients with stable chronic HF, the number of B-lines detected in LUS was associated with age, NYHA functional class and NTproBNP. Patients having ≥8 B-lines had a significant double risk of HF related hospitalization or all-cause death at one year. However, when strongly powerful prognostic variables such as NYHA class and NTproBNP were included in the model LUS did not retain an independent prognostic role.

P942
A registry-based algorithm to predict ejection fraction in electronic health records

A Uijl[1]; S Koudstaal[2]; I Vaartjes[1]; FW Asselbergs[2]; AW Hoes[1]; U Dahlstrom[3]; G Savarese[4]; LH Lund[4]

Funding Acknowledgements: This work has received support from the EU/EFPIA Innovative Medicines Initiative 2 Joint Undertaking BigData@Heart grant n° 116074

Background: Electronic health records (EHRs) provide abundant routine clinical care data to support research, but often lack phenotypic information needed to discern relevant subphenotypes. Left ventricular ejection fraction (EF) is required to discriminate the different heart failure (HF) phenotypes [i.e. HF with preserved (HFpEF), mid-range (HFmrEF) and reduced (HFrEF) EF], but is not collected in EHRs. This may represent a major limitation when using EHRs in HF research. Aim of this analysis was to create an algorithm that identifies HF EF phenotypes in routine care data using available patient's characteristics.
Methods: We included 42,061 HF patients from the Swedish Heart Failure Registry that collects data on EF and biomarkers. For the primary analysis we performed two logistic regression models to predict 1) HFrEF and HFmrEF vs. HFpEF; and 2) HFrEF vs. HFmrEF and HFpEF. In the secondary analysis we performed a multivariable multinomial logistic regression to create a prediction model for all 3 separate HF phenotypes: HFrEF vs. HFmrEF vs. HFpEF. The models included 22 predictors: age, sex, NT-proBNP, NYHA class, mean arterial pressure, heart rate, Body Mass Index (BMI), estimated Glomerular Filtration Rate (eGFR), history of ischaemic heart disease, atrial fibrillation, Chronic Obstructive Pulmonary Disease (COPD), diabetes, hypertension, anemia, cancer in previous 3 years, valvular disease, device therapy, RAS inhibitors, beta-blockers, diuretics, MRA, digoxin.
Results (Figure 1): The C-statistic, that measures the discriminative ability of a predictive model, was 0.774 (95% confidence interval 0.769 - 0.780) for HFrEF and HFmrEF vs. HFpEF, 0.756 (95% CI 0.752 – 0.761) for HFrEF vs. HFmrEF and HFpEF, 0.683 (95% CI 0.677 - 0.688) for HFpEF vs. HFmrEF vs. HFrEF. Strongest predictors for the HFpEF phenotype were older age, female sex, presence of hypertension, atrial fibrillation and anemia, while those for HFrEF were presence of a cardiac device (implantable cardioverter defibrillator or cardiac resynchronization therapy), increased levels of NT-proBNP, use of RAS-inhibitors and beta-blockers.
Conclusion: Baseline patient characteristics from EHR could be used to identify different EF phenotypes in HF. Both logistic models categorizing HFmrEF with either HFrEF or HFpEF performed better than the multinomial model. This may be explained by different phenotypes coexisting within HFmrEF and part of HFmrEF patients having transitioning EF.

Background: Heart failure with mid-range ejection fraction (HFmrEF) is a poorly defined entity, where evidences for optimal treatment are lacking. We describe the temporal trend of EF in HFmrEF and long-term outcome, as observed.
Methods: Patients enrolled in IN-CHF Registry were grouped, according to baseline EF, in preserved (HFpEF, >50%), mid-range (HFmrEF, 40-49%) and reduced EF (HFrEF, <40%). We reported clinical characteristics, long-term mortality and, when available, EF trend.
Results: Out of 7559 pts (72% males, age 69±13 yrs, EF 37±11%), 4338 had HFrEF (57%), 1792 HFmrEF (24%) and 1429 HFpEF (19%). Mortality at 21±23 months was lower in HFmrEF (8.4%, p .001) compared with HFrEF (11.2%), but not with HFpEF (9.7%).
In the subgroup with a second echocardiography (Table), mortality at 36±28 months was 4.5%, 7% and 7.3% (for HFmrEF, HFrEF and HFpEF respectively, p ns) when patients were phenotyped according to baseline EF, and 3.7%, 8.1% and 6.4% when grouped according to follow-up EF (p .01).
Conclusions: In IN-CHF Registry, HFmrEF patients were more similar to HFrEF, rather than to HFpEF patients. HFmrEF shows greater variability than other groups: only 60% of patients with HFmrEF at enrollment stayed in the same group at follow-up (vs 71% of HFrEF and 82% of HFpEF). These data suggest that clinical studies on HFmrEF should consider its peculiar temporal trend.

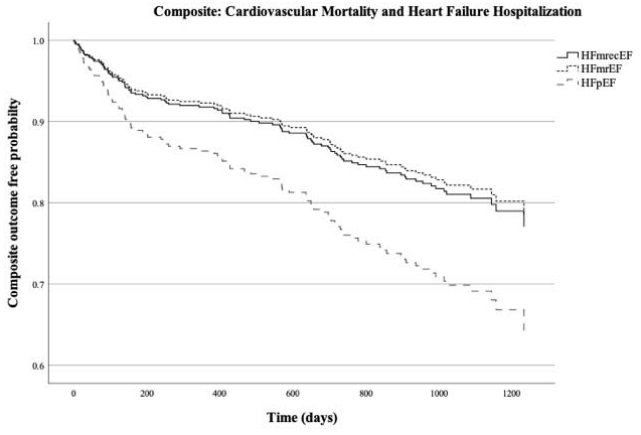
The impact of prior ejection fraction on clinical outcomes in patients with heart failure with mid-range ejection fraction

A Brann[1]; S Janwanishstaporn[2]; B Greenberg[1]
[1]*University of California San Diego, San Diego, United States of America*; [2]*Siriraj Hospital of Mahidol University , Bangkok, Thailand*

Background: Heart failure (HF) patients are classified according to ejection fraction (EF). Although HF with mid-range EF (HFmrEF) is recognized in guidelines, neither the clinical characteristics nor the natural history of this cohort of HF patients are fully defined. The heterogeneity of the HFmrEF population, which includes some patients whose EF had previously been preserved (HFpEF) and others with reduced EF that had partially recovered (HFmrecEF), contributes to this uncertainty.
Purpose: To compare the clinical characteristics and outcomes of patients with HFmrEF according to whether they previously had preserved EF that had fallen over time or reduced EF that had partially recovered.
Methods: All patients at our institution in 2015 with a diagnosis of HF who had an echocardiogram with an EF measured between 40-50% and had at least one prior echocardiogram three months or more prior were included. Patients were classified into groups according to whether their EF either: improved from a prior EF of <40% (HFmrecEF), was consistently between 40-50% on all past echocardiograms (HFmrEF) or had been greater than 50% on all past echocardiograms before falling into mid-range (HFpEF). Data was collected through retrospective review of the electronic medical record. Multivariable Cox regression analyses for outcomes were adjusted for age, gender, CKD, CAD and atrial fibrillation.



Results: Of the 915 patients with EF 40-50%, 467 patients who did not have a prior echocardiogram for comparison were excluded. Among the remaining 448 patients, 157 (35%) had HFmrecEF, 67 (15%) had stable HFmrEF, and 224 (50%) previously had HFpEF. Patients with HFmrecEF were younger and were more likely to have a history of symptomatic HF and CKD. Patients with HFpEF were more likely to be female. Most other variables were similar in the 3 patient groups. Over a median follow-up time of 2.2 years, prior HFpEF when compared to HFmrecEF patients exhibited a trends towards higher all-cause mortality (adjusted HR 1.52, confidence interval [CI] 0.96-2.41, p=0.074), higher likelihood of all-cause hospitalization (adjusted HR 1.38, CI 1.01-1.09, p=04), and higher likelihood of the composites of all-cause mortality and HF hospitalization (adjusted HR 1.6, CI 1.02-2.21, p<0.02) and cardiovascular mortality and HF hospitalization (adjusted HR 1.71, CI 1.09-2.69, p=0.02). No significant differences in outcomes between HFmrecEF and HFmrEF were seen.
Conclusion: These findings demonstrate the diversity of the HFmrEF population. They suggest that the natural history of patients identified by an EF in the 40-50% range differs depending on their prior EF. Notably, HFpEF patients whose EF had reduced into the 40-50% range were at higher risk for events than patients in the other sub-groups.

Factors influencing the hospital re-admission rates of heart failure patients: insights from the North-West of England.

T Tahir Nazir[1]; A Nugroho[1]; S Ahmad[2]; I Ahmed[2]
[1]*University of Manchester, Manchester, United Kingdom of Great Britain & Northern Ireland*; [2]*Royal Preston Hospital, Preston, United Kingdom of Great Britain & Northern Ireland*

Introduction: Heart failure (HF) affects 2% of Europe's population; prevalence increases with age and approximately one in every five people aged 70 and above suffers from HF. Nearly 5% of all UK hospital admissions are related to the heart failure. It is a costly condition, with most of its expenditure related to hospital care of patients with heart failure.Objectives/ Purpose
Although HF patients have low in-patient mortality, their re-admission rates are significantly high; UK data shows that 10-20% require re-hospitalisation within 1 month and 50- 75% within 1 year of hospital discharge. We explore the factors influencing the hospital readmission in this patient cohort.
Methods: Hospital episode statistics (HES) data for north west of England hospitals for HF related hospital admissions, length of stay (LOS) and 28 day readmission rates for the year 2017/18 were reviewed. This was triangulated with the Clinical Commission Groups (CCG) records on readmissions and the adherence with guideline directed therapy and demographic data related to ageing and household income and finally, data on configuration of heart failure services from community and hospital based HF teams by using a survey .
Results: From June 2017 -June 2018; HF related non-elective hospital admission rates varied (210-530/ 100,000 population) in five hospitals in the Northwest of England. Unplanned 28 days readmission rates were even more markedly variable with the lowest being 51 and highest 93 (per 100,000) population. Lower readmission rates were seen in the institutions where patients were stabilised after intravenous to oral diuretic switch and where the HF services were led by a HF specialist cardiologist (p0.02). Lower length of stay was associated with higher readmission rates (p0.001).
Clinical commissioning groups (CCG) data also supported this trend; lower adherence to first line HF therapy associated with higher readmission rates. Increased proportion of local elderly population (4-23% >65 yrs) and lower weekly household income (<£250/ week) was also associated with higher readmissions (CI 95%, P<0.05). This was most likely due to a higher disease and comorbidity burden resulting high hospital admission rates.
Conclusion HF related hospital readmissions continue to be a significant issue for the UK health economy. Population demographics, socio-economic status, configuration and leadership of local HF services, adherence to guideline directed therapy and a push to reduce in-patient length of stay; all seem to play a part in determining the rehospitalisation rates. Multi-faceted strategies tailored to the local needs are required to tackle this important issue.

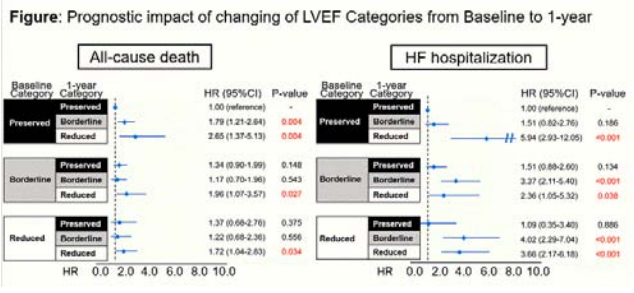
BNP, brain natriuretic peptide; BP, blood pressure; CCB, calcium antagonist;IHD,ischemic heart disease; LVDd, left ventricular end-diastolic diameter; LVMI, left ventricular mass index.

Background: Transition of left ventricular ejection fraction (LVEF) and its prognostic impact is not well established in patients without heart failure (HF).
Purpose: To examine the relationship between temporal changes in LVEF and their clinical impacts in patients at risk of HF.
Methods: We enrolled 3,935 consecutive asymptomatic patients at risk of HF in the CHART-2 Study, and divided them into 3 groups by baseline LVEF (Preserved, ≥50%, N=3,478; Borderline, 41-49%, N=291; Reduced, ≤40%, N=166). We examined the transitions among the 3 groups from baseline to 1-year for all-cause death and HF hospitalization.
Results: Borderline and Reduced at registration transiently changed to other groups at 1-year, whereas Preserved did not; at 1-year, Borderline transitioned to Preserved and Reduced by 50.0% and 14.4%, and Reduced transitioned to Preserved and Borderline by 25.3% and 31.3%, respectively, whereas Preserved transitioned to Borderline and Reduced only by 3.6% and 0.8%, respectively. Transitions from Preserved to Borderline, Preserved to Reduced, and Borderline to Reduced, and Reduced to Reduced were significantly associated with increased 5-year mortality. Transitions from Preserved to Reduced, and Borderline to Borderline, Reduced, and Reduced to Reduced were significantly associated with increased 5-year incidence of HF hospitalization, whereas transitions from Borderline or Reduced to Preserved were not (Figure). The linear regression analysis showed that Preserved, Borderline and Reduced patients had different sets of factors related to LVEF changes, but LV dilatation was commonly associated with LVEF decrease in Borderline and Reduced groups (Table).
Conclusions: Temporal decrease in LVEF was significantly associated with worse outcomes among asymptomatic patients at risk of HF, suggesting the importance to improve or maintain LVEF for ameliorating the long-term prognosis in those patients.



Prognostic impact of LVEF categories

P948

The 6-min walk test in assessment for mortality in patients with heart failure

M Grundtvig[1]; T Eriksen-Volnes[1]; E-BH Helgesen[2]; ME Hansen[2]; L Gullestad[3]
[1]St Olavs Hospital, Fagenheten, Trondheim, Norway; [2]Akershus University Hospital, Medicine, Lørenskog, Norway; [3]Oslo University Hospital, Department of Cardiology, Division of Cardiovascular and Pulmonary Diseases, Oslo, Norway

Background: Exercise testing is recommended in patients with heart failure (HF) to obtain an objective evaluation of functional capacity and to guide exercise prescription according to current ESC guidelines (IIA – evidence C). While peak oxygen consumption is a strong predictor of cardiovascular events and death, the value of the 6 min walk test (6MWT), which is easier to perform, is less clear.Purpose The aim of the present study was to examine the 6MWT in relation to mortality in our HF registry.Method All the patients were assessed at the first visit to the specialized outpatient HF clinics (N=5924) where a 6MWT is included in the protocol. Patients were divided into tertiles of distance walked (category 1-3 where 1 walked longest). Patients who did not perform the test was assigned category 4 (N=1990). Cox regression analysis of time to death using available demographic and measured variables was examined.
Results: 6MWT (mean meter ± SD) were 549±60, 415±33, 237±91 for tertile 1-3, respectively. Patients in category 3 and in those that did not perform the test, category 4, were older, had poorer renal function, lower systolic blood pressure, used more diuretics, had more anemia and stroke and had a higher proportion of women than categories 1 and 2. The figure shows the Kaplan Meier plot of the differences in mortality for the categories and these were highly significant (p<0.001). In Cox regression analysis of time to death, the categories of the 6MWT were highly significant independent predictors for mortality adjusted for age, NYHA functional class, s-sodium, eGFR, systolic blood pressure, gender and daily dose of diuretic (p<0.001). The 6MWT was also a highly significant independent predictor for mortality when used as a continuous variable (p=0.001).Conclusions The 6MWT is easy to perform and is a powerful tool in assessing the risk for mortality in outpatients with HF. This suggests that it should be used on a regular basis in the work up of these patients.

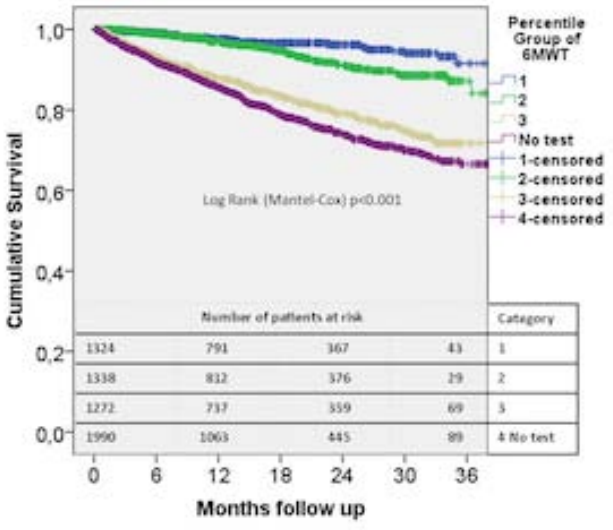


Figure 6MWT

P949

Comparison of of inflammation based prognostic scores in patients with stable heart failure with reduced ejection fraction

A Anna Cho[1]; H Arfsten[1]; J Novak[1]; G Goliasch[1]; PE Bartko[1]; N Pavo[1]; M Huelsmann[1]
[1]*Medical University of Vienna, Vienna, Austria*

Background. Elevated inflammatory markers are characteristic for heart failure with reduced ejection fraction (HFrEF) correlating with disease severity and prognosis. Evidence emerges that heart failure is triggered by inflammation directly, meaning that the progression of HF is a function of individual inflammatory host response.We aimed to investigate and compare the impact of well-established inflammation based scores on survival of stable patients with stable HFrEF.
Methods: Patients with stable HFrEF undergoing routine ambulatory care between January 2011 and November 2017 have been identified from a prospective registry. Comorbidities and laboratory data at baseline were assessed. All-cause mortality was defined as the primary study endpoint. The modified Glasgow Prognostic Score (mGPS) as well as the Neutrophil-to-Lymphocyte ratio (NLR), the Monocyte-to-Lymphocyte ratio (MLR) and the Platelet-to-Lymphocyte ratio (PLR) were calculated. The association of the scores with heart failure severity and impact on overall survival were determined.
Results: Data was complete and analyzed for a total of 443 patients. The median age of the study population was 64 years (IQR 53-72) and 73% of the patients were male. The median body mass index (BMI) was 26.6kg/m2 (IQR 23.8-30.2). Median NT-proBNP levels were 2053pg/ml (IQR 842-4345) with most patients presenting in the NYHA classes II (178, 40%) and III (173, 39%). Patients received well titrated dosages of guideline recommended heart failure therapy. The mGPS was 0 for 352 (80%), 1 for 76 (17%) and 2 for 14 (3%) patients, respectively. All scores correlated with heart failure severity reflected by NT-proBNP [p<0.001 for mGPS] and NYHA class [p<0.001 for mGPS]. All scores were associated with all-cause mortality in the univariate analysis, however after adjustment for age, gender and kidney function only the mGPS and PLR remained significantly associated with outcome [adj. HR 2.87 (2.00-4.11), p<0.001 for mGPS and 1.25 (1.02-1.54), p=0.030 for PLR]. The ROC was highest for mGPS and MLR [0.652 and 0.656 respectively]. Solely mGPS remained significantly associated with mortality when NT-proBNP was included in the multivariate model [adj. HR 1.87 (95%CI 1.20-2.91), p=0.006 for mGPS]. Kaplan Meier analysis confirmed the discriminatory power of mGPS (Figure 1).
Conclusions: Enhanced inflammation is more common in advanced heart failure. Among established inflammation scores merely mGPS is associated with survival in HFrEF patients independently of NT-proBNP. This relationship emphasizes the significance of the individual proinflammatory response on prognosis.This easily available score may help clinicians to identify HFrEF patients with worse prognosis with urgent need for intensified therapy and/or alternate treatment options.

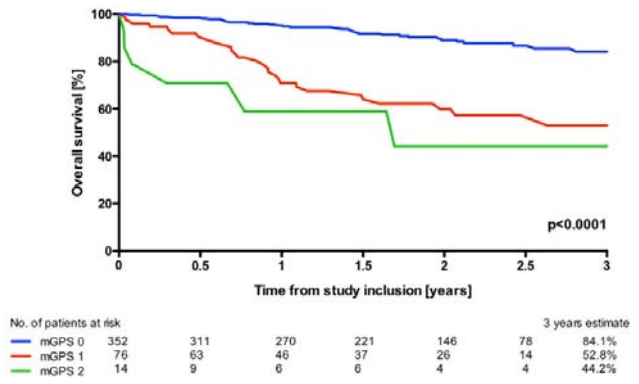

Figure 1

P950

The effect of ejection fraction change during follow-up on outcomes in patients with heart failure with mid-range ejection fraction

JC Jeong Cheon Choe[1]; JH Choi[1]; RE Kim[1]; AR Kim[1]; JY Shin[1]; J Ahn[1]; JS Park[1]; HW Lee[1]; JH Oh[1]; HC Lee[1]; KS Cha[1]; TJ Hong[1]
[1]*Pusan National University Hospital, Department of Cardiology, Pusan, Korea (Republic of)*

Background: Limited data are available on the role of ejection fraction (EF) change in heart failure with mid-range EF (HFmrEF).
Purpose: We investigated the effect of EF change on outcomes in HFmrEF patients.
Methods: Among 252 consecutive patients with primary diagnosis of HFmrEF (baseline EF 40-49%) and baseline and follow-up echocardiogram in an urban tertiary referral center (October 2013 to March 2017), 79 (31.3%) were in HFmrEF with improved EF (EF≥50% at follow-up echocardiogram) (iHFmrEF), 132 (52.4%) were in HFmrEF with consistent EF (EF 40-49% at follow-up echocardiogram) (cHFmrEF), and 41 (16.3%) were in HFmrEF with reduced EF (EF<40% at follow-up echocardiogram) (rHFmrEF) groups. The clinical characteristics and composite events (cardiovascular death and cardiovascular readmission) were compared.
Results: The iHFmrEF group had higher rates of female and coronary artery disease (CAD) with revascularization than rHFmrEF or cHFmrEF groups. There were comparable in other characteristics among 3 groups. Significantly lower values of left ventricular (LV) end diastolic diameter and LV end systolic diameter and higher levels of EF were observed in the iHFmrEF group than the rHFmrEF or cHFmrEF groups. There were equivalent in other echocardiographic parameter among 3 groups. Composite event occurred in 100 patients (39.7%), with significantly lower rates in the iHFmrEF group. After risk adjustment, iHFmrEF was associated with decreased risk of composite event than cHFmrEF (hazard ratio [HR] 0.586, 95% confidence interval [CI] 0.351-0.978, p=0.041) and rHFmrEF (HR 0.325, 95% CI 0.172-0.613, p=0.001). Additionally, female (odds ratio [OR] 0.404, 95% CI 0.233-0.699, p=0.001), CAD with revascularization (OR 0.361, 95% CI 0.208-0.630, p<0.001), and spironolactone use (OR 0.434, 95% CI 0.234-0.805, p=0.008) were predictive for increased EF.
Conclusions: In HFmrEF patients, improved EF at follow-up echocardiogram was observed in approximately one-third of patients. Moreover, it was predictive for better clinical outcomes and affected by sex, CAD with revascularization, and spironolactone use.

Hospitalisation for heart failure: short term cost savings associated with outcomes reported from the DECLARE-TIMI 58 trial

B Bernt Kartman[1]; P Mcewan[2]; H Bennett[2]; C Edmonds[3]; I Gause-Nilsson[1]
[1]*AstraZeneca, Gothenburg, Sweden*; [2]*Health Economics and Outcomes Research Ltd, Cardiff, United Kingdom of Great Britain & Northern Ireland*; [3]*AstraZeneca , Cambridge, United Kingdom of Great Britain & Northern Ireland*

On behalf of: DECLARE-TIMI 58 Investigators
Funding Acknowledgements: This study was funded by AstraZeneca

Background: Type 2 diabetes mellitus (T2DM) and heart failure (HF) represent a considerable burden to patients, healthcare systems and society globally. The Dapagliflozin Effect on Cardiovascular Events (DECLARE)-TIMI 58 trial evaluated the effects of dapagliflozin on cardiovascular (CV) and renal outcomes in patients with T2DM and either established CV disease or multiple risk factors (MRF) for CV disease. The trial demonstrated that treatment with dapagliflozin was associated with a lower rate in the composite of CV death or hospitalisation for heart failure (HHF) compared to placebo (hazard ratio: 0.83; 95% confidence interval: 0.73 to 0.95); a finding driven by a lower rate of HHF in dapagliflozin-treated patients (hazard ratio: 0.73; 95% confidence interval: 0.61 to 0.88).
Purpose: To estimate the direct healthcare costs associated with HHF event rates reported from DECLARE-TIMI 58, from a US payer perspective.
Methods: DECLARE-TIMI 58 event rates were used to predict HHF incidence in a hypothetical cohort of 1,000 people with T2DM, over a 4-year time horizon. A range of published HHF event costs ($26,893–$37,076, 2017 $) were applied to predicted HHF events. Long-term costs associated with managing HF were not considered. Future costs were discounted at 3% per annum. Sensitivity analyses were conducted for pre-defined DECLARE-TIMI 58 subgroups.
Results: Over a 4-year modelled time horizon, 24 HHF events were predicted per 1,000 patients treated with dapagliflozin versus 33 HHF events for placebo (difference: –9 events). When modelled by prior HF status, more events were avoided in those with prior HF due to higher underlying event risk in this subgroup (difference: –33 events per 1,000 patients). Total estimated costs associated with HHF were $630,237–$868,875 per 1,000 patients treated with dapagliflozin versus $860,164–$1,185,864 per 1,000 patients treated with placebo (difference: $229,927–$316,989). For the overall population, a 27% reduction in HHF costs was estimated over 4 years, compared to 21% and 35% reductions estimated in the established CV disease and MRF subgroups, respectively.
Conclusions: The reduction in HHF events demonstrated for dapagliflozin versus placebo in the DECLARE-TIMI 58 trial will translate to savings within healthcare systems in clinical practice. Further to hospitalisation costs estimated in this study, additional savings associated with HF management may be attained in those without prior disease. These short-term cost savings complement other previously shown benefits of dapagliflozin related to improved glycaemic control and weight loss.

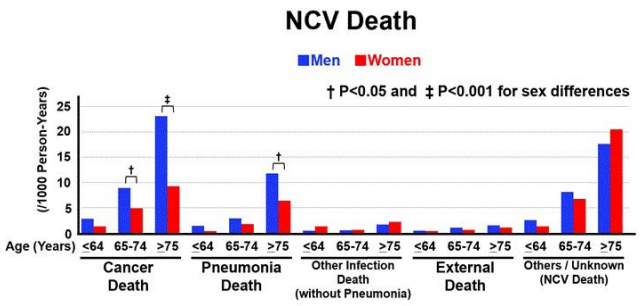
P952

Sex difference of mortality and mode of deaths in elderly patients with chronic heart failure - A report from the CHART-2 Study-

K Kotaro Nochioka[1]; MS Sato[1]; YS Sakata[1]; MM Miura[1]; SK Kasahara[1]; HA Aoyanagi[1]; TF Fujihashi[1]; SY Yamanaka[1]; TS Shiroto[1]; KS Sugimura[1]; JT Takahashi[1]; SM Miyata[2]; HS Shimokawa[1]
[1]Tohoku University Graduate School of Medicine, Department of Cardiovascular Medicine, Sendai, Japan; *[2]Tohoku University Graduate School of Medicine, Departments of Evidence-based Cardiovascular Medicine, Sendai, Japan*

Funding Acknowledgements: The Japanese Ministry of Health, Labour, and Welfare; The Japanese Ministry of Education, Culture, Sports, Science, and Technology; Japan AMED

Background: Limited data exist on the sex difference of mortality and mode of deaths in elderly patients with chronic heart failure (CHF).
Purpose: To examine the sex difference in mortality and mode of death comparing older versus younger CHF patients.
Methods: We compared the mortality and mode of deaths of older and younger Stage C/D CHF patients in the Chronic Heart Failure Analysis and Registry in the Tohoku District (CHART)-2 (N=4876, mean 69 years, women, 32%) by age; G1, <64 years, N=1521 (54.3±8.8 years, women, 22.8%,); G2, 65-74 years, N=1510 (69.9±2.9 years, 30.7%); and G3, >75 years, N=1845 (80.3±4.4 years, 40.2%).
Results: From G1 to G3, the prevalence of women, left ventricular ejection fraction (LVEF) and plasma levels of B-type natriuretic peptide (BNP) increased (all P<0.001). Although NYHA functional class -, chronic kidney disease, cancer, LVEF, and BNP had significant impacts on all-cause mortality in all groups, their impacts were less evident in G3 as compared with G1. In both sexes, 5-year mortality increased (9.9, 17.3 to 39.9%, P<0.001) along with a decrease in the proportion of cardiovascular mortality and an increase in non-cardiovascular mortality. Between the sexes, all-cause and cardiovascular mortality were comparable whereas women had a significantly lower incidence of non-cardiovascular mortality than men in G2 (9.1% vs. 13.3%, P=0.024) and G3 (18.9% vs. 26.1%, P<0.001), which was attributable to the higher incidence of cancer death and pneumonia death in men than in women (Figure).
Conclusions: Compared with younger CHF patients, the elderly were characterized by more severe clinical background, the increased proportion of non-cardiovascular death and worse prognosis with different impacts of prognostic factors. Sex differences exist in non-cardiovascular mortality in the elderly. These results indicate that HF management in the elderly should include a multidisciplinary approach to improve mortality.



Mode of deaths by sex and age categories

Lomonosov Moscow State University, Moscow, Russian Federation*

On behalf of: EPOCHA study group

Background: usually survival rate in heart failure (HF) are evaluated in patients who admitted to hospital or come to clinical visit. However, there are lack of data of survival rate in population regarding the fact that some patients would not sick for medical health
Purpose: to find out how the survival rate of heart failure patients over 17 years of follow-up in a representative sample of the population.
Methods: medical data of the representative sample in the six regions of Russia were analysed to find out the prevalence of heart failure.
Results: 16000 patients were enrolled in the study in 2002 years. The long term prognosis was known for 9349 of them. The mortality one-year mortality was 0.69%, 2.56%, 4.42%, 6.25% in patients without CV diseases, with CV deasese but without HF, with mild and severe HF respectively. During 5 and 10 years of follow-up, 50% and 100% with severe HF died respectively. At the end of follow-up, 70% with mild HF died.
Conclusion: This analysis showed a quite poor prognosis of patients with both CV diseases and HF in Russia. The implementation of new treatments and prevention measures are required to improve the prognosis of these patients.
Limitations: As this was epidemiologic study BNP levels were no measured and echocardiography were not evaluated. There is a possibility that some patients in the mild HF group didn't have HF.

Burden of heart failure rehospitalizations in heart failure with preserved versus reduced ejection fraction from Asia

WT Wan Ting Tay[1]; THK Teng[1]; W Ouwerkerk[1]; J Tromp[1]; D Sim[1]; FR Jaufeerally[2]; KTG Leong[3]; PSD Yeo[4]; HY Ong[5]; LH Ling[6]; AM Richards[6]; CSP Lam[1]
[1]National Heart Centre Singapore, Singapore, Singapore; [2]Singapore General Hospital, Department of Internal Medicine, Singapore, Singapore; [3]Thomson Medical Centre, Thomson Cardiology Clinic, Singapore, Singapore; [4]Gleneagles Hospital, Apex Heart Clinic, Singapore, Singapore; [5]Mount Elizabeth Medical Centre, Singapore, Singapore; [6]National University Health System, Cardiovascular Research Institute, Singapore, Singapore

Funding Acknowledgements: The Singapore Heart Failure Outcomes and Phenotypes study had been funded by the National Medical Research Council of Singapore.

Background: Data on the burden of rehospitalizations for heart failure (HF) in Asia are scarce.
Purpose: To determine the frequency, clinical correlates and prognostic significance of HF rehospitalizations in patients with preserved ejection fraction (HFpEF; EF≥50%) and reduced EF (HFrEF; EF<50%) in a multi-ethnic population-based cohort in Asia.
Methods: Patients from the prospective population-based Singapore Heart Failure Outcomes and Phenotypes (SHOP) study were included. Stabilized HF patients underwent detailed clinical assessment at baseline and were followed up over 2 years for death or hospitalization. Analyses accounted for death as a competing event.
Results: Of 1099 patients (age 62 ± 12 years, 24% women, 22% HFpEF) followed over a median of 1.53 (interquartile range [IQR] 0.54–1.95) years, 171 (15%) died and 2310 readmissions were recorded in 662 patients. Of these rehospitalizations, 1233 (42%) were due to cardiovascular causes, and 876 (30%) were due specifically to HF as a primary cause. The median number of all-cause rehospitalizations was 3, median length of stay (LOS) was 4 (IQR 2-7) days and cumulative LOS was 12 (IQR 5-31) days.
Patients with HFrEF were readmitted as frequently as patients with HFpEF (31% vs 27% and 30% vs 32% with 1-2 and 3 or more rehospitalization records respectively, p=0.416) and had similar cumulative LOS. Compared to patients with HFrEF, patients with HFpEF were more frequently readmitted for non-cardiovascular causes (38% vs 47%, p=0.005) but as frequently readmitted for HF (36% vs 30%, p=0.166). Patients who were more frequently readmitted to the hospital tended to be older, were enrolled as an inpatient, have lower heart rate, New York Heart Association class III/IV, a history of coronary artery disease, atrial fibrillation/flutter, hypertension or diabetes but less likely to be on ACE-inhibitor/ARB and beta blockers at baseline, regardless of HF type (all p for interaction >0.05).
Having 3 or more rehospitalizations (vs none) was associated with higher odds of all-cause mortality (odds ratio [OR] 1.86, 95% CI 1.14-3.05; p=0.013) in HFrEF, but not in HFpEF (OR 0.48, 95% CI 0.15-1.54; p=0.219) (p for interaction 0.008).
Conclusion(s) : Asian patients with HF have a high burden of rehospitalizations, regardless of HF type. While total and HF hospitalization burden is similar in HFpEF and HFrEF, non-cardiovascular causes are more prominent in HFpEF. Recurrent hospitalizations in HFrEF portend higher short-term mortality.

P955

Prediction of heart failure decompensations using artificial intelligence techniques

V Vanessa Escolar Perez[1]; A Lozano[1]; N Larburu[2]; J Kerexeta[2]; A Artetxe[2]; G Artola[2]; R Alvarez[2]; B Juez[3]; A Echebarria[1]; A Azcona[1]
[1]Hospital de Basurto, Cardiology, Bilbao, Spain; [2]Vicomtech Research Centre, San Sebastián, Spain; [3]Hospital de Basurto, Bilbao, Spain

Introduction - The creation of large databases and advances in ICT (information and communication technologies) have allowed the development of artificial intelligence or machine learning techniques.
- These methods are capable of creating algorithms based on the data supplied with the aim of helping in the usual clinical practice.
Objectives and methods
- The objective is to determine which parameters measured by telemonitoring (blood pressure, heart rate, O2 saturation, weight and questionnaire) are the best predictors of heart failure (HF) decompensations in our group.
- Data were collected from telemonitored patients in the HF Unit of our hospital from May 2014 to February 2018, with the following variables: baseline characteristics and HF decompensations (decompensations include, in addition to hospitalizations, administration of iv diuretic at home, emergency room or day hospital and adjustment of oral diuretics).
Results
- The study contains 242 patients (138 men and 104 women), with an average age of 78 years (SD 10.9). The most prevalent heart disease is ischemic (33%), followed by idiopathic (18%). The mean LVEF is 42.4 (SD 15.21). 138 patients (57.4%) were in atrial fibrillation. The mean time of evolution of HF is 5.8 (SD 7.08).
- During the 46 months of follow-up, a total of 562 heart failure decompensations were detected. Of these, 379 were managed at home (286 with oral diuretic adjustment, 80 with intravenous treatment and 16 with subcutaneous furosemide pumps). There were 151 hospital admissions and 32 emergency visits that did not require hospital admission (resolution of the decompensation with the intravenous treatment administered in this department).
- Figure 1 specifies monitored parameters, established alerts, sensitivity (Se) and false alert rate per patient and year (FA/pt-y).
- Weight variations (1 kg increase in 3 days or 3 kg in 5 days) and desaturation below 90% in pulse oximetry are good predictors of HF decompensation according to Se and FA/pt-y values. Regarding to the questionnaire, "worse" answers in questions 1 and 2 are very good predictors of decompensation. Questions 3 and 4 also have good predictive values, but less than questions 1 and 2.
Conclusions - Significant weight increases, desaturation below 90%, perception of clinical worsening, including development of edema, worsening of functional class and orthopnea are good predictors of heart failure decompensation.

Parameter to study	Threshold number	Type of alert	Se	FA/pt-y
SBP	<95 or <150	Yellow	0.28	11.4
	<85 or >150	Red	0.08	1.4
DPB	<60 or >110	Yellow	0.23	9.1
	<50 or >100	Red	0.04	0.9
HR	<55 or >90	Yellow	0.30	11.2
	<50 or >90	Red	0.08	1.4
O2Sat	<94	Yellow	0.15	3
	<90	Red	0.39	13.5
Weight variations	1 kg increase in 3 days or 3 kg in 5 days	Red	0.52	9.55
n	**Questionnaire**	**Answer**	**Se**	**FA/pt-y**
1	Well-being	Worse	0.37	2.7
2	Ankle	Worse	0.35	2.9
3	Walks	No	0.37	18
4	Shortness of breath	Yes	0.41	19.93

Prevalence of heart failure in cardiac intensive care unit

H Hala Badran[1]; N Faheem[1]; MA Elgharably[1]
[1]Menoufiya University, Shebin, Egypt

Background: Cardiac care unit (CCU) is increasingly becoming a very vital part of management of critically ill patients. There is limited information about the prevalence of heart failure (HF) and their outcome in this critical population.
Objectives: This registry represents data fromour hospital, as representative to tertiary academic centre, and provide an epidemiological snapshot of the HF patients, their risk profile and their short term outcome during hospital stay.
Methods: This is a local single center cross sectional observational registry of patients admitted to CCU one year from July 2015 to July 2016. Data were collected through special software programme. This registry includes the data of 1006 patients admitted to the CCU. Patients with clinical and laboratory evidence of HF were systematically studied.
Results: Our registry showed that the prevalence of HF was 29.4% of the total CCU admissions. 72.7% were HFrEF and 27.3% were HFpEF. Male patients were the most prevalent(60.1%) with mean age (60.4±10). Hypertension and smoking (59.5%, 45.6%) were the commonest CV risk factors in HF patients followed by obesity (41.2%). Diabetes was prevalent in 40.2% and dyslipidemia in 35.8% of patients. Cardiogenic shock was existing in 22.3%(n=66) of HF patients followed by atrial fib/flutter (16.8%, n=50). Acute coronary syndrome (ACS) patients was the underlying etiology of HF in 26.7%(n=79). 13.2% of HF patients had prior PCI, 7.8% had CABG, 3.7% had prior valve surgery. History of prior admission to the hospital was existing in 87.4%. LBBB was the commonest ECG findings in 24.6%, followed by AF (22.3%). Ischemic ECG changes were more prevalent in HFrEF type (21%), while voltage criteria were most prevalent in HFpEF type (12.5%). On ECHO examinations, HFrEF showed higher prevalence of severe mitral and tricuspid regurge and higher prevalence of RWMA. Duration of hospital stay was much higher in HF group, specially in HFrEF type with mean value of 8.91±7. During in-hospital course, HF mortality was 25.7% of the total CCU mortality. Moreover, HFrEF

mortality represented 94.4% of HF mortality. Using multivariate regression analysis, the presence of hypertension doubles (2.1; IC at 95%: 1.16-3.76) probability to develop HF, compared to its absence. LBBB and AF increase the likelihood to develop HF by 7 times, each mm decrease in LA size reduces the odds of heart failure by 6% (Odds ratio 0.94; IC at 95% 0.9-0.98), each one time decrease in incidence in ACS reduce the probability of HF incidence by 15%.
Conclusion: HF is the primary reasons for admission into the CCU in 30 % of cases. Acute coronary syndrome is the commonest etiology of HF. Mortality among CCU patient was comparable to reports elsewhere. Hypertension, AF and LBBB are independent predictors of HF in such populations.

Chronic Heart Failure - Diagnostic Methods

P957
The ratio of fibroblast growth factor 23 to phosphorus as a predictor of cardiovascular death in heart failure patients with reduced ejection fraction.

D Damien Gruson[1]; SA Ahn[1]; V Carbone[1]; MF Rousseau[1]
[1]Cliniques Saint-Luc UCL, Brussels, Belgium

Background: high-concentration of phosphorus has been associated to an increased risk of cardiovascular events. Fibroblast growth factor 23 (FGF-23) is an important regulator of the phosphorus homeostasis, displays multiple direct effects on cardiac function and seems also to participate to adverse cardiac remodeling. Recently, several reports demonstrated that FGF-23 is a strong and independent predictor of adverse events in patients with heart failure (HF).
Purpose: To examine the utility of the FGF-23 to phosphorus ratio as a predictor of cardiovascular events in HF patients with reduced ejection fraction (HFrEF).
Methods: Our evaluation included seventy six HF patients (women n=14; men n=62; NYHA II-IV; mean age: 67 years; mean EF: 22 %). A two-site enzyme immunoassay was used to measure levels of C-terminal FGF-23 (C-term FGF-23). The primary outcome was cardiovascular death.
Results: The FGF-23 to phosphorus ratio ranges from 7 to 5769 (RU/mL/mM) and was higher in HF patients with NYHA III-IV (156.4) than in patients with NYHA II (28.9). Ratios were not significantly different between dilated and ischemic cardiomyopathies (82.2 vs. 87.7). The FGF-23 to phosphorus ratio correlated with left ventricular ejection fraction ($r = -0.26$; $P = 0.02$), estimated glomerular filtration rate (eGFR; $r = -0.29$; $P = 0.01$), BNP ($r = 0.44$; $P < 0.001$) and Nt-proBNP ($r = 0.55$; $P < 0.001$). After 8 years of follow-up, 57 patients reached the primary endpoint. Concentration of the FGF-23 to phosphorus ratio was significantly higher in HF patients who died in comparison to survivors (105.6 vs 46).
Conclusion: The FGF-23 to phosphorus ratio may be useful to identify patients with HFrEF with a higher risk of developing adverse cardiovascular events.

P958
Soluble ST2/LVMI correlates with native T1 mapping value in 3T cardiac magnetic resonance in patients with dilated cardiomyopathy

YH Yong Hyun Park[1]; SY Lee[2]; SM Jung[2]; SH Lee[2]; KS Choo[2]; JS Kim[2]
[1]Pusan National University Yangsan Hospital, BUSAN, Korea (Republic of); [2]Pusan National University Yangsan Hospital, Yangsan, Korea (Republic of)

Background: Native T1 mapping and extracellular volume fraction (ECV) of cardiac magnetic resonance imaging (CMRI) are known to detect not only interstitial fibrosis but also, pre-fibrotic phase of cardiomyopathy. Soluble ST2 (sST2), a member of the interleukin-1 receptor family, assumed to play a significant role in inflammatory response of fibroblast. Several reports have already shown no significant correlation between sST2 and late gadolinium enhancement (LGE), which indicates myocardial fibrosis. The aims of the study was to assess the relationship of serum sST2 level and ECV or native T1 mapping value in patients with dilated cardiomyopathy (DCM).
Method: This study included 19 DCM patients, who underwent 3-Tesla CMRI including precontrast and postcontrast T1 mapping (modified look-locker inversion recovery [MOLLI] sequence) and LGE imaging from August 2017 to May 2018. Each sST2 concentration obtained within 7 days pre/post CMRI, was indexed by being divided with left ventricular (LV) mass obtained from CMRI cine images. Mean native T1 value was calculated by averaging 4 cuts of precontrast T1 mapping images. ECV values were obtained according to the formula including patient's hematocrit. Correlation analysis was evaluated with Pearson coefficient.
Result: The average age was 49.5±11.3 yrs and male patient were 12 out of 17 (63.2%). The LV ejection fraction was 29.5±7.2% and serum brain natriuretic peptide (BNP) was 1270.2±1352.7pg/mL. The sST2/mass index showed a moderate linear correlation with Native T1 value ($p = 0.012$, $R2 = 0.382$) (Figure 1). However, there were no significant correlation between sST2/mass index and ECV and LGE.
Conclusion: sST2/LMVI showed linear correlation with Native T1 mapping value which might imply pre-fibrotic inflammatory phase of DCM, i.e. early phase of DCM. Further studies are needed to assess the clinical implication of sST2 as a marker of active inflammation in the early phase of DCM.

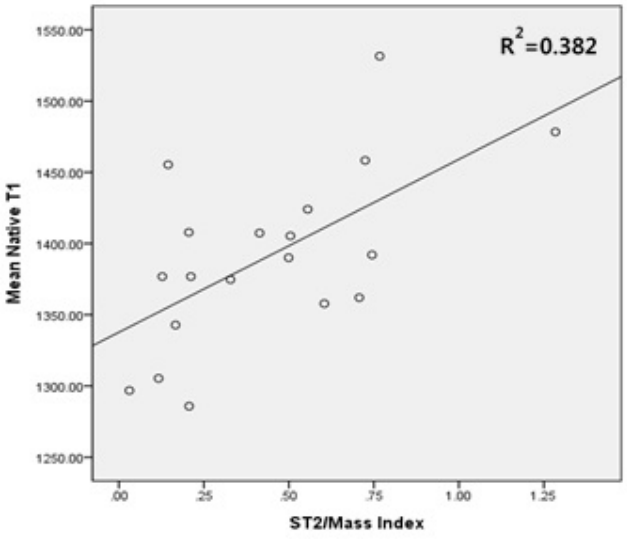

Figure 1

P959
Dynamics of the stimulating growth factor sST2 and interleukin 33 in acute myocardial infarction

FD Akhmatova[1]; VN Larina[1]; IM Doronina[2]; IU Titova[2]
[1]Pirogov Russian National Research Medical University , Moscow, Russian Federation; [2]City Clinical Hospital 13, Moscow, Russian Federation

Introduction: Interleukin (IL)-33 and stimulating growth factor sST2 are molecules with an opposite pathophysiologic implications in the myocardial response after acute myocardial infarction (AMI). The kinetics of IL-33 and sST2 level and their correlation with left ventricular (LV) function remains poorly defined, both may be a target for the purpose of monitoring of the disease.
Objective: To study the dynamics of stimulating growth factor sST2 and Interleukin 33 in acute myocardial infarction with left ventricular dysfunction and left ventricular preserved function.
Materials and methods: The study included 30 patients with AMI. LV dysfunction was estimated in the 1st day of AMI, the criterion of which was an increased NTproBNP concentration of more than 300 pg/ml or a decrease in LV ejection fraction (EF) less than 50%. Two groups were formed for studying: 1st group - 16 patients with LV dysfunction, an average age was 49 [46; 51] years; the 2nd group - 14 patients without LV dysfunction, an age was 56 [51; 59] years, p=0,15. The blood serum concentration of interleukin 33 (IL 33, the pg/ml) and the stimulating growth factor sST2 (ng/ml) was defined on the 1st day and on the 14th day and in 6 months.
Results: The troponin level in the groups did not differ: 3.53 [2.3; 6.0] ng/ml and 2.38 [1.46; 3.3] ng/ml, $p = 0.54$. There were significant differences on the 1st day of AMI on the LV EF value: 1st group - 47.0 [45; 55]%, 2nd group - 56.0 [55; 62]%, $p = 0.04$; and differences on the NTproBNP oncentration: 1st group - 859.11 [309, 98; 1370] pg/ml, 2nd group - 44.5 [22.15; 129.2] pg/ml, $p = 0.003$.
In the 1st group, the serum sST2 concentration was significantly higher on the 1st day of AMI than on the 14th day: 31.87 [27.40, 38.76] and 25.63 [22.8; 28.93] ng/ml, $p = 0.01$. After 6 months the sST2 value was 31.30 [21.06, 36.49] ng/ml, $p = 0.42$. Values of IL33 in the 1st group did not have significant dynamics for the entire follow-up period: on the 1st day - 4.08 [3.76; 5.15] pg/ml, on the 14th day - 4.38 [3.95; 5,15] pg/ml, after 6 months - 5,39 [4,91; 5.49] pg/ml, $p>0.05$.
In the 2nd group significant differences in serum sST2 concentration were not detected during the whole follow-up period: on the 1st day - 29.71 [29.36; 33.51] ng/ml, on the 14th day - 25.99 [18.49; 38.78] ng/ml, after 6 months - 25.1 [9.62; 33.93] ng/ml, $p>0.05$. The values of IL33 in the serum on 1st day were 3,76 [3.65; 4.53] pg/ml, on 14th day - 4.33 [4.33; 4.43] pg/ml, $p> 0.05$. After 6 months, IL33 concentration was significantly increased - 4.82 [4.72, 5.2] pg/ml, $p = 0.04$.
Conclusions: The increase in serum sST2 concentration in the acute period of myocardial infarction is associated with left ventricular systolic dysfunction and

heart failure. Increasing the concentration of IL33 in the late post-infarction period is associated with preserved left ventricular ejection fraction and can be used to identify favorable outcome of the myocardial infarction.

P960

BNP as the biomarker of diagnosis and prognosis in long-term mortality in a cohort with HFpEF and HFrEF in the south of Brazil

E Eduardo Pitthan[1]; VN Hirakata[1]; JN Barbisan[1]
[1]*Institute of Cardiology of Rio Grande do Sul, Porto Alegre, Brazil*

Background: The elderly population with Heart Failure with preserved Ejection Fraction (HFpEF) and Heart Failure with reduced Ejection Fraction (HFrEF) display different etiologies, profiles and comorbidity rates, with a consequent variable impact in prognosis. PURPOSE: To evaluate and to compare the risk of mortality and the Hazard Ratio (HR) of the BNP and other prognostic clinical variables as the causes of long-term mortality registered in death certificates (CID10) in an elderly cohort with the gold standard for HFpEF and HFeEF. METHODS: Six hundred thirty-four patients, who presented at the emergency room, from March 2006 through September 2012, with dyspnea and suspicion of HF, took part of this study. The accuracy of BNP to identify patients with heart failure and the search from the association with the level of BNP (POCT Biosite) and with the long-term prognosis were evaluated. The Hazard Ratio (HR) of mortality risk factors in bivariate and multivariate analysis was measured. The cause of death was identified through the search of death certificates in registries, informed by the Brazilian MIS - Mortality Information Service. RESULTS: A sample with 634 patients included, the majority of patients were white (93%) and women (63%), average age 77,3 sd +- 8,6 years and 40,5% > 80 years. The BNP presented AUC 0.93 (CI 95%, 0.88 to 0.97). The best cutoff of BNP was 180 pg/ml with S 0.83 (CI 95%, 66.7 to 80.4) and Sp 0.90 (CI 95%, 76.7 to 95.4). LR + 6.7 (95 %, 3.1 to 14.3), accuracy of 77.7. Survival analysis throughout the 78 months of the study was carried out by the Kaplan-Meier curve. The death certificates analysis, total deaths and Hazard ratios follow in Table 1.
Conclusions: The level of BNP has showed the strongest mortality risk factor of prognostic biomarker of long-term mortality in a cohort of patients with HFpEF and HFrEF.

Table 1-Comparison of risk of mortality

Causes of DeathTotal deaths n=340/634	HFrEFn=124	HFpEF n=216	p	AdjustedHR (CI 95%)

Association between severity of heart failure and chemerin level

Y Yulia Kovaleva[1]; B Shelest[1]
[1]*Kharkiv National Medical University, Kharkiv, Ukraine*

Chemerin is suggested to be associated with cardiovascular function. Recent data showed that chemerin is associated with the coronary artery disease, and severity of coronary atherosclerosis, arterial stiffness, augmented risk of cardiovascular events, at the same time, it is not known about chemerin and risk of heart failure (HF). The aim was to investigate association between circulating chemerin concentrations and severity of HF in hypertensive patients.
Methods: 64 hypertensive patients were enrolled into the study with I and II functional classes of heart failure in accordance to New-York Heart Association classification. The average age was 57.32±7.78, males 29 (44.6%). Chemerin was measured by ELISA. Exercise tolerance was assessed with help of 6-minute walking test (6MWT).
Results. Chemerin values at admission exceeded the control values and averaged 289.76 ± 78.48 ng/ml. A direct correlation was established between the severity of CHF and the average levels of chemerin (p<0.001, r=0,59), which at FC I - 185.43 ± 57.81 ng / ml, at FC II - 343.87 ± 86.38 ng/ml. After 6 months, all patients showed a tendency to a decrease chemerin's level, the differences between the mean values at admission and after 6 months were reliable (p=0.048). In the most severe patients, despite ongoing therapy, the level of chemerin remained high or tended to increase, which coincided with an increase in the clinical manifestations of heart failure and exercise tolerance indices. The average level of triglycerides in patients with HF at admission to the hospital was 3.17 ± 1.68 mmol/l, total cholesterol - 5.67 ± 1.52 mmol/l. The average triglycerides at II FC HF exceeded those at FC I (3.59 ± 1.63 mmol/l and 2.65 ± 1.83 mmol/l, respectively), but the differences were not significant. Significant direct correlations between triglyceride levels and chemerin (r=0.355, p<0.05) and C-reactive protein (r=0.39, p <0.05) were found. Relative ratio analyses demonstrated that RR:2.306, CI:1.372-3.877, RD: 0.511, Sensitivity: 0.804, Specificity: 0.778.
Conclusion: The serum chemerin level is a highly informative marker of severity and prognosis of HF. The connection between chemerin and the activity of inflammation, exercise tolerance and the severity of HF was established.

The effect of CPAP and oral appliances treatment on biomarkers in patients with heart failure and OSA

I Andreieva[1]
[1]*State Institution "Zaporizhia Medical Academy of Post-Graduate Education Ministry of Health of Ukrai, Zaporizhzhia, Ukraine*

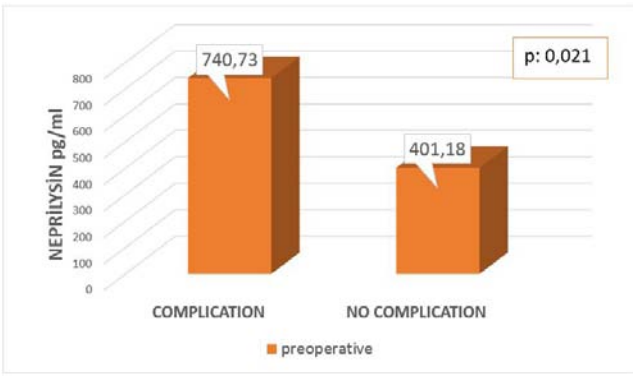
Introduction: Untreated obstructive sleep apnea (OSA) is associated with an increased risk of heart failure. Circulating biomarkers represent as a safe, convenient, and inexpensive possibility for cardiovascular risk assessment and stratification. Nevertheless, no studies have examined the treatment effect of continuous positive airway pressure (CPAP) and oral appliances (OA) in patients with OSA and heart failure (HF) on galectin-3 and soluble ST-2. Results about changes of NT-pro-BNP level after OSA treatment are controversial.
Purpose of the study was to evaluate the effect of CPAP and oral appliances treatment on serum NT-proBNP, Galectin-3 and soluble ST-2 level in patients with HF and OSA at 3 months after treatment.
Methods: We conducted a prospective study in 152 patients with heart failure and moderate or severe OSA divided into groups with heart failure with reduced (HFrEF) (74 patients) and with heart failure with preserved ejection fraction (HFpEF) (78 patients). All patients were randomized to OA and CPAP groups. Serum NT-pro-BNP, galectin-3, and soluble ST-2 were measured prior to and after 3 months of therapy. Patients who have prior CPAP treatment were excluded from the study.
Results: As compared with baseline, NT-proBNP significantly decreased after 3 months in patients with HFrEF in CPAP and OA groups (CPAP: 737±292 vs. 441±165 pg/ml, p<0.001; OA: 893±179 vs. 488±182 pg/ml, p<0.001) and in patients with HFpEF in CPAP group (CPAP: 425±167 vs. 193±65 pg/ml, p<0.001). A statistically significant difference of level of NT-proBNP was not observed in patients with HFpEF and OA. No significant differences were showed in Galectin-3 at 3 months in patients with HFrEF (CPAP: 20,31±9,22 vs. 18,64±8,51 pg/ml, p=0,624; OA: 21,42±7,96 vs. 17,89±9,24 pg/ml, p=0,872) and HFpEF groups (CPAP: 19,46±10,04 vs. 17,72±9,51 pg/ml, p=0,388; OA: 18,51±8,67 vs. 17,89±9,16 pg/ml, p=0,755). Significant changes of ST-2 were found in patients with HFrEF and from CPAP group (CPAP: 72,16±39,18 vs. 43,05±19,88 ng/ml, p<0.001; OA: 78,46±28,17 vs. 67,15±29,33 ng/ml, p=0,069).
Conclusions: There were statistically significant changes in NT-proBNP level in patients with HFrEF in the CPAP and oral appliances groups, and in patients with HFpEF in the CPAP group at 3 months of treatment. No significant differences were showed in Galectin-3 in all groups at 3 months. Significant changes of ST-2 were found in patients with HFrEF from CPAP group.

P963

Changes in plasma neprilysin levels after left ventricular assist device implantation and association of outcomes during 1-year follow-up

E I Elif Ilkay Yuce[1]; E Demir[1]; E Simsek[1]; P Ozturk[2]; Z Parildar[3]; C Engin[2]; T Yagdi[2]; M Ozbaran[2]; S Nalbantgil[1]; C Gurgun[1]
[1]Ege University, cardiology department, Izmir, Turkey; *[2]Ege University, cardiovascular surgery department, Izmir, Turkey*; *[3]Ege University, biochemistry department, Izmir, Turkey*

Introduction: Plasma Neprilysin levels increase with neurohormonal system activation seen in heart failure and inducing degradation of natriuretic peptides which increases fibrosis and decreases diuresis. After left ventricular assist device (LVAD) implantation neurohormonal system activation mostly decreased, but it is not known whether it returns to normal physiologic set levels. There is also a lack of data on association with pre-LVAD elevated Neprilysin levels and the adverse outcomes over first year.
Purpose: We aimed to evaluate the changes in neprilysin plasma levels between preoperative period and at the 3rd month after LVAD implantation, and association of the first year adverse outcome.
Methods: Patients who had LVAD implantation procedure between January 2017 and October 2017 were included in the study, prospectively. Plasma Neprilysin levels measured before and 3 months after operation. The patients were followed for mortality and adverse events including stroke, pump thrombosis, gastrointestinal bleeding and right ventricular failure during 1 year follow-up period.
Results: 47 patients with a mean age of 54±11 years were included in the study. Female to male ratio and the average BMI of the patients were 40/7 and 25,7±3,89 kg/m2, respectively. Plasma Neprilysin levels significantly decreased from 175,28pg/ml to 75,3 pg/ml after the 3 months of LVAD implantation (p:0,007). Totaly 13 patients died after LVAD implantation during the one year follow-up period and preoperative plasma neprilysin levels detected high in this 13 patients (1116,55 ± 1007,68pg/ml, 566,74 ± 795,68pg/ml, p:0,002).
33 patients had LVAD adverse complications in the first year. Patients with LVAD complications seen in the first year were found to be statistically significantly higher in patients with preoperative plasma neprilysin levels than those without complications (740,73±1158,55 pg/ml; 401,18±400,79 pg/ml; p:0,021). 12 patients developed right heart failure. In patients with right heart failure preoperative plasma neprilysin levels were detected high compared to without complication 35 patients (950,16 pg/ml; 558,57pg/ml; p:0,013).
Conclusion: Although neurohormonal system activation after LVAD implantation has decreased, it does not completely return to normal. The high level of preoperative neprilysin in the patients who died within 1 year after the LVAD implantation showed that increased preoperative neurohormonal activity may be related to death.In particular, preoperative neprilysin level may be predictive of right heart failure and other adverse events in the first year after LVAD implantation

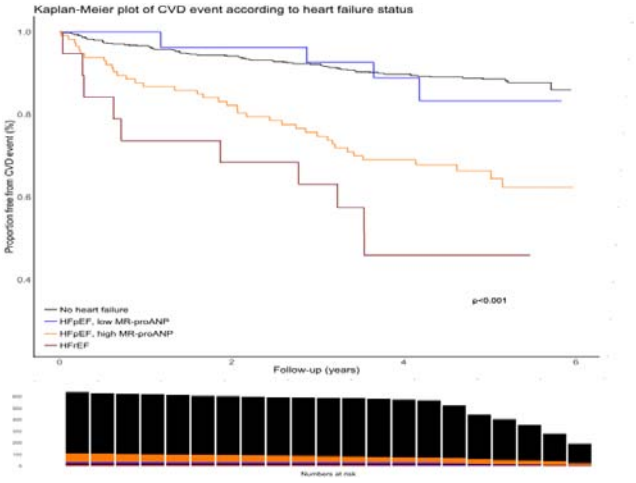


P964

MR-proANP effectively risk stratifies patients with type 2 diabetes regardless of presence of heart failure

J Jensen[1]; M Schou[1]; C Kistorp[2]; J Faber[3]; TW Hansen[4]; MT Jensen[1]; HU Andersen[4]; P Rossing[4]; T Vilsboll[4]; PG Jorgensen[1]
[1]Herlev and Gentofte Hospital, Department of Cardiology, Copenhagen, Denmark; *[2]Rigshospitalet, Department of Endocrinology, Copenhagen, Denmark*; *[3]Herlev and Gentofte Hospital, Department of Endocrinology, Copenhagen, Denmark*; *[4]Steno Diabetes Center Copenhagen, Copenhagen, Denmark*

Background/Introduction: We have previously reported that, in patients with type 2 diabetes (T2D), a cut-off of 60 pmol/l for the cardiac biomarker mid-regional pro-atrial natriuretic peptide (MR-proANP) effectively ruled out heart failure (HF) with reduced ejection fraction (HFrEF) but had limited diagnostic value regarding HF with preserved ejection fraction (HFpEF). Whether this cut-off carries relevant prognostic information is unknown.
Purpose: To investigate whether MR-proANP can improve risk stratification in T2D patient with and without HF.
Methods: In this prospective cohort study, T2D patients (n=806) from two specialized diabetes clinics were characterized with clinical variables, echocardiography and MR-proANP. HF was predefined as follows: A left ventricular ejection fraction (LVEF) ≤40% defined HFrEF. Patients with dyspnea and at least one of the following defined HFpEF: LVEF >40% and ≤50%, E/e´septal ≥15, LV hypertrophy (LV mass >95 g/m2 for women; >115 g/m2 for men) or left atrial enlargement (>34 ml/m2). Information on incident cardiovascular disease (CVD) events were retrieved through national registries. A CVD event was defined as the composite of admission with CVD (including HF, coronary revascularization, myocardial infarction, cardiac arrest, cerebrovascular disease and peripheral artery disease) and CVD death.
Results: During a median follow up of 4.8 years, 126 CVD events occurred. Overall, an MR-proANP level ≥60 pmol/l was associated with an increased risk for CVD events (univariate; hazard ratio (HR) 2.09 [95% confidence interval 1.7;2.52], p<0.05, multivariable model including age, gender, known duration of T2D, body mass index, systolic blood pressure, known CVD and albuminuria; HR 1.75 [1.4;2.23], p<0.05). Compared to patients without HF, patients with HFrEF had the highest risk for CVD events (univariate; HR 6.25 [3.23;12.11], p<0.05, multivariable model; HR 3.35 [1.65;6.80], p<0.05) followed by patients with HFpEF and an MR-proANP level ≥60 pmol/l (univariate; HR 3.47 [2.34;5.13], p<0.05, multivariable model; HR 2.55 [1.64;3.97], p<0.05). Conversely, HFpEF patients with an MR-proANP level <60 pmol/l did not have a significantly higher risk compared to patients without HF (p>0.05). Adding MR-proANP to the multivariable model, showed a net reclassification improvement (NRI) of 27.1% [7.6;46.6], p<0.05, and adding HF status showed an NRI of 32.8% [13.5-52.0], p<0.05.
Conclusions: A cut-off for MR-proANP of 60 pmol/l effectively identified patients with T2D who had an increased risk of CVD events and values below were associated with a favourable prognosis even in the presence of HFpEF. These findings support the use of MR-proANP as a diagnostic rule out tool in patients with T2D.



CVD event according to HF status

P965

Growth Differentiation Factor-15. A new, long-term prognostic biomarker in chronic heart failure with preserved or mid-range ejection fraction

A B Ana Belen Mendez Fernandez[1]; A Ferrero-Gregori[1]; A Garcia-Osuna[2]; S Mirabet-Perez[1]; MJ Pirla-Buxo[1]; J Cinca-Cuscullola[1]; J Ordonez-Llanos[2]; E Roig Minguell[1]
[1]Hospital de la Santa Creu i Sant Pau, Department of Cardiology , Barcelona, Spain; *[2]Hospital de la Santa Creu i Sant Pau, Department of Biochemistry, Barcelona, Spain*

Antecedents. Chronic heart failure (HF) with mid-range or preserved ejection fraction (HFmrEF, HFpEF) are HF phenotypes requiring better prognostic stratification; the prognostic role of biomarkers in those patients is not well-known.

Aim. To assess the prognostic value of Growth Differentiation Factor-15 (GDF-15) in patients with HFpEF or HFmrEF.
Methods. HFpEF and HFmrEF patients were sampled during their first visit to a HF Unit, and GDF-15 and amino-terminal proBNP (NT-proBNP) were analyzed by automated immunoassays. All-cause mortality was the endpoint analyzed.
Results. 311 patients with CHF, 29% HFmrEF, 32% women, mean age 68±13 years were included. No differences existed in the GDF-15 or NT-proBNP concentrations between both HF phenotypes. During a follow-up lasting up to 88-months (interquartile range 9-30 months), 98 patients (31.5%) died, most (71%) by cardiovascular causes. Death patients have higher median concentrations of GDF-15 (4,085 vs. 2,270 ng/L, p<0.0001) and NT-proBNP (1,984 vs. 1,095 ng/L, p<0.0001). Multivariable analyses identified New York Heart Association functional class (NYHA-FC) III or higher, systolic blood pressure, left atrial size and age>65 years as independent predictors (p between 0.04 and 0.0001) of all-cause mortality. When GDF-15 and NT-proBNP concentrations were added to these clinical variables, only GDF-15 added value to prediction of all-cause mortality (p=0.01).
Using the clinical predictors obtained for global mortality, a score was constructed that could predict the risk of cardiovascular mortality for a given patient during follow-up. We assign a scale of 34 points based on the coefficient β of each variable. This score allowed estimating the risk of cardiovascular mortality. The cumulative incidence function curves distinguished two groups: a low risk group (<21 points) and a high risk group (≥ 21 points).
Tertiles of GDF-15 (<1625, 1625-4330 and >4330 ng/L) were related to the 5-years survival; 78% of patients in the lowest tertile survived compared with only a 16% survival for the highest GDF-15 tertile.
Conclusions. GDF-15 appears as a strong, independent biomarker to identify HFmrEF or HFpEF patients with worse prognosis.

MORTALITY SCORE					
	β	Adjustment factor (x10)	Risk groups	Num of patients	Incidence of survival (%)
NYHA3	0,361	4	<21 points	139	72%
SBP<120 mmHg	0,366	4	≥21 points	159	21%
LA >50 mm	0,539	5			
Age >70 years	0,916	9			
GDF15 >1860 pg/ml	1,223	12			
TOTAL		34 points

Serum surfactant B concentration increases during physical exercise but does not predict patient survival

A Anna Drohomirecka[1]; K Kozar-Kaminska[1]; A Wojciechowska[1]; A Kasprzyk-Pawelec[1]; K Kodziszewska[1]; K Komuda[1]; T Rywik[1]; T Zielinski[1]
[1]*Institute of Cardiology, Warsaw, Poland*

Funding Acknowledgements: Statutory grant of Institute of Cardiology no. 2.45/VII/15

Background: Serum surfactant B is a recognized marker of alveolar-capillary barrier damage. Surfactant B may also be a predictor of worse survival in patients with heart failure.
Purpose: To assess whether physical exertion results in augmentation of alveolar-capillary barrier damage as measured by increase in serum surfactant B concentrations and whether it impacts patient survival.
Material and Methods: Fifty one patients – 43 men and 8 women (aged 55.6±7.5 years) with advanced heart failure (NYHA II-III/IV, EF≤35%, mean 21.7±5.4) underwent complex cardiologic assessment, including cardiopulmonary exercise test (CPX). CPX was performed on a bicycle ergometer according to RAMP protocol with increments of 10 Watt/min. Venous blood samples were collected before and immediately after CPX. Serum surfactant B was determined by enzyme-linked immunosorbent assay. All patients were followed up for mean of 23.5±12.6 months. Cumulative endpoint was were defined as: any death, urgent heart transplantation or urgent LVAD implantation.
Results: Serum surfactant B concentration increased significantly after CPX (median [IQR]: 77.5 [60.5-106.5] vs 87.2 [63.5-111.9] ng/ml, p<0.001). Moreover, surfactant B levels both at rest and post-CPX were positively correlated with NT-pro-BNP (R=0.32, p=0.02 and R=0.41, p=0.003, respectively). Patients with more advanced symptoms of heart failure showed greater increase in surfactant concentration after physical exertion when adjusted for basal value (NYHA class II-II/III: median 1,64 [IQR:-3.0-8.6%] vs NYHA class III-III/IV: median 8.7 [IQR: 2.4-16.8%], p=0.02). Among indicators of physical capacity analysed during the CPX VE/VCO2 slope and anaerobic threshold showed correlation with increase of surfactant concentration during exercise (R=0.29, p=0.04 and R=-0.44, p=0.002, respectively). Neither surfactant levels (rest, post-CPX) nor post-CPX change in surfactant level were predictive of patient prognosis.
Conclusions: Increased leakage of surfactant B into the systemic circulation reflects exacerbation of alveolar-capillary barrier damage as a consequence of hemodynamic changes in pulmonary vascular bed taking place during exertion in patients with advanced heart failure. However, it does not seem to significantly affect patient prognosis.

Novel urinary peptidomic classifiers predict mortality in heart failure patients: (HOMAGE)

B Blerim Mujaj[1]; ZYZ Zhenyu Zhang[1]; LT Lutgarde Thijs[1]; AC Andrew Clark[2]; HM Harald Mischak[3]; EN Esther Nkuipou-Kenfack[4]; JC John Cleland[5]; FZ Faiez Zannad[6]; JAS Jan A Staessen[1]

On behalf of: on behalf of the Heart 'Omics' in AGEing (HOMAGE) investigators

Background. Heart Failure (HF) is associated with a high death rate. Biomarkers predicting a patient's risk will help identify those patients in need of more intensive monitoring and therapy. However, whether urinary peptidomic classifiers predict the risk of death in HF patients remains unknown.
Methods. We analyzed data of 355 patients (women, 27.6 %, mean age, 70±10) from the Hull cohort, which is included in HOMAGE database. HF patients were identified, and their clinical data extracted. Each patient's blood and urine samples were collected at baseline. The multidimensional HF1 and HF2 peptidomic classifiers were measured on baseline urine samples. Using the Cox regression, we modeled the association between survival time and HF1 and HF2, while adjusting for risk factors, including sex, age, haemoglobin, creatinine, and sodium. Additionally, we ran analyses stratified, using same models, on left ventricular ejection fraction (EF<50%, >50%).
Results. During a median follow-up of 19 months (5-95% range: 1-82 months), 125 (35.2%) patients died. In the fully adjusted model, HF1 was not associated with an increased risk of death (hazard ratio [HR], 1.16; 95% confidence interval [CI]: 0.92–1.46], but HF2 was (HR 1.48; CI, 1.04–2.11]. After stratification for EF (>50%), the HF2 classifier predicted a two-fold increased risk of death in HFpEF subjects (HR, 1.95; CI, 1.00–3.85).
Conclusions. Novel peptidomic biomarkers may provide new insights into HF pathophysiology, improve risk stratification and patient management.

P968

Influence of galectin-3 and soluble ST-2 on risk of death and heart failure hospitalization in patients after ST-elevation myocardial infarction treated with primary percutaneous coronary intervention

A Agata Tyminska[1]; A Kaplon-Cieslicka[1]; K Ozieranski[1]; M Budnik[1]; A Wancerz[1]; P Sypien[1]; P Balsam[1]; M Peller[1]; G Opolski[1]; KJ Filipiak[1]
[1]*Medical University of Warsaw, 1st Department of Cardiology, Warsaw, Poland*

Funding Acknowledgements: Grant from Medical University of Warsaw

Background: Despite modern reperfusion strategies, myocardial infarction leads to deleterious processes resulting in left ventricular remodelling (LVR) and heart failure (HF). Galectin-3 (Gal-3) and soluble ST-2 (sST-2) are involved in LVR as a result of inflammation and fibrosis. There is an evidence of a high prognostic value of both biomarkers in predicting outcomes in HF patients. However, studies evaluating the role of Gal-3 and sST-2 in patients after ST-segment elevation myocardial infarction (STEMI) treated with primary percutaneous coronary intervention (PCI)are insufficient.
Purpose: The study group (SG) was followed-up forthe primary endpoint combined of cardiovascular (CV) death or HF hospitalization at one-year. Additionally, we compared Gal-3 and sST-2 concentrations to the control group (CG).
Methods: The analysis was based on data collected in a prospective BIOSTRAT (Biomarkers for Risk Stratification After STEMI; NCT03735719) study.From October 2014 to April 2017, 117 consecutive patients (without HF history) with first-time STEMI treated with PCI were recruited. The CG consisted of 41 patients with risk factors for CV diseases, but without history of coronary artery disease or HF. Blood for Gal-3 and sST-2 measurements were sampled 72-96 hours after admission.
Results: Median age was 61 and 60 years (p=0.21), while 70% and 53% (p=0.33) were men (in the SG and CG, respectively). Median left ventricular ejection fraction in the SG was 48%, and 60% in the CG (p<0.001). Median Gal-3 and sST-2 concentrations in the SG were 7.1 ng/mL (5.6-8.8) and 23.4 ng/mL (18.0-32.0), while in the control group – 6.3 ng/mL (4.6-7.8; p=0.03) and 17.9

ng/mL (15.7-23.3; p=0.001), respectively. Data on the primary endpoint was available for 104 patients (89%). During the one-year observation, 9 patients (8.65%) reached the primary endpoint. In the univariate analysis higher Gal-3 and sST-2 concentrations, among other variables, were predictors of the primary endpoint (Gal-3 hazard ratio [HR]: 1.34, 95% confidence interval [CI]: 1.17-1.54, p<0.001; sST-2 HR 1.05, 95% CI: 1.02-1.08, p=0.001). Gal-3 ≥9.57 ng/mL and sST-2 ≥45.99 ng/mL had sensitivity of 78% and 44%, and specificity of 85% and 97%, respectively, for prediction of the primary endpoint during follow-up.Both, Gal-3 and sST-2 correlated positively with length of stay in intensive cardiac care unit, C-reactive protein, N-terminal pro-B-type natriuretic peptide and negatively with glomerular filtration rate. Gal-3 correlated positively with age, Killip and New York Heart Association class. There was no significant correlation between sST-2 and age.

Conclusion: In patients after first-time STEMI, Gal-3 and sST-2 are predictors of mortality and HF hospitalization and their assessment after STEMI may play a useful role in the CV risk stratification.

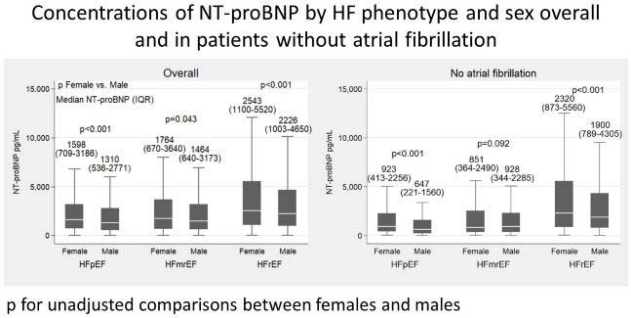
P970

N-terminal pro-B-type natriuretic peptide in chronic heart failure: The impact of sex across the ejection fraction spectrum

U Ljung Faxen[1]; LH Lund[1]; A Stromberg[2]; DC Andersson[1]; C Linde[1]; U Dahlstrom[2]; G Savarese[1]
[1]Karolinska Institutet, Department of Medicine, Stockholm, Sweden; *[2]Linkoping University, Department ofCardiology , Linkoping, Sweden*

Funding Acknowledgements: Swedish Research Council [grants 2013-23897-104604-23 and 523-2014-2336], and the Swedish Heart Lung Foundation [grants 20120321 and 20150557]

Objective: The aim was to assess sex-specific differences in N-terminal B-type natriuretic peptide (NT-proBNP) regarding concentrations, associations with patient characteristics, and prognostic role, in a large and unselected population with chronic heart failure (HF) with preserved (HFpEF), mid-range (HFmrEF), and reduced ejection fraction (HFrEF).
Methods and results: In 9847 outpatients with HFpEF, HFmrEF, and HFrEF (49 vs. 35 vs. 25% females) from the Swedish HF Registry, median concentrations of NT-proBNP were 1598 pg/mL in females vs. 1310 pg/mL in males (p<0.001) in HFpEF, 1764 vs. 1464 pg/mL (p=0.043) in HFmrEF, and 2543 vs. 2226 pg/mL (p<0.001) in HFrEF. The differences persisted after adjustment HF severity, age, body mass index, presence of atrial fibrillation, kidney function, and anemia, p<0.001 for HFpEF and HFrEF, vs. p=0.006 in HFmrEF. In patients with HFpEF in sinus rhythm, median NT-proBNP was 43% higher in females, 923 vs.647 pg/mL.
Associations between patient characteristics and high NT-proBNP (defined as above the median in females and males in the three HF phenotypes) were largely similar in both sexes. High NT-proBNP was associated with the composite of all-cause death or first HF hospitalization in both sexes and across the EF phenotypes; adjusted hazard ratios (95% confidence intervals; CI) 2.10 (1.63-2.70) vs. 1.76 (1.38-2.23) in HFpEF females vs. males, 1.86 (1.43-2.43) vs. 1.84 (1.50-2.27) in HFmrEF, and 1.46 (1.23-1.73) vs. 1.51 (1.37-1.67) in HFrEF (no significant interaction NT-proBNP*sex across the EF spectrum).
Conclusion: Concentrations of NT-proBNP were higher in females across the EF spectrum, with large relative differences in HFpEF. Associations with patient characteristics and outcomes were nonetheless similar in both sexes. The findings support the use of NT-proBNP for prognostic purposes in chronic HF, regardless of sex, but the sex-differences, in HFpEF in particular, merit further investigation and might have implications for optimizing trial eligibility.



p for unadjusted comparisons between females and males

P971

Significance of etiological diagnosis of hypertrophic cardiomyopathy phenocopies

E Szogi[1]; ZS Majoros[1]; A Kovacs[1]; B Muk[1]; M Szabo[1]; T Borsanyi[1]; M Dekany[1]; CSL Nyeki[2]; RG Kiss[1]; N Nyolczas[1]
[1]Medical Centre, Hungarian Defence Forces, Budapest, Hungary; *[2]Semmelweis University, Budapest, Hungary*

Introduction: Clarification of the etiology of phenocopies of hypertrophic cardiomyopathy (HCM) is of great importance due to the growing numbers of widely available therapeutic options.
Purpose: The aim of our study was to determine the diseases responsible for HCM phenocopies in the patient group managed at our Heart Failure Outpatient Clinic.
Methods: We examined 58 heart failure patients with HCM phenotype (left ventricular wall thickness ≥ 15mm) at our Heart Failure Outpatient Clinic between 1 January 2016 and 31 July 2018. After an echocardiography was performed, every patient underwent cardiac magnetic resonance imaging (CMR) test as well.
Results: The final diagnosis after the CMR test was HCM in half of the patient group (29 patients), hypertension-related left ventricular hypertrophy (LVH) in 18 patients, cardiac amyloidosis in 8 patients, and respectively 1-1 case of Löffler endocarditis, non-compaction cardiomyopathy and Fabry disease. From the 8 patients, that the CMR suggested cardiac amyloidosis (CA), 3 proved to be transthyretin (ATTR) amyloidosis, and 2 AL amyloidosis. In one case, after the negative medical examinations (serum electrophoresis, free light chain measurement, 99mTcHDP scintigraphy, gingival biopsy), a myocardial biopsy has been performed, confirming a previously sufferred myocarditis. In the last 2 cases, due to one patient's non-compliance, and the other patient's death, no further testing could be carried out. Currently, 1 of the 3 ATTR patients is already receiving tafamidis treatment, in the other two cases, treatment initiation is in progress. The 2 AAL patients are being treated in co-operation with haematologists. The patient suffering from Fabry's disease is receiving enzyme replacement therapy and the patient with Löffler endocarditis is treated with steroid therapy.
Conclusions: The etiological diagnosis of HCM phenocopies suspected by echocardiography is of great importance, because this could allow an effective and often prognosis improving treatment in a large number of patients.

Diverse effects of neprilysin inhibition by sacubitril/valsartan on different forms of natriuretic peptides in patients with HFrEF.

SA Sviatoslav Galochkin[1]; EE Feygina[2]; AG Semenov[2]; IA Meray[1]; ZD Kobalava[1]
[1]Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation; *[2]HyTest Ltd., Turku, Finland*

Background: Sacubitril/valsartan (SV) is a novel heart failure (HF) medicine. The drug combines angiotensin II receptor blocker and inhibitor of neprilysin (NEP), a protease responsible for a breakdown of natriuretic peptides (NPs) of A- and B-type. The effect of NEP inhibition on the levels of different NPs forms still remains unclear. In this study we explored effects of SV on both clinical status of HF patients with reduced ejection fraction (HFrEF) and levels of different NPs forms.
Methods: 22 HFrEF patients, age 27-87 (median 66, IQR 57.25-76), 86.4% male, presenting baseline LVEF 15-40% (median 27.5%, IQR 25-34.75%), NYHA class II (27.3%), III (50%) and IV (22.7%) received SV for 30 weeks. We examined changes in LVEF, NYHA class and biomarkers in EDTA-plasma samples at baseline and at 30 weeks after SV initiation. NT-proBNP was measured by Pathfast™ assay and in-house immunoassay based on monoclonal antibodies (MAbs) targeting nonglycosylated regions of NT-proBNP. In-house intact proBNP assay (N- and C-terminal epitopes) and total BNP assay (C-terminal epitope and epitope comprising the site of NEP cleavage) were used. All MAbs were from HyTest Ltd. ANP was measured by in-house immunoassay utilizing anti-ANP MAb 23/1 (Biorad) and rabbit polyclonal anti-ANP antibody.
Results: We observed more than 30% NT-proBNP level decrease in 13 patients (65%) and considered them as responding group; in 7 patients (35%) NT-proBNP level increased or did not change (non-responding group). There was no difference in NYHA functional class dynamics in responding and non-responding groups: 84.6% and 85.7% of patients exhibited NYHA class improvement correspondingly (P=1.000). However, LVEF improvement (more than 20% increase) between responding and non-responding groups differed significantly (P=0.0023): only 15.4% of patients from responding group demonstrated decreasing or unchanging LVEF, while no LVEF increase was observed in non-responding group.
NT-proBNP dynamics analyzed by Pathfast™ and our glycosylation-independent assay in responding group differed in 4 cases (30.8%). Both proBNP and total BNP levels had moderate correlation with NT-proBNP measured by in-house assay (r=0.731 and 0.788 correspondingly), and no correlation with NT-proBNP measured by Pathfast™ (r=0.336 and 0.394 correspondingly).
ANP level (available for 9 out of 22 patients) changes showed no association with NT-proBNP dynamics: 3 patients in responding group showed a dramatic increase

in ANP level, 2 patients demonstrated ANP decrease to undetectable level at 30 weeks and 2 patients had no change in ANP concentration.
Conclusions: Diverse effects of SV therapy on different forms of NPs in both responding and non-responding patients suggest differential impact of NEP inhibition on metabolism of NPs in individuals. One can speculate that monitoring different forms of NPs provides useful insights regarding beneficial effects of SV therapy in HF.

P973
Timing of echocardiographic evaluation of patients with advanced heart failure. Is it time consuming?

P Kostakou[1]; V Kostopoulos[1]; V Giannaris[1]; CH Olympios[1]; N Nikolaos Kouris[1]
[1]*Thriassio General Hospital, Athens, Greece*

Echocardiography constitutes the cornerstone in diagnosis and management of patients (pts) with heart failure (HF). Technological developments thoroughly improves the estimation of these pts but also may increase significantly the duration of the examination offering data not always necessary for the specific clinical condition. The aim of the study was to test the hypothesis that although focus echo was used the duration of the examination was prolonged.
Methods: We studied 20 consecutive pts with advanced HF in an EACVI (European Association of Cardiovascular Imaging) accredited echo lab as everyday routine examinations. The studies were performed by a highly experienced echocardiographer, EACVI accredited using an updated echo machine. All pts underwent a full conventional echo study and according to each case additional methods were used (3D, strain analysis, dyssynchrony analysis, contrast and RV function advanced analysis). All measurements and calculations were performed off line and the reporting time was also estimated. Patients with atrial fibrillation and poor image quality were excluded.
Results: The pts' (65% men) mean age was 57.4±13.8 years and the underlying pathophysiology was ischemic cardiomyopathy (55%), dilated cardiomyopathy (30%) and other (15%, lupus erythematosus, peripartum cardiomyopathy and hypertension). Mean EF was 23±5% and concomitant at least moderate MR was present in 65%. 3D measurements were performed in 90% of pts, LVGLS was calculated in 35%, dyssynchrony in 25%, RV function measurements in 25% and contrast was used in 10%. Time for images acquisition was 26.25±7.6min, time for conventional measurements was 9.6±0.9min and time for calculations (2D and 3D EF, MR quantification) was 7.2±0.8min. Need for contrast administration added 1min, dyssynchrony estimation 1.35min, LVGLS analysis 2min and further RV function 3min. Reporting time with printed report was completed in 14.2±0.8min. Mean total time from beginning of study till the report was written was 57.8±8.9min.
Conclusion: Echocardiographic evaluation of patients with advanced HF is time consuming even if the study is focused and a protocol is used and exceeds the time that is needed even for complex valvular disease estimation.

P974
Short-term echocardiographic evaluation by global longitudinal strain in patients with HFrEF treated with sacubitril / valsartan

S Mazzetti[1]; C Scifo[1]; R Abete[1]; D Margonato[1]; M Chioffi[1]; J Rossi[1]; M Pisani[1]; G Passafaro[1]; M Grillo[1]; D Poggio[1]; A Mortara[1]
[1]*Polyclinic of Monza, Clinical Cardiology,, Monza, Italy*

Introduction: Sacubitril/Valsartan combination therapy (ARNI) in the PARADIGM HF study showed important results in reducing mortality, re-hospitalization and improving quality of life in patients with heart failure and reduced left ventricular function (HFrEF). However, at present, few data have been presented that have analyzed hemodynamic and functional effects of this drug.
Objective: The aim of the present study was to assess the main echocardiographic parameters, including Global Longiudinal Strain (GLS), in patients with chronic SC who were treated with ARNI. Ventricular strain may be considered the gold standard for the analysis of variations in left ventricular function.
Methods and Results 30 outpatients were enrolled (22 males, mean age 64+10 years) with the following baseline characteristics: LVEF 28+9, NYHA II-III, idiopathic etiology 46% ischemic 48%, valvular 6%. In all patients ARNI was titrated according to the ESC guidelines, with a starting dose of 100mg die and a progressive increase to the maximum tolerated dose. In 12 pts it was not possible to reach the maximum dose because of severe hypotension (n=10) and of significant worsening of renal function (n=2). Eighteen pts (60%) were treated with the maximum dose of 200 bid. Assessment of echocardiographic data was obtained in all patients at baseline and at 3-6 months of follow-up. In addition to the main echocardiographic parameters (FE, LVEDV, LVESV, E/A, decT, VolAsx, TAPSE, mitral regurgitation) the GLS (total, epicardial and endocardial) was also evaluated. Main echo data are shown in the table.
Conclusions: Treatment with ARNI in patients with HFrEF significantly increases LVEF at mid term, but more precociously, it affects global longitudinal strain which improves already at 3 months. This study confirms the favorable action of ARNI on the left ventricular function, and underlines how the strain method represents today the reference tool for detecting even minimal short-term changes in ventricular function.

Cardiac output and cardiac index by echocardiography modalities versus thermodilution: a comparative study

H K Adam Kwa[1]; M H Aziman[1]; M H Isa[1]; N Kasinathan[1]; M F Usman[1]; MNH Abd Rani[1]
[1]*National Heart Institute, Kuala Lumpur, Malaysia*

Introduction: Accurate measurement of cardiac output (CO) and cardiac index (CI) is crucial in making decision on therapeutic management of patients under various cardiac pathology. Despite the invasive nature, thermodilution method (TD) using pulmonary artery catheter placement is accepted as a reference standard for CO measurement method. Various transthoracic echocardiography (TTE) modalities can be utilised to calculate CO and CI, though the agreement with TD is not established firmly based on past studies. This present study aims to identify by statistically significant value of CO and CI measured by TTE modalities in comparison with TD, and to evaluate the level of agreement between these two methods.
Methods: Sixty-one patients admitted for elective TD procedure through Swanz-Ganz pulmonary artery catheter were included. Measurements of CO and CI by TD were obtained. TTE modalities which are Teicholz, modified Simpson and doppler-based techniques were utilised to calculate CO and CI through product of stroke volume with heart rate. The relationship between CO and CI by TTE measurements with TD was studied using Pearson's correlation, then their strength and direction of linear association was evaluated by performing regression analysis. Finally, Bland-Altman analysis was used to assess the level of agreement between these two methods of CO and CI measurement.
Results: The normality of the data distribution was checked using Kolmogorov-Smirnov test and skewness of the data was between -2 to 2. By Pearson correlation and linear regression, the TTE modalities of systemic and pulmonary Doppler were significantly correlated in terms of CO and CI. The r value of CO for systemic and pulmonary Doppler were r= 0.435 and 0.365; p<0.05 while in terms of CI, r= 0.367 and 0.322; p < 0.05 respectively. According to the Cohen (1988), the r values obtained indicate medium strength of relationship between TD with systemic and pulmonary Doppler. Based on Bland-Altman analysis, there were also agreements between TD with systemic and pulmonary Doppler as the differences in data were scatter plotted within the limit of agreement (LOA). Systemic Doppler CO and CI showed the least data differences with TD CO and CI. For CO, the mean of bias was -0.12 l/min with the 95% LOA of -3.94 l/min and 3.69 l/min, whereas for CI, the mean of bias was 0.018 l/min with the 95% LOA of -1.71 and 1.74 l/min. The proportional bias was determined by the regression of mean differences data when B value nearest to zero and t value <0.05 to reject null hypothesis.
Conclusion: This study shows that Doppler-based techniques are novel echocardiography modalities in assessing CO and CI as there is reasonable agreement with the reference method. With sufficient study in the future, clinical decision can be made with high level of assurance based on these non-invasive TTE modalities alone when current gold standard invasive TD is not feasible.

P976
Prognostic value of myocardial fibrosis amount and localization assessed by cardiac magnetic resonance in patients with non ischemic dilated cardiomyopathy with left ventricular systolic dysfunction

L Lupi[1]; D Farina[2]; E Gavazzi[2]; I Papa[1]; M Piazzani[1]; D Fabbricatore[1]; G Arabia[1]; A Castiello[1]; R Maroldi[2]; M Metra[1]; S Nodari[1]
[1]*University of Brescia, Department of Clinical and Surgical Specialities, Cardiology section , Brescia, Italy*; [2]*University of Brescia, Department of Clinical and Surgical Specialities, Radiology section, Brescia, Italy*

Background: Myocardial fibrosis detected with cardiac magnetic resonance (CMR) has emerged in recent years as an important prognostic value in patients (pts) with heart failure (HF).
Purpose: to evaluate the prognostic role of myocardial fibrosis amount and localization in pts with non ischemic dilated cardiomyopathy (DCM) and left ventricular systolic dysfunction.
Methods: We enrolled retrospectively pts suffering from DCM with left ventricular ejection fraction (LVEF) ≤45% underwent CMR with administration of paramagnetic contrast agent followed at our HF Department from January 2012 to December 2016. We evaluated demographic, laboratory, therapeutic and imaging parameters (left and right ventricular ejection fraction, myocardial mass, presence of late gadolinium enhancement (LGE), LGE localization, number of LGE segments). The composite endpoint was death from any cause and hospitalization for cardiovascular (CV) causes or HF.
Results: We enrolled 184 pts (69% male, mean age 56 ± 12 years). 90 pts (49%) showed left ventricular LGE. Table 1 shows the parameters that were predictive of events at univariate analysis. At multivariate analysis, only the presence of LGE confirmed its prognostic value (HR 8,009; IC 95% 2,504–25,621; p=0,0001). With the increase in the number of LGE segments there was a significant trend of worsening of the prognosis (p=0.03). In particular, the presence of more than 3 LGE segments was associated with a worse outcome (HR 1.3, IC 95% 1.16-2.02, p=0.008). The localization at basal septum was associated with an increased risk of events, especially arrhythmias, compared to the other localizations.
Conclusions: the amount and localization of myocardial fibrosis are independent predictors of death and CV and HF hospitalization in pts affected by DCM and may allow early detection of pts at high risk of poor prognosis, needing more aggressive treatment and closer follow-up visits.

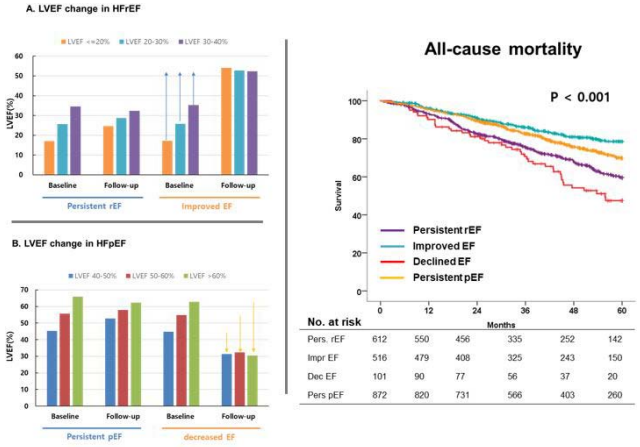
Global longitudinal strain for prediction of ejection fraction change in heart failure

JJ Jin Joo Park[1]; JH Lee[2]; IC Hwang[1]; JB Park[3]; JH Park[4]; GY Cho[1]
[1]Seoul National University Bundang Hospital, Division of Cardiology,, Seongnam, Korea (Republic of); *[2]Chunbuk National University Hospital, Department of Internal Medicine, Cheongju-Si, Korea (Republic of)*; *[3]Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea (Republic of)*; *[4]Chungnam National University Hospital, Daejeon, Korea (Republic of)*

Background: In patients with heart failure (HF) the left ventricular ejection fraction (LVEF) changes during follow-up. Myocardial strain is a marker for LV contractility and a good prognostic factor.
Purpose: We sought to evaluate whether global longitudinal strain (GLS) can predict changes in LVEF in HF patients.
Methods Of 4312 patients hospitalized for acute HF 2,105 underwent echocardiography at baseline and follow-up (median interval: 406 days). GLS was measured at the index admission. HF phenotypes were defined as persistent HF with reduced EF (persistent HFrEF, LVEF ≤ 40% at baseline and follow-up), HF with improved EF (HFiEF, LVEF ≤ 40% at baseline and improved to >40% at follow-up), HF with declined EF (HFdEF, LVEF>40% at baseline and declined to ≤40% at follow up) and persistent HF with preserved EF (persistent HFpEF, LVEF ≥40% at baseline and follow-up).
Results 1130 patients had HFrEF at baseline: during follow-up 54% and 45.8% had persistent HFrEF and HFiEF, respectively. When stratifying the patients according to LVEF, HFiEF patients archive LVEF > 50% regardless of baseline LVEF, whereas patients with persistent HFrEF did not show significant EF change. Among 975 patients with HFpEF at baseline, 10.5% and 89.5% had HFdEF and persistent HFpEF at follow-up, respectively. Similarly, patients with HFdEF experienced a decline in LVEF to ca. 30% regardless of baseline LVEF. Regarding the clinical outcomes, HFiEF had the best and HFdEF the worst prognosis (figure).
The median GLS was 10%, 7.7% and 13.7% in all, HFrEF and HFpEF, respectively. Patients with HFiEF had higher GLS than persistent HFrEF (7.9±3.2% vs. 8.7±3.45%, P<0.001), whereas HFdEF had lower GLS than persistent HFpEF (14.1±4.6% vs. 11.8±4.5%, P<0.001). In multivariable analysis, each 1% increase in GLS was associated with a 10% increased risk for HFiEF (P<0.001) and 7% reduced risk for HFdEF among patients with baseline HFrEF and HFpEF, respectively.
Conclusions In patients with HF, the changes in LVEF during follow-up are associated with different outcomes. GLS can be used to predict the LVEF changes in both HFrEF and HFpEF patients.



EF change and outcomes

P978
Left atrial function in HFpEF and HFmrEF patients; relation to pulmonary artery systolic pressure

A Vrettos[1]; L Al Saikhan[2]; C Plymen[1]; J Chilcott[1]; L Matiti[1]; P Nihoyannopoulos[1]
[1]Imperial College Healthcare NHS Trust, Cardiology, London, United Kingdom of Great Britain & Northern Ireland; *[2]Imperial College Healthcare NHS Trust, Hammersmith Hospital, Echocardiography Department, London, United Kingdom of Great Britain & Northern Ireland*

Background: Heart failure with preserved ejection fraction (HFpEF) and with mid-range ejection fraction (HFmrEF) are conditions sharing similar diagnostic criteria and symptoms. Left ventricular diastolic dysfunction has often been considered central to the pathophysiology of both, as determined by current conventional echocardiographic measures of elevated filling pressure and/or an increased in left atrial (LA) volume. While studies have shown that LA function and pulmonary artery systolic pressure (PASP) are an important determinant and an indicator of LV filling pressures, the relationship between LA mechanical function and PASP in such patients is unclear.
Methods: A total of 108 consecutive outpatients diagnosed with HFpEF (n=70) with an Ejection Fraction (EF) ≥ 50%, or HFmrEF (n=38) with an EF of 40-49% were prospectively enrolled. Pulmonary artery systolic pressure was estimated using tricuspid regurgitation gradient and right atrial pressure. The following conventional parameters were also obtained on a resting echocardiogram: mitral E/A, E/e', left atrial volume indexed (LAVi) and LV EF. Left atrial phasic function was analysed using 2D-Specle Tracking. Peak-atrial longitudinal strain (PALS) and peak-atrial contraction strain (PACS) were measured, reflecting LA reservoir and pump function respectively. We looked at the relationship of LAVi, traditional parameters of systolic and diastolic function and LA strain, with PASP in this cohort.
Results: There were 20 (29%) HFpEF patients with elevated PASP (≥40mmHg), and 12 (32%) in the HFmrEF group. At univariate analysis, there were significant correlations between PASP and the following echocardiographic measurements in the HFpEF and HFmrEF groups respectively: E/e' (r=0.47 p<0.001, r=0.37 p<0.05), mitral E/A (r=0.48 p<0.001, r=0.46 p<0.01), LAVi (r=0.45 p<0.001, r=0.17 p=NS), PALS (r=-0.48 p<0.001, r=-0.57 p<0.001) and PACS (r=-0.44 p<0.001, r=-0.50 p<0.01). Peak-atrial longitudinal strain had the highest correlation coefficient with PASP in both groups. There was no significant correlation between LV EF and PASP in either group. Stepwise multiple linear regression analysis of LAVi, parameters of LV diastolic dysfunction and LA strain showed that PALS was the best independent predictor of PASP in the HFmrEF group (standardised Beta coefficient =-0.51, p<0.001), and had the greatest area under the curve to predict the presence of high PASP at Receiver Operating Characteristics analysis (area under the curve = 0.82, p<0.01).

Conclusion: This study shows that a reduced LA reservoir function is associated with an increased PASP in patients with HFpEF and HFmrEF, reflecting perhaps that the large blood volume which is directly aspirated from pulmonary bed into LV, leads to the rise in pulmonary artery pressures. Reduced LA reservoir function has excellent predictive value in both heart failure groups, and emerged as an independent predictor of high PASP in patients with HFmrEF.

Chronic Heart Failure - Treatment

Small tolerated enalapril doses before ARNI administration predicts adverse events during ARNI up-titration

A Ntalianis[1]; IP Petropoulous[1]; I Stamoulopoulos[1]; E Repasos[1]; G Maglaras[1]; A Mareti[1]; M Kondylis[1]; N Zografos[1]; A Koen[1]; K Tampakis[1]; A Misegiannidis[1]; E Venieri[1]; N Makris[1]; I Kanakakis[1]; I Paraskevaidis[1]
[1]University of Athens Medical School, Dept of Clinical Therapeutics, Alexandra Hospital, Athens, Greece

Background/Introduction: The maximum recommended dose (200 mg BID) of sabutipril-valsartan (ARNI) is associated with better prognosis in patients with heart failure and reduced ejection fraction (HFrEF). Theoretically, small tolerated enalapril doses might associate with lower ARNI tolerated doses
Purpose: To investigate the possible association of small tolerated enalapril doses before ARNI with adverse events after ARNI switch.
Methods: Patients with HFrEF (EF£35%), NYHA class II and III at maximum tolerated dose of β-blocker, enalapril and spironolactone were considered eligible for the study. All patients were switched from enalapril to ARNI which it was progressively up-titrated every week from 50mg BID to 100mg BID and eventually 200mgX2. Enalapril dosage £5 mg BID prior to ARNI was considered as "low dose" (LD), while a dose> 5 mg / BID was considered as a "high dose" (HD).
Results: A total of 33 patients with a mean age of 59.5 years (84.8% with ischemic myocardiopathy) were prospectively included. 82% of patients were receiving LD of enalapril before ARNI and 18% HD. Overall, 70% of the patients were titrated to the maximum dose of ARNI. Fewer LD patients were up-titrated to the maximum target ARNI dose as compared with the HD group patients (66.6% vs. 83.3%, p=0.01). Only patients in the LD group experienced adverse events during ARNI up-titration (1 patient asymptomatic hypotension, 2 patients symptomatic hypotension and 2 patients hyperkalaemia).
Conclusions: Low tolerated enalapril doses before ARNI administration are associated with a lower probability of ARNI up-titration at the maximum recommend dose and more adverse effects during ARNI administration.

Introduction: Sacubitril/valsartan (S/V) introduction in the heart failure (HF) with a reduce ejection fraction (rEF) therapeutic algorithm was the biggest advance in this syndrome treatment in recent years. Given the small amount of time elapsed since S/V introduction, there are no comparative data between real-life populations and the PARADIGM-HF Trial population.
Objective: To characterize a population followed in the HF Clinic of a Tertiary Hospital medicated with S/V and to compare it with the PARADIGM-HF Trial population.
Methods: Prospective data recording study of pts with HFrEF treated with S/V. Clinical and demographic characteristics, S/V doses, adverse effects and concomitant therapy data were recorded. Comparisons with the PARADIGM-HF S/V treated population were established by Student's T-test and ANOVA.
Results: One hundred and two pts were included. Median follow-up time since S/V first dose was 6 (4-10) months. The present study population presents statistically higher mean age, NTproBNP and serum creatinine levels (Cr) when compared to the PARADIGM-HF population. There was a greater number of pts in NYHA functional class I and II and ischemic etiology was less frequent. There were no significant differences regarding gender, systolic blood pressure or baseline ejection fraction (Table 1).
This real World population had a higher rate of β-blocker and mineralocorticoid receptor antagonist prescription (Table 1). In this population, 59 pts (57.8%) started on S/V at the dose of 24+26mg and 43 pts (42.2%) at the intermediate dose. The average maximum tolerated dose was significantly lower than that reported in PARADIGM-HF (175±84 vs 375±71 mg/day, <0.001): low dose in 28 pts (27.5%), intermediate dose in 54 pts (52.9%) and high dose in 20 pts (19.6%). The mean dose of ACEi/ARB before S/V initiation was lower than that reported in PARADIGM-HF (dose equivalent to enalapril 14.75±11.75 mg/day vs 18.9±3.4, P =0.01) and 4 pts (3.9%) were medicated with ACEi/ARB previously. The rate of ICD and/or CRT was much higher in the real world population (table 1).
S/V was discontinued in 7 pts (6.9 vs 2.3%, P = NS): in 4 pts due to hypotension (3.9 vs 0.9%, P =0.011), in 1 due to cough (1 vs 0%, P =NS), in 1 due to angioedema (1 vs 0.4%, p =0.003) and in 1 due to HF decompensation (1 vs 0%, P =NS).
The mortality rate in this study population was 3.9% (4 pts).
Conclusions: When comparing the PARADIGM-HF Trial population with a real World population it is evident that the latter is composed of older patients with higher levels of NTproBNP and Cr. In this every-day HFrEF population maximal S/V tolerated doses were lower than those reported in PARADIGM-HF. The rate S/V discontinuation due to adverse events was similar, attesting the safety of the drug.

Use of sacubitril-valsartan in heart failure with reduced ejection fraction: real world experience

FAC Ferreira[1]; S Cristina[1]; AF Raposo[1]; EM Albuquerque[2]; I Nabais[1]; CS Matias[1]; MA Nogueira[1]; RCA Vasconcellos[3]; GMM Proenca[1]
[1]Hospital of Cascais, Lisboa, Portugal; *[2]Amil Serviços Medicos SA, Rio de Janeiro, Brazil*; *[3]United Health Group, Minetonka, United States of America*

Introduction: Sacubitril/Valsartan (Sac/Val) significantly reduces hospitalizations and mortality of heart failure patients (pts) with reduced ejection fraction (HFrEF). Considering that real world evidence is still scarce, it's important to report our experience regarding safety and efficacy of this drug, after approximately one year of its introduction in Portugal. Methods: From November 2017 to January 2019, 74 patients (pts) were switched from Angiotensin-Converting Enzyme Inhibitor/Angiotensin Receptor Blocker (ACEI-ARB) to Sac/Val. Data of 66 pts (80% men), with ischemic etiology (61%) and left ventricular ejection fraction (LVEF) of 28,9 +/-6,8% were retrospectively analyzed. Mean age was 71,4 +/-12,0 years old. At the start of therapy with Sac/Val, 50% of pts were in NYHA class II, 39,3% in NYHA class III and 6% in NYHA class IV. Mean NTproBNP before the switch of therapy was 5888,6 +/- 5846,1 pg/ml. Considering ESC guideline Class I Recommendation for HF therapy, 92% of pts were using betablockers, 91% ACEI/ARB, 61% mineralocorticoid/aldosterone receptor antagonist, 74% loop diuretics and 15% ivabradine.

Seventeen percent had CRT and 21% ICD. In 31 pts (46,9%), initial Sac/Val dose of 24/25mg bid was not augmented. In 36,3% of pts was possible to achieve an intermediary dose of 49/51mg bid and in 15,1% the maximum dose was achieved. Clinical efficacy (HF hospitalization, death, NYHA class improvement), safety (arterial pressure, serum potassium, creatinine), NTproBNP and echocardiographic (LVEF) parameters were analyzed. Results: There was an improvement of NYHA class, with only 2 (3%) pts remaining in NYHA class IV. Two (3%) pts had worsened NYHA class. Among the remaining pts, 34 (51,5%) improved NYHA class. There were 4 (6%) unplanned hospitalizations for HF after switch of therapy and there were 2 deaths of refractory HF. About safety concerns, sac/val had been discontinued in 1 pt because of hypotension, and in another one because of worsening renal function. In 62 pts there were no major events associated with therapy switch: mean arterial pressure was 125,9+/-18,7 mmHg, serum potassium (4,5+/-0,4 mmol/L) and renal function (Cr 1,2+/-0,4mg/dl) remained stable. There wasn´t any report of angioedema. LVEF after switch therapy improved from 28,9+/-6,8 to 37,5+/-9,0%. Conclusion: Therapy with Sac/Val, when associated to other ESC guideline Class I Recommendation HF therapies, was effective in improving NYHA class and reducing hospitalizations being associated to low risk of complications.

The dangers of non-heart failure hospitalisation for heart failure patients: frequent medication changes without follow up

E O' Donoghue[1]; A Brennan[1]; C O' Dowling[1]; J Mc Cormick[1]; R Trueick[1]; A Mc Hugh[2]; K Mc Donald[1]
[1]*St Vincent's University Hospital, Dublin, Ireland*; [2]*Dundalk Institute of Technology, Department of Nursing, Midwifery and Health Studies, Louth, Ireland*

Introduction: Pharmacotherapy in heart failure (HF) has become increasingly complex with each patient's prescription the product of weeks or months of careful titration. The admission to hospital of HF patients for non-cardiac issues may lead to medication changes (MC) for reasons that may be either indicated or potentially inappropriate. Failure to communicate MC to the HF or cardiology team during admission or to arrange follow up with HF services may leave the patient exposed to potentially adverse outcomes.
Purpose: This study set out to examine the frequency with which HF MC occurred when patients who attend the heart failure unit (HFU) are admitted to hospital for non-cardiovascular reasons. Additionally we determined whether a rationale was documented and if patients were informed of the changes. Where changes were identified, appropriate follow up in HFU was arranged.
Methods: In an ongoing prospective single-centre observational study, we reviewed a daily list of admissions via the Emergency Department for patients that attend the HFU. Discharge notes were screened to assess if MC were made, and if so, whether there was a documented rationale for the change. Following this a phone call was made to the patient in order to assess their understanding of the change in HF therapy.
Results: To date, from a total of 584 non-HF admissions we randomly selected 73 patient charts. Fifty percent of patients carried a diagnosis of HFrEF (Heart Failure with Reduced Ejection Fraction) and 50% of patients were diagnosed with HFpEF (Heart Failure with Preserved Ejection Fraction). Patients studied had an average age of 74.6 years and an average length of stay of 10 days. Dominant cause for admission was respiratory infection. We noted a MC in 52% (n=38) of patients. Diuretics were the agents most frequently changed in 42% of cases (n=16). Changes were noted also in beta blockade (n=10), ACE inhibitors/ARBs (n=10), MRAs (n=1) and nitrates (n=1). There was no contact with the cardiology service in regard to any of these changes. A documented rationale was noted in 65% of cases (n=25). To date phone calls have been made to 27 patients who had MC. Of these, 44% (n=12) stated that their admitting teams knew of their attendance at HFU. Fifty one percent of patients (n=14) were aware that MC occurred, while 25% (n=7) had these changes explained to them. No patients were advised to follow up with the HFU.
Conclusion: The incidence of MC is high in this vulnerable patient cohort when they are admitted to hospital for non-cardiovascular reasons. While there is a stated rationale in many cases, these alterations were not discussed with cardiology service, and follow up with the HFU was not requested. This sequence of events may leave patients susceptible to adverse HF events following discharge from hospital. In an effort to guard against such events we recommend closer links are established between services both in hospital and at outpatient level.

On behalf of: Gómez Leiva, Veronica V

INTRODUCTION. In Mexico, heart failure (HF) has a prevalence of 1.6 million persons and annual incidence of 600,000 new cases.Sacubitril/Valsartan (S/V) has proved to be superior than conventional therapy decreasing the number of readmissions in the emergency room, days in the intensive care unit, total hospitalizations days, improve in quality of life and survival, echocardiography has shown improvement in the left ventricular ejection fraction (LVEF) and reverse remodeling achieved.PURPOSE. Compare the echocardiographic parameters, quality of life, institutional costs, tolerance and side effects in patients with heart failure with reduced ejection fraction before and after 3 months therapy with S/V.METHODS. Patients diagnosed with HF, LVEF ≤35%, persistence of symptoms and treated with conventional therapy were recruited to initiate S/V therapy. After written consent was obtain, echocardiographic parameters (LVEF, diastolic diameter, systolic diameter, diastolic function and pulmonary artery systolic pressure), quality of life: 6-minute walk test (6-MWT) and Kansas City cardiomyopathy questionnaire (KCCQ) and institutional cost were measured; follow-up was made at three months, with the same parameters.Data analysis was made with SPSS statistical program (v 24.0). Data is presented as means and standard deviations, frequencies and percentages. The distribution of variables was determined with the Shapiro-Wilk test; Wilcoxon and Friedman test were used. Statistically significant was taken at p <0.05.RESULTS. 25 patients were enrolled. Baseline characteristics: mean age 54 years (± 13.7), women 32%, non-ischemic 52%, 52% without pacemaker, 12% with implantable cardioverter defibrillator (ICD), 12% with cardiac resynchronization therapy (CRT) and 24% with ICD-CRT. 68% were non responders (59% ischemic), 20% responders (60% non-ischemic) and 12% super responders (all non-ischemic).Echocardiographic parameters exhibited the reverse remodeling achieved, improvement in the LVEF (26.1% ± 7.3 to 29.9 ± 8.5, p 0.02), diastolic diameter (61.2±9.5 to 60.4±7.2, p 0.57), systolic diameter LV (50.8±11.8 to 50.3±10.8, p 0.80), pulmonary artery systolic pressure (32.4±15.4 to 32.6±17.1, p 0.64), diastolic function (grade II to grade I or absence, p 0.23). Improvement in the 6-MWT (430.6±152.6 to 472.3±91, p 0.16), KCCQ (41.7±14.2 to 56.7±7 p 0.005).Hospitalized (4.7±10.2 to 0.2±1, p 0.02) and disabilities (8.8±22.9 to 0.1±0.8 p 0.08) days decreased, dose tolerance (100mg bid) was 80% with a decrease in side effects. Institutional cost for three months with triple therapy was US $54,547.74 and for S/V was US $ 9,659.45.CONCLUSION. The therapy with S/V for the treatment of patients with HF and LVEF ≤35% with persistence of symptoms shows an improvement in the quality of life by KQ, reverse left ventricular remodeling, further institutional saving was US $ 44,888.29 this could be related with a decrease in hospitalizations days.

P987

The efficacy of nicorandil for patients with ischemic chronic heart failure

FG Batar[1]; S Batar[2]; R Mitea[2]; I Bitea[3]; G Eminovici[2]; M Teodoru[2]; I Manitiu[2]
[1]*County Hospital, Cardiology, Sibiu, Romania*; [2]*Lucian Blaga University , Sibiu, Romania*; [3]*County Hospital, CVAIC Centre, Sibiu, Romania*

BACKGRAUND Nicorandil, combination of nitrate component and sarcolemmal adenosine triphosphate-sensitive potassium channel opener, is a potent vasodilator of coronary and peripheral vessels and has been used as an antianginal agent, but its effect in heart failure (HF) patients has not been fully established. Therefore, we examined impacts of nicorandil in ischemic HF patients in a small cohort.
PURPOSE To assess the efficacy of therapy with nicorandil in hospitalized with ischemic chronic heart failure.
METODS 12 HF patients with ischemic etiology were prospectively registered and divided into 2 groups based on oral administration of nicorandil during hospitalization : nicorandil group (n = 6) and non-nicorandil group (n=6). Patients were randomly assigned to be treated with or without oral nicorandil. BNP levels were measured at admission and at 5th day. Echocardiography was performed and the patients undergo cardiopulmonary exercise test.

Comparisons of clinical features

	nicorandil group	non-nicorandil group	p
age	63.8±4.19	69.7±5.6	0.26
male	66.6%	66.6%	
LVEF (%)	39.33	39.83	0.95
E/e	6.62±2.2	8.13±0.7	0.17
MAPSE	11.2±2.5	12.8±5.1	0.71
ΔBNP	221	14	0.038

LVEF left ventricular ejection fraction, BNP B-type natriuretic peptide, MAPSE mitral annular plane systolic excursion

RESULTS 66,6% of the patients were men, mean age was 67 years and mean length of inpatient stay was 7.8 days. We found a positive correlation between initial BNP and the number of hospitalized days in nicorandil group (r=0.64) and a negative correlation between initial BNP and the number of hospitalized days in non-nicorandil group (r=-0.73). The difference between levels of BNP after 5 days of treatment and initial BNP in the two groups is statistically significant (p=0.038). Ventilatory efficiency (VE/Vco2) is significantly different between the two groups (p=0.022).
Conclusion: The patients in the nicorandil group had higher decrease of BNP levels without shortening the length of hospitalization. Further studies with larger cohorts are needed.

P988

Sequential nephron blockade with diuretics improves diastolic dysfunction in patients with resistant hypertension

D David Fouassier[1]; A Blanchard[1]; G Bobrie[1]; P Boutouyrie[1]; M Azizi[1]; JS Hulot[1]
[1]*European Hospital Georges Pompidou, Paris, France*

Introduction: Hypertension is one of the major contributors to cardiac diastolic dysfunction.
Different therapeutics strategies have been proposed to control blood pressure (BP) but their independent impact on cardiac function remain undetermined. In patient referred to our center for uncontrolled hypertension, we compared changes in cardiac parameters between two strategies consisting of sequential nephron blockade with intensive diuretics (NBD) or sequential renin angiotensin blockade (RAB).
Purpose: To determine evolution of BNP (brain natriuretic peptides) levels and echocardiographic (TTE) parameters of diastolic dysfunction according to strategies to control BP.
Results: BNP levels were not significantly different in the two groups at baseline (mean±SD 30.1±37pg/mL in NBD versus 22.6±22.3pg/mL in RAB, p=0.147) but significantly decreased in NBD at week 12 : 20.1±22.7pg/mL versus 55.2±60.4pg/mL in RAB, p<0.0001. At week 12, only 9 (12%) patients in NBD presented BNP levels > 35pg/mL vs. 37 (55%) in RAB (p<0.001). Concordantly, echographic parameters such as left ventricular end-diastolic diameter (mean mean±SD, 49±4mm in NDB and in 52±5mm in RAB, p=0.004) and left atrial area (16.9±3.6cm^2 in NBD and 19.1±3.7cm^2 in RAB, p=0.003) improved significantly in NBD group. According to ESC guidelines for evaluation of LV diastolic dysfunction by TTE, the proportions of patients presenting ≥2 criteria in NBD and RAB group respectively were 31.2% and 19.3% at baseline vs. 3.1% and 32.2% after 12 weeks (p=0.001). In a multivariate analysis, NBD treatment was significantly associated with a decline in BNP levels (p<0.01) even after adjustment on daytime systolic BP lowering, heart rate, renal function, age and gender.
Conclusion: In patients with uncontrolled hypertension, intensive nephron blockade with sequential addition of diuretics improves markers of diastolic dysfunction independently of BP lowering.

BACKGROUND: Device therapy in addition to medical treatment improves prognosis in a subset of patients with heart failure and reduced ejection fraction. However, some patients remain symptomatic or their heart failure even progresses despite cardiac resynchronization therapy (CRT). The aim of the study was to evaluate the proportion of patients who could benefit from optimization of medical therapy by using sacubitril/valsartan, ivabradine or both following CRT implantation.
METHODS: Post-hoc analysis of a single-center, double blind, controlled trial, in which, patients scheduled for CRT were randomized to empiric (n=93) or imaging-guided left ventricular lead placement (n=89). All patients underwent clinical evaluation and blood sampling at baseline and 6 months following CRT implantation. The proportion of patients meeting the indication for sacubitril/valsartan (irrespective of angiotensin-converting enzyme inhibitor or angiotensin 2 receptor blocker dosage) and/or ivabradine in current guidelines was evaluated at baseline and after 6 months.
RESULTS: Of 182 patients with an indication for CRT, 146 (80%) also had an indication for optimization of medical therapy at baseline by adding sacubitril/valsartan, ivabradine or both. Of the 179 survivors at 6 months, 136 (76%) were still symptomatic after device implantation; of these, 51 (38%) patients had an indication for optimization of medical therapy: sacubitril/valsartanin 37 (27%), ivabradine in 7 (5%), and both drugs in 7 (5%) patients. Seven (18%) patients without indication at baseline developed an indication for medical optimization 6 months after CRT implantation.
CONCLUSION: In the present study, 38%of those who remained symptomatic 6 months after CRT implantation were eligible for optimization of medical therapy with sacubitril/valsartan, ivabradine or both. Patients with CRT may benefit from systematic follow-up including evaluation of medical treatment.

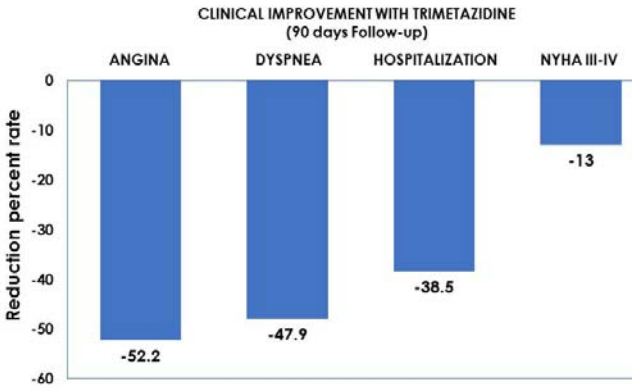
Ischemic heart disease (IHD) is the main cause associated with heart failure (HF), generating high mortality and hospitalization rates. Our purpose was to evaluate clinical prognosis, mortality and functional capacity of Trimetazidine (TRI) in patients with HF associated with IHD.
Material and method: Consecutively both genders patients, over 18 years old with HF and IHD diagnosis according to ESC clinical guidelines were included. They receive standardized treatment. We excluded patients with acute myocardial infarction, cerebrovascular disease/transient ischemic attack or clinical decompensation in the last 6 months. Oral 35 mg of TRI was added every 12 hours. In follow-up mortality, clinical deterioration and hospitalization was evaluated.
Results: Basal: We included 31 patients, only one woman. History of: Diabetes 39.1%, Hypertension 52.2%, Myocardial infarction 73.9%, Angioplasty 26.1%, CABG 13% and smoking 52.2% . 78.3% were in I-II NYHA class. Angina in 56.5%, Exertional Dyspnea 87%, Dyspnea at rest 47.8%. BMI 28.1± 4.5 Kg/m2. (34.8% were obese) Systolic BP 124.0±22.9 mmHg, LVEF: 33.2±10.3 (HFrEF:69.6 %). Sinus rhythm in 82.6%, Resynchronization therapy (CRT) in 13%%. Labs: Creatinine 1.4±1.0 mg/dL, Sodium 136.9±2.4 mEq/L, NT-pro-BNP:5285.2±284.7 pg/ml. Basal clinical index risk scores: GRACE 106.2 (52-148), MAGGIC 18.7±6.5 (7-31), EMPHASIS 4.7±6.5(2-10). Treatment: ACE-I 87%, betablockers 78.3%, spironolactone 74%, aspirin 73.9%. Preceding TRI Global Readmission rate (GRR) were 52.2%.
Follow-up (90 days). 87% were in NYHA class I-I. Exertional Dyspnea 39.1% (47.9% reduction, p<0.001), Dyspnea at rest 21.7% (26.1% reduction, p<0.001), Angina 4.3%1 (52.2% reduction, p<0.001). NT-pro-BNP 1994.5±221.5 pg/ml (p<0.05). No statistics differences in LVEF and serum creatinine. Treatment: ACE-I 95.7%, (increase 8.7%). Readmission rates were: HF: 8.3%, Non-cardiac: 5.9% , and GRR: 13.7%;(-38.5% reduction p<0.001). No Ischemic hospitalization. No mortality observed.
Conclusions: With oral TRI addition to standard treatment, We observed a significant decrease in ischemia and HF clinical symptoms. Reduction in HF, ischemia and global hospitalization. No mortality was documented.



REDUCTION RATES IN CLINICAL PARAMETERS

P991

Careful volume assessment appears to be the critical factor in achieving clinical trial dose of sacubitril/valsartan in the community.

M Ferre-Vallverdu[1]; RB Pharithi[1]; E O'connell[1]; M Walshe[1]; J Barton[1]; D O'hare[1]; M Ledwidge[1]; J Gallagher[1]; K Mcdonald[1]
[1]*St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland*

Introduction: In the PARADIGM-HF trial, sacubitril/valsartan (S/V) has been shown to improve morbidity and life expectancy in HF-REF patients. Real world data, while limited, indicate a similar clinical response. However, achievement of clinical trial dose (CTD; 97/103 mg BD) of S/V appears to be a challenge with only one data set to date reporting CTD in >50% of their cohort. Early data indicate that CTD may be more effective in improving important metrics such as LVEF. Therefore, identifying methods of facilitating achievement of CTD would be of importance.
Methods: 322 HF-REF patients were switched from ACEi/ARB to S/V between May 2016 and August 2018. Patients still on the titration process (n=25) were excluded. Baseline and follow-up clinical characteristics were collected. Univariate and multivariate test were used to analyze predictors of achieving CTD.
Results: 12.4% patients have not tolerated S/V as a result of symptomatic hypotension (52.4%), impairment of renal function (23.6%), gastrointestinal symptoms (13.5%) and hyperkalaemia (10.5%). Of the 257 patients successfully started on this agent, CTD has been achieved in 75.5% patients, 11.4% patients have been maintained on 49/51mg BD and 8.1% patients on 24/26mg BD. Symptomatic hypotension (73.6%) has been the main impediment to achieve CTD, followed by renal deterioration (12.2%) and then hyperkalaemia and gastro-intestinal symptoms (5.3% each). Multivariate analysis of variables related to achieving CTD showed that down-titration of loop diuretic was the most important predictor (Table 1). Reduction in diuretic has been required in 37.2% of patients with a mean reduction in diuretic need of 10mg furosemide equivalent/patient.
In conclusion, achievement of CTD with S/V is achievable in the majority of community population. Hypotension being the major barrier to achieving maximum dose and the need to down titrate diuretic in a large percentage of the population strongly underline the need to pay close clinical attention to volume status during the titration process.

Table 1. Predictors of reaching CTD

	Univariate	Multivariable		
	OR (95%CI)	p value	OR(95%CI)	p value
Age	0.99 (0.97-1.01)	0.23	1.02 (0.99-1.05)	0.19
Male	1.04 (0.61-1.78)	0.87	0.78 (0.4-1.54)	0.48

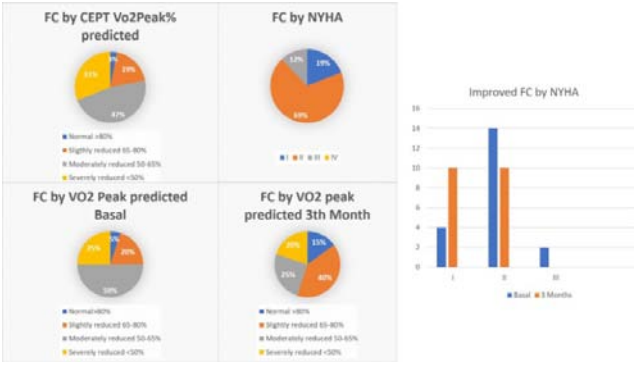
Cardiopulmonary exercise testing as a fundamental tool in the assessment of the functional class in treating sacubitril / valsartan. Results at 3 months

C Cristina Beltran Herrera[1]; V Suberviola Sanchez-Caballero[1]; S Briongos[1]; C Cortina[1]; M Sarrion[1]; A Sanchez[1]; E Gomez[1]; A Estevez[1]; I Ponz[1]; D Vaqueriza[1]; M Dominguez[1]; ML Giganto[1]; S Jimenez[1]; L Mora[1]; R Munoz[1]
[1]*University Hospital Infanta Leonor, Madrid, Spain*

Introduction: Sacubitril-Valsartan (ARNI) has demonstrated to improve the functional class (FC) measured by NYHA in patients (pts) with heart failure (HF) and ventricular dysfunction. The most objective method of assessing FC in HF is the peak oxygen uptake (Vo2) in a cardiopulmonary exercise test (CPET). Our objective is to assess whether the use of ARNI in pts with HF also improves the FC measured by peakVo2.
Methods: We analyzed 20 pts with HF and left ventricular dysfunction, treated with ARNI according to ESC guideliness. FC was determined before ARNI (basal) and 3 months after treatment by NYHA and by CPET. According to the % peakVo2 reached, by the Wasseman predicted values, the FC estimated was: normal FC> 80% predicted, FC slightly reduced 60-79%, FC moderately reduced 59-50% and FC severely reduced <50%
Results: 85% males, 69 ± 9 years, LVEF 31 ± 4%, NTproBNP 2039 ± 2020, 45% ischemic C., 50% C idiopathic C. 100% use of beta-blockers
The correlation between baseline FC estimated by NYHA and estimated with peak VO2 was poor (Fig 1 A). In both groups there was a tendency to improve FC by both NYHA and by CPET. (Fig 1 B, D). According to our series, pts with the greatest improvement in FC by CEPT had worse baseline peakVO2 consumption (912 vs 1170 ml / min, p = 0.03), lower weight (74 ± 8 vs 95 ± 18 kg, p = 0, 02) and were older (74 ± 5 years vs 61 ± 10 years, p = 0.19)
Conclusions: There is a poor correlation between FC assessed by NYHA and measured by CEPT in pts with ventricular dysfunction. Pts have worse FC by CEPT than by NYHA. Treatment with ARNI tends to improve the FC estimated by both methods after 3 months. It is especially in older pts, without overweight conditions and with worse basal situation that improve better in our series. This data points to a functional objective improvement with ARNI.



FC by NYHA and CEPT after 3 months

P993

Safety profile of sacubitril-valsartan in heart failure with reduced ejection fraction with chronic kidney disease, a real life study

A Alejandro Recio Mayoral[1]; FJ Cortes Cortes[1]; P Caravaca Perez[1]; DF Arroyo Monino[1]; M Ribadeneira Ruiz[1]; I Fernandez[1]; MP Ruiz Garcia[1]; M Chaparro Munoz[1]; A Castro Fernandez[1]
[1]*Virgen Macarena University Hospital, Seville, Spain*

Background/Introduction: Sacubitril/valsartan (S/V) has shown to decrease the risk of cardiovascular mortality in heart failure with reduced ejection fraction (HFrEF) patients and might be a promising therapeutic approach in patients with renal dysfunction. However, its effects in patients with associatedchronic kidney disease(CKD) is unknown, as there is no evidence to support any recommendation.
Purpose: Weaimed to evaluate the tolerability and safety profile of S/V in advanced CKD patients with HFrEF.
Methods: This study was performed as a prospective, single-center descriptive study from January 2016-January 2018.By using baseline estimated glomerular filtration rate (GFR), patients were stratified in 2 groups, without and with CKD (<60 ml/min/1.73 m2). Patients were evaluated monthly during the first 3 months and in month 6 and 12 after initiated S/V. The safety pre-specified primary end-point was the composite of angioedema, symptomatic hypotension, renal impairment and hyperkaliemia.
Results: Of the 336 consecutive HFrEF patients included (69±11 years, female (87; 25.9%)in whom were initiated S/V,131 had CKD (stage 3, 112 patients, 33.3%; stage 4, 19 patients, 5.7%).More than half of the patients (54,8%) suffered from ischemic cardiomyopathy with a mean left ventricular ejection fraction of 30.5±6.8%. The majority, 51.8%, were on NYHA functional class II (NYHA III 37.3%; IV 4.5%).No significant differences were found in S/V dose achieved and remained between patients without and with CKD (low dose, 20.4 vs 26.4%; medium dose 28.2 vs 35.2% and highest dose 48.6 vs 34.1%, respectively). At 1 year follow up, the combined primary end-point was numerically higher in patients with CKD compared with those patients without, although did not reach significant difference (14.4 vs 21.8, p=0.1): angioedema (1 vs 0.8%, p=0.52), symptomatic hypotension (7.9 vs 14.3%, p=0.18), severe renal impairment (0 vs 4.5%, p=0.07) and potassium ≥5.5 mmol/L (8.4 vs 16.7%, p=0.06). In 9 patients was necessary discontinue S/V, 4 without CKD and 5 with.
In both subgroups of patients, no significant changes were found in mean GFR during follow up.
Conclusions: CKD could be an acceptable treatment to reduce cardiovascular risk in HFrEF patients with CKD, with a good tolerability and safety profile

P994

Early left ventricular reverse remodeling after sacubitril-valsartan treatment. Subanalysis of SAVE-RLife study

M Galvan Ruiz[1]; M Singh[1]; M Sanmamed Giron[1]; M Groba Marco[1]; M Lopez Perez[1]; M Blanco Nuez[1]; V Quevedo Nelson[1]; P Pena Ortega[1]; J Medina Suarez[1]; D Rua-Figueroa Erausquin[1]; JR Ortega Trujillo[1]; JR Morales Gonzalez[1]; E Caballero Dorta[1]; A Antonio Garcia Quintana[1]

[1]University Hospital of Gran Canaria Doctor Negrin, Las Palmas De Gran Canaria, Spain

On behalf of: SAVE-RLife Group

Introduction: Few data on echocardiographic parameters of reverse remodeling has been published after the use of sacubitril-valsartan (SV) treatment. Objective: To analyse the reverse remodeling response in terms of echocardiographic parameters after the use of SV and evaluate the predictors for a left ventricular reverse remodeling.

Methods: This is an observational, ambispective, multicentre study that included all patients with stable HFrEF who started SV between SEP2016 and DEC2018. Patients with an echocardiogram (TTE) after at least 6 months of treatment were included. Reverse ventricular remodeling was defined as an increase in LVEF≥5%.

Results: A follow up TTE was perform in 84 out of 276 patients (30.4%). The mean age was 65 ± 10 y, 25% women. The main aetiologies of HFrEF were IHD (46.9%) and dilated cardiomyopathy (39.3%), and most frequent comorbidities were 69.3% hypertension, 44% DM, 50% Dyslipidemia, 31.3% AF and 27.4% CKD. TTE values are shown in Table 1. Patients with non-ischemic cardiomyopathy (non-IHD) had a greater improvement in LVEF (29.9±7.2 to 41.3±12.7 Vs non-IHD vs 30.4±6.9 to 32.7±9.8 in IHD patients). ; p<0.001) and a greater reduction of LVED (67.6±8 to 60.9±8.9 in non-IHD vs 62.53±7 to 60.50±8.1 in IHD, p<0.001). Other predictors of LV reverse remodeling are shown in Figure 1.

Conclusions: In our study, SV improves LVEF and reverse remodeling. Predictors of reverse remodeling were: non-IHD etiology, earlier initiation of SV since diagnosis of HF, estimated glomerular filtration rate at baseline >60 ml/min and achievement of the highest dose of SV.

Echocardiographic outcomes

N=84	Baseline value (mean±SD)	Follow - up value (mean±SD)	MEAN DIFFERENT	P value
LVEF (%) (n = 84)	30.44± 7.41	37.83± 12	7.39	< 0.001

Impacts of mineralocorticoid receptor antagonists on mortality in heart failure patients with beta-blockers

NP Kato[1]; K Kinugawa[2]

[1]Linkoping University, Department of Social and Welfare Studies, Linkoping, Sweden; *[2]University of Toyama, The Second Department of Internal Medicine, Toyama, Japan*

Introduction: Mineralocorticoid receptor antagonists (MRA) is an important drug for patients with heart failure with reduced ejection fraction (HFrEF). Although beneficial impacts of MRA on the patient's survival have been shown from landmark trials, Japanese registry data did not consistently support it. Beta-blockers have a key role for MRA to provide beneficial effects. In these Japanese studies β-blockers might not be used enough to make MRA work.

Purpose: To examine impacts of MRA on mortality of the Japanese HFrEF patients treated with β-blockers.

Methods: Of all consecutive patients who were hospitalized in the university hospital because of HF between 2002 and 2010, 144 patients with left ventricular EF (LVEF) ≤35% who were introduced β-blockers in the hospital were analysed (age 60.1±15.0 years, male 78%, LVEF 27.0±5.9 %). Follow-up period was 3-years. Primary and secondary end points were all-cause death and cardiac death respectively. Data were collected from medical records. In order to examine impacts of MRA, Kaplan-Meier survival curve analysis and Cox regression analysis were performed.

Results: A prescription rate of MRA among the HFrEF patients increased from 45% in 2002 to 78% in 2010. All of MRA at baseline were spironolactone and mean daily dosage was 28.5±13.2 mg. Mean daily dosage of β-blockers was 8.8±8.6 mg in the carvedilol equivalent dosage. Patients treated with MRA (n=86) were likely to have higher NYHA class III or IV (56% vs. 41%), lower LVEF (27% vs. 29%) and lower systolic blood pressure (114 vs. 120 mmHg) compared with patients without MRA (n=58). Dosage of loop diuretics in patients with MRA was higher than that in patients without MRA (31.2 mg vs. 19.8 mg in the furosemide equivalent dose, p<0.01) at baseline, but no significant differences were observed at the end of follow-up (32.5 mg vs. 24.4 mg). After the follow-up, all-cause mortality in patients without MRA was significantly higher than patients with MRA (13% vs. 2.7%, p=0.03 by log-rank test). In the Cox regression analysis after adjustment for NYHA class, systolic blood pressure and loop diuretics, the absence of MRA remained to predict higher all-cause mortality (hazard ratio=0.18, 95% confidence interval=0.04 to 0.94). Meanwhile, no significant difference was observed in cardiac death (p = 0.17) between the two groups.

Conclusions: One of the MRA, spironolactone, reduces all-cause mortality among Japanese HFrEF patients treated with β-blockers. Our finding emphasizes an importance of β-blockers under the MRA treatment in HFrEF patients.

P996

Response rate to sacubitril-valsartan in the community. Is there a clear phenotype?

R B Pharithi[1]; M Ferre-Vallverdu[1]; E O'connell[1]; M Walshe[1]; J Barton[1]; D O'hare[1]; C Sweeney[1]; F Rathore[1]; K Mcdonald[1]; J Gallagher[1]; C Watson[1]; M Ledwidge[1]; K Mcdonald[1]

[1]St Vincent's University Hospital, Heart Failure Unit, Dublin, Ireland

Introduction: Several clinical trials have now shown that the combination ARNI, sacubitril-valsartan (S-V) significantly improves mortality and morbidity among

HF-REF patients. Real world experience is less expansive and it is unknown if there is a particular clinical phenotype with HF-REF who are more likely to respond.
Methods: To assess patient responsiveness to S-V in a community from May 2016 to present. All patients have had defined stable HF-REF on maximal tolerated disease modifying therapy. Response to S-V definition: 30% reduction in NT-proBNP and/or a 5% increase in LVEF(LVEF taken ≥2 mths post last titration). Univariate and multivariable analyses were used.
Results: 322 HF-REF patients were commenced on S-V (median age 70 [61.9-76.2] years; male 75.1%). All patients were on ACEi/ARB prior to S-V. 90.7% were prescribed beta-blockade and 71.9% MRA. 12.4% did not tolerate S-V. 7.7% in titration were excluded. 46.3% met the NT-proBNP criteria for responder status while 49.3% had LVEF increase by >5%. 78.4% met either responder criteria components (table 1). Non-responder patients were older, hypertensive, and had more CKD, ischaemia and atrial fibrillation (all p≤0.5). Absence of ischaemia was the only independent predictor to response (p=0.018). Diuretics were decreased in 37.2% of patients. Mean reduction of 10±37mg.
Conclusion: Though majority of patients responded to sacubitril-valsartan, non-responders had increased disease burden. Responders were younger, had better renal function and required diuretic dose decrease.

RESPONDER CRITERIA AND PHENOTYPE

PATIENTS MEETING RESPONDER CRETERIA	n/N		
NTproBNP down >30% from T1 to follow up	99/214 (46.3%)		
LVEF up >5% from T1 to follow up	70/142 (49.3%)		
NTproBNP down >30% AND LVEF > 5%	35/185 (18.9%)		
NTproBNP down >30% OR LVEF > 5%	134/171 (78.4%)		
Diuretic decrease	93/250 (37.2%)

Treatment of patients with heart failure with reduced ejection fraction (HFrEF) in Germany: differences between cardiologists and primary care physicans

U Uwe Zeymer[1]; R Groves[2]; T Merkel[2]
[1]Institut für Herzinfarktforschung, Ludwigshafen Am Rhein, Germany; *[2]Novartis Pharma, Nuremberg, Germany*

Funding Acknowledgements: Novartis Pharma

Background: Simultaneosly two prospective non-interventional patient registries were conducted to assess the treatment of chronic heart failure with reduced ejection fraction (HFrEF) therapy: AURORA assessed HF therapy as provided by primary care physicians in Germany, whereas ARIADNE assessed HF therapy as provided by private practice based cardiologists / internal medicine specialists across Europe.
Purpose: Here, two real-world cohorts of HFrEF patients treated by primary care physicans vs. specialists are compared.
Methods: Consecutive patients with symptomatic chronic HF (NYHA II–IV) and reduced LVEF were eligible for both studies. Baseline demographics, medical history and heart failure medication data are presented here according to HFrEF Treatment (Sacubitril/Valsartan) SacVal or "conventional" standard of care HF therapy (SoC) as per index visit. AURORA enrolled 1260 HFrEF patients treated by 220 primary care physicians (PCP) throughout Germany. ARIADNE data represents a subgroup of 4768 patients enrolled in Germany by 340 specialists.
Results: The baseline characteristics and HF treatments are given in the table.
Conclusion: In Germany characteristics and treatment of patients with chronic HFrEF differ between primary care physicans and specialists, with a higher rate of guideline recommended therapy by specialists. For both PCP- and specialist-treated patients, a higher HF symptom burden (NYHA class/LVEF) at baseline resulted in a more common selection of Sac/Val therapy above conventional HF therapy.

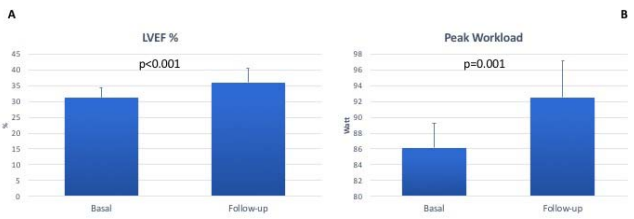
Effects of sacubitril/valsartan on cardiac performance and exercise capacity

S Paolillo[1]; M Mapelli[2]; F De Martino[2]; E Salvioni[2]; M Prastaro[1]; E Pirozzi[1]; I Mattavelli[2]; P Gargiulo[1]; F Marsico[1]; C Vignati[2]; P Perrone Filardi[1]; P Agostoni[2]
[1]Department of Advanced Biomedical Sciences, Section of Cardiology, Federico II University of Naples , Naples, Italy; *[2]Cardiology Center Monzino IRCCS, Milan, Italy*

Background: Sacubitril/Valsartan has emerged as a novel therapy in the treatment of heart failure (HF) with reduced ejection fraction (HFrEF), showing lower rates cardiovascular mortality and HF hospitalization compared to standard therapy. Although the recent widespread use of sacubitril/valsartan in clinical practice, data on exercise capacity of HF patients on treatment are still lacking.
Methods: We enrolled patients with HFrEF in two Italian experienced HF centers, who started sacubitril/valsartan according to 2016 ESC Guidelines recommendations. Patients underwent clinical assessment, venous blood sample collection, transthoracic echocardiography and cardiopulmonary exercise test at baseline (before starting sacubitril/valsartan) and after reaching the maximum tolerated dose. Baseline and follow-up data were compared to assess the effects of sacubitril/valsartan on cardiac performance and exercise capacity.
Results: Thirty-two patients (87% males, mean age 65.8±9.5) were studied in the present preliminary analysis. In 3 patients the treatment was interrupted do to different reasons (2 hypotension, 1 renal dysfunction). The mean reached dose was 143±66 mg and 56% of patients reached the maximum dose (200 mg). Comparing baseline analysis with follow-up assessment (104±60 days) we observed a statistically significant, however not clinically relevant, decrease in systolic and diastolic blood pressure (respectively, 119±16 vs. 109±17 mmHg, p=0.01; 73±8 vs. 67±8 mmHg, p=0.01) and a stability of renal function (eGFR MDRD 71.2±20 vs. 70.8±20 ml/min/1.72m2; p=ns) and potassium levels (4.51±0.41 vs. 4.59±0.45 mmol/l). Regarding cardiac performance and exercise capacity, a significant increase in EF (31.2±3.1 vs. 36±4.6%; p<0.001) and in workload reached at peak exercise (86.2±37.5 vs. 92.5±39 watt; p=0.001) was observed at follow-up (Figure 1A and B). Peak VO2showed a trend toward increased values at follow-up, however at the moment not significant (14.2±4.4 vs. 14.7±4.1 ml/kg/min; p=ns), similarly ventilatory efficiency during exercise (VE/VCO2 slope) showed a slight, however not significant, improvement (31.2±6.2 vs. 30.1±5.8, p=ns) during follow-up assessment.
Conclusion: Medium-term treatment with sacubitril/valsartan is safe and leads to an increase in systolic function, assessed by EF, and in maximum workload reached at the peak of the exercise. A trend toward an improvement in peak oxygen uptake and ventilatory efficiency is reasonable, however longer follow-up is needed to clarify the specific effect of sacubitril/vasartan on exercise capacity.



P999

Self-motivation, self-regulation and self-care in patients with heart failure: a sequential mixed-method study

H S J Han Shi Jocelyn Chew[1]; K L D Sim[2]; X Cao[1]; S Y Chair[1]
[1]*The Chinese University of Hong Kong, Nursing, Hong Kong, Hong Kong*; [2]*National University Heart Centre, Cardiology, Singapore, Singapore*

Background: Though self-care improves patient outcomes and quality of life, it remains suboptimal in majority of heart failure. Interventions such as education programs have been shown to improve self-care but insufficiently due to patients' low motivation to change lifestyle habits. Better understanding of how behaviour change materialise in this population is needed.
Purpose: To understand the mechanism by which self-care is motivated and improved in patients with heart failure.
Method: Explanatory sequential mixed-method. Suitable heart failure patients were purposively sampled from a quantitative study conducted at one tertiary hospital. Thematic analysis with constant comparison was employed. Qualitative and quantitative data were integrated using the Temporal Self-regulation Theory used to guide the study.
Results: Seventeen participants were interviewed. Mean age was 56, mostly male (76.5%), Chinese ethnicity (82.4%), married (82.4%), earning less than $3 000(70.6%), secondary school educated (47.1%), working full-time (41.2%), Buddhist (35.3%), New York Heart Association functional (NYHA) class II (70.6%) and staying with their family (100%). Mean self-care maintenance score was suboptimal (44.5; cut-off score 70). Two motivators associated with emotional attachment were identified: to bargain for more time to (1) love family - by preventing worry and grief and providing support and (2) love self - by righting the wrongs an regain feeling of normalcy. Three barriers were identified: (1) difficulty adopting physical activity due to – time constraint and fear of overexertion; (2) difficulty deviating from sociocultural dietary norms and habits due to – convenience of eating out, difficulty making dietary requests, respecting cooks other diners and unhealthy food habits and (3) difficulty controlling the future due to – perceived short residual lifespan and perceived futility. Personalised strategies to overcome each barrier includes: integrating physical exercise into daily living and enjoyable activities, self-monitoring, making food adaptations, meal preparations, damage control, self-regulation (i.e. ignoring, distracting, substituting and cognitive reframing) and positive thinking.
Conclusion: Clinicians and case managers could motivate and empower self-care by eliciting each patients' motivators of change and facilitate the development of plans and strategies to improve lifestyle habits using the results of this study.

Benefits of full yogic breathing for patients with chronic heart failure

A Shevelyok[1]; G Kravchenko[2]; V Venzheha[1]; N Vatutin[1]
[1]*M. Gorkiy Donetsk national medical university, V. K. Gusak Institute of Urgent and Recovery Surgery, Donetsk, Ukraine*; [2]*16th city clinical polyclinic, Outpatient department, Minsk, Belarus*

Background: Chronic heart failure (HF) remains the leading cause of morbidity and mortality all over the world. Slow yogic breathing has been shown to improve cardiovascular and psychological parameters among healthy individuals, but its potential benefit for HF patients is unclear.
Purpose: To evaluate the effectiveness of full yogic breathing in patients with acute decompensated HF.
Methods: The study included 130 patients (mean age 65.2±5.7 years) hospitalized for acute decompensated HF with reduced left ventricular ejection fraction (<40 %). All patients were divided into two groups: 66 patients received only standard therapy of HF (angiotensin-converting enzyme inhibitor, β-blockers, aldosterone antagonists, digoxin, diuretics) and 64 ones additionally practiced the full yogic breathing during all hospitalization period. On-admission and discharge measurement included 6-minute walk test, evaluation of dyspnea by the Borg scale, transthoracic echocardiography, forced vital capacity (FVC), arterial oxygen saturation (SpO2) and quality of life (QoL) assessment by the Minnesota Living with Heart Failure Questionnaire. Length of hospitalization was assessed in all participants.
Results: The statistical analyses were significant for favorable changes in the breathing group, compared to the control, for 6-minute walk test distance (P = 0.016), severity of dyspnea (P = 0.024), FVC (P < 0.01), SpO2 (P = 0.036) and scores for the total QoL (P < 0.01). No difference was found in echocardiography parameters between groups. Average length of hospitalization was less in breathing group compared to the control (16.2±2.2 versus 19.8±2.9 days, P < 0.001). After adjustment for significant covariates in Cox regression models, full yogic breathing practice was an independent predictor of reduction of hospitalization length for acute decompensated HF (odds ratio (OR) 0.16, 95 % confidence interval (CI) 0.05-0.38) and improvement of NYHA class (OR 0.24, 95 % CI 0.18-0.56).
Conclusion: In acute decompensated HF patients full yogic breathing practice in addition to standard therapy is associated with a significant improvement of exercise intolerance, lung function, NYHA class and QoL and reduction of hospitalization length.

Analysis of the effectiveness of health education imparted by nursing in an heart failure unit

G Lopez Moyano[1]; M Maria Del Carmen Duran Torralba[1]; C Rus Mansilla[1]; G Cortez Quiroga[1]; M Santisteban Sanchez De Puerta[1]; M Delgado Moreno[1]; Y Rustarazo Garcia[1]
[1]*Hospital Alto Guadalquivir, Cardiology, Andujar, Spain*

Introduction: The education for health developed by nursing in the Heart Failure Unit(HFU) is decesive to promote self-care and improve the quality of life.
Aims: Analyze the impact of nurse education through how it is modified European Heart Failure Self-care Behaviour (EHFS) scale during the year of inclusion in the HFU and in which areas self-care has more impact.
Methods: Descriptive, prospective, longitudinal study that included 93 consecutive patients assessed in the HFU from 2014 to 2017. Self-care was analyzed through EHFS and how this scale varied throughout the year of inclusion. Several NOCS were analyzed: weight control, Blood pressure (BP) control, diet control, exercise, and quality of rest by liker scale and compared at 6 and 12 months. All patients received personalized education and also group this last in the first 6 months
Results: the average age of the patients was 67 ± 12 years, 70% males. The EHFS at the beginning of the program was 42.7 ± 1.8, at 6 months 22.7 ± 1.3 and at 12 months 23.5 ± 1.6, being statistically significant the difference found in the baseline and the 6 months. Basically, adequate weight control was performed by 14% of the patients, BP control by 17%, appropriate diet by 24%, physical exercise by 20%, and up to 75% communicated good quality rest. At 6 months up to 80% of patients performed adequate weight control, 86% adequately BP control, 52% fulfilled a low sodium diet, 57% performed moderate physical exercise and up to 84% showed adequate rest quality. After 12 months, 62% of the patients had adequate weight control, 73% had BP control, only 48% had an appropriate diet, 66% continued with moderate physical exercise and 89% showed good quality of rest.
Conclusion: The health education provided by nursing at the HFU is very effective in the first 6 months assessed through the EHFS. Although diet and physical exercise are the factors where it is more difficult to have a positive impact, it is more lasting in time when it is achieved. Weight control and BP control are easy habits to acquire but the patient, after the first 6 months, usually abandons them early. Group education can have a positive impact because of the "group effect".

P1002

Comparative analysis of the European Heart Failure Self-Care Behavior Scale and the Self-care of Heart Failure Index in hospitalized patients with heart failure.

E Ekaterina Kartamyscheva[1]; YU Lopatin[1]
[1]*Volgograd State Medical University, Department of Cardiology, Volgograd, Russian Federation*

Background. Self-care is an important factor providing a successful management of patients with heart failure (HF). Several tools are using for the measurement of self-care in HF.
Purpose. The purpose of our study was to compare Russian versions of the European Heart Failure Self-Care Behavior Scale_9 (EHFScBS_9) and the Self-care of Heart Failure Index, version 6.2 (SCHFI) in the assessment of the self-care in hospitalized HF patients.
Methods. 50 hospitalized patients with HF (NYHA I-III), mean age 62.2 ± 9.6 years, 56% of them were male, mean left ventricular ejection fraction 52.1 ± 10.3% were included into the study. The management of patients with HF, including patient's education was performed according to the current ESC/HFA Guidelines 2016 and the Russian Guidelines 2017. The level of self-care was assessed on admission and before discharge from the hospital by using EHFScBS_9 and SCHFI.
Results. The coefficient α-Cronbach for EHFScBS_9 was 0.788 on admission and 0.798 at discharge from the hospital. Test-retest reliability of this scale was 0.892 (p<0.01). The coefficient α- Cronbach for SCHFI was 0.722 on admission and 0.785 at discharge from the hospital, test-retest reliability was 0.832 (p<0.01). Both scales demonstrated an improvement in the ability to self-care in hospitalized HF patients. Total score of the EHFScBS_9 was decreased from 22.0±8.6 on admission to 20.4±7.5 at discharge from the hospital (p<0.01). The total score of the SCHFI was increased from 129.7±38.9 on admission to 143.9±41.4 at discharge from the hospital (p <0.01). The greatest improvement of the EHFScBS_9 was noted in items: "if my shortness of breath increases I contact my doctor or nurse" from 2.3±1.5 initially to 2.0±1.3 at discharge from the hospital (p<0.01); "if my feet/legs become more swollen than usual I contact my doctor or nurse" from 2.5±1.6 to 2.2±1.5 (p<0.01). The greatest improvement of the SCHFI was observed in items: "check

your ankles for swelling" from 2.5 ± 1.0 to 2.8 ± 0.9 (p<0.01), "reduce your fluid intake" from 2.4 ± 1.0 to 2.8 ± 0.9 (p<0.01) and "take an extra water pill" from 2.3±1.4 to 2.7±1.1 (p<0.01), "do something that will relieve your symptoms" from 2.2 ± 0.9 to 2.5 ± 0.8 (p<0.01), respectively. Analysis of concurrent validity showed an average inverse correlation between the scales, both on admission (r= −0.309; p=0.029) and at discharge from the hospital (r= −0.434; p<0.01).Conclusion. Russian versions of the European Heart Failure Self-Care Behavior Scale and the Self-care of Heart Failure Index are effective tools for the assessment of self-care in patients with heart failure, and can be used both in clinical studies and in real clinical practice.

P1003

Utility of the implementation of a standardized evaluation program for therapeutic adherence in heart failure

M Maria Del Carmen Duran Torralba[1]; G Lopez Moyano[1]; C Rus Mansilla[1]; G Cortez Quiroga[1]; M Santisteban Sanchez De Puerta[1]; M Delgado Moreno[1]; A Fernandez Suarez[1]; D Fatela Cantillo[1]
[1]Hospital Alto Guadalquivir, Cardiology, Andujar, Spain

Introduction: The therapeutic adherence in patients with heart failure (HF) is important to avoid readmissions. The Morisky-green test (MG) is one of the most used but has limitations. We designed a health intervention consisting of a standardized assessment of adherence and knowledge of drugs complemented with individual education implemented by nursing in patients with HF. Aims: To assess whether the implementation of a standardized evaluation of therapeutic adherence is more effective than the application of the MG test. Assess whether the knowledge of the drugs and the intervention on it, by nursing, translates into greater therapeutic adherence compared with the conventional approach.
Methods: The standardized evaluation consists of a first area where compliance is assessed based on what the patient communicates and the verification of the correct intake of drugs and the second area assesses the knowledge of the action of these and the ability to respond to a decompensation through knowledge of the flexible diuretic regimen. With the first area, we identify the patient who complied or not and with the second, we identify the patients who need to reinforce health education due to little or no knowledge of the medication
Results: We included 100 consecutive patients, assessed in the HF Unit at the time of inclusion, included in the period of January 2014 and January 2018. The mean age was 70 ± 13 years, 61% were men, 72% were HFrEF, 18% HFmid-range EF and 10% HFpEF. All patients were first given the MG questionnaire and subsequently the standardized evaluation. According to the MG test, 3 non-compliant patients (3%) were identified. After standardized evaluation, 12 non-compliers (12%) were identified, this difference being significant (p <0.01). In addition, 92 patients (92%) were identified with little knowledge about the drugs and the ability to act in the face of decompensation.
Conclusions: The implementation of the standardized evaluation to asses therapeutic adherence en HF allowed to identify more accurately the non-compliant patients, compared with the MG test. It also presented as an added advantage, the identification of those patients with poor capacity to respond to a decompensation and act early to avoid readmissions

P1004

A propensity-matched study of moderate to severe obesity and mortality in heart failure

P Pao-Hsien Chu[1]; YY Lu[2]
[1]Chang Gung Memorial Hospital Tapei, Taipei, Taiwan, Province of China; *[2]Linkou Chang Gung Memorial Hospital, Cardiology, Tao-Yuan, Taiwan, Province of China*

Background: Obesity has been shown to be an independent risk factor for cardiovascular morbidity and developing heart failure. However, a plethora of evidence supports "obesity paradox" in heart failure patients. In the Taiwan Society of Cardiology-Heart Failure with Reduced Ejection Fraction (TSOC-HFrEF) registry, an inverse association between body mass index (BMI) levels and all-cause mortality has also been proven in Taiwanese heart failure population. The study divided heart failure patients by BMI into 4 groups, and obesity was defined as BMI≤27. We think there may exist controversy that patients with more than moderate obesity (body mass index ≥≤30 kg/m2) may not have the same survival advantage as their counterparts. Therefore, this study aimed to investigate the associations of moderate to severe obesity (defined as BMI≥30 kg/m2 in Taiwan) with heart failure patients' outcome.
Method: Patients who were admitted to our Hospital during Aug 2013 and Dec 2014 with the diagnosis of acute decompensated heart failure were enrolled retrospectively. Patients with BMI≥30 were selected as severe obesity group. Control group were selected from the other patients by 1:2 propensity score matching to balance the baseline condition and comorbidity. The primary outcome was the occurrence of all-cause death, and the secondary outcome was the occurrence of cardiac death during 3-year follow-up. All death was considered cardiac unless there was a clear noncardiac cause. We used Kaplan-Meier and Log Rank analyses to compare the all cause mortality and cardiac death between the 2 groups.
Result: 984 patients were enrolled in this study. Of these patients, 42 (4.2%) were BMI≥30. Only 32 patients passed the propensity matching test and other 64 patients with BMI<30 were selected as control. The mean BMI were 32.37 in the severe obesity group and 24.35 in the control group. Their baseline characteristics are shown in Table 1. There are significant differences in clinical characteristics between 2 groups, with a lower incidence of hypertension and lower level of B-type natriuretic peptide (BNP) in the obesity group. There is no significant difference in other clinical characters. During 1-year follow-up, 3 were lost follow up in the obesity group and 8 in the control group. The incidence of all-cause mortality (10% vs 9%, p=0.678) does not differ significantly between the 2 groups. After 3-year follow-up, another 6 were lost follow up in the obesity group and 5 in the control group. There is still no significant difference of all-cause mortality (26% vs 18%, p=0.118). But the obesity group has more incidence of cardiac death (26% vs 12%, p=0.004).
Conclusion: Heart failure patients with moderate to severe obesity may not share the same survival benefit as mild obesity patients. However, this study result is limited by the small number of populations.

P1005

The impact of self-control and self-help education on quality life of patients with chronic heart failure in Uzbekistan

RT Shukurov[1]; TA Abdullaev[1]; I A Igor Tsoy[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

The aim. Study of the impact of self-control and self-help methods on the quality of life (QOL) in chronic heart failure (CHF).
Materials and methods. The study included 204 pts with CHF aged from 19 to 82 years (mean age - 58.7 ± 12.9). Patients were treated in a hospital with simultaneous training of self-control and self-help. Medical therapy was carried out according to ESC recommendations. All pts, initially and after 24, 52 weeks, were evaluated for quality of life using Minnesota questionnaire "Life with heart failure".
The results. When analyzing the results of the survey, it was found that the average value of QOL in pts with CHF initially averaged 68.3 ± 12.2 points. Gender differences in QOL of patients with CHF were determined: for men, the average value of QOL was 62.8 ± 10.1 points, for women, 71.4 ± 13.2 points (p <0.05). An increase in NYHA class is accompanied by a significant stepwise deterioration in the indicator of QOL, with each class corresponding to a certain level of QOL (II −53.1 ± 9.4 points; III - 67.2 ± 11.9 points; IV - 81.6 ± 13.8 points). Evaluation of QOL during the observation period revealed a tendency towards a positive trend compared with baseline data. The improvement in QOL by the 24th week was noted on 14.1% (58.7 ± 11.4 points), and by the 52nd week - on 28.1% (49.1 ± 9.5 points) compared with baseline (p <0.05).
Conclusion. Self-control and self-help education and dynamic control over the implementation of doctor's recommendations allows in clinical practice to improve the quality of life of patients.

P1006

The influence of socio-clinical variables on the level of self-care in heart failure patients

I Uchmanowicz[1]; K Katarzyna Lomper[1]; B Prochota[2]; M Wleklik[1]; M Lisiak[1]; A Chudiak[1]
[1]Wroclaw Medical University, Department of Clinical Nursing, Wroclaw, Poland; *[2]Health Facility , Olesno, Poland*

Introduction: Heart failure (HF) is an increasingly important problem for public health. It is estimated that 1-2% of the world's population suffer from HF. The costs of hospitalization constitute a significant part of the total costs of treatment of HF patients. Therefore, there is a need to pay attention to the role of self-care in the therapeutic process of HF patients.
Objectives: The aim of the study was to evaluate the influence of socio-clinical variables on the self-care level in HF patients.
Methodology:The study included a sample of 100 patients diagnosed with HF (mean age: 73.78 years) hospitalized at the Department of Internal Medicine of the Health Care Centre in our city. The analysis of medical records and the own authorship questionnaire were used to collect basicsocio-clinical data. A standardized 9-item European Heart Failure Self-care Behavior Scale (EHFScB) questionnaire was used to assess the self-care level.
Results: Statistical analysis showed a significant difference in the level of self-care and such variables as marital status (p=0.001), taking Digoxin (p=0.002), taking diuretics (p=0.015), NYHA classification (p=0.001). Linear correlation showed that age was a negative predictor of the level of self-care

(B=-0.356, p<0.001). Multivariate analysis showed a negative impact of the NYHA functional class IV on the self-care level of the study group patients (B=-23.595, p=0.048).
Conclusions: The socio-clinical factors have a significant impact on the level of self-care in HF patients. It is necessary to take interventions improving the level of self-care in HF patients.

P1007
Effects of time perspective and executive function on self-care in patients with heart failure: a cross-sectional study

H S J Chew[1]; K L D Sim[2]; K C Choi[1]; S Y Chair[1]
[1]The Chinese University of Hong Kong, Nursing, Hong Kong, Hong Kong; [2]National University Heart Centre, Cardiology, Singapore, Singapore

Background: Time perspective refers to one's consideration about future consequences of current behaviours. Executive function refers to a set of cognitive processes mainly working memory, inhibition and mental flexibility that allows for higher order thinking. Both has been shown to change behavioural intentions and actual behaviours through self-regulation but has yet to be explored in the heart failure self-care context. Improving self-care such as sodium restriction and increasing exercise could improve clinical outcomes, decrease rehospitalisation and enhance quality of life.
Purpose: To examine the effects of time perspective and executive function on heart failure patient's self-care.
Methods: Cross-sectional study. 147 heart failure patients from a tertiary hospital completed questionnaire and cognitive measures of self-care, time perspective, intention and executive function. Multiple regressions, mediation and moderation analyses was conducted using the PROCESS macro for SPSS were conducted.
Results: Self-care level was suboptimal (87.1% below cut-off score). Non-adherence rates were high for medication adherence (10.8%), physical activity (general: 55.8%; at least 30 minutes: 68.7%), weight monitoring (76.2%) and sodium restriction (at home: 46.9%; outside: 71.4%). Self-care was associated with time perspective (r =.362), executive function (r=.174) and intention (r =.184). Time perspective mediated the self-care intention-behaviour relationship, explaining 62.0% of the total effect and was not moderated by executive function. The indirect effect of intention on self-care through time perspective was 1.205 with a bootstrapped 95% confidence interval (0.532 , 2.145). There were differences in time perspective (mean=4.538, standard deviation (SD)=.834; t=3.109, p=.002 CI:.158,.711) and executive function (mean=5.47, SD=1.60; t=3.012, p=.003; CI:.251,1.208) for patients below and above 61 years old. Majority of the patients were male (77.6%), Chinese (70.1%), married (65.3%), have at most secondary school education (41.5%), family income less than SG$ 3000 (65.3%), employed full-time (41.5%), stays with someone (87.1%) and most importantly, rely on themselves as caregiver (61.9%) (Table 1). The median left ventricular ejection fraction (LVEF) was 27%, majority were of New York Heart Association class II (55.1%) and has at least 3 comorbidities estimated using the Charlson comorbidity Index score.
Conclusion: Clinicians and counselors could motivate patients' self-care by enhancing future-oriented time perspective tailored according to age. As executive function may be difficult to improve in older patients, executive function demands could be outsourced to visual reminders or other personalized systems like planners. Further research could be done on health message framing and personality types to develop more effective interventions to improve self-care habits.

P1008
Real world usage and outcomes of all HFrEF patients treated with sacubitril/valsartan in Belgium

T Sente[1]; R Van Landuyt[2]; M Vanlierde[2]; S Vancayzeele[1]
[1]Novartis Pharma, Medical Affairs, Vilvoorde, Belgium; [2]Novartis Pharma, Market Access, Vilvoorde, Belgium

Background: The angiotensin receptor neprilysin inhibitor sacubitril/valsartan (s/v) was granted reimbursed market access in Belgium on November 1, 2016 for the treatment of adult patients (≥18 years) with symptomatic heart failure with reduced ejection fraction (HFrEF; LVEF≤35% and optimally treated with an ACEi or ARB). In Belgium, s/v can only be initiated by cardiologists and internists. However, information on its real world use is scarce. Purpose: To provide data on real world clinical practice of all HFrEF patients treated with s/v in Belgium. Methods: A nationwide, retrospective cohort study was performed based on patient level linkage of integrated electronic healthcare datasets including administrative payer claims, national health registries, pharmacy claims and medical records. All HFrEF patients receiving reimbursement for s/v in Belgium between November 2016 and December 2018 will be included, regardless of prior history or length of follow-up. Results: An interim functional analysis was performed covering data from 2200 HFrEF patients treated with s/v, being 69.3% men. S/v was prescribed in 97.7% (n=2149) by cardiologists and 2.1% (n=46) by internists. 515 different physicians prescribed s/v and the average number of prescriptions per physician was 4.3. 48.3% were in NYHA II, 46.4% in NYHA III and the remaining in NYHA IV patients (5.2%). 28.7% of patients were between 60-70 years and 32.1% between 70-80 years. 16.8% of patients were over 80 years of age. The number of s/v packs delivered steadily increases over time for all dosages. Most patients were initiated s/v at the lowest dose of 24/26mg twice a day (BID), and only 24.1% achieved the target dose of 97/103mg BID after one year of treatment. Conclusion: The majority of the HFrEF patients treated with s/v in Belgium are male with NYHA II and ≥60 years. Almost all applications for s/v reimbursement came from physician specialists in cardiology. Real life data shows that most patients were initiated at the lowest dose of s/v. Final analysis is expected in March 2019 and will consist of a full real life profile of every single Belgian HFrEF patient treated with s/v providing the first insights on s/v utilization, outcomes and patient profiles in Belgium.

P1009
Sacubitril-valsartan and its effect on ventricular remodeling

M Maria Abellas Sequeiros[1]; S Del Prado[1]; G Alonso Salinas[1]; A Lorente Ros[1]; JM Vieitez Florez[1]; JL Moya Mur[1]; A Garcia Martin[1]; JJ Jimenez Nacher[1]; C Fernandez Golfin[1]; JL Zamorano Gomez[1]
[1]University Hospital Ramon y Cajal de Madrid, Madrid, Spain

Introduction: Based on the PARADIGM HF trial, sacubitril-valsartan has been included in ESC guidelines for the treatment of chronic heart failure with reduced ejection fraction (HFrEF). Angiotensin receptor-neprilysin inhibitor has demonstrated to improve left ventricular ejection fraction (LVEF). Is LVEF the only parameter modified?
Methods: To answer this question, a series of patients with HFrEF attending the advanced heart failure unit who initiated sacubitril-valsartan was prospectively assessed. Aetiology and baseline characteristics were collected. LVEF and ventricular volumes were evaluated by transthoracic echocardiogram before and after 6 and 12-month treatment. T- test was conducted for the comparison of paired data.
Results: Eighty-four patients initiated sacubitril-valsartan. Patients with drug discontinuation or without echocardiogram before and 6-12months after therapy were excluded. Seventy patients were evaluated. Mean age was 73 years old; 58 (83%) patients were men and 54% had ischaemic aethiology. 53% had atrial fibrillation and 54% were diabetic. Mean LVEF was 31,1% and median estimated glomerular filtration rate was 65,4 ml/min. Regarding to optimal medical treatment: 97% were on angiotensin-converting-enzyme inhibitor, 91% beta-blocker and 77% were receiving a mineralocorticoid-receptor antagonist.
Left ventricular ejection fraction significantly improved after 6-month treatment (31,1±4,8 vs 40,7±10,2; p<0,001). Lower left ventricular end systolic (109,2±41,4 vs 83,0±47,2; p=0,006) and end diastolic volumes (163,2±57,9 vs 136,5±57,1; p=0,021) were described. There is a tendency to support these observations also after 12 months: LVEF remained lower (p= 0,003), as well as left ventricular end systolic volume (p=0,058).
Conclusions: Neprilysin inhibition has a beneficial effect on ventricular structure, improving not only ventricular volumes, but also ejection fraction. Longer follow-up periods need to be assess, as this improvement might change therapeutic approaches based on LVEF, for example, the indication of cardiac resynchronization therapy.

P1010
Short and medium-term safety and tolerability of Sacubitril-Valsartan and Empaglifozin joint intake

HMC Herminio Morillas Climent[1]; JSM Julia Seller Moya[1]; EGJ Emilio Galcera Jornet[1]; EAT Edgardo Alania Torres[1]; AVL Alvaro Vicedo Lopez[1]; YRP Ydelise Rodriguez Pichardo[1]; AL Ainhoa Larumbe[1]; AVM Alfonso Valle Munoz[1]
[1]Denia Marina Salud Hospital, Alicante, Spain

Background: Sacubitril-Valsartan has improved the prognosis of patients with heart failure and reduced ejection fraction. Empaglifozin has reduced heart failure incidence in patients with type 2 diabetes. However, data regarding safety and tolerability of joint intake are scarce.
PURPOSE: The aim of our study is to describe clinical use of Sacubitril-Valsartan together with Empaglifozin coadministration in real world practice, with special focus on safety and tolerability.
Methods: We performed a single-centre, retrospective evaluation of Sacubitril-Valsartan and Empaglifozin joint prescription from the date of the first drug prescription until the 20th December 2018. Inclusion criteria was any sustained prescription of both drugs by Cardiology and/or General Practitioners. Patients were excluded if no data were available or prescription had an incorrect indication.

We collected baseline characteristics of the patients, data of tolerance and information regarding laboratory markers. Statistical analysis was performed using SPSS Software for MAC, 20.0 version. Changes in cuantitative values over time were analyzed using T-Test.

Results: From the 3rd of March 2016 to the 20th of December 2018, 41 patients were included in the study. Three patients were excluded from the final analysis (1 due to unavailable data, 2 because of incorrect prescription of Sacubitril-Valsartan with LVEF > 45%).

Thirty-eight patients remained, of which 62% were men. Mean age was 68 years old. All the patients were diabetic, 67% hypertensive and 80% received statins. Ischaemic heart disease was the main cause of heart failure (65%). At baseline, 60% of the patients reported NYHA functional class II symptoms.

Sacubitril-Valsartan was started first in 14 patients, Empaglifozin in 11 patients, and both drugs were started at the same time in 13 patients, usually after heart failure admission.

During a medium follow-up of 432 +/- 202 days, only 4 patients (10,53%) were admitted to the hospital due to acute heart failure. No cardiovascular nor renal deaths were registered.

Creatinine (Cr) levels remained stable during follow-up, with a non-significant decrease of Cr values from 1,043mg/dl (SD = 0,33) at baseline to 1,034 mg/dl (SD = 0,29) at the end of the study. Blood test at intermediate time-points showed similar results (Cr = 1,068; 0,987, and 0,997mg/dl at blood test 2, 3 and 4 respectively). Cr increase above 40% of baseline levels was detected only in 3 patients (7,89%) and reversible in all, without any case of severe acute kidney injury.

Glycated hemoglobin (HbA1c) showed a mild and also non-significant reduction during the study, from 6,834% (SD = 1,19) at baseline to 6,723% (SD = 0,99) in the last visit. Glycemic values improved shortly after initiating Sacubitril-Valsartan or Empaglifozin (HbA1c 6,410 at blood test 2, p = 0,065).

Conclusions: Combination of Sacubitril-Valsartan and Empaglifozin is frequent, safe, and well tolerated in real world clinical practice.

P1011

Angiotensin receptor-neprilysin inhibition improves peak oxygen consumption in reduced heart failure patients

C Catia Ferreira[1]; AS Martinho[1]; JP Almeida[1]; AZ Freitas[1]; JA Ferreira[1]; C Domingues[1]; J Milner[1]; S Costa[1]; F Franco[1]; H Vieira[1]; R Coutinho[1]; R Baptista[1]; L Goncalves[1]
[1]*University Hospitals of Coimbra, Cardiology A, Coimbra, Portugal*

Background and Purpose: The addition of Angiotensin Receptor-Neprilysin Inhibitors (ARNI) to standard therapy of heart failure with reduced ejection fraction (HFrEF) has proved to improve outcomes. Cardiopulmonary exercise testing (CPET)-derived ergometric variables, as peak oxygen consumption (VO2), are used to determine heart transplant (HTx) eligibility. We aimed to analyse the impact of ARNI therapy in CPET variables.

Methods: We conducted a retrospective, observational cohort study, including 19 patients with symptomatic HFrEF with a left ventricular (LV) ejection fraction (LVEF) <35% and whose functional capacity was evaluated by CPET less than 6 months before initiating ARNI. We excluded patients who had implanted a cardiac resynchronization therapy device (CRT) or were submitted to heart surgery less than 6 months before the first CPET. A follow-up CPET was conducted 7±4 months after starting ARNI.

Results: Mean age was 55±12 years and 90% were male.Mean LVEF was 26±6% and before initiating ARNI, all patients were on optimal medical therapy, including angiotensin-converting enzyme inhibitors/angiotensin receptor blockers (100%), ß-blockers (94.7%) and mineralocorticoid receptor antagonists (89.5%). Moreover, 9 patients had an implantable cardioverter defibrillator (D) and 9 patients had a CRT-D.Regarding aetiology, 11 had ischemic heart disease, 6 had dilated cardiomyopathy, 1 had corrected transposition of great arteries and 1 had LV non-compaction. The majority of the patients (73.7%) were on maximal doses of ARNI (97/103mg bid); the remaining were on intermediate dose (49/51 bid). Following ARNI, peak VO2significantly increased from 15.4±5.2 to 17.0±4.0 mL.kg-1.min-1(mean absolute increase of +1.5 mL.kg-1.min-1, p=0.03). Among the 7 patients with peak VO2<14 mL.kg-1.min-1, 3 (43%) improved peak VO2to values >14 mL.kg-1.min-1, pulling the patients out of one of the classical HTx eligibility markers. Regarding other ergometric variables, a numerically increase was observed in mean total exercise duration (12:45 to 13:27 min), in respiratory exchange ratio (RER) (1.08±0.11 to 1.12±0.08) and in peak oxygen pulse (9.9±2.7 to 10.6±2.6 mL.beat-1). Conversely, the mean respiratory efficiency index (VE/VCO2) following ARNI remained similar.

Conclusion: In this cohortof HFrEF patients, ARNI significantly improved peak VO2, a major prognostic predictor. Importantly, 3 out of 7 patients with a peak VO2within the HTx threshold recovered to ineligibility values.

P1012

Sacubitril/Valsartan use in a real world experience: data from a large single-center population of heart failure patients with reduced ejection fraction

M Massimo Mapelli[1]; E Salvioni[1]; F De Martino[1]; I Mattavelli[1]; P Gugliandolo[1]; C Vignati[1]; A Magini[1]; S Rovai[2]; S Paolillo[3]; PG Agostoni[1]
[1]*Cardiology Center Monzino IRCCS, Milan, Italy*; [2]*University of Siena, Siena, Italy*; [3]*Federico II University Hospital, Naples, Italy*

Background: Sacubitril/Valsartan has emerged as a novel therapy in the treatment of heart failure (HF) with reduced ejection fraction (HFrEF), showing a lower cardiovascular mortality and HF hospitalization rates compared to standard therapy. Although the recent widespread use of Sacubitril/Valsartan, real life data are still lacking.

Methods: We performed a retrospective analysis of 201 monocentric patients with HFrEF, who started Sacubitril/Valsartan between September 2016 and December 2018 and followed at our HF ambulatory.We collected demographic data, clinical history with ongoing medications, baseline clinical characteristics and follow up (i.e. period of treatment until last contact with the hospital or by telephone call) about tolerated dose of Sacubitril/Valsartan, interruption of treatment, hospitalization for HF, deaths.

Results: Baseline characteristics of our population and of PARADIGM trial are presented in Tab. 1 and Fig.1A. One hundred and five patients also performed a cardiopulmonary exercise test before starting treatment, showing a mean peak VO2 of 14.9 ± 4.7 ml/min/kg (60 ± 17 % of predicted), with VE/VCO2 slope of 34.3±8.2, VO2/work of 9.4±1.5. During follow up (268 ±185 days) 36 patients had hospitalization for HF, while 20 patients interrupted treatment with Sacubitril/Valsartan (7 hypotension, 5 renal insufficiency, 1 angioedema, 7 not known/patient decision) and 9 deceased. Dose administered at baseline and at the end of follow-up is reported in Fig. 1B.

Conclusions: Compared to PARADIGM trial, our real-life population has similar characteristics and HF gravity. For clinical reasons during follow up only 31% reached the maximum dose. In future more studies are needed to analyze the prognostic impact of low vs. higher doses.

Effects of Sacubitril/Valsartan in real-world HF and reduced ejection fraction (HFrEF) population.

M Polito[1]; G Vitulano[1]; A Rispoli[1]; F D'auria[1]; A Gigantino[2]; R Citro[2]; D Bonadies[2]; G Iaccarino[3]; M Michele Ciccarelli[1]
[1]University of Salerno, Salerno, Italy; *[2]AOU S. Giovanni e Ruggi, Salerno, Italy*; *[3]"Federico II" University of Naples - Dept of Advanced Biomedical Sciences, Naples, Italy*

Background: The PARADIGM-HF has shown the superiority of Sacubitril/Valsartan (S/V) compared to Enalapril in HFrEF. However, its impact of in a clinical setting is yet to be elucidated. In this study, we aimed to evaluate the effects of S/V compared to standard HF therapy (ST) in our HFrEF population. Methods and results:180 patients with chronic HFrEF from our outpatient clinic were prospectively enrolled. Ninety patients were treated with ST, up-titrated to the maximum tolerated dose, maintained for at least 3 months, and ninety patients started the association with S/V as still symptomatic. The primary endpoint was rehospitalizations for worsening HF, cardiac death and the composite endpoint at 12 months of follow-up (FU). The secondary endpoint was the evaluation of the effects of S/V on the symptoms, on LV remodeling, on eGFR, compared to ST at 6-months FU. S/V group showed significantly lower HF rehospitalizations (3.3% vs 21.1%;p < 0.0001) and composite endpoint (6.7% vs 25.6%;p =0.001), whereas cardiac death was substantially not different between two groups. Moreover, in S/V group LVEF increased from 30 (27-38) to 35.5 (30-42) % (p= 0.001), LVESV decreased from to 119 (95-155) to 96 (83-130) mL (p=0.033) as well as sPAP from 30 (25-40) to 27 (25-36) mmHg (p=0.024) already at 6 months. Conversely, no statistically significant differences in term of parameters of LV and RV function were found in ST group. Finally, S/V group showed an improvement of eGFR (60 ± 22 mL/min vs 68 ± 23 mL/m2; p= 0.034), in comparison to ST group in which, despite a better baseline eGFR, even a worsening of eGFR (70 ± 21 mL/min vs 60 ± 19;p=0.021) was recorded at 6 months.
Conclusions: In our real-world HFrEF population, S/V reduces hospitalization and improves cardiac function in HFrEF. Furthermore, S/V preserves renal function in comparison to ST in HFrEF patients.

On behalf of: SAVE-RLife group

Introduction: The mean age of patients included in the PARADIGM-HF trial was 63.8±11.5 years. Objective: To analyse the use, safety and efficacy of sacubitril-valsartan (SV) in different age groups.
Methods: This is an observational, ambispective study that included all patients with stable HFrEF who started SV between SEP2016 and DEC2018. The cohort was divided into three age groups: patients <65 years (y); 65 - 74 y and >75 y.

Results: 276 patients were included, 68 patients women (24,6%), 44.6% were <65 y (n=123); 29.3% between 65 - 74 y (n = 81) and 26.1% were > 75 y. The basal treatment was similar in all groups, except for a greater use of aldosterone antagonists in patients <65 y vs >75 y (73% vs 56.9%, p=0.071). We observe in age group >75y a significant reduction in the estimated glomerular filtration rate (GFR) at baseline and after the use of SV (<65 y from 77.80 to 77.51 ml/min, 65 - 74 y from 66.39 to 60.72 ml/min >75 y from 61.28 to 56.74 ml/min, p<0.001), while the reduction of proBNP after using SV is independent of the age range (- 1316; - 1386; - 1492 pg/ml respectively; p=ns). A trend toward clinical improvement in NYHA class is present in all age groups (Figure 1). LV remodeling, defined as LVEF increase and LV end-diastolic diameter (LVED) decrease after the use of SV, was observed in the three age groups, without any significant differences (+ 7.93, + 4.52, + 5.51 of increase in LVEF, p=ns; and - 2.37, - 2.58, - 0.16 of decrease in LVED, p=ns). There are no differences in adverse events between the different age groups (Table 1).
Conclusions: These results add data about the SV use in elderly patients. We show that SV is a safe and effective drug in this subgroup of patients. Despite a higher prevalence of comorbidities, an improvement in functional class without increasing side effects is observed.

Allopurinol safety and efficacy in heart failure patients: a systematic review

H Yarmohammadi[1]; M M Ansari-Ramandi[2]; S Beikmohammadi[3]; B H Hosseiny Fahimi[4]; N Naderi[3]
[1]Medical Students Research Committee, Shahed University, Tehran, Iran (Islamic Republic of); *[2]Syed Mostafa Khomeini Hospital, Tabas, Birjand University of Medical Sciences, Birjand, Iran (Islamic Republic of)*; *[3]Rajaie Cardiovascular Medical and Research Center, Iran University of Medical Sciences, Tehran, Iran (Islamic Republic of)*; *[4]Department of Cardiology, Universitätsmedizin Schleswig-Holstein, Lubeck, Germany*

Introduction: Heart failure is a prevalent morbid disease with a high economic burden for the healthcare system. There has been data supporting that allopurinol, a xanthine oxidase inhibitor, can improve the endothelial dysfunction, cardiac function, and quality of life in these patients.
Purpose: Review allopurinol efficacy and safety in heart failure patients to shed light on improvement in different outcomes.
Methods: Electronic search in Medline, Scopus, Web of Science and Google Scholar was conducted for mesh terms of "allopurinol" and "heart failure" and updated on 11/1/2019 for the last time. Only articles in English or Persian language and only human interventional studies about allopurinol efficacy or safety in heart failure patients were eligible for inclusion. The title, abstract and full text of search results were screened after excluding duplicates, letters, congress abstracts, and reviews and then articles assessed for their risk of bias according to Quadas2. Included 17 articles were used to extract data about treatment outcomes. Screening, data extraction, and risk of bias evaluation were cross-checked with a second author, based on PRISMA guideline.
Results: Most of the included articles were randomised clinical trials. About half of the studies were mainly focused on cardiac function. The other main focus of the studies were endothelial dysfunction and cardiac biomarkers. Only one study focused on cardiac rhythm in heart failure patients. The majority of the included patients had left ventricle ejection fraction (LVEF) of less than 40%. The most administered allopurinol dose was 300 mg daily. There were many outcomes reported in the studies which were categorized into three groups (Imaging, laboratory data, and others). Flow-mediated vasodilation and LVEF, uric acid level and N terminal-pro B type natriuretic peptide (N terminal-pro BNP), New York heart association functional class and 6-minute walk test were the most frequently measured parameters in imaging, laboratory and other outcomes respectively. Out of the studies, most of them showed significant improvement in the above parameters. Two studies evaluated the quality of life from which one reported significant improvement. Only one study used strain imaging for evaluation of cardiac function which showed significant improvement. Two studies showed no significant improvement of N terminal-pro BNP and one of them which was also using imaging did not show improvement in LVEF. In a study evaluating two doses of Allopurinol, the higher 600 mg daily dose was significantly better in improving the outcomes. Allopurinol was well tolerated and the most reported adverse effect was skin rash.
Conclusion: Although there is evidence that allopurinol significantly improves endothelial dysfunction, cardiac biomarkers, and function, there is a need for more high quality randomised controlled trials to give insight about which patients benefit most from its use.

Initial experience of a nursing consultation in the uptitration of neurohumoral treatment in patientes with heart failure and reduced ejection fraction

V Vanessa Escolar Perez[1]; A Lozano[1]; A Echebarria[1]; A Azcona[1]
[1]Hospital de Basurto, Cardiology, Bilbao, Spain

Introduction: - Nursing is a cornerstone for the follow-up of patients with HF, carrying out important educational work, follow-up (including telemedicine projects) and, more recently, in the up titration of drugs with prognostic impact.
- Recently the HF Unit of our hospital has incorporated HF nursing in the up titration of drugs.
Objectives and methods
- The objective is to describe the characteristics of the patients referred to the nurse's consultation, the treatment that the patients were prescribed at the first visit and the treatment achieved.
- We collected patient data from the implementation of the nursing consultation in November 2017 until September 2018.
- The up titration was carried out following a protocol drawn up by the unit's professionals, in which consultations are carried out every 2 weeks with ECG and blood analysis and a progressive increase in drug doses.
Results
- Twenty-six patients (21 men and 5 women) with an average age of 60.7 years (SD 13.1) were included. The most prevalent heart disease is ischemic (46.2%), followed by idiopathic (42.3%). The mean LVEF is 27.4 (SD 7.8). 15 patients are in sinus rhythm and 2 in atrial fibrillation.
- Figure 1 describes the characteristics of the pharmacological treatment of the patients in the first nurse's consultation and upon completion of titration. High dose of beta-blocker was reached in 54% of patients and high dose of ACEI-ARA-ARNI in 84%. The reason for not achieving higher doses of beta-blocker was sinus bradycardia. In patients who did not reach the maximum dose of ACEi-ARA, it was due to symptomatic hypotension.
- In patients in whom the titration has been completed, the time invested was 9.4 weeks (SD 5.2). During this phase there were no HF decompensations requiring emergency visits or hospital admissions.
Conclusions: - Drug titration is possible in patients with HF and reduced LVEF, and maximum doses can be safely reached in most cases.

The impact of the use of sacubitril/valsartan on clinical and echocardiographic parameters in heart failure patients

A Abdallah Almaghraby[1]; M Abdelnabi[2]; T Kemaloglu Oz[3]; M Elgowelly[1]; Y Saleh[4]; H Badran[5]
[1]Alexandria University, Alexandria, Egypt; *[2]Medical research institute, Alexandria, Egypt*; *[3]Medipol university - Camlica hospital, Istanbul, Turkey*; *[4]Michigan state university, Michigan, United States of America*; *[5]Ain Shams University, Cairo, Egypt*

Background: Sacubitril/valsartan is a guideline-recommended alternative drug to Angiotensin-Converting enzyme inhibitors (ACEIs) or Angiotensin II Receptor Blockers (ARBs) to reduce morbidity and mortality in patients with chronic heart failure with reduced ejection fraction (HFrEF). Recent guideline update specifically advises switching symptomatic HFrEF patients to sacubitril/valsartan for further reduction of morbidity and mortality.
Purpose: The aim of the work was to demonstrate the clinical effects of the use of sacubitril/valsartan instead of the conventional ACEIs or ARBs in HFrEF patients.
Methods: A total number of 23 patients with miscellaneous causes of heart failure (14 patients had ischemic etiology, 8 patients had dilated cardiomyopathy and 1 patient had peripartum cardiomyopathy) presented in the setting of heart failure (NYHA III-IV) with normal creatinine clearance. Through clinical examination and baseline 2D transthoracic echocardiography (TTE) was done with an emphasis on left ventricular ejection fraction (LVEF) and end diastolic volume (EDV). All patients received sacubitril/valsartan instead of ACEs inhibitors or ARBs together with beta-blockers, diuretics and Mineralocorticoid antagonists when indicated. Follow-up after 6 months was done to assess patient clinical status as regards heart failure symptoms and follow up TTE as regards LVEF and EDV.
Results: The mean age of the patients was 46.89 ± 15.4 years, 14 patients (60.87 %) had a baseline NYHA III while 9 patients (39.13%) had NYHA IV. Mean baseline LVEF and EDV were 27.3% ± 8 and 277.11 ± 57.67 ml respectively. At 6 months follow-up, 21 patients (91.3%) had NYHA I while 2 patients had NYHA II (8.7 %), mean LVEF and EDV were 49.05% ± 10.27 and 202.79 ± 64.86 ml respectively. (P<0.001)
Conclusion: According to this small case series, the use of sacubitril/valsartan was not only associated with improvement of heart failure symptoms but also it was linked to evident improvement of TTE parameters in the form of improved LVEF and reduced EDV at 6-months follow-up.

The efficacy of "Get With the Guidelines Heart Failure," a retrospective analysis

P Perry Fisher[1]; A Goldstone[1]; D Rizk[1]; D Brodsky[1]; N Berezovskaya[1]
[1]Beth Israel Medical Center, New York, United States of America

Background: Heart failure (HF) represents an immense burden to our patients and, consequently, to healthcare expenditure. In an era of pay-for-performance initiatives, during which financial penalties are enforced for HF-related readmissions, reducing these occurrences has become of tantamount importance to hospital systems throughout the United States. In an effort to improve heart failure management as well as hospital readmission rates, the American Heart Association (AHA) created a collaborative quality improvement program entitled: Get With the Guidelines – Heart Failure (GWG-HF). It is the aim of this study to evaluate the efficacy of this initiative in reducing readmissions.
Methods: A university medical center in a major US city performed a retrospective chart review of randomly selected HF hospitalizations on a yearly basis for the GWG-HF initiative. This data was used to compare two years, 2012 and 2016; one in which the hospital's GWG-HF performance was sub-par (2012, N=416) and the other in which performance warranted a Gold-Standard award for adherence to guidelines (2016, N=301). GWG-HF "Achievement Measures" were selected as comparative variables between the two years.
Results: Of the GWG-HF "Achievement Measures," post-discharge appointments displayed the most significant difference between the comparison groups with 97.3% of patients having an appointment scheduled in 2016 and only 74.6% in 2012, a statistically significant difference of 22.7% (p<0.0001, 95% CI 17.1-28.1). Additionally, evidence-based beta Blocker use exhibited a statistically significant difference between the comparison years with 99.2% usage in 2016 and 91.8% in 2012, a 7.4% difference (p=0.0031, 95% CI 2.6-12.2). Measuring the LV function and ACEi/ARB/ARNi use were achievement measures with non-statistically significant differences in the two populations.
Conclusion: The GWG-HF "Achievement Measures" of scheduling post-discharge appointments and utilizing evidence-based beta Blockers were better enforced during a period with fewer 30-day readmissions. While this finding does not, in and of itself, imply a causal relationship it does lend support to the notion that compliance with GWG-HF ultimately reduces HF-related readmissions.

P1020

Echocardiographic assessment of treating patients with chronic heart failure with mid-range ejection fraction by external counterpulsation

R Rovshan Alakbarov[1]; T Jahangirov[1]
[1]Abdullaev's Research Institute of Cardiology, Baku, Azerbaijan

Introduction: The new 2016 European Society of Cardiology Heart Failure (HF) Guidelines propose a new HF classification includes a new HF category with mid-range EF (HFmrEF, LVEF 40-49%). The influence of the external counterpulsation on patients with HFmrEF is unclear.
Purpose: The aim of this study was to evaluate the echocardiographic parameters of patients with HFmrEF treated with external counterpulsation (ECP).
Methods: We studied 57 patients with stable CAD undergoing one course of external counterpulsation therapy. We categorize the patients into two groups: HFmrEF (EF 40-49%) and control group (EF>50%). Echocardiographic assessment included evaluation of the chamber size and ejection fraction by 2D and Doppler measurements.
Results: The mean age of the patients was 63.07 ± 7.44 years (43 (75.4%) men and 14 (24.6%) women). The mean age of the patients included in the HFmrEF group and control group was 64.13 ± 6.86 and 62.69 ± 7.67 years (p=0.45). There were 13 men and 2 women in the HFmrEF group and 30 men and 12 women in the control group (p=0.24). All patients treated with one course of the ECP therapy (33.87 ± 5.93 and 35.02 ± 4.57 sessions, p = 0.7714). The mean EF before treatment was 44.23 ± 3.21% and 62.18 ± 6.78% (p<0.0001). After the treatment by the ECP the mean EF in both group were 52.13 ± 7.01% and 65.73 ± 6.63% respectively (p<0.0001). When comparing the dynamics of the EF and stroke volume between two groups following data obtained: for EF: +7.90 ± 7.44 and +3.55 ± 4.27% (p=0.0487); for stroke volume: +6.35 ± 13.08 and +2.51 ± 8.03 ml (p=0.0176). After the end of treatment 9 out of 15 patients in the HFmrEF group (60%) had an EF more than 50%. When comparing the dynamics of changes in the echocardiographic parameters in the HFmrEF group and the control group, non-statistically changes observed in the following parameters: end-diastolic diameter of the LV (-0.06 ± 0.18 and -0.06 ± 0.31 sm, p=0.3504), end-diastolic volume of the LV (-0.69 ± 18.43 and -0.27 ± 12.07 ml, p=0.9783), left atrial volume (-3.73 ± 16.13 and -5.19 ± 14.79 ml, p=1.0), the ratio between early mitral inflow velocity and mitral annular early diastolic velocity (E/e', -0.65 ± 3.89 and -0.40 ± 2.74, p=0.9566).
Conclusion: ECP treatment was associated with an increase in EF and stroke volume in patients with HFmrEF.

P1021

Early effects of Sacubitril/valsartan on exercise tolerance in patients with heart failure with reduced ejection fraction.

G Vitale[1]; S Sarullo[2]; C Nugara[1]; F M Filippo Maria Sarullo[1]
[1]Buccheri La Ferla Fatebenefratelli Hospital, Palermo, Italy; *[2]University of Palermo, Palermo, Italy*

Introduction. Sacubitril/valsartan in patients with heart failure (HF) with reduced ejection fraction (HFrEF) was shown to be superior to enalapril in reducing the risk of death and hospitalization for HF.
Purpose. Our aim was to evaluate the cardiopulmonary effect of sacubitril/valsartan HFrEF patients.
Methods. In this observational study 94 patients with HFrEF underwent serial cardiopulmonary tests (CPET) after initiation of sacubitril/valsartan in addition to recommended therapy.
Results. At baseline, 38% of patients had New York Heart Association (NYHA) class III HF, mean left ventricular ejection fraction (LVEF) was 27 ± 6%. After a mean follow-up of 7.4 ± 3.6 months systolic blood pressure decreased from 117±14 mm Hg to 101±12 mm Hg (p < .0001); Peak oxygen consumption (VO2) improved from 14.7±3.3 mL/kg/min at baseline (% of predicted = 54.2±14) to 17.3±4.7 mL/kg/min after follow-up (% of predicted = 65.3±17.6) (p < .001), oxygen pulse increased from 11.6±2.9 at baseline to 13.7±4.2 mL/kg/min at follow-up (p < .001). VE/VCO2 Slope decreased from 34±6.3 to 31.9±6 (p= .024).

Conclusion. In ambulatory patients with HFrEF, administration of sacubitril/valsartan improved exercise tolerance, peak oxygen consumption and ventilatory efficiency at 7.4 ± 3.6 months follow-up. Further studies are necessary to better clarify underlying mechanisms of this functional improvement.

P1022

In-hospital management of disease modifying drugs in heart failure with reduced ejection fraction - an opportunity to improve?

I Nabais[1]; I Costa[2]; F Adragao[3]; I Egidio[4]; P Moniz[5]; L Campos[4]; I Araujo[5]; C Fonseca[5]

[1]Hospital de Cascais, Medicina Interna, Cascais, Portugal; *[2]Hospital de São José, Medicina Interna, Lisbon, Portugal*; *[3]Centro Hospitalar Universitário do Algarve - Hospital de Portimão, Medicina Interna, Portimão, Portugal*; *[4]Hospital de Sao Francisco Xavier, Medicina Interna, Lisbon, Portugal*; *[5]Hospital de Sao Francisco Xavier, Unidade de Insuficiência Cardíaca, Lisbon, Portugal*

Introduction: Heart failure (HF) is a syndrome with high morbimortality and its prevalence continues to grow. New therapeutic options are an opportunity to change the natural history of the disease. Guidelines recommend in-hospital maintenance or initiation of all disease-modifying drugs (DMD), with titration as much as possible before discharge.
Objective: To analyse in-hospital management of DMD in HF with reduced ejection fraction (HFrEF) patients admitted in an Acute Heart Failure Unit (AHFU).
Methods: Retrospective study of consecutive hospitalizations due to acutely decompensated HF, over a year, examining hospital databases. HFrEF patients discharged from the AHFU were selected to evaluate medication at admission, in-hospital and at discharge.
Results: From the 181 AHFU admitted patients, 76 HFrEF were included. At admission 68.4% were on renin-angiotensine-aldosterone inhibitor (RASi) - 50.0% ACEi, 9.2% ARB, 9.2% ARNI; 72.4% on beta blocker (BB) and 65.8% on aldosterone antagonists (ARM). At discharge 77.6% were on RASi - 57.9% ACEi; 9.2% ARB; 10.5% ARNI; 85.5% BB and 77.6% ARM; 57.9% were on triple DMD therapy and 10.5% on Ivabradine. Regarding ACEi: 34.1% started, 18.2% increased and 27.3% maintained ambulatory dose; Regarding ARB: 14.3% started, 14.3% increased, 42.9% maintained ambulatory dose. Regarding ARNI: 25% started, 23.5% increased 50% maintained ambulatory dose. Although during hospitalization all DMD were titrated to patients maximum tolerated dose, at discharge most patients on RASi (83.1%) and BB (80.0%) were not on maximum recommended doses according to guidelines, while on ARM only few patients (27.1%) didn't reach maximum doses. Very few patients needed to reduce or suspend DMD medication at discharge - 5.8% reduced and 21.2% suspended RASi, mainly due to low blood pressure (50.0%) and renal disease (30.0%); 12.7% reduced and 10.9% suspended BB mainly due to low blood pressure (38.9%) and bradycardia (22.2%); 6% both reduced and suspended ARM mainly due to renal disease (60.0%).
Conclusion: While being a predictor of bad prognosis, hospitalization was an opportunity to optimize HFrEF treatment. At discharge patients' DMDs maximum tolerated doses were frequently inferior to guideline's recommended maximum dosages. Although in line with other real-life registries and even trials, titration should always be re-challenged in an early post-discharge assessment.

P1023

Adherence to therapy in patients with chronic heart failure

EV Elena Efremova[1]; AM Shutov[1]; SV Shevchenko[2]; MJU Kortunova[2]; KA Lyukshonkova[1]; ES Semyonova[1]

[1]Ulyanovsk State University, Ulyanovsk, Russian Federation; *[2]Central City Clinical Hospital, Ulyanovsk, Russian Federation*

Adherence to therapy depends on many factors, including the cost of the drugs, tolerance and effectiveness, which are not easy to assess. Antiplatelet drugs have low cost, good tolerability and public awareness. Moreover antiplatelet therapy is an essential component of the treatment in majority of cardiology patients. The aim of this study was to investigate adherence to therapy patients with chronic heart failure (CHF) and comorbidity on the model of antiplatelet drugs.
Methods. 203 patients with CHF (130 males and 73 females aged 61.8±9.6 years) were studied. CHF was defined according to ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure, 2016. The main causes of CHF were coronary artery disease with arterial hypertension in 154 (75.9%) patients. Age-adjusted Charlson Comorbidity Index (ACCI) was estimated. Comorbidity was regarded as high at index ≥ 6 scores. Quality of life, personal characteristics were evaluated. Adherence to antiplatelet therapy of comorbid patients was assessment with Four-Item Morisky Green Levine Medication Adherence Scale.
Results. Age-adjusted Charlson Comorbidity Index was 5.0±2.1 scores. The total number of drugs was taken by patients with CHF was 4.6±1.7. Patients with CHF with high comorbidity took more drugs than patients with CHF low comorbidity (4.9 ± 1.8 and 4.2 ± 1.7 respectively, p = 0.03). Antiplatelet therapy was recommended in 190 (97.6%) examined patients with CHF, of which acetylsalicylic acid (ASA) was obtained in 186 (97.9%) patients with CHF, clopidogrel - 4 (2.1%) patients. The dose of ASA was 75–100 mg. The majority of patients (163; 85.8%) had CHF of ischemic genesis. Only 99 (52%) patients had high adherence to antiplatelet therapy. Main cause of nonadherence was irregular forgetfulness (28;31% patients), side effects from the gastrointestinal tract (12;13.1%) and a large number of recommended drugs (20;21.1%). There was an inverse relationship between adherence to antiplatelet therapy and the number of drugs (r= -0.49; p <0.0001), between level of adherence to antiplatelet therapy and a violation memory of patients with CHF (r= −0.31, p=0.032). Patients with poor adherence were characterized with disadaptive obsessive-phobic type of attitude to their disease (χ2=6.22; =0.01) and the 'projection' psychic defense mechanism (=0.02). The emotive type of character accentuation prevailed (<0.001) among patients with high adherence to antiplatelet treatment.
Conclusion. Comorbidity leads to the destination antiplatelet therapy in patients with chronic heart failure. Low adherence to antiplatelet treatment is associated with personality features of chronic heart failure patients and polypharmacy due to high comorbidity.

P1024

Hemodynamic and clinical effects of ARNI therapy in patients with advanced heart failure undergoing repeated Levosimendan infusions

G Masciocco[1]; M Varrenti[1]; A Verde[1]; C Santolamazza[1]; MG Cipriani[1]; A Garascia[1]; E Ammirati[1]; E Perna[1]; M Frigerio[1]; M Cottini[2]

[1]ASST Great Metropolitan Hospital Niguarda, Heart Failure and Transplant Unit, Niguarda Cardio Center , Milan, Italy; *[2]ASST Great Metropolitan Hospital Niguarda, Cardiac Surgery Unit, Niguarda Cardio Center, Milan, Italy*

Background: repetead Levosimendan infusions (rp-Levo) improve hemodynamics and symptoms in patients (pts) with advanced heart failure (aHF). Sacubitril/Valsartan, which benefit are known in pts with moderate HF, could be attempted.
Methods: from Jan 2016 to Dec 2018, 30 aHF outpatients had rp-Levo 12,5 mg (0.05-0.1 mcg/Kg/min) every 3-4 weeks awaiting heart transplantation (HTx). Seven pts (5 M, 2 F, age 53+/-10y, 3 ischemic etiology) could be weaned from rp-Levo after starting ARNI. Data at baseline (T0), at rp-Levo withdrawal (T1, median time on rp-Levo 11mo), and after 6 months (T2, median time on ARNI 8mo) were compared.
Results: Sacubitril/Valsartan median dosage was 132 + 139 mg. Changes over time are presented in the Table. An improvement in hemodynamics and RV function was observed on rp-Levo, reaching statistical significance on ARNI.Inferences: ARNI therapy could be attempted in stable pts with aHF, even if on rp-Levo, and may give a significant improvement of the hemodynamic profile despite end-stage LV dysfunction. The role of ARNI in aHF pts, including HTx candidates, deserves to be explored.

Comparison among all groups

Efficacy of bromocriptine on 2-year prognosis of life in patients with peripartum dilated cardiomyopathy

ST Mirzarakhimova[1]; TA Abdullaev[1]; I A Igor Tsoy[1]; RS Bekbulatova[1]
[1]*Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan*

The aim: assessment of the life expectancy of patients with peripartum cardiomyopathy at 2 years of follow-up, depending on bromocriptine prescription.
Material and methods: 50 pts with PCMP were examined, aged from 20 to 41 years old (average 28.2 ± 0.8 years). The complex of examinations included: ECG, HMECG, Echo-KG, 6-minute walk test (6MWT) with determination of the NYHA classes. Repeated contact with patients or relatives was held annually. It was studied 2 year life prognosis.
The results. All patients, depending on the destination bromocriptine, were divided into 2 grs. I group of 15 pts with PCMP, who, in addition to the standard therapy of HF, were prescribed bromocriptine at an average dose of 3.85 ± 1.25 mg. The II gr of 20 pts received optimal therapy according to ESC recommendations.
The study of the dynamics of the disease revealed that in the bromocriptine gr, complete restoration of LV function (increase in LVEF more than 55%) was observed in 7 (47%) cases, while in the standard therapy gr, LV recovery was observed only in 35% of cases (7). While no deaths were recorded in I gr, mortality in II gr was 15% (n = 3), (1 death due to progression of HF, 2 cases due to the development of SCD). During the second year of observation, another 1 patient died due to the progression of HF in II gr. As a result, cumulative mortality was 20% (n = 4).
Conclusion. Thus, the analysis of the dynamics of mortality in patients with the peripartum form of DCM showed that, against the background of optimal therapy, the additional administration of bromocriptine has a positive effect on the prognosis of life with the possibility of complete restoration of LV function.

P1026

Quality of heart failure treatment treated by residential cardiologists -The HeartFailureBavaria Project

F Bisenius[1]; KJ Osterziel[2]; H Steinert[3]; H Stroemer[4]; J Brandl[4]; M Hanke[1]; S Silber[5]; C Malsch[1]; G Ertl[1]; S Frantz[6]; P Heuschmann[7]; S Stoerk[1]
[1]*University Hospital Wuerzburg, Comprehensive Heart Failure Center, Wuerzburg, Germany*; [2]*Cardiopraxis.com, Amberg, Germany*; [3]*Residential Cardiology Nuernberg, Nuernberg, Germany*; [4]*Residential Cardiology Wuerzburg, Wuerzburg, Germany*; [5]*kardiologische-praxis.com, Muenchen, Germany*; [6]*University Hospital Wuerzburg, Department of Internal Medicine I, Wuerzburg, Germany*; [7]*University of Wuerzburg, Institute of Clinical Epidemiology and Biometry, Wuerzburg, Germany*

On behalf of: HeartFailureBavaria Study Group
Funding Acknowledgements: Federal Ministry of Research & Education, grant #01EO1004 & # 01EO1504

Background & Purpose: The quality of heart failure (HF) therapy in the hospital setting is fairly well known through clinical trials and registries, but largely undescribed in the setting of primary care and residential cardiology. HeartFailureBavaria was initiated as a network project aiming to describe characteristics and quality of care in patients with HF treated by resident cardiologists in the German healthcare setting.
Methods: 106 resident cardiologists across Bavaria agreed to characterize their consecutive HF patients on a structured case report form focussing on HF type and severity, comorbidities, diagnostic assessment, and interventional and medical treatment. Periodic benchmark reports were issued to the project group.
Results: Between 5/2014 and 12/2016, 70 cardiologists contributed information on 5497 patients with a cardiologically confirmed diagnosis of HF for the present analysis: median age 72 years; 66% male; NYHA II/III/IV in 50/36/5%; LVEF <40% (i.e., HFrEF)/40-49% (i.e., HFmrEF)/≥50% (i.e., HFpEF) in 29/29/42% of patients, respectively; sinus rhythm 60%; atrial fibrillation 29%; median heart rate 71 bpm; median QRS interval 118 ms. Frequent comorbidities were: hypertension 74%, coronary heart disease (CHD) 51%, hyperlipidemia 50%, valvular heart disease 32%, diabetes 28%, renal insufficiency 25%, COPD 12%.
Pharmacotherapy in groups of LVEF (<40/40-49/≥50%) was ACEi 69/65/57%, ARB 23/29/30%, betablocker 90/87/80%, MRA 64/48/27%, diuretics 88/75/71%, glycoside 14/10/13%, ivabradine 6/4/2% (all p<0.005, respectively). Patients aged <72 years vs. older patients received more often MRA (52% vs. 39%), triple therapy with ACEi/ARB, betablocker and MRA (46% vs. 32%), and antiplatelet therapy (54% vs. 44%); by contrast, older patients more often received diuretics (83% vs. 68%), and anticoagulation (56% vs. 33%; all p<0.001, respectively). Men and women with HFrEF were treated similarly, except for men in NYHA class III receiving betablockers more often than women: 92% m vs. 84% w, p=0.004. However, when considering all patients of all types of HF, men received individual substance classes and their combination more often (about 4-10% more often) than women, with the exception of diuretics (both sexes treated similarly) and glycosides (6% more often in women). Device therapy and interventions were: ICD 14%, CRT-D 9%, CRT-P 1%, PCI 29%, CABG 16%. The ratio of implanted to indicated devices was 0.54 for ICD (indication criteria: NYHA II/III, CHD, LVEF≤35%), and 0.32 to 0.42 for CRT (depending on the applied indication criteria).
Conclusion: HF patients cared for by residential cardiologists exhibited a good level of adherence to pharmacotherapy guidelines, without major gender-specific differences. There remains potential for improving cardiac device therapy. Despite lacking evidence how to optimally treat patients with HFpEF (and HFmrEF), utilization of respective substance classes was very similar to HFrEF patients.

P1027

To evaluate the safety and tolerability of ARNI initiation in inpatient versus outpatient setting in an Asian population: a real world study

Y Yiliang Zheng[1]; K Chng[1]; JS Hon[1]; H Chan[1]; CY Khoo[1]; CT Ng[1]; L Teo[1]; D Sim[1]
[1]*National Heart Centre Singapore, Cardiology, Singapore, Singapore*

Introduction: TRANSITION and PIONEER HF trials showed that entresto, an angiotensin receptor neprilysin inhibitor (ARNI), can be initiated early and safely in patients with heart failure reduced ejection fraction (HFrEF) shortly after an acute heart failure episode during hospitalization. However, it is unclear whether the results can be translated to the Asian population.Purpose: To compare the tolerability of ARNI initiation and continuation rate in both inpatient and outpatient settings.
Methods: A retrospective review of all patients who were prescribed ARNI from 1 November 2015 to 30 September 2018 in a tertiary institution in Singapore was performed. Data on the incidence of adverse drug reactions (ADRs), continuation rate of ARNI and reasons for ARNI discontinuation were collected from electronic clinical documents. 1022 patients were identified. 287 of 339 patients in the Inpatient Group and 549 of 683 patients in the Outpatient Group were included. Exclusion criteria include missing data, defaulted medication and initiation of ARNI in another institution.
Results: In the Inpatient Group, 89 patients (30%) experienced ADRs, 26 (30%) experiencing ADRs whilst inpatient and discontinuation rate is 48 (55%). In the Outpatient Group, 93 patients (17%) experienced ADRs and discontinuation rate is 47 (51%). Reasons for discontinuation of ARNI in both groups were similar - common reasons include worsening kidney function and hypotension.
Conclusion: Although inpatient ARNI initiation may be associated with higher rates of ADRs, tolerability and continuation of ARNI are similar in both groups. This may provide further evidence that ARNI can be safely initiated inpatient and allows optimisation of treatment for patients with HFrEF.

	Inpatient Group	Outpatient Group	Total
Total patients included	287 (34.3%)	549 (65.7%)	836
Male	209 (72.8%)	426 (77.5%)	
Mean age ± SD	64 ± 12.1	62 ± 12.3	
Mean EF before initiation of ARNI ± SD (%)	24 ± 7.2	26 ± 12.3	
Mean SBP before initiation of ARNI ± SD (mmHg)	116 ± 17.8	121 ± 20.2	
Total ADRs	87 (30%)	93 (17%)	180
Worsening kidney function	28 (32%)	11 (12%)	39
Asymptomatic hypotension	27 (31%)	20 (22%)	47
Symptomatic hypotension	21 (24%)	12 (13%)	33
Total discontinuation	48 (55%)	47 (51%)	95

P1028

The optimize-heart failure care program in our heart institute in Vietnam

PHUONG Do Thi Nam[1]; HUAN Do Quang[1]; BAN Ha Ngoc[1]; DUNG Do Van[2]; M R Cowie[1]; HAO Do Thi[1]; THANH Nguyen Chi[1]; HANG Nguyen Thi Thuy[1]; DUC Nguyen Huu[1]; TIEN Nguyen Thi Tuyen[1]; LAN Dang Le Thuy[1]; TRANG Tran Kieu Diem[1]; DEP Le Thi[1]; THU Phan Thanh[1]
[1]*Heart Institute, Ho Chi Minh city, Viet Nam*; [2]*Medecine and Pharmacy University, Ho Chi Minh city, Viet Nam*

Our heart institute in Vietnam taken part in the Optimize Heart Failure (OHF) program since October 2016. The aims of this program are to improve patients outcomes by improving heart failure (HF) patients' awareness of their condition, and by optimizing HF treatment according to a locally-agreed guidelines (based on the ESC guidelines)

with checklists to improve guideline adherence in hospital and at subsequent clinic review.
All HF patients with left ventricular ejection fraction < 50% hospitalized in our Institute have been included in the program since October 2016. The patients received education about diet, exercise, weight control and the detection of worsening HF symptoms at home, and HF treatments. All patients were reviewed at 2 months (M2) and 6 months (M6) for clinical signs, treatments and outcomes (readmission and death at 30 days, 60 days and 6 months after discharge). We also performed a telephone survey at 6 months after discharge to check their knowledge and their self-management on the four education topics. The start-up step (basic program) enrolled 401 patients (October 2016 and November 2017) and the full program has enrolled 211 patients to date (Jun 2018-November 2018). All patients were treated according to the same protocol but the full program also included reinforcement of patient education and practitioner guideline adherence.
Data will be presented to show our real word evidence: an improvement of knowledge and practice of HF patients in all of the 4 education themes and an improvement in pharmaceutical prescription rate (including renin-angiotensin-aldosterone system inhibitors, beta-blockers, mineralocorticoid receptor antagonist, and ivabradine for HF patients with NYHA II-IV and sinus rhythm). The rate of readmission and the mortality at 30 days and at 60 days after discharge were also improved with the full program compared with the basic program.
Conclusion: Pharmaceutical guideline adherence has been improved in Vietnam by using simple checklists and regular hospital educational meetings for healthcare professionals. Educational reinforcement helps patients retain information and to follow lifestyle and medical advice. The OHF Care Program is simple, inexpensive, and easy to implement in our country, and may well be easy to implement in other developing countries.

P1029

The effect of inhibitors of angiotensin receptors and neprilysin on the clinical and functional status of patients with dilated cardiomyopathy

TA Abdullaev[1]; I A Igor Tsoy[1]; OK Hudoyberganov[1]; YR Akhmatov[1]; AM Karimov[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

The aim. Evaluation of clinical efficacy in patients with CHF of non-coronary etiology at the stage of inpatient and outpatient treatment.
Materials and methods. The study included 64 pts with CHF III-IV FC on NYHA, non-coronary etiology hospitalized for developing decompensated HF, which were divided into 2 groups: Group I comprised 32 people who were prescribed sacubitril / valsartan in an average dose of 28.45 ± 15 , 5 mg / day. Patients in group II (n = 32) took ACE inhibitors in recommended doses.
Results. Tolerability was rated as satisfactory in both groups. 2 patients noted a more significant hypotension in the group of ARNI when initiating therapy, with the stabilization of SBP and DBP by the end of the hospitalization, and therefore, the drug was continued to be administered. After 1 month of observation, when assessing the clinical and functional status of patients with DC, there was a significant decrease in the total weight in both grs on 11% and 9%, HR - on 11% and 12%, respectively, in grs I and II. There was a significant effect on central hemodynamic parameters, and the increase in SBP and DBP in I gr was 13% and 9%, while in II gr, the increase in SBP and DBP was only 5% and 7%, respectively. There was a significant decrease of HR on 21% and 12% more significant in I gr ($p < 0.01$). Objective improvement in functional status was observed in both grs. Thus, in I gr, 6MWT indicators improved from 84.00 ± 36.30 to 280.00 ± 83.21m, while in II gr it was, from 82.00 ± 46.32 to 240.00 ± 76.35m (all $p < 0.01$). When analyzing the quality of life using the Minnesota questionnaire, it was noted that the total score was significantly reduced in both intra- and intergroup comparison (from 86.25 ± 20.12 to 18.20 ± 12.14 in I gr and from 88,25 ± 26.78 to 28.12 ± 15.13 in II gr).
Conclusion. The use of standard HF therapy in the inpatient and outpatient stages is accompanied by an improvement in the indicators of quality of life and clinical and functional status. At the same time, when ARNI was prescribed, a greater positive effect on the initial parameters was noted.

P1030

Indicators of echocardiographic examination with the use of sacubitril/valsartan in patients with CHF caused by dilated cardiomyopathy

TA Abdullaev[1]; I A Igor Tsoy[1]; RS Bekbulatova[1]; YR Akhmatov[1]; ZT Mashkhurova[1]
[1]Specialized Cardiology Center of the Republic of Uzbekistan, heart failure , Tashkent, Uzbekistan

The aim: Evaluation of the effect of RAAS inhibitors and neprilisine inhibitors (Sakubitril / Valsartan) on echo indicators in patients with dilated cardiomyopathy (DC)

Materials and methods: The study included 64 patients with chronic heart failure of III-IV NYHA classes, caused by DC, divided into: Gr I - 32 who were prescribed sacubitril / valsartan at an average dose of 28.45 ± 15.5 mg/day. Pts in gr II (n = 32) took ACE inhibitors in recommended doses. Echocardiography - the survey was carried out according to the standard technique.
Results. A significant positive effect was noted, accompanied by an increase in LV EF from 30.93 ± 6.43% to 34.71 ± 4.24% (10%) in I gr and from 28.28 ± 7.5% to 30.01 ± 6,33% (6%) in II gr, with a decrease in the cardiac meassures: LA-6% and 5%, EDD-8% and 4%, ESD-10% and 5%, respectively to I and II grs, with no significant differences between them. At the same time, it was noted that the indicators of the MPAP in I gr had a greater decrease compared with II gr (initially 57.67 ± 14.08 and 56.67 ± 9.08 42.17 ± 8.48 mm Hg, in dynamics - 42.17 ± 8.4 and 48.67 ± 12.08 mm Hg (by 27% and 15% respectively), in parallel with the decrease of RV – on 9% and 5%
Conclusion. The use of standard therapy for heart failure leads to a positive effect on echocardiographic parameters, while the appointment of ARNI has a greater positive effect compared with ACE inhibitors.

P1031

Inpatient versus outpatient introduction of angiotensin receptor neprilysin inhibitor in chronic heart failure patients

M Aleyan[1]; N Mewton[2]; C Bergerot[2]; L Green[3]; E Hugon-Vallet[3]; M Ovize[2]; L Sebbag[4]
[1]Civils Hospices of Lyon, Lyon, France; [2]Hospital Louis Pradel of Bron, Centre d'Investigation Clinique, UMR Inserm 1407 , Lyon, France; [3]Hospital Louis Pradel of Bron, Filière Insuffisance Cardiaque, CHU Louis Pradel, Lyon, France; [4]Civils Hospices of Lyon, Pôle Transplantation Cardiaque, CHU Louis Pradel, Lyon, France

Background: According to current guidelines, angiotensin receptor neprilysin inhibitors (ARNIs) are indicated in ambulatory patients with chronic heart failure (HF) and reduced ejection fraction (EF).
Purpose: To assess the safety and effects of ARNI introduction in HFrEF inpatients compared to outpatients in a retrospective single-center registry.
Methods: In an observational retrospective and mono-centric registry at our institution we included all HFrEF patients who received a Sacubitril/Valsartan prescription from July 2015 to November 2016 . All patient data was recorded in their medical files at baseline at follow-up at 6 months for safety, and efficacy. Patients were retrospectively classified into 2 groups according to ARNI introduction mode: inpatient or outpatient.
Results: 89 patients were included in our registry: 49 were outpatients and 40 inpatients. Mean systolic blood pressure at ARNI start was similar between outpatients and inpatients (117±15 versus 110±16 mmHg, respectively; p=0.06) as was glomerular filtration rate (GFR) (67.8±26.1 versus 64.0±25.2 ml/min, respectively; p=0.49). At 6 months follow-up, ARNIs had been continued in 90% of the outpatients versus 92% of the inpatients (p=0.79). There was a trend toward more symptomatic hypotension episodes in the inpatient group compared to the outpatient group (30,7% versus 18.6%, respectively; p=0.2) but GFR remained similar between groups (66.8±29 vs 59.5±25 ml/min; p=0.23) and the was no difference in hyperkalemia incidence between the outpatient and inpatient groups (4.7 versus 7.8%, respectively; p=0.56). In both groups, there was a significant improvement in NYHA class and LVEF at 6 months compared to baseline status.
Conclusions: In a monocentric observational registry, there was no significant difference in safety and efficacy in ARNI prescription between inpatients and outpatients with chronic HFrEF.

P1032

Management of patients with advanced heart failure and type 2 pulmonary hypertension.

I Malek[1]; M Hegarova[1]; H Al-Hiti[1]; J Vrbska[1]; J Pirk[1]; I Netuka[1]; V Melenovsky[1]
[1]Institute for Clinical and Experimental Medicine, Prague, Czechia

Introduction: Pulmonary hypertension (PH) is a common sequel of chronic heart failure, often with precapillary component. High pulmonary arteriolar resistance (PAR) is a negative prognostic sign and can complicate heart transplantation (HTx). The aim of this analysis was to present the approach to the patients (pts) with precapillary PH who were listed for Htx in our institution.
Patients and methods: Consecutive patients (pts) evaluated for HTx during period 1/2010 – 12/2017 were analysed, with a view to subgroup with precapillary PH. Hemodynamic investigations were performed using Swan-Ganz thermodilution catether. Precapillary PH unacceptable for HTx was defined as PAR > 4 Wood units and/or transpulmonary gradient (TPG) > 15 mm Hg, measured under euvolaemic conditions. Reversibility of PH was stated when PAR and TPG declined to values acceptable for HTx after testing by prostaglandin E1 or sildenafil.

Results: The criteria for unacceptable PH fulfilled 85 pts (69 men, 21-73 yrs). Reversibility of PH was achieved in 69 % of them.

Subsequently, all the pts were closely monitored in order to achieve optimal therapy. Fifty pts were treated with PDE5 inhibitor sildenafil (Revatio fi. Pfizer 60-120 mg/d). Duration of therapy was 9-91, median 10 months. Thirty nine (78%) pts were responders, only one did not tolerate the treatment.
Left ventricular mechanical circulatory support Heart Mate II fi.Thoratec (MCS) was implanted in 39 pts, in 15 of them solely for PH. Decrease of PAR was achieved in 27/28 measured pts.
All the pts were listed, HTx was subsequently performed in 65 (77 %), 9 (11 %) died on waiting list (WL), one pt. was left on MCS, 2 were excluded for comorbities, others are still on WL.
HTx was performed in 39 pts on special protocol ("ovesized donor heart", postoperative NO inhalation) and in 26 pts on MCS. In the early postoperative period 10 (15 %) of pts developed transient right ventricular failure, none died due to graft failure.
Conclusions: Precapillary PH in pts with advanced HF require special management. With contribution of sildenafil and MCS majority of pts can proceed to successful HTx.

P1033

Neuroendocrine inhibition in patients with heart failure and severe aortic stenosis undergoing TAVI

J E Pino[1]; F Ramos Tuarez[1]; P Torres[1]; K Chen[1]; M Kabach[1]; A Alrifai[1]; L Lovitz[1]; R Cubeddu[2]; M Rothemberg[2]; R Chait[1]; M Nores[2]
[1]University of Miami/ JFK Medical Center, Cardiovascular Disease, Atlantis, United States of America; *[2]JFK Medical Center, Atlantis, United States of America*

Background: Neuroendocrine inhibition with beta-blockers (BBs) and renin-angiotensin system inhibitor (RAS-i) has been postulated to decrease morbidity and mortality in patients with heart failure and reduced ejection fraction. However, there is inconclusive data about the role of BBs and RAS-I in patients with severe aortic stenosis (AS) undergoing transcatheter aortic valve implantation (TAVI).
Purpose: We aim to demonstrate that BBs and RAS-i will decrease morbidity and mortality in patients with severe AS after the left ventricular outflow obstruction has been resolved with TAVI.
Methods This is a retrospective cohort study of patients with severe AS that underwent TAVI between April 2012 and March 2016 in a tertiary cardiovascular center. The presence of neuroendocrine inhibition with BBs, RAS-i or both (BBs +RAS-i) was assessed. Evaluated outcomes included 30-day and 1-year mortality, length of stay, acute kidney injury (AKI), stroke and heart failure readmission (one month).
Results Out of the 372 patients that underwent TAVI in our institution, 158 (42%) were female with a mean age of 84.9 ± 6.7 years and mean STS score of 6.93 ± 4.01. A total of 127 (34%) patients had heart failure with reduced ejection fraction, 291(78%) had hypertension, and 79(21%) had diabetes mellitus. Their mean creatinine was 1.13-±0.58 mg/dl, mean AV-area was 0.65 ± 0.17 cm2 and mean AV-gradient was 49.4 ± 13.2 mmHg. A transfemoral approach was performed in 261 (70%) of the patients. Neuroendocrine inhibition was present in 324 (87%) patients, of these, 284 (76.3%) were on BBs, 151 (41%) were on RAS-i, and 111 (30%) were on BBs + RAS-i. See Table 1 for clinically relevant outcomes.
Conclusions This study suggests that neuroendocrine inhibition with RAS-i is associated with lower hospital stay and 30-day mortality in patients with severe AS and heart failure undergoing TAVI. The rate of post-TAVI AKI was not affected by the presence of RAS-i. Beta-blockers failed to demonstrate any significant outcome.

P1034

The effect of lisinopril on the functional state of the kidneys in patients with renal dysfunction

UK Kamilova[1]; ZD Rasulova[1]; DR Masharipova[1]; DR Tagaeva[1]; BB Utemuratov[1]; BB Toshev[1]; RA Khakimova[1]
[1]Republican Specialized Scientific-Practical Medical Center Therapy and Medical Rehabilitation, Cardiology, Tashkent, Uzbekistan

Purpose. To study the effect of lisinopril on the indicators of the functional state of the kidneys of patients with I-III functional class (FC) of chronic heart failure (CHF) depending on the degree of renal dysfunction (RD).
Methods. A total of 118 patients with ischemic heart disease from I-III FC CHF, who were examined at baseline and after 6 months of standard therapy with - lisinopril. All patients were divided into 2 groups depending on the estimated glomerular filtration rate (eGFR): 30≤60 ml/min/1.73m2 – 89 patients. The average age of patients was 60.3 ± 6.6 years. To determine the functional state of the kidneys, the level of serum creatinine (Cr) and eGFR were determined by formula CKD-EPI.
Results. Analysis of eGFR showed that among 29 patients with eGFR<60 ml/min/1.73 m2: in 12 patients 30≤60 ml/min/1.73m2 in the first group Kp and eGFR were 83.7±14.7 μmol/l and 79.6±14.8 ml/min/1.73m2 respectively.
In the group of patients with eGFR>60 ml/min/1.73m2, against the background of a 6-month therapy with lisinopril, a significant decrease in Kp and an increase in eGFR by 8% ($p<0.005$) and 9.6% ($p<0.005$), respectively;. in the group of patients with eGFR= 59–45 ml/min/1.73m2 (CKD 3A stage), with a 6-month therapy of lisinopril, there was a significant increase in eGFR by 8% ($p<0.05$), respectively. In the group of patients with eGFR=44–30 ml/min/1.73m2 (CKD 3B stage), with a 6-month therapy of lisinopril, there was only a tendency to improve these indicators.
Conclusion. In patients with CHF with intact eGFR>60 ml/min/1.73m2 and moderate RD with eGFR=59-45 ml/min/1.73m2, the use of lisinopril in standard therapy showed significant nephroprotection. In patients with chronic heart failure with RD with 30>eGFR<45 ml/min/1.73m2 with a 6-month therapy of lisinopril, there was only a tendency to improve indicators of RD.

P1035

Levosemindan using in pediatric patients with end-stage heart failure: single center experience.

T Tatyana Ivanova-Razumova[1]; Al Baigalkanova[1]; U Ahash[1]; A Janatkyzy[1]; R Kaliev[1]; TM Alpysbaeva[1]; K Mahambetova[1]
[1]National research cardiac surgery center, pediatric cardiology, Astana, Kazakhstan

Background: in adult patients with end-stage heart failure repetitive levosimendan infusions are widely used. In this population multiple infusions of levosimendan leads to improvement of hemodynamics and relief of symptoms, and also decrease rehospitalization rates. But data's about repeated levosimendan infusions effects in children and infants with decompensated heart failure are limited.
Purpose: to evaluate effectiveness and safety of multiple levosimendan infusions in pediatric patients with end stage heart failure.
Methods: from January 2015 up to December 2018 65 children's with end-stage heart failure were under observation in our center. Median age – 5,4 years (range 2 month – 15 years). Boys 28 (43%), girls – 37 (57%). For all patients standard clinical investigations, ECHO, pro-BNP levels, 6-MWT (in patients older 6 year) were performed at baseline before first administration of levosemindan and 3 days after, and then in the same schedule during next hospitalisations. We have done 2-3 levosimendan administrations during one hospitalization with 7-10 days interval. Median period between rehospitalisations was 3 month. Total number of infusions

P1033: Table 1.

	Beta-blockers	RAS-inhibitors	RAS-i plus beta-blockers

HF (Heart Failure)

was – 358. The continuous infusion of levosimendan was uptitrated to a maximum dose of 0.2 mg/kg/min in all patients, first 24 hours – we have administrate drug in dose 0,1 mg/ kg/min, next 24 hours – 0,2 mg/kg/day.
Results: Total number of infusions for 65 patients during 3 year composed 358. In 16 patients (24%) with hypotension we have used combination of levosimendan and dobutamin. ECHO data's: mean left ventricle ejection fraction (LVEF) before and after first levosimendan administration was not significantly changed – 18 ± 5% vs 20 ± 6,3% respectively. However, during follow-up period after 5-6 infusions mean LVEF significantly increased 25 ± 3,8 % ($p<0.005$). Baseline mean pro-BNP level was – 22000 ± 7567 pg/ml, after the first two infusions it was significantly decrease – 15000 ± 5500 pg/ml ($p<0.005$). During follow-up period continued decreasing of pro-BNP level has been noted. Mean pro-BNP level after 6 infusions was 7500 ± 1853 pg/ml, significantly lower in comparison with baseline ($p\leq 0.03$). There were no serious adverse events in the study population.
Conclusions: our data shows that multiple levosimendan infusions in children with end-stage heart failure demonstrate positive clinical and hemodynamic effects, well tolerated without severe adverse events. Further evaluation is required for determine optimal levosimendan administration regimen, frequency and combination with other inotropic drugs in children's with severe heart failure..

Availability and accessibility to heart failure treatment in latin america

SGC Stephania Galindo Coral[1]; JEG Juan Esteban Gomez Mesa[2]
[1]Valle del Lili Foundation, Cardiology Department and Clinical Research Center, Cali, Colombia; *[2]Valle del Lili Foundation, Heart Failure/Cardiology department, Cali, Colombia*

On behalf of: CIFACAH investigators
Funding Acknowledgements: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors

Introduction: Economic deprivation is considered an independent risk factor for Heart Failure (HF), beside this, there are other specific risk factors with greater incidence in Latin America (LA), such as hypertension, rheumatic fever and chagas disease. Prevalence of HF in LA is estimated in 1.0-2.0%. Decreased hospitalization and mortality are related to adherence to guideline-directed medical therapy (GDMT) and cardiac devices.
Purpose: Inadequate access to HF therapies deteriorates quality of life, increases hospitalization and mortality. This paperwork aims to reveal data about treatment access in LA; this information will help to generate new health policies and fulfill the specific needs for each country.
Methods: A descriptive observational study was conducted in 19 countries of LA. A structured questionnaire was sent to each national coordinator of the Council of Heart Failure and Pulmonary Hypertension of the Interamerican Society of Cardiology. This questionnaire evaluated "availability" (available: yes, no) and "accessibility" (type of access: public, private, patient, donation or research) to 21 pharmacological agents , cardioverter defibrillator (ICD) and cardiac resynchronization therapy (CRT). Data was collected since January 2017 until June 2018.
Results: All countries had "Availability" to cardiac devices (Table 1)and to, at least, one of the GDMT options. Public access (ideal coverage) to at least 50% of all therapies was found in 52.6% of countries (Figure 1) and patient access to at least 50% of all available therapies was found in 15.8% of countries.
Conclusion: LA has availability to, at least, one option for each of the GDMT therapies in HF patients. Public access is high for dobutamine (84.2%), moderate for devices (63% and 57.9% for CRT and ICD), and low for new GDMT options (21.1% for Ivabradine and ARNi: Sacubitril/Valsartan). Donation and research are still needed to access some treatments in some countries. Results will help health authorities and cardiovascular institutions to overcome economic deprivation effects and reach higher accessibility to GDMT and devices in each country.

Table 1.Access to cardiac devices

Type of access	ICD n(%)	CRT n(%)
Public	12(63,2)	11(57,9)
Private	4(21)	5(26,3)
Patient	2(10,5)	2(10,5)
Research	-	-
Donation	1(5,3)	1(5,3)
Not available	-	-

Decongestion therapy: does it differ from discharge to usual life conditions and among heart failure patients?

F Adragao[1]; I Nabais[2]; I Costa[3]; I Egidio[4]; P Moniz[5]; L Campos[4]; I Araujo[5]; C Fonseca[5]
[1]Centro Hospitalar Universitário do Algarve - Hospital de Portimão, Medicina Interna, Portimão, Portugal; *[2]Hospital de Cascais, Medicina Interna, Cascais, Portugal*; *[3]Hospital de São José, Medicina Interna, Lisbon, Portugal*; *[4]Hospital de Sao Francisco Xavier, Medicina Interna, Lisbon, Portugal*; *[5]Hospital de Sao Francisco Xavier, Unidade de Insuficiência Cardiaca, Lisbon, Portugal*

Introduction: Most decompensations of heart failure (HF) are due to congestion. At discharge from hospitalization patients are supposed to be in their dry weight, as congestive signs at this time are a predictor of rehospitalizations and mortality. Although most times euvolemic state is obtained during hospitalization, ambulatory habits and lifestyle diverge from hospital conditions, and medication might need to be adjusted.
Objective: To evaluate the adequacy of the prescribed diuretic dose at discharge on ambulatory conditions at reassessment after 2 weeks (average), and if there are differences on the diuretic dose among ejection fraction groups.
Methods: Retrospective study of consecutive hospitalizations due to decompensated HF in an Acute Heart Failure Unit (AHFU) over one year, between November 2017 and October 2018, examining hospital databases. Patients who were reassessed in a period of 30 days in Day Hospital (DH) were selected, and diuretic therapy changes were assessed.
Results: Of 162 patients discharged directly from the AHFU, 142 (87.7%) were referred to DH revaluation; of these, 29 didn't attend to the booked appointment, with a final population of 113 patients. The mean time to reassessment was 12 days, with 37 (32.7%) patients needing to increase diuretic dose at this time due to congestion (average of 3.6 kg weight increase) – 81.0% needed to increase loop diuretic dose, 45.9% thiazidic-like and 8.1% mineralocorticoid receptor antagonists (MRA). 70.2% of them were with sequential nephron blockage. 51.4% patients needed endovenous diuretic administration in the first evaluation and 3 were rehospitalized before 30 days after discharge due to decompensated HF. Out of 76 patients that didn't need diuretic adjustment in their visit, only 2 were readmitted in 30 days due to decompensated HF. 31.0% of non-reduced ejection fraction (non-HFrEF) needed diuretic adjustment and 34.5% of reduced ejection fraction (HFrEF)needed it as well.
Conclusion: Nearly a third of patients revaluated at DH needed diuretic adjustment at the first visit, with no difference between HFrEF and non-HFrEF. This supports the importance of early revaluation after discharge for therapy readjustment, preventing future readmissions. In our experience, revaluation at 12 days allowed not only adjustment of oral diuretic dose but also administration of IV diuretic, preventing 84.2% rehospitalizations. Diuretic doses at discharge might be appropriate for in-hospital setting, but commonly not enough at ambulatory environment. Future studies should be directed to the increase of diuretic dosage at discharge in order to prevent early readmissions and mortality.

P1038

The European Heart Failure self-care behaviour scale: psychometric testing of the Hebrew version

T Ben Gal[1]; V Yaari[1]; B Avraham[1]; NP Kato[2]; L Klompstra[2]; A Stromberg[3]; T Jaarsma[2]

[1]Tel Aviv University, Heart Failure Unit, Cardiology Department, Rabin Medical Center, Tel Aviv, Israel; *[2]Linkoping University, Department of Social and Welfare Studies, Linkoping, Sweden*; *[3]Linkoping University, Department of Medical and Health Sciences and Department of Cardiology, Linkoping, Sweden*

Background: Regular assessment of self-care behaviour is important to tailor patient's care and to evaluate effectiveness of interventions such as educational programs or heart failure (HF) disease management programs. The European Heart Failure Self-care Behaviour Scale (EHFScBS) is a validated instrument used worldwide.
Aim: To develop and evaluate validity and reliability of the Hebrew version of the 9 item EHFScBS in Israel HF patients.
Methods: In order to develop the Hebrew version of the EHFScBS, forward and back translation was performed according the standard translation process of the scale. Content validity of the scale was assessed by Israeli HF experts including HF nurses and HF cardiologists and usability was assessed by HF patients. For the psychometric evaluation, 102 HF patients (mean age 61±12 years, male 75%, NYHA II and III 42% and 51% respectively) from 2 studies performed in 2007 and 2015-2017 in a tertiary teaching hospital in Israel, were analysed. As for validity, content validity, construct validity and known-groups validity were assessed. Reliability was evaluated with internal consistency. This 9-item scale ranges from 0-100, with higher scores indicating better self-care behaviour.
Results: Experts reported that items concerning general self-care to reduce weight and smoking cessation were missing. Patients found the scale easy to complete after a short explanation and took no more than 10-15 minutes to complete it. An explore factor analysis using a principal component analysis with varimax rotation extracted two factors. Factor 1 consisted of 5 items regarding health maintenance behaviour such as "take a low-salt diet" (items 1, 5, 7, 8 and 9) and factor 2 included 4 items about consulting behaviour such as "if short of breath increases I contact my doctor or nurse" (items 2, 3, 4 and 6). Known-groups validity testing revealed a significant difference before and after an educational intervention in the total score (n=40, 41.6 ± 23.8 vs. 67.6 ± 21.8, p < .01). Values of Cronbach's alpha in total score, factor 1 and 2 were 0.78, 0.68 and 0.76, suggesting that internal consistency of this scale was acceptable.
Conclusions: Our study provides support for usability, validity and reliability of the 9-item Hebrew version of the EHFScBS. The scale in the current format is ready to use for assessing self-care behavior in Israeli HF patients.

Chronic Heart Failure - Clinical

P1039

Formation of cardio-renal syndrome in patients with chronic heart failure and type 2 diabetes, depending on the choice of glucose-lowering therapy

N Natalia Koziolova[1]; P Karavaev[1]; A Veklich[1]

[1]Perm Medical University, Perm, Russian Federation

Objective: To evaluate the contribution of various glucose-lowering drugs and their combinations to the formation of cardio-renal syndrome in patients with chronic heart failure (CHF) and chronic kidney disease (CKD).
Materials and methods: 223 patients with CHF were examined, among whom 98 patients had a history of type 2 diabetes mellitus. In 67 subjects, CKD was identified. The diagnosis of CHF was confirmed by the presence of myocardial dysfunction according to echocardiography and an increase in the concentration of N-terminal fragment of the brain natriuretic peptide (NT-proBNP) in the blood of more than 125 pg / ml by ELISA. The diagnosis of CKD was confirmed by lowering the estimated glomerular filtration rate using the formula CKD-EPI (eGFR) <60 ml / min / 1.73 m2 for at least 3 months.
The filtration function of the kidneys was also determined by the level of cystatin C in the blood and Cystatin-based eGFR (CKD-EPI). Depending on the received sugar-lowering therapy, patients with CHF and CKD were divided into four groups: the first group included 21 patients (31.3%) taking metformin, the second group included 12 (17.9%) patients receiving insulin therapy, the third - 15 (22.4%) surveyed taking sulfonylurea drugs, in the fourth group - 29 (43.3%) people who used a combination of metformin and sulfonylurea drugs.
Results: the groups did not differ by gender, age, comorbidity or concomitant therapy, as well as in type of CHF depending on LV EF (for rLVEF pmg=0,124; for mrLVEF pmg =0,459; and for pLVEF pmg =0,691). The average LV EF was, respectively, 52,3±7,8%, 56,0±9,2%, 51,8±6,0%, 58,5±9,1% (pmg =0,731).
NT-proBNP was significantly different between the groups: the maximum in the second group was 687.5±129.4 pg/ml, the minimum in the first group was 209.4±96.5 pg/ml, the intermediate value in the third and fourth group, respectively: 348.6±87.7 pg / ml and 367.9±99.7 pg / ml (pmg =0,002).
Parameters of the LV diastolic function were significantly different between groups: septal e', lateral e', E/e' in the second group were higher than in the first, third and fourth group (pmg <0.001 for all parameters). Groups did not statistically significantly differ in Creatinine-based eGFR (pmg = 0.216). Cystatin C and Cystatin-based eGFR did not depend on the choice of glucose-lowering therapy but correlated with NT-proBNP (r = 0.685, p <0.05 and r = -0.804, p <0.05, respectively). Conclusion: in patients with type 2 diabetes and CKD, the type of CHF does not depend on the choice of glucose-lowering therapy. In patients who take insulin therapy, more severe CHF is formed, assessed by NT-proBNP, and while taking metformin is less pronounced. The use of Cystatin-based eGFR (but not Creatinine-based eGFR) to assess the dynamics of CKD showed that the decrease in filtration function of the kidneys is not associated with the choice of glucose-lowering drugs, but depends on the CHF severity.

P1040

Iron parameters and erythropoietin level in patients with chronic heart failure.

M Smirnova[1]; P Chizhov[1]

[1]Yaroslavl State Medical Academy, Department Falulty therapy, Yaroslavl, Russian Federation

Introduction: chronic heart failure (HF) is a global health problem. One of the most common co-morbidities in HF is presence of iron deficiency (ID) and anemia. Anemia and ID is an independent predictor of high risk of cardiovascular complications in patients with HF. In the 2016 ESC guidelines for the diagnosis and treatment of HF, systematic measurement of iron parameters: serum ferritin and transferrin saturation (TSAT) is recommended in all patients with HF. The causes of anemia and ID in HF are different, such as insufficient intake of iron from food, increased levels of pro-inflammatory cytokines, hemodilution, chronic kidney disease and others. The role of erythropoietin (EP) in the development of anemia in patients with CHF and saved glomerular filtration has not been established.
Methods: Serum concentrations of iron, ferritin, TSAT, soluble transferrin receptors (STR), EP, 6-minute walk test were measured in 80 patients with chronic systolic HF [age: 70.82±7.66 years, men: 30, New York Heart Association (NYHA) class: 0/19/45/16] at a therapeutically department. The control group consisted of 10 patients without HF [age: 67.40±4.69 years, men: 3]. All standard echocardiography and tissue Doppler echocardiography (TDE) were performed with GE Vivid 7 Medical System. Conventional measurements include left ventricle (LV) cavity dimensions, wall thickness, fraction ejection and transmitral flow velocities, evaluation of diastolic parameters.
Results: comparison of iron metabolism in groups of patients with HF of different functional classes with the control group revealed a significant decrease in iron and ferritin levels and an increase in the concentration of STR in all groups of patients with HF (p<0,05). The level of STR in the serum of patients with NYHA 3-4 was significantly higher (p<0,05). In 62.5 % patients with HF were diagnosed with ID with low ferritin. Anemia, according to WHO criterias was detected in 30% patients, the level of hemoglobin corresponded to a mild degree. In all patients glomerular filtration rate corresponded to mild or moderate decrease. An increase in the concentration of EP was found in all patients with HF compared to the control group.
In patients with HF and ID, LV cavities were increased and ejection fraction was reduced with increasing NYHA classes. Patients with NYHA of 3-4 were observed decrease of contractile ability of myocardium of the left ventricle and the violation of diastolic function (p<0.05).
Conclusions: the frequency of anemia and iron deficiency increases about the progression of HF. In most patients with NYHA 3-4 there are signs of iron deficiency. In patients with HF with saved glomerular function, the EP content significantly increases with the increase of severity of HF. Iron deficiency in patients with HF is associated with decrease systolic and diastolic function of myocardium of the LV. Therefore detection and treatment of ID needed in addition to conventional therapy for HF.

P1041

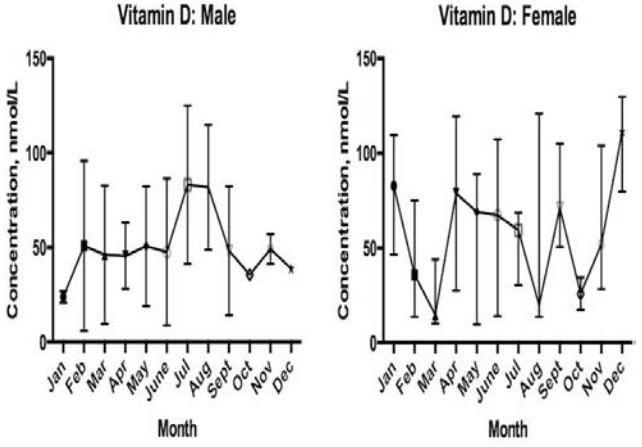
Ambulatory heart failure patients: temporal pattern of vitamin D

SI James[1]; K Millar[1]; L O'connor[1]; T Mannion[1]; B Mcadam[1]

[1]Beaumont Hospital, Cardiology, Dublin, Ireland

Introduction: Vitamin D insufficiency is common within the Irish population and heart failure (HF) patients are particularly at risk. Moreover, elderly HF patients are at risk of reduced sun exposure leading to reduction in vitamin D level. Various studies had investigated the role of vitamin D in improving outcome in heart failure and low vitamin D correlates to poor prognosis in patients with left ventricular assist device. Routine vitamin D blood measurement is not part of HF follow-up as per ESC

guidelines, yet it is vital in general well-being of patients. The aim of this study is to examine temporal vitamin D pattern in all heart failure subtypes patients attending the Heart Support Unit (HSU) of our Hospital.
Method: 343 consecutive patients attending HSU from period January to December 2017 were included. Vitamin D, ntProBNP, eGFR, creatinine, calcium, phosphate, and albumin levels was extracted. Descriptive statistical analysis was calculated. Range was described as median with inter-quartile range.
Result: Data was available in 294 of the 343 heart failure patients, 170 male (77 [65:83] years, 57.8%) and 124 female (81 [74:85] years, 42.2%) patients. Only 91 (30.9%) patients (48 were female) had vitamin D level checked at least once within the year. Female patients display bimodal dipping of vitamin D concentration reaching the level of insufficiency (<50umol/L) during winter and autumn (Figure 1). In the female cohort, vitamin D level was deficient at 15 [10:14] nmol/L mid-winter



Vitamin D distribution

versus 67 [14:107] nmol/L in mid-summer. 276 (93.9%) patients had ntProBNP level in 2017 with eGFR of 47.6 [33.4:64.7] (mL/min/1.73 m^2). Creatinine was marginally lower in male (122 [102:152] umol/L) compared to female (144 [80:152] umol/L). Calcium and Phosphate levels were normal, 2.3 [2.2:2.4] umol/L (both), and 1.0 [0.86:1.2] umol/L in male and 1.1 [0.98:1.3] umol/L in female. Albumin level was normal (37 [32:40] umol/L vs 37 [34:39] umol/L) respectively.
Conclusions: Vitamin D levels are not routinely check in HF patients especially in those who have impaired renal function which impacts on vitamin D metabolism but without obvious perturbations in calcium or phosphate homeostasis in this cohort. The temporal vitamin D pattern in female cohort dipped in winter and autumn, that may reflect the seasonal exposure to sun. Interestingly, no bimodal pattern observed in level of vitamin D in male heart failure cohort, possibly due to more engagement in physical activity outdoors. These finding suggest the need for routine vitamin D measurement and treatment in heart failure patients.

P1042

Angiotensin-converting enzyme inhibitors in female patients with diabetes mellitus in reduced ejection fraction heart failure

G Guliz Kozdag[1]; D Ural[2]; I Karauzum[1]; K Karauzum[1]; G Kahraman[1]; T Kilic[1]; J Wiley[3]; C Sanina[4]; C Baydemir[5]; A Vural[5]; A Agacdiken Agir[5]
[1]Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey; *[2]Koc University, Cardiology, Istanbul, Turkey*; *[3]Albert Einstein College of Medicine, Cardiology, New York, United States of America*; *[4]Montefiore Medical Center (Bronx), New York, United States of America*; *[5]Kocaeli University, Department of Biostatistics, Kocaeli, Turkey*

Back ground: Although sex-specific differences in cardiovascular medicine are well known, the exact influences of sex on the effect of cardiovascular drugs remain unclear. Furthermore, women are also less often treated with evidence-based drugs therapy. Angiotensin-converting enzyme inhibitors (ACE-I) should be prescribed to all patients with left ventricular systolic dysfunction. Patients may also have multiple comorbidities at the same time. Clinical guidelines for the management of type 2 diabetes (DM II) recommend individual therapy. If treatment is individualized for every patients the prognosis could be better in patients with multiple comorbidities. This study aims to evaluate the effects of ACE-I on all-cause mortality in reduced ejection fraction heart failure (HFrEF) according to patients' genders and the presence or the absence of DM II.
Method and Results: 399 male patients and 231 female patients with HFreF were recruited to the study. The EF of males was lower. More male patients were on the ACE-I than female patients. Almost 40% of the males and females had DM (Table 1). 105 patients (70%) with DM were on the ACE-I in the male group, 66 patients (67%) with DM were on the ACE-I in the female group, p=Not significant (NS). 207 male patients (52 %) and 106 female patients (46%) of the cohort died during a median follow-up duration of 54 months, p=NS. Although 26 of female patients (39%) with DM who were on the ACE-I treatment died, 20 of female patients (61%) with DM who weren't on the ACE-I treatment died (p=0.046) during follow-up. There was no significant statistical difference for all-cause mortality between the females with the ACE-I treatment (50%) who died and the females without the ACE-I treatment (35%) who died in the patients without DM (p=NS). It wasn't determine any difference for all-cause mortality among in the males with or without DM who were on ACE-I or were not on ACE-I in the patients with HFreF.
Conclusion: It was determined that more female patients with DM who were not on the ACE-I treatment died compared to the female patients with DM who were on the ACE-I treatment during the follow-up in the study. There wasn't similar difference in the male group.

General Characteristics of Patients

	Male (n=399)	Female (n=231)	p
Age (years)	66± 11	66± 13	NS
Ejection fraction (%)	24 ± 9	27± 10	0.001
Diabetes	151 (38%)	99 (43%)	NS
ACE-I	302 (76%)	158 (68%)	0.047
All-cause mortality	207 (52%)	106 (46%)	NS

Association of serum galectin-3 with depression in heart failure with reduced ejection fraction

I Alexanian[1]; J Parissis[2]; V Bistola[2]; G Bakosis[2]; M Thodi[2]; N Magiras[1]; L Pappas[1]; S Xydonas[1]; A Sideris[1]; G Filippatos[2]
[1]Evangelismos General Hospital of Athens, 2nd Department of Cardiology, Athens, Greece; *[2]Attikon University Hospital, Department of Cardiology, Athens, Greece*

Background / Introduction: Immunoinflammatory activation has been recognized as an integral feature of heart failure (HF) pathophysiology. Galectin-3, a β-galactoside-binding lectin, has been implicated in myocardial inflammation and fibrosis.
Purpose: We sought to examine the association of galectin-3 with indices of depression in patients with heart failure and reduced ejection fraction (Left Ventricular Ejection Fraction<40%) (HFREF).
Methods: We enrolled 87 consecutive patients with HFREF (age: 65.01±9.58years, 56% ischemic HF) regularly visiting our outpatient clinic. Galectin-3 concentrations in serum were determined by an automated quantitative test using the ELFA technique. Screening for depressive symptoms was performed using the Zung self-rating depression scale (SDS) and the Beck Depression Inventory (BDI). Statistical analysis was performed using SPSS 19.
Results: Serum galectin-3 levels were 21.77±13.12ng/ml. Galectin-3 concentrations showed a positive association with indices of depression, including SR raw score Zung (r= -0.397, p=0.011), and total score BDI (r= -0.348, p=0.035). In multiple linear regression analysis, galectin-3 independently positively predicted SR raw score Zung (B:0.351, 95%CI for B: 0.066 – 0.636, p=0.018), after adjusting for age, gender, NYHA, LVEF, logNT-proBNP, urea and Na. In ROC curve analyses, the optimal cutoff point for galectin-3 as a predictor for SR raw score Zung >40 (cut-off for depression) was 24.15ng/ml, associated with a 54.20% sensitivity and 81.20% specificity (AUC:0.694, 95%CI: 0.524 – 0.864, p=0.040). In multiple linear regression analysis, galectin-3 showed a trend to independently positively predict total score BDI (B:0.260, 95%CI for B: -0.024 to 0.543, p=0.071), after adjusting for age, gender, NYHA, LVEF.
Conclusion: Serum galectin-3 independently predicts symptoms of depression in HFREF

P1044

Evaluation of ventilation response during physical testing in patients with chronic heart failure and chronic obstructive pulmonary disease

KA Kira Ageeva[1]; VN Abrosimov[1]; NN Peregudova[1]
[1]Ryazan State Academician Medical University, Therapy Department, Ryazan, Russian Federation

Background: The determination of the exercise tolerance of patients with CHF and COPD is of great diagnostic and prognostic significance. For an objective assessment of the level of physical performance, it is recommended to use the test

with a 6-minute walk test (6MWT). The use of devices that allow monitoring the indicators ETCO2 and Sp2 during the whole study with the function of memory of results significantly increases the diagnostic value of the test.

Purpose: to determine the diagnostic possibilities of applying dynamic monitoring of CO2 and Sp2 indicators during 6MWT.

Methods: We studied 160 patients of both sexes. Patients with COPD II-IV, stable course (n = 68, age 64.9 ± 4.82 years), patients with CHF II-IV in New York Heart Association (NYHA) (n = 52, age 58.4 ± 3.24 years) . The control group consisted of patients without COPD and CHF (n = 40, age 55.35 ± 6.51 years). Conducted 6MWD in accordance with the recommendations of the European Society of Cardiology and the American Thoracic Society . The patient was instructed that his task was to walk as fast as possible for 6 minutes, while he himself determined the intensity of his load. Shortness of breath was assessed on the Borg scale, VAS, the dynamics of the patient's complaints, objective data (BP, pulse, NPV), a dynamic capnogram was recorded using a LifeSense LS1-9R (MedAir AB), a dynamic Sp2 was recorded using a Spiropalm 6MWT (Cosmed).

Results: The study found that the reaction of respiration and gas exchange at rest and during 6MWT in patients with COPD and CHF is different. PETCO2 alone patients with CHF in NYHA class II was 38.2 ± 2.13 mm Hg, in NYHA class III the PETCO2 was 34.4 ± 2.22 mm Hg., in NYHA class IV - 32.4 ± 1.14 mm Hg. The value of PETCO2 in patients with COPD II was 36.2 ± 2.43 mm Hg, in patients with COPD III - 34.1 ± 1.22 mm Hg., in patients with COPD IV was 32.2 ± 1.13 mm Hg. All patients completed 6MWT. The 6MWT distance in patients with CH in NYHA class II was 384.9 ± 10.56 m, in NYHA class III - 298.4 ± 10.24 m, in NYHA class IV - 162 ± 6.51 m. The 6MWT distance in patients with COPD II was 432.4 ± 8.9 m, with COPD III — 354.7 ± 9.9 m, and with COPD IV — 262 ± 9.5 m. 69.2% of patients reported shortness of breath as the main reason for stopping during 6MWD, and significantly more often in the group of patients with COPD ($p < 0.05$). A significant decrease in the rate of PETCO2 was observed in all patients with CHF during 6MWD. In the group of patients with COPD, a relative increase in the rate of PETCO2 was observed during the execution of 6MWD. When analyzing the trend of PETCO2, these patients showed signs of periodic respiration, in contrast to the control group. When analyzing the SpO2 index during 6MWD, a decrease in this indicator was found in both groups.

Conclusion: the dynamic monitoring of PETCO2 and SpO2 significantly expand the diagnostic value of the standard 6MWD.

P1045

Chronic obstructive pulmonary disease as comorbidity of the patient with heart failure: clinical profile and follow-up

CN Carlos Nicolas Perez Garcia[1]; D Enriquez Vazquez[1]; M Ferrandez Escarabajal[1]; M Perez Serrano[1]; R Bover Freire[1]; I Vilacosta[1]

[1]Hospital Clinic San Carlos, Instituto Cardiovascular Clínico San Carlos, Madrid, Spain

Introduction: chronic obstructive pulmonary disease (COPD) is a prevalent comorbidity in the patient with heart failure (HF). The decompensation of one entity is frequently in relation to the other, with the
consequent higher rate of readmissions and a worse impact on life quality and prognosis.

Purpose: the aim of this study was to compare patients with HF and COPD and those without COPD in terms of clinical profile and prognosis.

Methods: patients admitted to the Cardiology ward of a tertiary hospital with the diagnosis of HF were prospectively and consecutively collected for 12 months and subdivided into two groups (with and without a previous diagnosis of COPD). Both groups were compared in terms of clinical, analytical and imaging characteristics as well as follow-up.

Results: 336 patients were included with a median follow-up after discharge of 403 days. 44 (13.1%) presented COPD upon admission. Regarding baseline characteristics, significant differences were found in terms of sex (male predominance, 79.5 vs 48.3%, p <0.001), current smoking (20.5% vs 8.2%, p 0.01), former smoking (54.5% vs 29.5%, p 0.001) and home oxygen therapy (13.6% vs 2.7%, p 0.001). No significant differences were observed about the prevalence of other cardiovascular risk factors, clinical presentation, proportion of left or right ventricular dysfunction, medical treatment at admission or discharge. In terms of follow-up, readmissions for HF, as well as mortality from all causes and from HF were higher in patients with COPD, without reaching statistical significance. Mortality from other causes different from HF is significantly higher (19% vs 7%, p 0.01, figure 1).

Conclusions: COPD is a comorbidity common in patients with HF, without important differences in terms of clinical presentation or therapeutical approach, but with a negative impact in terms of mortality.

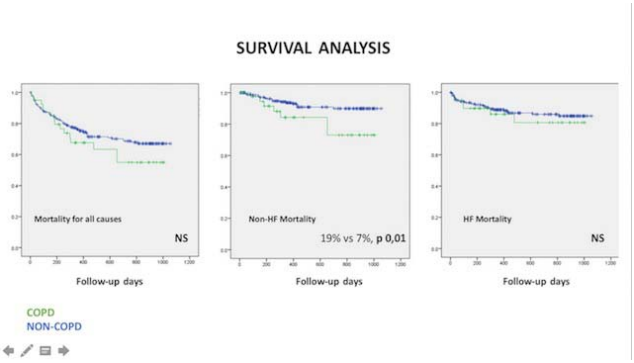

Figure 1. Survival analysis.

P1046

Chronic heart failure confers a higher risk of non-cardiovascular death in a patients with atrial fibrillation

M Polovina[1]; G Krljanac[1]; D Djikic[2]; I Petrovic-Djordjevic[2]; L Vajagic[3]; V Kovacevic[2]; I Veljic[2]; I Milinkovic[2]; J Simic[2]; M Asanin[1]; PM Seferovic[1]

[1]University Clinical Center of Serbia, Cardiology Clinic, Faculty of Medicine, Belgrade University, Belgrade, Serbia; *[2]University Clinical Center of Serbia, Cardiology Clinic, Belgrade, Serbia*; *[3]University Belgrade Medical School, Belgrade, Serbia*

Background: The coexistence of chronic heart failure (HF) and atrial fibrillation (AF) is common and associated with higher risks of stroke and cardiovascular (CV) mortality. The association between chronic HF and the risk of death from cancer and other non-CV disorders is not well established in patients with AF.

Methods: In a cohort of AF patients from a tertiary cardiology centre, we assessed the association between chronic HF (vs. no HF) and cause-specific non-CV death during the prospective 5-year follow-up. We also compared non-CV mortality rates between patients with HF and reduced ejection fraction (HFrEF) and patients with HF and preserved/mid-range ejection fraction (HFpEF/HFmrEF).

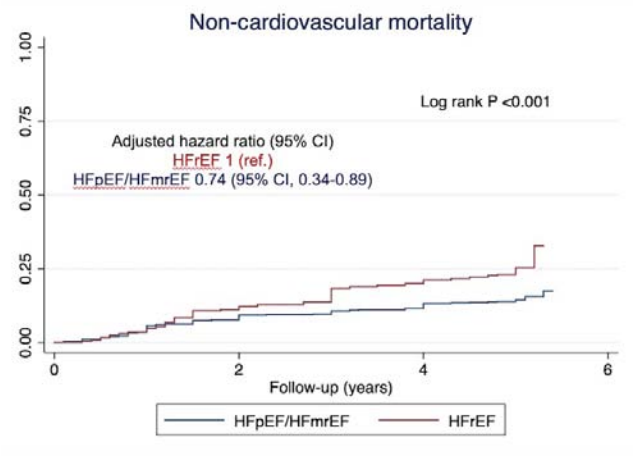
Results: The study included 1,803 AF patients (mean age, 71±12 years, 63% male). A documented history of chronic HF was present in 29%. Among AF patients with chronic HF, 41% had HFrEF and 59% had HFpEF/HFmrEF. At 5-year follow-up, there were 298 cases of non-CV death (rate, 3.7; 95% confidence interval, 3.3-4.1 per 100 patient-years). Following adjustment for age, sex, body mass index, smoking status, relevant comorbidities and medical treatment, AF patients with chronic HF compared with those without HF had significantly higher risk of non-CV death, including death due to specific causes: infection, cancer, and a composite of COPD, renal/hepatic dysfunction or bleeding (Table). Compared with AF patients with HFrEF, patients with HFpEF/HFmrEF had lower risk of non-CV mortality (Figure).

Conclusions: In patients with AF, chronic HF is an independent predictor of a higher risk of non-CV mortality, including a greater risk of dying from cancer, infection or worsening pulmonary, renal or hepatic disorders or bleeding. Non-CV death rate is lower in patients with HFpEF/HFmrEF compared to patient with HFrEF.

Adjusted non-CV mortality risk

	No of deaths (%)	Adjusted HR (95% CI) chronic HF vs. no HF	P-value
All non-CV deaths	298	2.6 (1.8-3.2)	<0.001
Infection	105 (35%)	2.1 (1.3-4.1)	0.009
Cancer	83 (28%)	3.1 (1.4-5.3)	<0.001
Composite: CODP, renal/hepatic dysfunction, bleeding	110 (37%)	2.4 (1.6-3.7)	0.003

HR - hazard ratio; CI - confidence interval; HF- heart failure; COPD - chronic obstructive pulmonary disease



P1047

Adherence to guidelines for diabetic patients with heart failure with reduced ejection fraction

H-Y Hung-Yu Chang[1]; C-W Hsieh[1]; M-C Fong[1]; A-N Feng[1]; K-C Huang[1]; W-T Lai[1]; W-H Yin[1]
[1]*Cheng-Hsin General Hospital, Taipei, Taiwan, Province of China*

Introduction: Heart failure (HF) and diabetes mellitus (DM) are two major global chronic diseases which often coexist. Despite a large number of published clinical guidelines, the adherence to treatment guidelines in real world practice were seldom reported. This study aimed to investigate the adherence to diabetes treatment guidelines in patients with HF and reduced ejection fraction (HFrEF).
Methods: Between 2015 and 2017, 345 diabetic patients with HFrEF in a HF referral center were recruited. Baseline characteristics, the prescription rates of diabetic medications and death from cardiovascular causes or unplanned hospitalization for HF in 2016, 2017 and 2018 were analyzed.
Results: Among these diabetic patients with HFrEF (age 65.2±12.6 y/o, 71.6% male, mean LVEF 27.5±6.9%, mean BMI 26.2±4.6 kg/m2), the prescription rates of sodium-glucose co-transporter 2 (SGLT2) inhibitor increased from 10.8% in 2016 to 18.8% in 2017 and 26.3% in 2018 (p<0.001), whereas the prescription rates of metformin, dipeptidyl peptidase 4 inhibitor, sulfonylurea, alpha-glucosidase inhibitor and insulin did not change significantly over time. The prescription rates of metformin and SGLT2 inhibitor were significantly higher in patients treated by cardiologists than in those treated by endocrinologists and other specialists (65.5% vs. 40.4% and 40.4%, p<0.001; 32.6% vs. 10.7% and 1.5%, p<0.001, respectively). Compared to those who received metformin with or without SGLT2 inhibitor treatment, patients who were not treated with guideline-recommended anti-diabetic medications had higher annual event rate of death from cardiovascular causes or unplanned hospitalization for HF (10.1% vs. 30.7%, p<0.001). After multivariate analysis, prescription of guideline-recommended anti-diabetic medications was associated with favorable outcomes (Odds ratio 0.39; 95% CI 0.25 to 0.59; p<0.001).
Conclusion: Adherence to treatment guidelines for diabetic patients with HFrEF is suboptimal and diverse among different specialists. Moreover, prescription of guideline-recommended anti-diabetic drugs was associated with better clinical outcomes. Our finding emphasizes the importance of training and collaboration in the management of these patients.

P1048

Measuring frailty in hospitalized heart failure patients using common lab parameters

RK Anam[1]; S Priyadarshni[1]; ML Zylberglait[1]
[1]*Aventura Hospital and Medical Center, Internal Medicine , Aventura, United States of America*

Background: Frailty is characterized by physiological decline and marked vulnerability to adverse health outcomes. It carries an increased risk of poor health outcomes including procedural complications, falls, institutionalization, disability, and death. Several indices have been used for evaluation of frailty historically. The criteria considered by Fried et al. includes 5 phenotypical variables and Rockwood et al. proposed a 7-point scale entirely based on clinical judgment. Recently, frailty indices based on routine laboratory parameters (FI-Lab) using blood, urine testing and standard physical measures have been introduced. Unlike clinical frailty indices which were evaluated only in community-dwelling individuals, these FI-Lab indices have also been validated in hospitalized patients. Even though frailty is a well-known predictor of mortality in cardiovascular patients, no studies have been done to find the relationship between frailty and heart failure (HF) using this easy to use, validated and time-saving FI-Lab.
Purpose: To find the relationship between Frailty and Heart failure in hospitalized patients using common lab parameters.
Methods: This is a retrospective cross-sectional study. Data were extracted from a corporate database, for the month of September 2017. FI-Lab has 23 variables; each available variable was scored 1 if the value fell outside of normal range (deficits). Sum of these deficits was divided by the total number of available variables. The result was then multiplied by 23. FI-Lab was used as a continuous variable, higher values are assumed to have a higher risk of frailty. Multiple linear regression and t-test were used to analyze the data using IBM SPSS statistics 24.
Results: The study population (n=4,681) had a mean age of 59±21 years and 50% were male. Documented HF diagnosis was found in 762 (16%) patients. Comparing patients with and without HF, statistically significant differences were found in age (72±15 years vs 56±20 years), diabetes mellitus (50% vs 26%), history of stroke (14% vs 7%), myocardial infarction (20% vs 5%), hypertension (8% vs 41%), and FI-Lab score (8.04±3.74 vs 5.84±3.89). HF was strongly associated with frailty status independent of age, gender, hypertension, diabetes, stroke, acute myocardial infarction and AFib in multiple linear regression analysis (B 1.1, p <0.001, CI [0.76, 1.44]).
Conclusion: Though the relationship between Frailty and HF has been studied previously using other frailty indices, the process lacked objective data or was time-consuming. Our study uses FI-Lab to evaluate frailty risk in HF patients, which can help providers in establishing a prognosis, determining procedural risks, and guiding treatments more effectively in a busy clinical environment.

P1049

Predictors of cognitive impairment in patients with chronic heart failure and reduced left ventricular ejection fraction

A Anastasiia Solonovych[1]; A V Liashenko[1]; I L Revenko[1]; L S Mkhitaryan[1]; L G Voronkov[1]
[1]*NSC Institute of Cardiology M.D. Strazhesko, Heart Failure Department, Kiev, Ukraine*

Background. Cognitive impairment (CI) is independent prognostic marker of adverse outcomes in patients (pts) with chronic heart failure (CHF). However, in routine clinical practice cognitive function in pts with CHF usually is not evaluated and clinical predictors of CI in CHF are studied insufficiently.
Objective. to establish predictors of CI in patients with CHF and reduced left ventricular ejection fraction of (rLVEF).
Methods. 124 stable CHF pts with rLVEF aged 18 to 75 years, NYHA II-IV were examined. Cognitive function was evaluated by using Mini-Mental State Examination (MMSE) scale. Cognitive dysfunction was defined as MMSE≤ 26 points. Besides routine examination, additional biochemical (determination of ceruloplasmin, citrulline, myeloperoxidase) and immunoenzymometric (determination of interleukin 6, NTproBNP, insulin) methods were used.
Results and discussion. CI was observed in 68.5% of pts. According to univariate regression analysis, CI was associated with age (OR 1.07, 95% CI: 1.03-1.11), duration of CHF symptoms (OR 1.02, 95% CI: 1.001-1.03), presence and duration of hypertension and coronary heart disease (CHD) (OR 3.46, 95% CI: 1.44-8.30 and OR 2.60, 95% CI: 1.14-5.90, respectively). Higher risk of CI have pts NYHA III-IV (OR 2.68, 95% CI: 1.22-5.87), with worse quality of life (OR 1.02, 95% CI: 1.002-1.04) and higher ceruloplasmin level (OR 1.02, 95% CI: 1.01-1.03). Lower risk of CI have pts with better functional status - the 6-minute walk test, Duke Activity Status Index (DASI) (OR 0.996, 95% CI: 0.99-0.999 and OR 0.96, 95% CI: 0.94-0.99, respectively), better adherence to therapy (OR 0.77, 95% CI: 0.60-0.98) and better endothelium-mediated vasodilatory response (OR 0.9, 95% CI: 0.83-0.98). In multivariate analysis, the independent predictors of CI in CHF were age, duration of hypertension, lower adherence to therapy and higher ceruloplasmin level.
Conclusion. CI is observed in the majority of pts with CHF, it associates with age, duration of CHF symptoms, presence and duration of hypertension and CHD. Higher risk of CI have pts with NYHA III-IV, worse quality of life and higher ceruloplasmin level. At the same time, lower risk of CI have pts with better functional status, better adherence to treatment and better endothelium-mediated vasodilatory response. The independent predictors of CI in CHF with rLVEF in multivariate logistic regression model are age, duration of hypertension, lower adherence to treatment and higher ceruloplasmin level.

P1050

Improving recognition and management of hyperkalemia in patients with HF: an online educational intervention

J Jelena Spyropoulos[1]; S Mendly[2]
[1]*Medscape LLC, New York, United States of America*; [2]*Medscape Global, London, United Kingdom of Great Britain & Northern Ireland*

Funding Acknowledgements: The funding for the advanced outcomes assessment was provided by an independent educational grant from Vifor Pharma

Background: Patients with heart failure (HF) who are receiving RAAS inhibitor therapy are at increased risk for developing hyperkalemia. However, guideline-recommended monitoring of serum potassium after initiation of RAAS inhibitors is lacking in real-world practice, and many patients who develop hyperkalemia are not optimally managed.
Purpose: To determine if an online continuing professional development (CPD) intervention could improve knowledge/competence and confidence of cardiologists and nephrologists related to assessment and management of hyperkalemia in the setting of HF.
Methods: Cardiologists and nephrologists electively participated in a video-based, 4-faculty educational discussion on diagnosing and treating hyperkalemia. The effects of education were assessed using a repeated pairs, pre-assessment/post-assessment study design. For all questions combined, a chi-square test assessed differences from pre- to post-assessment. P values <.05 are statistically significant. Cramer's V was used to assess educational effect. The activity launched on June 26, 2018 and data were collected through August 27, 2018.
Results: Overall significant improvements were seen after education for both cardiologists (N=333; P < .001; considerable educational effect, V=.205) and nephrologists (N=155; P < .001; considerable educational effect, V=.174). Pre-assessment, the average correct response rate was 37% for cardiologists and 50% for nephrologists, while post-assessment average correct response rates were 57% and 67%, respectively. Significant improvements were observed in cardiologists' and nephrologists' competence related to management of hyperkalemia (Table).
As a result of the education, 22% of cardiologists and 10% of nephrologists reported higher confidence in ability to maintain maximal doses of RAAS inhibitor therapy while managing concomitant hyperkalemia in their patients with HF.
Conclusion: The statistically significant improvements observed in this intervention demonstrate the benefits of using education to increase knowledge, competence and confidence of cardiologists and nephrologists, and suggest that this type of intervention has the potential to positively impact recognition and treatment of hyperkalemia in patients with HF.

Improvements in knowledge/competence

Topic	Cardiologists (N=333)Relative % improvement (post-assessment vs pre-assessment; P value)	Nephrologists (N=155)Relative % improvement (post-assessment vs pre-assessment; P value)
Managing risk for hyperkalemia in patients on RAAS inhibitor therapy	115% (30% vs 64%; P<.001)	61% (46% vs 75%; P<.001)
Appropriate use of potassium binders to treat hyperkalemia	68% (35% vs 59%; P<.001)	32% (50% vs 66%; P=.004)

P1051

Features of the arterial wall functional state in patients with chronic heart failure with a moderately reduced left ventricular ejection fraction and a persistent form of atrial fibrillation

N Natalia Koziolova[1]; E Polyanskaya[1]; S Mironova[1]
[1]*Perm Medical University, Perm, Russian Federation*

Objective: To evaluate the functional state of the arterial wall in patients with chronic heart failure (CHF) with a moderately reduced left ventricular ejection fraction (mrLVEF) and a persistent form of atrial fibrillation (AF).
Materials and methods: The study included 48 patients with a moderately reduced left ventricular ejection fraction (mrLVEF), which were divided into 2 groups depending on a heart rhythm disorder. The first group included 28 patients with persistent AF, the second one - 20 patients with sinus rhythm. The diagnosis of CHF with a moderately reduced LV EF was confirmed by the presence of LV EF in the range of 40–49%. Diastolic dysfunction was diagnosed according to tissue visualization of diastolic velocity of the mitral valve fibrous ring and an increase in the concentration of the N-terminal fragment of brain natriuretic peptide (NT-proBNP) in the blood using ELISA.
The functional state of the arterial bed was determined according to arteriography using the device "Arteriograph 24 Tensiomed" (Hungary).
Results: there were no statistically significant differences between groups by sex, age, comorbidity, therapy (except for anticoagulants and antiarrhythmic drugs). LV FV statistically significantly did not differ between groups: 46.5 [44.5; 47.0]% in the first group, 45.0 [42.0; 47.0]% in the second group (p = 0.605). The level of NT-proBNP in the 1st group was 289.7 [192.2; 421.0] pg / ml, in the 2nd — 127.7 [19.4; 373.6] pg / ml (p = 0.143).
Indicators of diastolic LV function differed statistically significantly between groups: in the first group, septal e '(p = 0.007), lateral e' (p <0.001), E / e '(p = 0.001) were higher than in the second group.
There were revealed statistically significant differences between groups in arteriography parameters.
Central blood pressure in aorta (CBPao), augmentation index (AIXao), aortic pulse wave velocity (PWVao) were higher in the first group than in the second: 147.0 [96.0; 152.5] mmHg versus 96.0 [90.0; 124.5] mmHg, (p <0.001); 30.2 [9.3; 44.5]% versus 13.4 [5.3; 29.4]%, (p <0.001); 9.7 [7.9; 12.1] m/sec vs. 6.6 [6.5;7.4] m/sec (p <0.001), respectively. Correlation analysis showed a direct strong interconnection between CBPao and E/E'(r = 0.750; p <0.05), and AIXao and E/E' (r = 0.707; p <0.05).
Conclusion: for CHF patients with moderately reduced LV EF and persistent form of AF, a statistically significant increase in central BP in aorta and arterial stiffness is more characteristic due to more pronounced LV diastolic dysfunction compared with CHF patients who have sinus rhythm.

P1052

Clinical predictors of the long-term progression of renal dysfunction in heart failure patients with reduced ejection fraction

D Dilek Ural[1]; O Argan[2]; K Karauzum[3]; I Karauzum[3]; G Kozdag[3]; A Agir[3]
[1]*Koc University School of Medicine, Istanbul, Turkey*; [2]*Kocaeli State Hospital, Department of Cardiology, Kocaeli, Turkey*; [3]*Kocaeli University, Faculty of Medicine, Department of Cardiology, Kocaeli, Turkey*

Renal dysfunction is a frequently encountered co-morbidity in heart failure patients with reduced ejection fraction (HFrEF) and deteriorates the prognosis of the patients significantly. The aim of this study is to evaluate the clinical determinants of the progression of renal dysfunction (PRD) in HFrEF patients in long-term follow-up.
Methods: A total of 414 patients with the diagnosis of HFrEF (left ventricular ejection fraction ≤40%) and with a clinical follow-up duration longer than one year were enrolled into the study. PRD was defined as a ≥25% decline in estimated glomerular filtration rate (eGFR) and a change in eGFR category, or a sustained decrease in eGFR ≥15 ml/min/1.73 m2 within 12 months during the follow-up period.
Results: Median baseline eGFR was 59 (42–79) mL/min/1.73 m^2 and 52% of the patients had moderate-severe renal dysfunction. During a median 39 (23–71) months follow-up, the mean decline in eGFR was -6,49 ± 11.05 mL/min/year. PRD was detected in 157 (38%) patients. In univariate analysis, significant clinical associates of the PRD were presence of right sided heart failure, inability to use an ACE inhibitor or an angiotensin receptor blocker, not using spironolactone and statins. Decline of eGFR was significantly correlated with the echocardigraphic variables (i.e. left atrial size, right ventricular diameter, pulmonary arterial systolic pressure), increased NT-proBNP, AST, ALT and decreased sodium, albumin and total cholesterol levels.
By linear regression analysis adjusted for clinical, therapeutic, echocardiographic and laboratory variables, abnormal liver function tests including increased ALT and low albumin levels showed highest associations with the yearly decrease in eGFR. In Cox regression analysis, low albumin level, followed by left atrial size, low hematocrit ratio, age and NT-proBNP level were significant determinants of PRD.
Conclusion: In long-term follow-up of HFrEF patients, biochemical variables indicating liver dysfunction and congestion (i.e. increased ALT, low albumin, low hematocrit and increased NT-proBNP levels) are the main predictors for PRD.

Background: Comorbidity affects the clinical aspects of heart failure (HF) and cardiac remodeling in comorbid patients. With the development of thyrotoxicosis

in patients with coronary heart disease (CHD) the risk of atrial fibrillation increases 4.5 times, and CH decompensation - 3.3 times.
Purpose: To study the clinical aspects of chronic heart failure (CHF) and the features of structural and functional remodeling of the left ventricle (LV) in patients with coronary artery disease and thyrotoxicosis.
Methods: 131 patients were enrolled into the study: the main group consisted of 30 patients with coronary artery disease (CAD), CHF and thyrotoxicosis; 1st comparison group - 35 patients with CHD and CHF, without thyroid pathology; 2nd comparison group - 35 patients with thyrotoxicosis without cardiovascular diseases (CVD); 3rd group - 31 patients with CHD and thyrotoxicosis with no signs of CHF. A rating scale of clinical state (RSCS) was used, a 6-minute walk distance (6MWD), an echocardiographic study (EchoCG) was performed, and the functional state of the thyroid gland was also determined.
Results: The evaluation of the clinical symptoms of CHF by RSCS did not reveal significant differences when comparing the indices between the main and 1st comparison groups, however, exercise tolerance in patients with CHF with CHD and thyrotoxicosis was significantly lower by 15.4% (p = 0, 01). There were revealed significantly lower values of indexed linear (EDD) and volume indices (EDV, ESV) of the LV in patients of the main group compared with the corresponding results in the group with IHD and CHF without thyrotoxicosis, which is due to increased cardiac output on the background of hyperactivity of the sympathetic nervous system during thyrotoxicosis . In patients with CHD, CHF and thyrotoxicosis, LV concentric hypertrophy (LVHL) was determined significantly more often - in 84% of cases than in patients with CHD and CHF without thyrotoxicosis - in 70% (p = 0.03). In both groups, the values of the LV ejection fraction corresponded to the intermediate type of HF (HFmrEF), and no significant differences were found between the indicators - 48.1 (41,0; 52,0) and 47,0 (40,0; 48,0) (p = 0.1). Transmitral blood flow indices indicate more pronounced signs of diastolic dysfunction (LVDD) in patients of the main group: V/V are lower by 12.5% (p = 0.01), isovolumetric relaxation time (IVRT) is by 11.11% (p = 0.02) compared with the results in patients of the 1st comparison group.
Conclusions: The peculiarities of structural and functional remodeling of the left heart in patients with CHF of ischemic genesis and thyrotoxicosis were revealed: significantly more frequent incidences of LVHL (84% of cases), lower values of EDD, EDV, ESV, expressed by LVDD, which is probably caused by significant activation of renin-angiotensin-aldosterone (RAAS) and, especially, sympatho-adrenal (SS) systems in conditions of attendant thyrotoxicosis.

Introduction: Cardiovascular diseases are the greatest cause of morbidity and mortality in patients after kidney transplantation. The incidence of congestive heart failure (CHF) in patients with a transplanted kidney is 2 to 5 times higher than the incidence in the general population. The incidence of CHF in patients with a transplanted kidney was 10.2% 12 months and 18.3% 36 months after transplantation. Diastolic left ventricular dysfunction is present in 45% of patients with a transplanted kidney. Heart failure (HF) is highly prevalent in patients treated with haemodialysis. Hypertension, renal anemia, and comorbid conditions such as coronary artery disease are important risk factors for HF.Aim: To determine the frequency of risk factors for occurrence and frequency of HF in kidney transplant patients and patients on chronic hemodialysis.
Patients ande methods: We conducted a prospective study that included 90 patients. All patients had their history data taken, ECG, complete physical examination and echocardiography. The difference in frequency of the observed parameters was tested by chi-sqyare test.
Results: Patients were divided into two groups: kidney transplant patients (60) and patients treated with hemodialysis (30). In the group with kidney transplant patients was 42 (70%) men and 18 (30%) women. In the group with patients treated with hemodialysis was 15 (50%) men and 15 (50%) women. The average age in kidney transplant patients was 42.22 ± 1.71 years, in the group with patients treated with hemodialysis was 52.97 ± 2.98 years. The mean duration of dialisys before kidney transplant in the group with kidney transplant patients was 43.00 ± 9.19 months. The average kidney graft survival was 9,1±9,68 years. The mean duration of dialisys in the group of patients treated with hemodialysis was 87.00 ± 15.6. CHF had 3,33% kidney transplant patients and 16,67% patients treated with hemodialysis. HF was significantly higher in patients treated with hemodialysis than in kidney transplant patients (p <0.05). Diastolic dysfunction had 36,67% patients treated with hemodialysis and 45% patients with transplanted kidney. Hypertension had 30% kidney transplant patients and 66,67% patients treated with hemodialysis. Left ventricular hypertrophy had 50% kidney transplant patients and 76,67% patients treated with hemodialysis. CHD had 13,33% kidney transplant patients and 36,67% patients treated with hemodialysis. Atrial fibrilation had 10% kidney transplant patients and 26,67% patients treated with hemodialysis. Mitral regurgation had 33,33% kidney transplant patients and 56,67% patients treated with hemodialysis.Aortic regurgitation had 15% kidney transplant patients and 33,33% patients treated with hemodialysis.Conclusion: We find statistically significant differences in the frequency of HF between kidney transplant patients and patients treated with hemodialysis.
